SYMPOSIUM 01: Climate disasters, human health, and public health responses

O-SY-001 Building community and health system resilience to climate disasters in Australia

Sotiris Vardoulakis

Australia has recently experienced severe climate disasters, ranging from bushfires and droughts to floods and vector borne disease outbreaks. IPCC identified the inability of institutions to manage climate risks as a key risk for Australia. The unprecedented 2019-20 wildfires and the 2022 floods have raised questions about the resilience of the Australian health system and communities to intensifying extreme events in the context of climate change.

The 2022 floods caused 23 deaths, large-scale community devastation, and disrupted health services. They increased COVID-19 and other infectious disease risks and long-lasting mental health consequences. Furthermore, they exposed health inequities and vulnerabilities related to non-communicable diseases in Aboriginal and low socio-economic communities.

The Black Summer (2019-20) wildfires caused 33 fatalities, extensive damage to property, and destruction of flora and fauna, as well as exposing millions of people to extreme levels of air pollution. Bushfire smoke, a complex mixture of particles and gases, was transported by the wind over long distances affecting populated areas for several weeks.

Public health interventions at both community, household and personal levels can mitigate the impact of climate disasters. The effectiveness, feasibility and scalability of these interventions, as well as any potential health co-benefits or other unintended consequences, need to be evaluated holistically taking into account quantitative and qualitative evidence. The impact of these interventions on health equity, particularly in relation to First Nations, at-risk and socioeconomically marginalized groups needs to be assessed, as these groups are typically more vulnerable to climate extremes.

Strengthening the long-term resilience of the health sector and communities to climate disasters is crucial. The HEAL (Healthy Environments and Lives) Network is taking leadership in environmental change and health research that will provide the evidence, capacity and capability, and tools urgently needed to build community and health system resilience to intensifying climate disasters in Australia.

O-SY-002 California wildfires: mental and physical health, unmet needs, and future directions

Irva Hertz-Picciotto

BACKGROUND: California's wildfires annually break records in size, fatalities, or buildings destroyed. Every year since 2017, records have been broken for deaths, structures destroyed, or area burned. The toll on mental health, respiratory conditions, and other outcomes constitutes a major public health challenge.

METHODS: Online surveys of households in counties affected by fires or smoke collected information about experiences during wildfires, unmet needs, and health conditions before, during and after the fires. Both a convenience sample, and a probability sample of households were recruited. One respondent replied for all household members. Lack of access to shelter, food, electricity, cell phone service, and other basic necessities was documented. Separate multinomial models were fit to the incident respiratory and mental health outcomes that occurred during and after the fires, with the goal to identify major independent predictors of symptoms in those time periods. All models hierarchically adjusted for intra-household correlations. Potential predictors included sociodemographic characteristics, cumulative PM2.5 exposure during wildfires, prior health, and fire-related experiences (evacuations; loss of home, job, loved one; etc.).

RESULTS: The sociodemographics, prior asthma, and wildfire PM2.5 exposure predicted increases in respiratory symptoms. Different factors associated with greater mental health disturbances. The study demonstrated how needs changed over time. Multivariate models showed that people of color had higher risks for respiratory symptoms, both as a direct association and through their greater prevalence of prior asthma, indicating a particularly high health burden from wildfire smoke.

CONCLUSIONS: Climate change challenges epidemiology to identify specific high risk subgroups; determine factors that mediate or buffer adverse health impacts; investigate synergies across multiple extreme events/disasters or multiple health consequences; clarify differences in health risks from traffic or industrial versus wildfire air pollution; and work with communities to develop culturally appropriate protective strategies and to evaluate feasibility, effectiveness, co-benefits or negative effects of interventions.

O-SY-003 Climate change in the Caribbean: transforming vulnerabilities into resiliency

Jose Cordero

Significant climate events, such as hurricanes, have increased in frequency and intensity in the Caribbean during the 21st century. In 2017, two Class 5 hurricanes, Irma and Maria, hit Puerto Rico within two weeks, leaving a trail of devastation and death. Over 4,000 people died, most during the post-event period impacting mainly the vulnerable population, the elderly, those with chronic diseases, and the poor.

We conducted a rapid needs assessment in six targeted municipalities in Puerto Rico that Hurricane Maria severely impacted. We conducted 14 focus groups that included 110 persons and interviewed 15 key informants to examine the impact of hurricanes on their daily lives. These interviews, conducted about six months post-hurricane Maria, focused on how their key priorities changed from before to after the disaster.

We found access to health care was a significant priority post-disaster but the barriers to access were directly related to social determinants of health, including transportation, lack of communication services, food insecurity, access to safe water, and housing. We developed a community health promoter program to connect the vulnerable population to health care access and preparedness agencies. The program targeted the elderly and those with chronic diseases such as diabetes, hypertension and others.

We demonstrated that community health promoters were instrumental in connecting their patients to health care resulting in the improved health status of their chronic conditions. Similarly, the community health promoters established connections between patients and disaster planning agencies to identify suitable shelters to manage the health care needs of persons with chronic diseases post-disaster.

Deployment of community health workers can be an approach to reducing morbidity and mortality among persons with chronic diseases in the post-disaster situation. Deployment of community health workers can be an approach to reduce morbidity and mortality among persons with chronic diseases in the post-disaster situation.

O-SY-004 Heatwaves and forest fires and their combined effects in the Greater Athens area

Klea Katsouyanni[1,2], Antonis Analitis[1], Sofia Zafeiratou[1], Evangelia Samoli[1]
[1]National and Kapodistrian University of Athens, Athens, Greece, [2]MRC Centre for Environment and Health, Environmental Research Group, Imperial College London, London, UK

BACKGROUND: Previous severe heatwaves in Athens were associated with excess mortality. As example, the heatwave in July 1987 led to 100% increase in the monthly number of deaths. Also, the occurrence of forest fires burning more than 30km2 of land are associated with increased mortality (>90% increase in respiratory deaths). The aim of the present work is to quantify the effects of a heatwave combined with a forest fire event in July-August 2021.

METHODS: Data for weekly and daily temperature, particulate air pollution and number of deaths were recorded for the summer 2021 and the 10 previous years. for the 2020-21 period the daily number of deaths due to COVID-19 was also available. A Poisson regression analysis was applied to estimate the effect of the heatwave and forest fire episode on mortality. A comparison with what would be expected in terms of excess deaths, if the same associations observed in the 1987 heatwave were still applicable, was undertaken.

RESULTS: PM2.5 concentrations were increased to 73μg/m3 on the 9th heatwave day (2nd forest fire day). The weekly number of deaths increased up to 80% compared to the observed number of deaths during the same time period in 2017-2020. However, the observed impact in 2021 was smaller to what would be expected based on projections using exposure-response functions estimated for the 1987 heat wave. The increase in mortality during the 2021 heatwave could not be explained by an increase in COVID-19 related deaths.

CONCLUSIONS: The impact of the 2021 heatwave–forest fire event on the number of deaths for the Athens population was very severe. However, it was less than expected based on observations from an important heatwave in the same period in 1987. The difference is probably due to raised awareness and behavioral adaptation.

KEYWORDS: heatwave, forest fire, mortality, Athens

O-SY-005 Mortality burden of heatwaves in Sydney Australia is exacerbated by the urban heat island and climate change: can tree cover help mitigate the health impacts?

Geoffrey Morgan

Health Impact Assessment methods were applied to quantify the mortality burden of heatwaves in Sydney Australia, and assess the contribution of the Urban Health Island (UHI) effect to this burden. Using high resolution satellite observations to calculate UHI air temperature excesses and green cover, effects on heat-related mortality were determined. From future climate projections, mortality reduction benefits were estimated from green tree cover. Results show that >90% of heatwave-deaths could be prevented by removing the UHI. Tree canopy reduces urban heat and widespread tree planting could offset the increases in heat attributable deaths as climate warming.

SYMPOSIUM 02: Multimodal environmental influences on children and adolescent's brain, cognitive, and mental health outcomes

O-SY-006 Early-life urban exposome and brain structural connectivity and morphology in preadolescents

Anne-Claire Binter[1], Serena Fossati[1], Mark Nieuwenhuijsen[1], Martine Vrijheid[1], Hanan El Marroun[2], Mònica Guxens[1]

[1]ISGlobal, Barcelona, Spain, [2]Erasmus MC, Rotterdam, The Netherlands

Recent studies have linked air pollution to brain characteristics in children, but few studies have considered associations with other urban exposures. We investigated the associations between urban exposome and white matter microstructure and brain volumes in preadolescents.

We used data from 3,315 children of the Generation R cohort, The Netherlands. Residential levels of 20 built environment metrics, 6 natural spaces indicators, 12 air pollutants, and road-traffic noise were assessed during pregnancy and childhood. Diffusion tensor and structural brain images were obtained at 9–12 years. We estimated fractional anisotropy (FA) and mean diffusivity (MD) and several brain structure volumes. We ran multi-pollutant analysis between built environment and natural spaces indicators and each outcome using Deletion/Substitution/Addition algorithm. When an association was found, we ran mediation analyses to estimate whether the association was mediated by air pollution or noise.

Built environment and natural spaces indicators during pregnancy were not associated with FA nor MD. During childhood, building density and industrial or commercial land use (LU) were related to higher MD, and LU diversity was associated with lower MD (e.g., -0.02 95%CI (0,03; -0,01)). Total effects of building density and LU diversity were partially mediated by fine particulate matter elemental zinc (9.0% and 23.2%, respectively). Surrounding greenness during pregnancy was associated with smaller subcortical gray matter, pallidum and thalamus volumes, with no mediation by air pollution nor noise. Built environment indicators, including LU diversity and unhealthy food facilities density during pregnancy or childhood were associated with smaller hippocampus, larger amygdala and nucleus accumbens volumes, with a mediation up to 6.9% by elemental zinc or polycyclic aromatic hydrocarbons.

Early-life built environment and natural space indicators were related to brain structural connectivity and morphology in preadolescence, with a partial mediation by air pollution levels.

Birth cohort, urban exposome, air pollution, natural spaces, neuroimaging, child development

O-SY-007 Approaches to identify the contribution of understudied toxicants in complex metal mixtures

Johnnye Lewis[1], Li Luo[2]
[1]Community Environmental Health Program, University of New Mexico College of Pharmacy, Health Sciences Center, Albuquerque, USA, [2]Department of Internal Medicine and Comprehensive Cancer Center, University of New Mexico Health Sciences Center, Albuquerque, USA

BACKGROUND AND AIM: Exposures to complex mixtures are increasingly acknowledged to contribute to adverse health outcomes through complex joint or interactive effects. Emerging advanced statistical approaches facilitate appropriate analyses of complex mixtures by incorporating high correlations, nonlinearities, and interactions among individual exposures. Selection of appropriate analytical approaches for complex mixture analysis, and the interpretation of results, is dependent on the specific scientific goals. This presentation discusses and compares the use of complementary and combined approaches in analyses of metal mixture exposures in the Navajo Birth Cohort Study (NBCS).

METHODS: We compare results and interpretation from 1) Clustering methods that assess the study participant's co-occurring exposure patterns; 2) Regression methods with shrinkage and variable selection that identify a subset of exposure mixtures associated with the outcome of interest; 3) Kernel machine regression approaches that model mixture effects by incorporating interaction and nonlinear relationships; 4) Ensemble learning methods that provide outcome prediction by ranking each variable's predictive power, thereby handling a large number of variables; and 5) Causal analysis methods that provide inference that mimics interventional effects to control for confounders, reducing biased estimates that may limit generalizability.

RESULTS: Different approaches used have helped to identify not only the patterns of exposures in the population, but also understudied metals that, in mixtures, are significant contributors to birth outcomes and developmental delays in NBCS. The results obtained from different approaches have affected the interpretation and opened new avenues of investigation for understudied toxicants.

CONCLUSIONS: Using complex analytic strategies to parse effects of complex exposures supports both understanding of population-specific exposure-response relationships, and also the specific contributors to those responses and associated mechanisms that are generalizable to populations where metal-mixture mineralogic composition, chemistry, doses, and patterns of exposure will vary.

O-SY-008 Do complex mixtures of prenatal environmental and social exposures explain variation in risk for behavioral symptoms in adolescence?

Jaime Benavides[1], Lawrence Chillrud[1], Mariah DeSerisy[2], Jacob Cohen[2], Jeff Goldsmith[3], Marianthi-Anna Kioumourtzoglou[1], Amy Margolis[2]

[1]Dept. of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York City, USA, [2]New York State Psychiatric Institute and Department of Psychiatry, Vagelos College of Physicians and Surgeons, Columbia University, New York City, USA, [3]Dept. of Biostatistics, Columbia University Mailman School of Public Health, New York City, USA

BACKGROUND AND AIM: Prenatal exposure to environmental chemicals is associated with behavioral symptoms of mental health. These symptoms often emerge across adolescence and frequently co-occur, suggesting shared etiologic pathways. Prenatal chemical exposures are often correlated with each other and with social exposures such as maternal demoralization that are also associated with elevated behavioral symptoms. We aimed to identify how complex patterns of prenatal co-exposure to chemicals and social factors are associated with symptoms of psychiatric outcomes common in adolescence, such as attention problems, substance abuse, and psychotic symptoms.

METHODS: We used exposure and behavioral symptoms data from the Columbia Center for Children's Environmental Health Mothers and Newborns birth cohort (age 14-21). We use principal components pursuit (PCP) to decompose the exposure matrix into a low-rank matrix to identify consistent exposure patterns and a sparse matrix to isolate unique exposure events. To identify profiles of exposures (N=550), after running PCP, we used principal components analysis (PCA). We use multiple linear regression to test interactions between prenatal exposures and behavioral outcomes in adolescence (age 14-21) in N=253 participants.

RESULTS: We observed two subgroups of strong correlation among phthalate exposures and maternal demoralization. We identified similar patterns using PCA on the raw data. Prenatal Polycyclic Aromatic Hydrocarbons (PAH) exposure modified effects of early life stress (ELS) on underage alcohol use (interaction: z=1.95, p=.05). Relative to those with lower exposure, those with higher prenatal PAH and ELS had the highest risk for underage alcohol use.

CONCLUSIONS: Variability in phthalates and maternal demoralization within the cohort describe unique profiles of exposure. PCP analysis will more precisely identify consistent and interpretable prenatal exposure patterns while dealing with data missingness and outliers. Interactions between prenatal chemical and social exposures increase risk for psychiatric problems in adolescence pointing to modifiable pathways to reduce risk.

O-SY-009 Prenatal exposure to mixtures of replacement flame retardant chemicals and children's neuro-behavioral outcomes in a sample of children from socioeconomically disadvantaged communities

Theresa Bastain[1], Ixel Hernandez[1]
[1]*University of Southern California, Los Angeles, USA*

BACKGROUND: Organophosphate ester flame retardants (OPFRs) are persistent organic chemicals that are commercially applied to a wide variety of consumer products including electronics, building materials, foam-based furniture and children's clothing that have individually been shown to adversely impact neurodevelopmental outcomes including hyperactivity symptoms, working memory, IQ and depressive symptoms.

METHODS: We quantified nine prenatal OPFR urinary metabolites [DPHP, DNBP+DIBP, BDCIPP, BCEP, BBOEP, BCIPP, BMPP, BEHP and DPRP] by HPLC-MS/MS in samples from participants in the MADRES cohort--an ongoing pregnancy cohort in urban Los Angeles. Detection frequencies ranged from 99.8% for DPHP to 24.2% for DPRP. Specific-gravity adjusted OPFR metabolites detected in 60% or greater samples [DPHP, DNBP+DIBP, BDCIPP, BCEP, and BBOEP] were modeled continuously and log transformed, and values ≤ LOD were imputed as LOD/√2. The remaining four metabolites were modeled as detect/non-detect [BCIPP, BMPP, BEHP, and DPRP]. We assessed prenatal OPFR exposure associations with neurodevelopmental outcomes from the Child Behavior Checklist 1.5/5 in 151 predominantly Hispanic/Latino (~78%) children at age 3 years.

RESULTS: We found significant associations between several OPFR metabolite concentrations and neurobehavioral outcomes in single metabolite adjusted models [e.g., a 10% increase in DNBP+DIBP concentration was associated with a 3.3% (95% CI 0.02%-6.49%) increase in internalizing symptoms score and a 4.8% (0.82%-8.95%) increase in DSM pervasive symptoms score]. However, exposure to a particular compound does not occur in isolation; thus it is critical that multiple exposures be considered jointly in human studies. We will discuss various analytical approaches to quantify the effects of environmental mixtures and apply them to understand multiple OPFR chemical exposure effects on early childhood neurobehavioral outcomes in a highly exposed, socioeconomically disadvantaged population.

CONCLUSIONS: The application of mixtures methods will yield important insight into the conditional associations of co-exposures and enhance health risk assessment for child neurodevelopmental outcomes.

KEYWORDS: Neurodevelopment, children, chemical mixtures

O-SY-010 A life-course approach for examining the impact of air pollutants on adolescent anxiety and depression and the role of DNA methylation

Kelly Brunst[1], Liang Niu[1], Kimberly Yolton[2], Patrick Ryan[2]
[1]University of Cincinnati, Cincinnati, USA, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, USA

BACKGROUND AND AIM: Anxiety and depression are common in adolescents; yet, their etiology is poorly understood. Air pollutants are widely recognized for their ability to adversely impact neurodevelopment and elicit changes to the epigenome. It is unclear whether pollution-related epigenome changes impact mental health.

METHODS: The Infinium MethylationEPIC BeadChip was used to assess whole blood DNA methylation from 159 adolescents (age 12). Fine particulate matter (PM2.5) and elemental carbon attributable to traffic (ECAT), a surrogate of diesel exhaust, were measured using validated land use regression and satellite-based spatio-temporally resolved prediction models, respectively. Three exposure windows were investigated: early-life (birth), recent (12 months prior to yr. 12 visit), and lifetime average. Anxiety and depression were assessed by child report with the Spence Children's Anxiety Scale and Child Depression Inventory-2 at age 12. Regression and distributed lag models controlled for sex, race, age, and household income.

RESULTS: Five CpG sites, mapping to 5 genes, were differentially methylated as a result of recent PM2.5 exposure (FDR < 0.05). Distributed lag models suggest significant cumulative effects for most of the CpGs (4 out of 5) with the timing of exposure being an important factor for three CpG sites. The top hit (cg08349910, FDR=0.03) annotates to the gene SRGAP3 which is ubiquitously expressed in the developing nervous system. We observed the methylation status of cg08349910 to be associated with increased symptoms of generalized anxiety, social phobia, and total anxiety. Controlling for ECAT or including an interaction between ECAT and PM2.5 did not change these findings. Additional analyses are being conducted to include nitrogen dioxide and ozone.

CONCLUSIONS: These data suggest methylation at specific CpGs may serve as biomarkers for particulate matter exposure and identify children at increased risk for anxiety and depression.

KEYWORDS: Air pollution, DNA methylation, Mental health

SYMPOSIUM 03: Strengthening the global role of environmental epidemiology in the issue of water, sanitation and public health in Latin American and Caribbean countries

O-SY-011 The role of the University in the formation, discussion and training of researchers in environmental epidemiology. How to strengthen Latin America?

Sandra Cortes[1], Horacio Riojas[2], Dra. Marcela Tamayo[2]
[1]Departamento de Salud Pública. Advanced Center for Chronic Diseases (ACCDIS). Pontificia Universidad Católica De Chile, Santiago, Chile, [2]Instituto Nacional de Salud Pública, Cuernavaca, México

Since the 1990s, various initiatives have been organized to train persons on environmental health, and epidemiology with the support of the Pan American Health Organization (PAHO), governments, and public health centers. In Latin America and the Caribbean counties (LAC), a high prevalence of smoking, obesity, chronic respiratory and cardiovascular diseases, cancer, social vulnerability, and air and water pollution are reported. The consequences of COVID-19 and the evident biological, social and cultural crisis that Climate Change represents, are added.

This work analyzes the education and training of researchers on environmental epidemiology and its impact on public health actions in LAC.

Training programs in public health, environmental health, and epidemiology in LAC were reviewed, and a training case conducted by the PAHO and the Latin American chapter of the Society for Environmental Epidemiology (ISEE-LAC) is described.

Until March 2022, most of the LAC countries have postgraduate programs in Environmental management and control; a few programs are a focused on Environmental Epidemiology. Brazil, Mexico, Uruguay, Colombia, and Costa Rica stand out, and they have developed Environmental Health programs, including online versions. Given the limitations in the training of people specialized in Environmental Epidemiology, researchers from LAC universities and members of the ISEE-LAC, designed and executed the Basic Self-Learning Course in Environmental Epidemiology, on Campus Virtual Public Health. More than 6,000 participants from various LAC countries have signed up; of them, 932 people from different disciplines and countries have completed their training and are in a position to apply basic knowledge in environmental epidemiology.

Strengthening is required at all levels in the training of people in environmental epidemiology, with the support of governments and international agencies such as PAHO, to address environmental hazards, the health burden due to environmental deterioration, and the impacts due to climate change in LAC populations.

O-SY-012 Waterborne arsenic and fluoride exposure in Mexico: risk assessment and epidemiological research on their health effects

Paulina Farías Serra[1], Peter Knappett[2], Jürgen Mahlknecht[3], Jesús Alejandro Estevez-García[1], Erika Noelia Onofre-Pardo[1], María Luisa Pérez-Humara[1], Elodia Rojas-Lima[1], MSc Urinda Álamo-Hernández[1], Diana Olivia Amador-Rocha[4], Gretchen Miller[2], Jaime Hoogesteger[5], Yan Mei Li[4], Itza Mendoza- Sánchez[2], Isidro loza[4], Saugata Datta[6], Yong Huang[2], Genny Carrillo[2], Taehyun Roh[2], Dylan Terrell[7], Richard Woodwardw[2], Ismael Aguilar Barajas[3], Juan Antonio Torres Martínez[3], René Homero Lara Castro[8], Ricardo Ramírez Ambrosio[3], Abraham Mora-Polanco[9]

[1]National Institute of Public Health, Cuernavaca, Mexico, [2]Texas A&M University, College Station, USA, [3]Tecnológico de Monterrey, Monterrey, Mexico, [4]University of Guanajuato, Guanajuato, Mexico, [5]Wageningen University, The Netherlands, [6]Texas A&M University, San Antonio, USA, [7]Caminos de Agua, San Miguel de Allende, Mexico, [8]Universidad Juárez del Estado de Durango, Durango, Mexico, [9]Tecnológico de Monterrey, Puebla, Mexico

Many aquifers in Mexico contain toxic levels of arsenic and fluoride; still, 39% of the population relies on groundwater for drinking. Our objectives were to evaluate the health risks of fluoride and arsenic in drinking water in central [Cuenca Alta del Río Laja (CARL)] and northern [Comarca Lagunera (CL)] Mexico, and to compare economic and health trade-offs of different aquifer pumping scenarios.

In two CARL studies, we measured arsenic and fluoride in drinking water and fluoride in children's urine; health risks were estimated through hazard quotients (HQ). In 2018 we assessed dental fluorosis (n=39) and in 2019, we measured intelligence quotient (IQ) (n=74). Another study modeled the revenues, costs, health, and income outcomes from increasing, decreasing, or maintaining the aquifer pumping rates over 100 years. The fourth study assessed cancer and non-cancer risks in CL according to arsenic levels in 91 wells.

In CARL, children who drank groundwater had an increased fluoride risk of health effects (HQ= 1.5); 82% presented dental fluorosis, and their urine fluoride concentrations increased 0.96 mg/L per 1 mg/L increase in water fluoride ($p < 0.001$). Urine fluoride was negatively associated with IQ (β= -1.12, CI 95% -4.1, 1.8). Assuming increasing aquifer pumping rates in the next 100 years, arsenic and fluoride concentrations would increase to 40 µg/L and 2.1 mg/L, respectively, potentially diminishing IQ by 6 and 7 points, respectively. In CL, 90% of the sampled wells exceeded the WHO's arsenic drinking water guidelines; the carcinogenic risk ranged from 2.6×10^{-5} to 6.1×10^{-3}.

Children in CARL and CL are drinking groundwater with toxic fluoride and arsenic concentrations that increase their cancer and non-cancer health risks to unacceptable levels. The health and economic benefits of mitigating exposure to arsenic and fluoride greatly exceed the benefits of increasing pumping for more agricultural production.

KEYWORDS: arsenic, fluoride, water, Mexico

O-SY-013 Diseases and deaths from pesticides in Brazil

Paulo Junior Paz De Lima[1,2], Dra. Telma de Cassia dos Santos Nery[2]
[1]Brazilian Association of Researchers for Social Justice – ABRAPPS, Brazil, São Paulo, Brazil, [2]Thematic Health Commission of the São Paulo Forum to Combat the Impacts of Pesticides and Transgenics, São Paulo, Brazil

All released! for decades, Brazil has become a great granary and depository of pesticides used in its crops. The situation has worsened since 2008, when Brazil became the world's largest consumer of pesticides and, more recently, in the last 6 years after the release and authorization of registrations of new pesticides, by the governments of Temer and Bolsonaro, with many use of these pesticides in their countries of origin is prohibited. Between 2010 and 2021, 3,474 new pesticides were released, of which 76.5% were only between 2016 and 2021. and as an announced tragedy, the reflection of the general release, are the impacts on health and the environment resulting from the indiscriminate use of these pesticides. Objectives: To analyze data on mortality from cancer, suicide attempts, poisoning and deaths from pesticides for agricultural, domestic, public health, rodenticides and veterinary use between 2010 and 2020.

METHODS: Descriptive cross-sectional study. Data were collected from the database DATA/SUS/Ministry of Health.

RESULTS: There were 135,803 cases of intoxication, 73.2% of intoxications were not due to exposure at work; 70,920 suicide attempts and 3,944 deaths from poisoning, with 48.8% of the deaths being between black/brown and 36% white; 74.6% of intoxications were in urban residents and 21.9% in rural areas and 94.5% of deaths were not related to work. There were 8,099,845 cases of neoplasms, 92,217 of which were malignant neoplasms of the liver and intrahepatic bile ducts; 877,464 of congenital malformations.

CONCLUSIONS: The results point to a relationship between higher mortality rates from cancer, poisoning, suicide attempts and deaths from pesticide poisoning, proportionally increasing, as the consumption and sales of pesticides in Brazil increase annually. Most victims of poisoning are residents of urban areas and belonging to black/brown color/ethnicity and are not exposed to work.

KEYWORDS: Pesticides, intoxications, deaths, cancer, suicide

O-SY-014 Surveillance and epidemiological control network in Latin America – The importance of water and sewage monitoring. Overview of pesticides in water for human consumption in Brazil – Information through the website – Good water to drink “Água Boa de Beber”

Telma Cassia dos Santos Nery[1,2]

[1]Divisao de Pneumologia - Instituto do Coracao INCOR HCFMUSP, SAO PAULO, Brazil, [2]MIS - Companhia de Saneamento Basico do Estado de Sao Paulo - SABESP, Sao Paulo, Brazil

In March 1977, the Plan of Action resulting from the United Nations Conference on Water, Silver Sea: for the first time recognized water as a right by declaring that “All peoples, whatever their stage of development and their social and economic conditions, have the right to have access to drinking water in a quantity and quality equal to their basic needs”. This presentation of consultation and information on pesticides in the water for 5,000 municipalities. Through the site, pesticides analyzed in water for human consumption and their levels, some above the limits, are evidenced. Access facilitates analysis and adoption of epidemiological surveillance measures. Date of website: https://agua.mpf.mp.br/. CONCLUSION: Surveillance and epidemiological control network in Latin America, is very important.

KEYWORDS: Water, Quality, Pesticides

O-SY-015 The role of the World Alternative Water Forum (FAMA) and social mobilization

Edson Aparecido da Silva[1]

[1]*Observatório Nacional dos Direitos à Água e ao Saneamento – ONDAS, Brasilia, Brazil*

The fight to guarantee human rights to water and sanitation has a prominent moment during the World Alternative Water Forum (FAMA), organized simultaneously with the World Water Forum (FMA), organized by the World Water Council (CMA), every three years. The FAMA organizers adopt a narrative of concern about the need to "take care" of the planet's water and to ensure sanitation for the entire population, but in these meetings, small spaces of participation are reserved for civil society, whose sole objective is to legitimize decisions that seek to expand its control by the private sector, corporations, and agribusiness.

RESULTS: FAMA, occurs in opposition to the FMA and is configured in a space of democratic debate, exchange of experiences of struggle and resistance in defense of water and public sanitation and against privatizations. It brings together social, popular and trade union movements, the city and the countryside, indigenous populations, and various religiosities, allows discussions around water under the most varied perspectives, under the most varied views and experiences. The themes that have been highlighted in the FAMAs are the fight against privatization; the emphasis on the role of women in the fight for access to water, which in the privatization processes deepen. The need for global organization to cope with the processes of privatization and appropriation of water by capital; the importance of processes of derivatization of sanitation services around the world; the importance of democratic control over companies, and the strengthening of instruments of control and social participation. CONCLUSION: Every achievement of FAMA, which has been held since the first edition of the FMA in 1997, strengthens the ties between popular organizations around the world that fight in defense of water in a view to reaffirming that water is right and not merchandise.

KEYWORDS: Water Forum, Social Mobilization, Human right

SYMPOSIUM 04: PFAS hotspots and highly exposed communities: addressing community needs and advancing global collaborative exposure assessment and epidemiological research

O-SY-016 PFAS exposures in Veneto, Italy: the role of biomonitoring in addressing a serious public health threat

Cristina Canova[1], Gisella Pitter[2], Erich Batzella[1], Tony Fletcher[3], Francesca Russo[4]
[1]Unit of Biostatistics, Epidemiology and Public Health, Department of Cardio-Thoraco-Vascular Sciences and Public Health, University of Padova, Padova, Italy, [2]Screening and Health Impact Assessment Unit, Azienda Zero-Veneto Region, Padova, Italy, [3]London School of Hygiene and Tropical Medicine, London, UK, [4]Directorate of Prevention, Food Safety, and Veterinary Public Health-Veneto Region, Venice, Italy

BACKGROUND AND AIM: In 2013, high levels of perfluoroalkyl substances (PFAS) were identified in the drinking water of the Veneto region, Italy, primarily due to industrial emissions from a nearby PFAS manufacturer. for decades, the factory released wastewater into the ground, contaminating both surface water bodies and groundwater, mainly by perfluorooctanoic acid (PFOA), before charcoal filters were introduced. The groundwater contamination plume extends over 190 km2 and reached public waterworks serving 30 municipalities (roughly 130,000 inhabitants). This presentation will provide an overview of the Veneto health surveillance program and its impact.

METHODS: The health surveillance program started in January 2017 and continues for the prevention, early diagnosis and treatment of chronic disorders possibly associated with PFAS. The target population included 105,000 residents of the contaminated area born between 1951 and 2014. Data are collected through a structured interview on socio-demographic characteristics, personal health history and lifestyle habits; routine blood and urine tests; and the measurements of 12 PFAS. The population is being recruited for a second round, which started in September 2020.

RESULTS: By February 2022 55,597 individuals were recruited (60,5% of invited) in the 1st round, and 2,623 in the 2nd round. The PFAS with the highest serum concentrations was PFOA (median 36.8 ng/mL), about 20 times higher than in the Italian population with background exposures, followed by perfluorooctanesulfonic acid (PFOS) (median 3.8 ng/mL) and perfluorohexanesulfonic acid (PFHxS) (median 3.7 ng/mL).

CONCLUSIONS:This population is unique in that biomonitoring has been offered to the entire highly exposed population. The program includes a thorough assessment of individual exposure as well as behavioural and clinical risk factors for cardiometabolic disorders, providing tailored counselling for exposure and risk reduction, and the referral of subjects with altered biomarkers for subsequent diagnostic and therapeutic evaluation.

KEYWORDS: PFAS, biomonitoring, health surveillance program, PFOA contamination

O-SY-017 Risk assessment in PFAS “hotspot” populations – A challenge

Kristina Jakobsson[1], YiYi Xu[1], Ying Li[1], Christel Nielsen[2], Tony Fletcher[3]
[1]University of Gothenburg, Gothenburg, Sweden, [2]Lund University, Lund, Sweden, [3]London School of Hygiene and Tropical Medicine, London, UK

BACKGROUND: In Ronneby, a Swedish municipality of 30,000 inhabitants, one of the two municipal waterworks had delivered highly PFAS-contaminated water to 1/3 of the households for decades until detected in December 2013. Open serum samplings revealed very high serum PFAS-levels in the exposed population, dominated by PFHxS and PFOS. This prompted an extensive research program, ranging from large registry studies to mother-child cohort observations and studies on mechanistical aspects.
By now, 8 years later, the amount of epidemiological studies on health effects has increased exponentially, however mostly performed at general population with “background serum concentrations”. at substantially higher exposure levels there are still only a few populations studied: PFAS production workers, the PFOA-dominated C8 and Veneto studies, and our own studies with fire-fighting foam contamination. Thus, there remains a substantial lack of studies of exposure levels in the mid-range, of importance since these are precisely the levels now observed in populations next to “hotspots”, which are increasingly detected following environmental investigations around production facilities, firefighting training ranges and airports.

AIM: To discuss both conflicting and supportive findings on associations between PFAS exposure and health outcomes, with emphasis on dose-response relationships.

METHOD: Review of published epidemiological studies, focused on outcomes with evidence in both background and highly-exposed populations

RESULTS: The lack of information about the shape of the dose-response curve and the still limited understanding of PFAS toxicity mechanisms hampers risk assessment for general population groups with modestly elevated PFAS-levels, since extrapolation “upwards” from background levels might often not give the same results as extrapolation “downwards”. Moreover, PFAS mixtures differ.

CONCLUSIONS: There is a need for concerted actions among researchers to fill this knowledge gap by coordinated protocols for studies on PFAS and health outcomes in populations with higher than background exposure.

KEYWORDS: Dose-response, PFAS, epidemiology

O-SY-018 Perspectives in risk communication due to the PFOS pollution case in Korsoer, Denmark

Janne Møller[1], Paula Edeusa Hammer, Jonas Winkel Holm, Ann Christine Lyngberg
[1]*Holbæk Hospital, Holbæk, Denmark*

BACKGROUND: In spring 2021 Denmark identified the first PFOS-pollution case deriving from a firefighting school. Through the last 20 years, members of a local cow grazing association had consumed veal having grazed on the contaminated area. The department of Occupational Medicine in Holbaek was contacted by the chairman of the regional council, and asked to investigate the members. In August 2021 118 of the members were found to have elevated blood levels of PFOS.

AIM: To present our risk communication strategy on individual, group and community level.

METHODS: We gathered knowledge about PFAS by searching the literature and establishing collaboration with experts, research institutions and authorities to be able to perform adequate risk communication based on a risk assessment to the members of the cow grazing association, the Danish authorities and the media.

RESULTS: We provided risk communication at different levels. (1) Individual level on medical consultations and by availability through the phone as needed; (2) group level by oral and written information with members of the cow grazing association; and (3) community level by contact with the media, and participation on an expert group set up by the National Board of Health.

CONCLUSION: Understanding the different 'senders and receivers' in risk communication is important to avoid unnecessary concerns and costs.
Preliminary assessments is required before a proper exposure and risk assessment is done. It is important to consider how to present scientific uncertainties.
Risk perception influences behavior in both individuals, group and public health level often regardless laws, regulations and expert evaluations as risks always are interpreted politically or value-related.
Cooperation across professional groups and sectors is essential to be able to handle these types of cases constructively.

KEYWORDS: Risk communication, PFOS, PFAS, food contamination

O-SY-019 PFAS in serum of residents living in the neighborhood of a major PFAS manufacturer plant in Belgium

Ann Colles[1], Katleen De Brouwere[1], Annelies De Decker[2], Ilona Gabaret[2], Elly Den Hond[2], Hilde Van De Maele[3], Liesbet Van Rooy[3], Bart Bautmans[3]

[1]Vito - Health, Mol, Belgium, [2]Provincial Institute for Hygiene, Antwerp, Belgium, [3]Agency for Care and Health, Brussels, Belgium

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) contamination levels in the environment around a 3M PFAS production plant triggered the concern for health among residents in the neighbourhood. Following this concern, a blood collection was organized to assess residents' exposure levels.

METHODS: During the summer of 2021, 800 residents (+12 years old) living within 3 km of the 3M plant provided serum samples in which 13 PFAS compounds were measured, using ultra-performance liquid chromatography-tandem mass spectrometry. All participants completed a questionnaire.

Results and conclusion: The presentation will report the PFAS fingerprints in serum, the variation in PFAS serum levels within the community, and the key exposure determinants assessed using information retrieved from the questionnaire. PFAS exposure was dominated by PFOS (perfluorooctanesulfonic acid), with an important contribution of branched compounds. Consumption of locally-produced chicken eggs was identified as an important determinant for higher serum levels of several PFAS. Other significant determinants included geographical position of the homes, time living in the area, use of groundwater, contact with chemicals and soil particles and use of consumer products. The study results supported earlier implemented no-regret precautionary measures. We will also address the policy implementation of this study and the communication of the results to the local community, including advices for exposure reduction.

KEYWORDS: PFAS, exposure assessment, determinants, policy

O-SY-020 The PFAS hotspot HBM network: development of a HBM PFAS guidance document for emerging PFAS hotspots, based on shared experiences across PFAS hotspots in EU

Katleen De Brouwere[1], Ann Colles[1], Gudrun Koppen[1], Elly Den Hond[2], Lisbeth E. Knudsen[3], Maria Uhl[4]
[1]Flemish Institute for Technological Research (VITO), Mol, Belgium, [2]Provincial Institute for Hygiene, Antwerp, Belgium, [3]University of Copenhagen, Copenhagen, Denmark, [4]Umweltbundesamt, Vienna, Austria

BACKGROUND AND AIM: Several PFAS hotspots have been identified in various regions in Europe and new PFAS hotspots continue to be discovered. In order to address the health concern of citizens living in the neighborhood of PFAS hotspots, human biomonitoring (HBM) programs in hotspot regions have been conducted, are ongoing or planned. So far, HBM initiatives at PFAS hotspots have in nearly all cases been initiated and elaborated at the local or regional scale without structural collaboration across PFAS hotpots. In order to benefit from experiences and good practices on HBM studies at PFAS hotspots, a PFAS hotspot EU network group has been established under the HBM4EU project.

METHODS: Researchers involved in PFAS monitoring studies across several hotspots exchanges experience and views during several online meetings, contributed to an inventory and collaborated in working groups to draft a guidance document.

RESULTS: AND CONCLUSION: An inventory of HBM studies at PFAS hotspots was made according to a structured approach, including fields such as pre-phase, public concern, biomarkers of exposure, biomarkers of effects, information on determinants of exposure, risk communication and impact at societal and policy level. Based on this inventory and following discussions within the network, a guidance document was developed. The guidance document covers the following aspect: 1) identification and monitoring of PFAS hotspots, 2) biomonitoring and health assessment 3) risk communication in PFAS hotspots, and 4) policy recommendations. The guidance document aims to be useful for policy makers and scientist confronted with new PFAS hotpots. The network members recognized the need for more collaboration across hotspots. Development of common protocols and questionnaires for HBM at PFAS hotspots could be a first step, and will enhance the study power for research on PFAS exposure-effect associations.

KEYWORDS: PFAS, hotspots, exposure assessment, human biomonitoring, policy, collaboration

SYMPOSIUM 05: Undermeasured and undervalued: examining social-structural factors in women's and children's global environmental health

O-SY-021 Perinatal and children's environmental epidemiology: what about birth integrity?

Jessica Laine Carmeli[1]
[1]*Institute for Social and Preventive Medicine,University of Bern, Bern, Switzerland,* [2]*Imperial College London, London, UK*

BACKGROUND AND AIM: Birth integrity and violation of birth integrity are concepts that integrate theories of medicalization, risk, embodiment, and intersectionality into a multilevel framework. Violation of birth integrity is experienced widely across the globe and can coincide with environmental exposures and underly or modify many environmentally associated pregnancy, birth, infant, and children's health outcomes. Measuring the phenomenon of violation of birth integrity, such as obstetric violence, is critically important for the studies of the exposome, given the focus on comprehensive exposure assessment during sensitive periods.

METHODS: The aims of this work are to introduce birth integrity into the field of environmental epidemiology, to posit violation of birth integrity as embedded within the broader environmental reproductive justice framework, assess pathways to which violation of birth integrity lead to adverse maternal, infant, and child health, and to put forth research agendas and methodologies to assess and incorporate determinants and measurements of birth integrity into environmental epidemiology.

RESULTS: Birth integrity is embedded within sociocultural norms, local material structures, physiologies, intersectional and transnational powers, among others. Violation of birth integrity can lead to adverse health through several pathways, including epigenetic remodelling, childbirth trauma, among others, potentially leading to factors such as adverse birth outcomes, barriers to breastfeeding, interruption of bonding and attachment, and other adverse maternal and child health. Birth integrity interacts with other determinants of maternal, infant, child environmentally associated health.

CONCLUSIONS: Violation of birth integrity must be considered as a maternal health indicator. Neglecting prenatal/antenatal, birth, and postpartum experiences, particularly those surrounding birth integrity and violation of birth integrity is part of a broader epistemological biases in environmental epidemiology. Multilevel interventions are needed to simultaneously address these injustices, particularly in the areas of preconception health, maternal health, infant and child health.

KEYWORDS: perinatal health, exposome, environmental reproductive justice, birth, children's health

O-SY-022 Adverse childhood events and health-related quality of life among women undergoing hysterectomy for uterine leiomyoma

Ami Zota[1,2], MyDzung Chu[2], Cherie Marfori[3], Nadia Khati[4], Ayman Al-Hendy[5], Tamara Taggart[6]
[1]Department of Environmental Health Sciences, Columbia Mailman School of Public Health, New York, USA, [2]Department of Environmental and Occupational Health, The George Washington University Milken School of Public Health, Washington, USA, [3]Department of Obstetrics and Gynecology, The George Washington University, Washington, USA, [4]Department of Radiology, The George Washington University Hospital, Washington, USA, [5]Department of Obstetrics and Gynecology, University of Chicago, Chicago, USA, [6]Department of Prevention and Community Health, The George Washington University Milken School of Public Health, Washington, USA

BACKGROUND AND AIM: Psychosocial stress may increase fibroid risk, but associations with symptom severity, which often influence clinical management decisions, have been underexamined. Our objective is to examine associations between adverse childhood experiences (ACE) and symptom severity and symptom impact on health-related quality of life (HRQL) among women undergoing hysterectomy for treatment of their leiomyomas (fibroids).

METHODS: We recruited 103 premenopausal women into the Fibroids, Observational Research on Genes and the Environment (FORGE) study who were seeking evaluation of fibroids at the Medical Faculty Associates in Washington D.C. and intending to undergo hysterectomy at the George Washington University Hospital. for exposure classification, we assessed eight ACE categories related to child abuse and household challenges. for outcome classification, we used the Uterine Fibroid Symptom and Quality of Life (UFS-QOL). The five-level Likert scale responses were summed to create composite scores; a lower symptom severity score indicated fewer symptoms, while a higher HRQL score indicated better quality of life. We ran quasi-poisson regressions (log-link) to examine associations between ACE scores and UFS-QOL composite scores adjusting for age, race/ethnicity, and education (N=89).

RESULTS: The majority of participants were Black (73%); about half had private insurance (55%) and a college degree (49%). Cumulative ACE and symptom severity scores were higher among Black compared to non-Black women ($p \leq 0.03$). History of substance abuse in the household was associated with greater symptom severity (relative risk (RR) = 1.31, 95% CI: 1.07, 1.61), and worse HRQL (RR = 0.74, 95% CI: 0.55, 1.00). History of sexual abuse was also associated with worse HRQL (RR = 0.67, 95% CI: 0.48, 0.92).

CONCLUSIONS: Our study adds to the growing evidence that early life exposures to chronic stress may influence gynecologic health, including symptom-related quality of life.

KEYWORDS: Women's health, gynecological health, health disparities, social-structural stressors

O-SY-023 Maternal and newborn health risks of climate change: a call for awareness and global action

Nathalie Roos

Climate change has been identified as the biggest global health threat of the 21st century, with immediate harm in early life and significant lifelong consequences, and major implications for generations to come. Pregnant women and newborns are increasingly recognized as vulnerable populations in the context of climate change. The effects can be direct or indirect through heat stress, extreme weather events and air pollution, potentially impacting both the immediate and long-term health of pregnant women and newborns through a broad range of mechanisms. Low-income countries are particularly vulnerable to climate change because of poverty, poor sanitation, high prevalence of malnutrition, infections, non-communicable diseases, poor quality housing, and weak non-resilient health care systems. Climate adaptation plans need to consider these vulnerable populations and a broad multisectoral approach to improve overall resilience of societies.

O-SY-024 Environmental hazards, social inequality, and fetal loss: implications of live-birth bias for estimation of disparities in birth outcomes

Dana Goin[1], Joan Casey[2], Marianthi-Anna Kioumourtzoglou[2], Lara Cushing[3], Rachel Morello-Frosch[4]
[1]University of California, San Francisco, San Francisco, USA, [2]Department of Environmental Health Sciences, Columbia Mailman School of Public Health, New York, USA, [3]Department of Environmental Health Sciences, UCLA Fielding School of Public Health, Los Angeles, USA, [4]Department of Environmental Science, Policy, & Management and School of Public Health, University of California, Berkeley, Berkeley, USA

BACKGROUND: Restricting to live births can induce bias in studies of pregnancy and developmental outcomes, but whether this live-birth bias results in underestimating disparities is unknown. Bias may arise from collider stratification due to an unmeasured common cause of fetal loss and the outcome of interest, or depletion of susceptibles, where exposure differentially causes fetal loss among those with underlying susceptibility.

METHODS: We conducted a simulation study to examine the magnitude of live-birth bias in a population parameterized to resemble one year of conceptions in California (N=625,000). We simulated exposure to a non-time-varying environmental hazard, risk of spontaneous abortion, and time to live birth using 1,000 Monte Carlo simulations. Our outcome of interest was preterm birth. We included a social vulnerability factor to represent social disadvantage, and estimated overall risk differences for exposure and preterm birth using linear probability models and stratified by the social vulnerability factor. We calculated how often confidence intervals included the true point estimate (CI coverage probabilities) to illustrate whether effect estimates differed qualitatively from the truth.

RESULTS: Depletion of susceptibles resulted in a larger magnitude of bias compared with collider stratification, with larger bias among the socially vulnerable group. Coverage probabilities were not adversely affected by bias due to collider stratification. Depletion of susceptibles reduced coverage, especially among the socially vulnerable (coverage among socially vulnerable = 46%, coverage among non-socially vulnerable = 91% in the most extreme scenario).

CONCLUSIONS: In simulations, hazardous environmental exposures induced live birth bias and the bias was larger for socially vulnerable women.

KEYWORDS: live-birth bias; simulation; health disparities; environmental justice; fetal loss

O-SY-025 Federally-assisted housing and blood lead levels in the United States, 1999-2016

MyDzung Chu[1,2], Andrew Fenelon[3], Gary Adamkiewicz[4], Ami R. Zota[1]

[1]Department of Environmental and Occupational Health, Milken Institute School of Public Health, The George Washington University, USA, [2]Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, USA, [3]School of Public Policy and Department of Sociology and Criminology, Penn State University, University Park, USA, [4]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND/AIM: Despite declining blood lead levels (BLLs) in the US, lead exposure remains disproportionately high in older housing and for low-income and non-Hispanic Black households. Federal housing assistance is linked to lower BLLs among children, but has not been evaluated among all US residents and by program type.

METHODS: We used the National Health and Nutrition Examination Survey 1999-2016 data linked to the US Department of Housing and Urban Development (HUD) administrative records to identify HUD-assisted participants. We compared BLLs of those currently-assisted and those on the waitlist (will receive assistance within two years) using multivariable regressions for log-transformed and dichotomous (≥ 3 µg/dL) BLLs. We examined effect modification by program type (project-based: public and multifamily housing vs. housing choice vouchers) and race/ethnicity, and conducted subset analyses for women and children under 12.

RESULTS: Sociodemographic characteristics were similar in the currently-assisted and waitlist groups. BLL geometric means were 1.11 (SE: 1.03) and 1.41 (SE: 1.03), respectively ($p<0.05$). In adjusted models, HUD assistance was associated with 8% lower BLLs (95% CI: -13%, -2%). In stratified models, this association was stronger among project-based housing (-11%, 95% CI: -18%,-4%) compared to housing choice voucher (-5%, 95% CI: -12%, 2%) recipients. Non-Hispanic white participants experienced a stronger protective association (-16%, 95% CI: -25%, -6%) compared to Black participants (-3%, 95% CI: -10%, 5%) and Mexican-Americans (2%, 95% CI: -18%, 28%). The association was significant among women (-9%, 95% CI: -15%, -2%) but attenuated among children (-2%, 95% CI: -9%, 6%). Findings remained consistent for clinically-meaningful BLL cutoff ≥ 3 µg/dL.

CONCLUSIONS: Housing assistance is an important social-structural determinant of health that can reduce residential environmental exposures through better quality housing, routine maintenance practices, and/or compliance with residential lead paint laws. Increasing access to affordable housing for very low-income households advances environmental health equity.

SYMPOSIUM 06: The Multi-Country Multi-City (MCC) Collaborative Research Network: an international collaboration for global studies on environmental risks, climate change, and health

O-SY-026 The MCC Network: an international collaboration for global health research

Antonio Gasparrini[1], Aurelio Tobias[2]
[1]London School of Hygiene & Tropical Medicine, London, UK, [2]Spanish Council for Scientific Research (CSIC), Barcelona, Spain

BACKGROUND AND AIM: Addressing global environmental threats requires research studies based on large epidemiological assessments covering multiple regions. Multi-centre studies offer an excellent framework for this purpose but present various methodological and logistical issues. This overview contribution illustrates the experience of the Multi-Country Multi-City (MCC) Collaborative Research Network, an international collaboration working on a global research program on the associations between environment, climate, and health.

METHODS: The MCC Network has established an international collaboration based on mutual contribution and data sharing. This partnership has led to the collection of one of the largest databases for environmental health studies, with daily time series of health outcomes and environmental indices from 1,044 locations within 50 countries in the period 1969-2020. A research protocol formalizes a flexible mode of collaboration that offers scientific independence in addressing a variety of research topics, while ensuring collective participation and control on the use of data. The research is supported by intense methodological developments that have provided state-of-the-art study design and statistical techniques.

RESULTS: The MCC Network has contributed key evidence on environmental health risks, with peer-reviewed publications in leading environmental, epidemiological and medical journals. The research scope of the collaboration spans from studies of the health risks of known risk factors such as air pollution and non-optimal temperature, to analyses of more specific environmental stressors such as wildfires and extreme weather events, to projections of health impacts under climate change scenarios.

CONCLUSIONS: The research of the MCC Network has already provided an exceptional contribution to our understanding of environment-health associations and the impacts of climate change. The collaborative framework can be replicated to address other research questions in this area and beyond.

KEYWORDS: time series; pollution; temperature; climate change.

O-SY-027 Global analyses on health effects of temperature and climate change: the contribution of the MCC Network

Ana Maria Vicedo-Cabrera[1,2], Antonio Gasparrini[3,4,5], Multi-Country Multi-City Collaborative Research Network[6]
[1]Institute of Social and Preventive Medicine. University of Bern, Bern, Switzerland, [2]Oeschger Center for Climate Change Research. University of Bern, Bern, Switzerland, [3]Centre on Climate Change and Planetary Health, London School of Hygiene & Tropical Medicine, London, UK, [4]Department of Public Health, Environments and Society, London School of Hygiene & Tropical Medicine, London, UK, [5]Centre for Statistical Methodology, London School of Hygiene & Tropical Medicine, London, UK, [6]Multi-Country Multi-City Collaborative Research Network

Multi-location analyses have proven to be useful settings for assessing the health impact of environmental hazards at regional and global scales. This study design is being widely applied in climate epidemiology since it allows the quantification of health impacts across highly heterogeneous populations and the identification of vulnerability patterns using a common method. Since 2014, the MCC consortium has developed and applied advanced methodologies to provide robust estimations of mortality impacts of non-optimal temperatures at different spatiotemporal scales in the present time and future climate change scenarios. This was possible thanks to the wide geographical coverage and high statistical power of the data collected. In this work, we aimed to review and summarize findings from published global studies on temperature-related mortality impacts using the MCC dataset.

We collected published articles until March 2022 by the MCC Network on health impact assessments of non-optimal temperature and mortality. We included global historical assessments and health impact projections in which heat, cold or both were considered and then combined the estimates by topic and geographical region.

Findings from the 20 publications showed good agreement in terms of both spatial and temporal patterns. We found that heat and cold-related risks have decreased over time, and higher vulnerabilities are mostly found in Southeastern regions of Europe and Asia, and in large and highly urbanized cities. Results from the projection studies suggest that heat-related mortality would steeply increase in all regions, and in most of them, this increase would counteract the decrease in cold-related risks leading to a net increase in temperature-mortality under the most pessimistic scenarios.

The MCC collaborative research network has greatly contributed to advancing knowledge on the impacts of climate change on health by providing valuable and unique epidemiological evidence on the mortality impacts of non-optimal temperatures.

KEYWORDS: climate change, mortality, heat, cold

O-SY-028 Air pollution and daily mortality in the Multi-country Multi-city study: single and joint effect with heat

Massimo Stafoggia[1], Haidong Kan[2], MCC Collaborative Group
[1]Lazio Region Health Service - Rome, Italy, [2]School of Public Health, Fudan University, Shanghai, China

BACKGROUND AND AIM: The relationship between air pollution and daily mortality remains to be determined at a global scale. Moreover, few studies reported the interaction between air pollution and heat on mortality.

METHODS: We collected daily air pollution, temperature, and mortality data from the Multi-country Multi-city (MCC) network. The air pollutants included particulate matter (PM) with aerodynamic diameter <= 10 µm (PM10) and <= 2.5 µm (PM2.5), ozone (O3), carbon monoxide (CO), nitrogen dioxide (NO2), and sulfur dioxide (SO2). We applied a two-stage time-series analysis, with over-dispersed generalized linear models and multilevel meta-analysis. The joint effect between air temperature and pollutants was analyzed in the warm season, with product terms between non-linear air temperature and linear air pollutants.

RESULTS: We observed significant associations of air pollution with daily mortality. for instance, 10 µg/m3 increase in the 2-day moving average of PM2.5 and O3 concentrations were associated with increases of 0.44% (95% confidence interval [CI], 0.39 to 0.50) and 0.18% (95%CI, 0.12 to 0.24) in daily all-cause mortality, respectively. We also found evidence of interaction between heat and air pollution. for example, an increase in mean temperature from 75th to 99th percentile was associated with 9.0% (95%CI: 7.1%, 11.0%), 10.4% (95%CI: 8.4%, 12.4%), and 13.6% (95%CI: 10.6%, 16.6%) increases in mortality when PM10 was equal to 5th, 50th and 95th percentiles. Similarly, 10 µg/m3 increment in PM10 was associated with a 0.24% (95%CI: 0.02%, 0.46%), 0.46% (95%CI: 0.34%, 0.59%), and 0.76% (95%CI: 0.42%, 1.11%) increases in mortality when air temperature was at 5th, 50th and 95th percentiles, respectively.

CONCLUSIONS: We found robust evidence on the short-term effects of air pollution on daily mortality. We also found evidence of effect modification between air temperature and air pollutants on mortality during the warm period.

KEYWORDS: Mortality, Short-term Exposure, Temperature, Air pollution, Effect modification

O-SY-029 Mapping global mortality burden associated with multiple environmental stressors: a new framework by the MCC Network

Yuming Guo[1], Qi Zhao[1], Yao Wu[1], Bo Wen[1], Wenzhong Huang[1], Shilu Tong[2], Antonio Gasparrini[3], Shanshan Li[1]
[1]Monash University, Melbourne, Australia, [2]Shanghai Jiaotong University, Shanghai, China, [3]London School of Hygiene and Tropical Medicine, London, UK

BACKGROUND AND AIM: Current knowledge is limited on global burden of mortality associated with short-term exposure to environmental factors, because global observed data of mortality and environmental factors are not available. This presentation aims to illustrate extensions of the analytical framework established within the MCC collaboration to provide global maps of health impacts associated with exposure to environmental factors (e.g., non-optimal temperatures, temperature variability, and tropical cyclones).

METHODS: We used time-series data on mortality and environmental data from 750 locations in 43 countries and meta-predictors at a grid size of 0.5° × 0.5° across the globe. We developed a three-stage analysis strategy. First, a time-series regression was used to estimate the association between environmental factors and mortality for each location by. Second, a multivariate meta-regression model was used to model the association between location-specific estimates and meta-predictors. Finally, the grid-specific exposure–mortality association was predicted by the fitted meta-regression and the grid-specific meta-predictors. Excess deaths due to exposure to environmental factors were then calculated for each grid across the world.

RESULTS: Globally, 5,083,173 deaths (95% empirical CI [eCI] 4,087,967–5,965,520) were associated with non-optimal temperatures per year, accounting for 9.43% (95% eCI 7.58–11.07) of all deaths (8.52% [6.19–10·47] were cold-related and 0.91% [0.56–1.36] were heat-related). Totally 1,753,392 deaths (95% eCI 1,159,901–2,357,718) were associated with temperature variability per year, accounting for 3.4% (2.2–4.6) of all deaths. An overall estimate of 199,740 deaths (95% eCI 185,988–267,278) were due to exposure to tropic cyclones globally from 1980 to 2019. Those estimates show geographical and temporal heterogeneity across region and nation.

CONCLUSIONS: Estimating global, regional and national burden of mortality associated with short-term exposure to environmental factors is essential for developing preparedness and prevention strategies to reduce their impacts.

KEYWORDS: Global mortality burden, temperature, temperature variability, tropical cyclone

O-SY-030 The role of environmental factors in the COVID-19 pandemic: research from the MCC Network

Francesco Sera[1], MCC Collaborative Research Network
[1]*University of Florence, Florence, Italy*

BACKGROUND AND AIM: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has rapidly spread across the globe, traversing diverse climatic and environmental conditions. From the early phase of the pandemic, there has been speculation that weather conditions could modulate SARS-CoV-2 transmission patterns.

METHODS: In this talk, I will present the current evidence and methodological challenges in evaluating potential drivers of COVID-19 seasonality. I will also present the results of two global studies based on an extensive city-level dataset, collected by the Multi-Country Multi-City MCC Collaborative Research Network, where we studied the relationship between weather conditions and COVID-19 spread using ecological and time-series designs. Finally, I will discuss planned future studies based on data collected until March 2022.

RESULTS: We collected data from 455 cities across 20 countries around the globe over an observation period ranging from 3 February to 31 October 2020. for each location, daily COVID-19 cases were linked with meteorological (mean temperature, relative and absolute humidity and UV radiation) variables derived from the Copernicus ERA5 dataset, and with the Oxford Governmental Stringency Index to account for the effect of lockdown measures. These data were analysed using ecological designs (spatial and time-series approaches) giving evidence of effects of mean temperature and absolute humidity on COVID-19 transmission. However, these studies underline regional heterogeneity of weather-related effects on COVID-19 transmission and the dominant role of non-pharmaceutical interventions. We are extending the data collection until March 2022 to investigate the interdependent role of seasonality, meteorological factors, environmental stressors (air pollution), non-pharmaceutical interventions and vaccination.
Conclusion.
This research activity is an example of the flexibility of the MCC Network in adapting and using its collaborative platform and data collection to address urgent and challenging research questions.

SYMPOSIUM 07: Disparities in US drinking water quality and access

O-SY-031 Racial disparities in access to U.S. community water systems: effects on children's health

Jacqueline Gibson

BACKGROUND AND AIMS: Racial minority communities at the fringes of some U.S. cities and towns lack access to the regulated community water systems afforded to their non-minority neighbors. These communities rely on unregulated water sources that typically are not monitored or treated, leaving residents at risk of exposure to contaminants. This research assessed the effects of exclusion from municipal water service on children's lead (Pb) exposure and of early-life Pb exposure from drinking water on teenage juvenile delinquency.

METHODS: We linked blood Pb measurements for 59,483 children under age six to information about their drinking water sources, demographic characteristics, and household and neighborhood environmental variables. for 13,580 children who reached age 14 by the end of our study period, we also retrieved juvenile delinquency data. We examined associations between blood Pb and water source using a mixed-effects tobit regression model and the effects of Pb in drinking water on teenage juvenile delinquency risks using a two-stage, least-squares regression model.

RESULTS: In the full data set, children relying on unregulated water sources had blood Pb levels that were 20% higher ($p<0.001$) than children with community water service. Further, this early-life increased Pb exposure was significantly associated with an increased risk of juvenile delinquency. Compared to children with community water service, those relying on private wells had a 21% ($p<0.001$) higher risk of being reported for any delinquency and a 38% (($p<0.001$) increased risk of being reported for serious delinquency after age 14.

CONCLUSIONS: Access to a regulated community water supply is associated with decreased exposure to Pb, compared to reliance on unregulated private sources, presumably due to the requirement that community supplies monitor for and control Pb. In turn, decreased Pb exposure is significantly associated with decreased juvenile delinquency. These results underscore the public health benefits of community water supplies.

O-SY-032 Safe home water access for low-income families with young children

Angie Cradock[1], Jessica Barrett[1], Emily Nink[1], Cara Wilking[2]
[1]Harvard TH Chan School of Public Health, Boston, USA, [2]Independent Legal Consultant, USA

BACKGROUND: From 2015-2018, the U.S. Environmental Protection Agency found 7,463 public water systems serving 51 million people in the U.S. reported at least one health-based violation. Communities across the United States have unsafe drinking water due to aging public water supply infrastructure and home wells with unsafe levels of contaminants like arsenic and nitrate.
Aim: This presentation describes the costs, population reach, and considerations for local and state policies and programs that can ensure safe water access for pregnant people and low-income families with young children.

METHODS: This study used a mixed-methods analysis including legal review, case interview, and economic evaluation to identify the activities, resources, and costs associated with actions to provide more equitable access to safe home drinking water strategies for low-income families with children aged 0-5.

RESULTS: Researchers identified six strategies used in state and local settings to improve access to safe drinking water at home via home water quality testing, home well water treatment device installation, filter pitcher distribution, and lead service line replacement. If implemented over 5 years in their respective geographic areas, these strategies could reach 480 to 135,000 households each with annual costs per household of $75 to $1000 (USD).

CONCLUSIONS: Opportunities for improving access to safe drinking water at home should be tailored to features of the local water system, water source, and community context. In particular, policies and programs can be tailored to reach pregnant people and low-income families with young children, who are most at risk.

KEYWORDS: child, infant, drinking water, equity, lead, arsenic, nitrate

O-SY-033 Socioeconomic disparities in exposures to unregulated industrial contaminants in U.S. public drinking water supplies

Laurel Schaider[1], Amanda Hernandez[1], Christopher Swartz[1], Jahred Liddie[2]
[1]Silent Spring Institute, Newton, USA, [2]Harvard T.H. Chan School of Public Health, Boston, 02115

BACKGROUND AND AIMS
Communities of color and low-income communities often face disproportionately high burdens of exposure to pollution. Previous studies investigating environmental justice and drinking water quality have focused on regulated contaminants with established standards, but many other unregulated contaminants are also present in drinking water.

METHODS: We evaluated associations between the presence of unregulated industrial contaminants and the demographics of communities served by U.S. public drinking water supplies (PWSs). We compiled data for four unregulated contaminants (1,4-dioxane, 1,1-dichloroethane, HCFC-22, PFAS) from U.S. EPA's Third Unregulated Contaminant Monitoring Rule (UCMR3). We analyzed data collected in 2013-2015 from 4,815 U.S. PWSs, serving 284 million people, that reported concentration data for at least one target contaminant. We also compiled information on PWS characteristics, county-level demographic data from the U.S. Census Bureau, and data on potential sources including airports, fire-training areas, wastewater treatment plants, and relevant contaminant releases reported in the U.S. EPA Toxic Release Inventory.

RESULTS: We found that PWSs serving counties with higher proportions of Hispanic residents and more urban households were more likely to have ≥1 target contaminant detected and were more likely to exceed a federal guideline for PFOA/PFOS or 1,4-dioxane, even after accounting for PWS characteristics and the presence of potential sources. Target contaminants were more frequently detected in large PWSs (>10,000 customers) compared to smaller systems and in groundwater systems compared to surface water systems. We did not find consistent associations between detection of UCMR3 contaminants and proportion of Black residents or proportion of residents considered deprived (according to the U.S. Census Bureau's Multidimensional Deprivation Index).

CONCLUSIONS: Our findings provide new insight into the extent of socioeconomic disparities in exposures to drinking water contaminants and highlight the need to consider cumulative exposures to contaminants in drinking water.

KEYWORDS: Environmental justice, drinking water, contaminants, PFAS, industrial pollution

O-SY-034 Nitrate contamination in Maryland drinking water and policy reforms to safeguard private wells

Darya Minovi[1]
[1]*Center for Progressive Reform, Washington, USA*

Forty-two million Americans get their drinking water from unregulated water sources, primarily private wells. In lieu of federal action, several U.S. states have adopted policies and programs to protect private well owners, who tend to live in rural, underserved areas. The presentation shares the findings of a national policy review of key programs adopted by states, such as providing free water quality test kits and establishing a public database of private well water quality results, to safeguard public health. The presentation will also share a case study of Maryland, where policymakers have sought to enhance resources for well users and transparency regarding well water quality. These strategies provide a model for other states and nations seeking to alleviate disparities in access to safe drinking water.

KEYWORDS: drinking water, nitrate, water access, water pollution

O-SY-035 Lead contamination of drinking water is an EJ issue

Ronnie Levin[1]
[1]*Harvard School of Public Health, Boston, USA*

Lead exposures are not distributed evenly, including from US public drinking water. Lead contamination of drinking water is disproportionately reported or uncovered in low income and minority communities. Risk factors include distressed municipalities and rural areas; a history of underinvestment in public infrastructure, including water infrastructure; and old and poorly maintained housing stock combined with high rates of rental housing. Even within average or affluent communities, low income and minority neighborhoods exhibit higher rates of lead contamination of drinking water with disparities in lead pipe removal. The proposed massive US investment in infrastructure improvements is insufficient to equalize those inequities.

O-SY-036 The US Safe Drinking Water Act's systemic failure to equitably safeguard vulnerable Americans from contaminants Including nitrates

Erik D. Olson[1]
[1]*Natural Resources Defense Council, Washington, USA*

The US Safe Drinking Water Act was intended to protect Americans against tap water contamination. While modest progress has been made, systemic problems exist. Nitrate contamination is a key case in point. US EPA's nitrate standard was set in 1975 at a level of frank health effects; the law was weakened in 1996. Enforcement of the current unprotective standards has been anemic, with widespread noncompliance. Lax enforcement of drinking water standards disproportionately affects low-income communities and communities of color. Resolving these issues requires statutory revisions, strengthened standards, additional funding, restructuring of small non-viable systems, and better compliance and enforcement.

SYMPOSIUM 08: Magnetic Resonance Imaging (MRI); a cross-cutting tool at the intersection of environmental epidemiology and developmental neuroscience

O-SY-037 Pre-natal and neonatal neuroimaging in the BiSC cohort

Jordi Sunyer[1,2], Jesús Pujol[3], Gerard Martínez-Vilavella[3], Ioar Rivas[1,2], Cecilia Persavento[1], Marta Muniesa[4], Elisenda Eixart[4], Mireia Gascón[1,2], Maria Foraster[1,2], Maria Dolors Gómez-Roig[4], Elisa Llurba[5], Payam Dadvand[1,2]

[1]Barcelona Institute for Global Health-ISGlobal, Barcelona, Spain, [2]Universitat Pompeu Fabra, Barcelona, Spain, [3]MRI Research Unit, Department of Radiology, Hospital del Mar, Barcelona, Spain, [4]BCNatal, Hospital Sant Joan de Déu and Hospital Clínic, Universitat de Barcelona, Barcelona, Spain, [5]Obstetrics and Gynaecology Department, High Risk Unit, St Pau University Hospital, Barcelona, Spain

BACKGROUND AND AIM: The Barcelona Life Study Cohort (BiSC) aims to evaluate, among others, the effect of pre-natal urbanome on pre- and postnatal brain structure and function in a cohort of 1086 mothers-child pairs recruited during the years 2018-2021.

METHODS: We conducted transvaginal neurosonography at week 32 in 1014 (93%) pregnant women and brain MRI in 132 neonates at day 28 of life, done while the infants were asleep.

RESULTS: Neurosonography reliably captured size of different brain structures, depth and degree of maturation of specific cortical fissures and sulci, and the area of the corpus callosum and lateral ventricles in around 80% of the acquisitions. Complete acquisition of MRI was obtained in 54 of the 132 neonates (41%). Anatomical acquisition was obtained in 104 and 108 babies (3D-T1 and Flair-T2, respectively), fMRI in 74 babies (resting state) and DTI in 63 babies.

CONCLUSIONS: Early-life brain imaging variables, that have been shown to have a predictive value for outcomes in postnatal life, or to be associated with myelination affected by urbanome (such as pre-selected sensorimotor pathways and white matter tracks) could be reliably measured in general population studies.

KEYWORDS: Pregnant women, neonates, brain development.

FUNDING: This project has received funding from the ERC-AdG-2018 AIR-NB project (GA: 785994).

O-SY-038 Resting-state functional connectivity patterns are associated with metal mixture exposure in young adolescents

Megan Horton[1], Elza Rechtman[1], Christine Austin[1], Paul Curtin[1], Azzurra Invernizzi[1], Esmeralda Navarro[1], Demetrios Papazaharias[1], Libni Torres-Olascoaga[1], Luis Bautista[2], Sandra Martínez-Medina[3], Rafael Lara-Estrada[4], Erika Proal[2], Vivianca Villicana[2], Cheuk Tang[5], Martha M. Téllez-Rojo[2], Robert O. Wright[1], Manish Arora[1]

[1]Icahn School of Medicine at Mount Sinai, New York, USA, [2]Center for Nutrition and Health Research, National Institute of Public Health, Mexico, [3]National Center for Perinatology, Mexico City, Mexico, [4]National Research Laboratory in Imaging and Medical Instrumentation, Metropolitan Autonomous University, Mexico, [5]Department of Diagnostic, Molecular, and Interventional Radiology, Icahn School of Medicine at Mount Sinai, USA

BACKGROUND AND AIM: Early-life metal mixture exposure may increase the risk for anxiety and depression in adolescence. The neural circuitry subserving internalizing phenotypes begins developing in utero and is vulnerable to early-life exposures. Resting state functional magnetic resonance imaging (rs-fMRI) provides a novel tool to examine underlying mechanisms of metal-associated neurodevelopmental outcomes. We investigate relationships between early-life metal exposure and functional connectivity in pre-adolescents.

METHODS: In preliminary analysis of 67 children (8-14years; 34 females) enrolled in the Programming Research in Obesity, Growth, Environment and Social Stressors (PROGRESS) study, we estimated weekly exposure (14th week gestation through one year of age) to 15 metals (Ba, Bi, Cd, Co, Cr, Cu, Li, Mg, Mn, Mo, Ni, Pb, Sn, Sr, Zn) in deciduous teeth using laser ablation-inductively coupled plasma-mass spectrometry. Using graph theory analysis of rs-fMRI data, we computed global and local efficiency (GE, LE) and eigenvector centrality (EC) in 111 brain areas (Harvard Oxford Atlas). We used lagged weighted quantile sum (lWQS) regression to examine time-varying associations between metal mixtures and GE, LE or EC in the whole brain and anterior cingulate cortex (ACC), globus pallidus (GP), and insula, adjusting for sex and age.

RESULTS: We observed prenatal and postnatal windows between the metal mixture and LE; -13 to 4 weeks, peak βLE (week -2) = -0.23, 95%CI -0.02, -0.45 and 16 to 43 weeks; peak βLE (week 42) = -0.42, 95%CI -0.13, -0.70 and one prenatal window for GE at -18 to -11 weeks, peak βGE (week -18) = -0.35, 95%CI -0.07, -0.64. The metal mixture was significantly associated with decreased EC in the ACC, GP and insula at different critical windows spanning gestation and infancy.

CONCLUSIONS: Our results combining lWQS modeling with graph theory analysis of rs-fMRI may inform mechanistic understanding of environmentally-associated neurodevelopmental outcomes.

O-SY-039 Prenatal exposure to endocrine disrupting chemicals and brain development in adolescents

Akhgar Ghassabian[1], Michiel van den Dries, Leonardo Trasande, Suzanne Spaan, Kurunthachalam Kannan, Anjoeka Pronk, Tonya White, Henning Tiemeier, Mònica Guxens
[1]*New York University Grossman School of Medicine, New York, USA*

BACKGROUND AND AIM: Despite growing concerns regarding the neurotoxicity of phthalates and bisphenols, brain differences associated with gestational exposure to these chemicals are understudied. We investigated the extent to which prenatal exposures to these endocrine disrupting chemicals are associated with global brain volumetric measures in adolescents and whether brain measures mediate the association of prenatal exposures with child IQ.

METHODS: We included 908 mother-child pairs from Generation R, a population-based birth cohort, with data on maternal gestational phthalate and/or bisphenol concentrations and T1-weighted magnetic resonance imaging in children at age 10 years. Child IQ was assessed at age 14 years. Maternal urinary concentrations of phthalate metabolites and bisphenols were measured at early, mid-, and late pregnancy. We examined the associations of pregnancy-averaged, creatinine-adjusted concentrations of individual phthalate metabolites as well as ∑di-2-ethylhexyl phthalate, phthalic acid, and bisphenol A with and brain volumetric measures using linear regression. We used mediation modelling to identify the proportion mediated by brain measures in the association of prenatal exposures and child IQ.

RESULTS: Higher maternal concentrations of monoethyl phthalate (mEP) were associated with smaller total gray matter volumes in offspring at age 10 years (β per log10 increase in creatinine adjusted mEP=-10.27, 95%CI:-17.85, -2.69). Total gray matter volumes partially mediated the association between higher maternal mEP and lower child IQ (natural indirect effect=-0.27, 95%CI: -0.55,0.00, proportion mediated=20%). An association of higher monoisobutyl phthalate (mIBP) and smaller cerebral white matter volumes was present only in girls, with cerebral white matter volumes mediating the association between higher maternal mIBP and lower IQ in girls. We found no association between maternal prenatal bisphenols and global brain volumetric measures or child IQ.

CONCLUSIONS: Our findings suggest the global impact of prenatal phthalate exposure on the brain that extends into adolescence and underlies impaired general cognition.

KEYWORDS: MRI; Pregnancy, phthalates

O-SY-040 Ambient air pollution and functional brain network development in adolescence

Devyn Cotter[1,2], Claire Campbell[1,2], Kirthana Sukumaran[2], Rob McConnell[2], Kiros Berhane[3], Joel Schwartz[4], Daniel Hackman[5], Hedyeh Ahmadi[2], Jiu-Chiuan Chen[2,6], Megan Herting[2,7]

[1]Neuroscience Graduate Program, University of Southern California, Los Angeles, USA, [2]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [3]Department of Biostatistics, Columbia University Mailman School of Public Health, NY, USA, [4]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [5]USC Suzanne Dworak-Peck School of Social Work, University of Southern California, Los Angeles, USA, [6]Department of Neurology, Keck School of Medicine of University of Southern California, Los Angeles, USA, [7]Children's Hospital Los Angeles, Los Angeles, USA

Air pollution is linked to neurodevelopmental delays, but its association with brain network development has yet to be investigated utilizing a longitudinal cohort. We aimed to characterize the relationship between PM2.5, O3, and NO2 exposure at ages 9-10 years and 2-year longitudinal changes in functional connectivity (FC) in regions important for emotional and cognitive functioning, namely the salience, frontoparietal, and default-mode brain networks as well as the amygdala and hippocampus.

7719 participants from the Adolescent Brain Cognitive Development (ABCD) Study® were included. Annual averages of pollutants were assigned to the child's primary residential address using an ensemble-based exposure modeling approach. Resting-state functional MRI was collected on 3T MRI scanners at baseline and follow-up visits. Single- and multi-pollutant mixed-effect linear models, with subject and study site as random effects, were constructed to examine the putative exposure effect on intra-network, inter-network, and subcortical-to-network FC change, by testing age-by-pollutant interactions and adjusting for sex, race/ethnicity, household income, parental education, handedness, scanner type, and motion during scanning.

After Bonferroni correction, single- and multi-pollutant models revealed inter-network FC increased with age for individuals with higher PM2.5 exposure but decreased with age for those with higher NO2 exposure. Similarly, subcortical-to-network FC increased with age for those with higher PM2.5 exposure but decreased with age for individuals with higher O3 exposure. There were no significant intra-network associations with pollutant-by-age interactions. PM2.5 and O3 were negatively correlated ($r=-0.18$, $p<2.2e-16$); PM2.5 and NO2 were positively correlated ($r=0.20$, $p<2.2e-16$); no correlation existed between O3 and NO2 ($r=-0.02$, $p=0.15$).

In normative development, inter-network segregation is expected. Our findings indicate that higher levels of exposure to PM2.5 in childhood relate to distinct changes in age-related patterns of network segregation, suggesting functional network immaturity. However, functional network segregation does not seem to be hindered by increased exposure to NO2 and O3.

O-SY-041 Outdoor residential air pollution exposure and the development of brain morphology across childhood: a longitudinal study

Michelle Kusters[1,2], Ryan Muetzel[2], Albert Ambrós[1], Henning Tiemeier[3], Mònica Guxens[1,2]
[1]ISGlobal, Barcelona, Spain, [2]Department of Child and Adolescent Psychiatry/Psychology, Erasmus MC, University Medical Centre, Rotterdam, The Netherlands, [3]Department of Social and Behavioral Science, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Emerging evidence suggests a relationship between exposure to air pollution and brain morphology in children, but little is known about how air pollution exposure influences the development of brain structures throughout childhood. We aim to study the association of air pollution exposure during pregnancy and childhood with the development of brain morphology from age 6-16 years.

METHODS: We used data from 4,243 children of the Generation R study, a birth cohort in Rotterdam, the Netherlands. We estimated the concentrations of fourteen air pollutants at participant´s home addresses during pregnancy and childhood, using land use regression models. We included structural brain images at three time points, namely at age 6-10 years, 9-12 years, and 13-16 years. We assessed the association between the air pollutants and brain volumes with linear mixed models, fitting an interaction term for age and each pollutant. Models were adjusted for socioeconomic status and lifestyle characteristics.

RESULTS: Higher air pollution exposure during pregnancy was associated with a slower decrease of cortical grey matter volume starting at around age 10 and a slower increase of corpus callosum volume (e.g. -12.7 mm3 increase in corpus callosum volume [95%CI -22.0; -3.3] with each year of age per 10 µg/m3 increase in nitrogen dioxide exposure). Childhood exposure was associated with a faster decrease of putamen and caudate nucleus volume, and a slower increase of hippocampus volume. Higher exposure to air pollution during pregnancy and childhood was associated with a slower increase of thalamus volume. Air pollution exposure was not associated with cerebellum, amygdala, nucleus accumbens or globus pallidus volume.

CONCLUSIONS: Air pollution exposure was associated with region-specific differences in age-related growth trajectories. Air pollution exposure during childhood might affect different brain regions than exposure during pregnancy.

KEYWORDS: air pollution, neurodevelopment, children, traffic

SYMPOSIUM 09: Infections and the environment

O-SY-042 Immunotoxic chemicals, childhood infections, and long-term health effects

Maribel Casas[1]
[1]*Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain*

BACKGROUND AND AIM: Environmental chemicals can act as immunotoxicants by dysregulating the immune system, and can modulate the effects of infectious agents. Several studies link exposure to environmental chemicals with susceptibility to infectious diseases in adults and children, but results are inconclusive. Also, the role of subclinical infections in long-term health effects has been little examined. We will present specific results from ongoing analyses in children and also discuss priority areas for research on the immunotoxic effects of environmental chemicals.

METHODS: Results from ongoing analyses in three European birth cohorts [Born in Bradford (BiB), UK; Environment and Childhood (INMA), Spain), and Mother Child cohort study (RHEA), Greece], with information on immunotoxic chemicals in early life, humoral response to common natural infections, and long-term health effects, will be presented. The effects of common infections in children in relation to chemical exposures and their combined effects on the immune system and long-term health effects will be reviewed.

RESULTS: Results from the RHEA cohort showed that maternal levels of polychlorinated biphenyls (PCBs) may increase susceptibility to persistent viral infections in the first years of life. Also, exposure to dichlorodiphenyltrichloroethane (DDT) during pregnancy and in childhood was associated with lower immunoglobulin-G levels against varicella from 6 to 11 years of age. Evidence of the immunotoxic effects of historical persistent organic pollutants such as PCBs and DDT is strong; however, evidence is still limited for the emerging chemicals including per- and polyfluoroalkyl substances and the non-persistent ones such phthalates and phenols.

CONCLUSIONS: Exposure to immunotoxic agents in early-life may modulate humoral response to common natural infections in children. The potential for some of the most widely used chemical compounds to interfere with the developing immune system during critical periods of development is of great concern for public health given the current context of emerging epidemics.

O-SY-043 Ambient air-pollution and COVID-19

Manolis Kogevinas[1]
[1]*Isglobal- Barcelona Institute for Global Health, Barcelona, Spain*

BACKGROUND AND AIMS: The COVID-19 pandemic is challenging the world's economic and health systems, and introduced completely new challenges. The outbreak of COVID-19 highlighted the links between the occurrence of new infections, the environment and climate at a global scale and the need for trans-disciplinary approaches. Emerging evidence links ambient air pollution with COVID-19 disease, an association that is methodologically challenging to investigate.

METHODS: I will review the evidence on ambient air pollution Covid -19 disease and disease severity and discuss potential biases. I will further discuss new research areas on the association of air-pollution with post-COVID-19 condition (long-COVID) and with immune response associated with natural infection and with vaccine response.

RESULTS: More than 100 studies have been published globally on air-pollution and Covid-19 reporting more than 400 separate pollutant-COVID-19 effect estimates. Most studies to date have employed ecological designs, associating group-level air pollution exposures with aggregate COVID-19 outcomes over a broad geographic domain. Many of these studies relied on COVID-19 disease incidence estimated from surveillance data. Differences in the associations between long-term and short term exposures to air pollution and COVID-19 incidence and severity have been poorly evaluated. Studies using individual-level designs, which can avoid the potential for clustering of cases and that did extensive adjustment for potential confounders including contextual variables, convincingly show that exposure to air pollution is associated with COVID-19 disease and mortality. The few existing studies evaluating immune response show an association of air-pollution with higher levels of antibody response among infected and also depressed immune response among non-infected vaccinated. There is still scarce evidence on air pollution and long-COVID.

CONCLUSIONS: The pandemic has highlighted the deep interconnections between the environment and infectious diseases and specifically the association of air pollution with COVID-19 through multiple biological pathways.

KEYWORDS: COVID-19; air pollution; long-COVID; immune response

O-SY-044 Climate change and cascading risks from infectious disease

Jan C. Semenza[1]
[1]*Heidelberg Institute of Global Health, University of Heidelberg, Stockholm, Sweden*

BACKGROUND AND AIM: Climate change is considered as one of the greatest threats to human health in the 21st century, with significant increases in temperature extremes, heavy precipitation, and severe droughts. This study examines cascading risk pathways from climate change for vector-, water-, food, and air-borne infectious diseases in a global context.

METHODS: The peer-reviewed literature that examined the specific aims of this study, climate change and cascading risks from infectious disease, was reviewed and assessed the association between climate change and disease transmission. Climatic and other cascading drivers of infectious disease with projections under different climate change scenarios was also assessed.

RESULTS: Weather and climate events, population movement, land use changes, urbanization, global trade, and other drivers can catalyze a succession of secondary, causally connected events, that can disrupt critical infrastructure, vital for a functional society. Climate hazards can activate cascading risk pathways that can lead to a range of health impacts, including infectious disease outbreaks. Cascading effects from climate hazards include stagnant water that serve as breeding ground for mosquitoes after a flood; contamination of drinking water after a storm surge; breakdown of vector control programs after a hurricane; or cholera outbreak after a drought.

CONCLUSIONS: A narrow, siloed, and linear assessment of these risks will misinform decision- and policymakers of the magnitude and pattern of future risks, and of the opportunities to modify policies to reduce inherent vulnerabilities and enhance infectious disease control programs. Elucidating cascading risk pathways from infectious diseases is a first step towards tackling infectious disease threats from climate change.

O-SY-045 Looking forward: COVID-19 and greenhouse gas emissions

Kristie Ebi[1]
[1]*University of Washington, Seattle, USA*

BACKGROUND AND AIM: The COVID-19 pandemic dramatically changed the global economy, thus decreasing carbon dioxide emissions by nearly 7%, raising hopes that a legacy of the pandemic would be a permanent shift in the trajectory of emissions.

METHODS: Greenhouse gas emissions over the course of the pandemic will be reviewed, along with the implications of greenhouse gas emissions along various recovery pathways.

RESULTS: During the first year of the pandemic, surface, especially road, transport was affected the most, primary the result of restrictions aimed at reducing infection rates. These changes altered exposures to PM2.5 (increase) and ozone (decrease), potentially reducing premature mortality and avoiding hospital admissions. Scenarios of possible recovery pathways include focusing on returning to the “old” economy, decoupling GDP growth from CO2 emissions, and focusing on achieving a more sustainable and inclusive climate-resilient pathway. Incorporating health co-benefits into estimates of the cost of mitigation policies and technologies could help motivate individuals to countries to shift to climate-resilient and environmentally sustainable pathways.

CONCLUSIONS: Achieving the Paris Agreement goal of keeping warming at less than 2□C above pre-industrial temperatures requires rapid reduction of greenhouse gas emissions, more rapid than occurred during the COVID-19 pandemic. Quantifying health co-benefits of mitigation can be a key element in achieving a more sustainable and resilient future.

KEYWORDS: climate change; greenhouse gas emissions

Tuesday, September 20

SYMPOSIUM 10: A new era in global climate change and human health research funding and action

O-SY-046 A new era in global climate change and human health research funding and action – NIH

Gwen Collman[1], Aubrey Miller[1], Joshua Rosenthal[1]
[1]*National Institutes of Health, Bethesda, USA*

BACKGROUND: The U.S. National Institutes of Health (NIH) have supported climate change and health-relevant research for decades. Through the years 2010 to 2020, annual NIH support for climate change and health research hovered around $10 million funded by 21 NIH components. The NIH Climate Change and Health Initiative, launched in 2021, is an NIH-wide effort to develop the first coordinated NIH plan for research on the impacts of climate change on human health.

METHODS: The Initiative created a core framework in 2021 that was informed by a month's long planning and engagement process. Directors of seven Institutes and Centers at the NIH have joined together to create a strategic framework document that highlights the core focus areas of the work. The group released a Public Request for Information to gather input from community organizations and academic scientists and conducted a federal and international landscape assessment to map out organizations working in the space. Internally, NIH conducted a portfolio analysis of funded climate research from the past decade, engaged staff through workshops, and developed an internal data call for planned climate related programs.

RESULTS: The strategic framework will guide a community of practice comprising outstanding and committed scientists, trainees, and specialists. Key areas of interest outlined include: Health Effects Research, Health Equity, Intervention Research and Training and Capacity Building. The framework also identifies nine key areas of supporting science for climate change and health research.

CONCLUSIONS: Climate change is impacting health and communities around the world but there remain many key research knowledge gaps. NIH's role as a leading funder of biomedical and human health research can play an important role in coordinating research to better understand health impacts, health adaptation, and outcomes in communities impacted related to climate change. There is perhaps no greater opportunity for NIH to fulfill its mission than by providing global leadership in the response to the burgeoning climate change and health crisis.

KEYWORDS: Climate change; public health; research

O-SY-046a A new era in global climate change and human health research funding and action – EPA

Bryan Hubbell[1]
[1]*Environmental Protection Agency, Washington D.C., USA*

BACKGROUND: The EPA's Air, Climate, and Energy (ACE) research program is responding to climate change and environmental justice priorities through research that addresses multiple dimensions of climate change and health.

METHODS: The ACE program conducts research focusing mainly on cumulative impacts of climate change, air pollution, and non-chemical stressors that impact human health and the environment. ACE utilizes its tools to investigate the health consequences of extreme events including heat, wildfires, and floods, as well as longer-term health impacts associated with overall warming and transformations in the nation's energy and transportation systems and built environment. The ACE program also conducts research to support adaptation and resilience solutions that reduce health impacts and promote equitable outcomes in communities with environmental justice concerns.

RESULTS: ACE research has produced studies showing how future extreme weather and air quality will be impacted by different climate change scenarios, demonstrating that climate change will increase the health burden from ozone and increase the intensity of rainfall events during storms. ACE research has also evaluated the relative air quality and health impacts of prescribed fires and wildfires, showing that well-designed prescribed fires can potentially reduce the overall smoke-related health impacts from wildland fires, which are growing in size and intensity due to climate change. ACE has also funded grants to 12 institutions to evaluate strategies to reduce exposures to smoke during wildland fires.
CONCLUSION: Climate change is having direct and indirect impacts on the health of people. More extreme weather events, heat waves, spread of infectious diseases and detrimental impacts on air and water quality are having impacts on our health. EPA is currently focusing on research and planning to address this issue in their future work.

KEYWORDS: Climate change; public health; environmental justice

O-SY-047 A new era in global climate change and human health research funding and action – CDC

Erik Svendsen
[1]*Centers for Disease Control and Prevention, Atlanta, USA*

BACKGROUND: In 2021, the Centers for Disease Control and Prevention (CDC) established an agency-wide Climate and Health Task Force in response to Executive Order 14008, Tackling the Climate Crisis at Home and Abroad. The Task Force's objective is to reduce the health impacts of climate change by developing a comprehensive approach to integrate climate and health activities across CDC programs, coordinate with external partners, and increase capacity to prepare for and respond to the health impacts of climate change, particularly among those disproportionately affected. The new agency-wide climate and health strategy emphasizes health equity, surveillance, preparedness, research and communication.

METHODS: The agency created mission and vision statements that focus on the need to address climate-related health inequities at home and abroad. The Task Force subsequently identified five focus areas for the climate and health strategic framework: Health Equity and Environmental Justice; Surveillance, Analytics, Modeling, and Forecasting; Preparedness, Response, Prevention, and Adaptation; Research, Implementation Science, and Evaluation; and Education and Dissemination.

RESULTS: for each focus area, an overarching goal and several priority outcomes have been developed, along with key implementation actions for each outcome, evaluation metrics and implementation timelines. Several of the focus areas have important intersections with other agency priorities, including health equity, emergency preparedness and data modernization initiatives.
CONCLUSION: Climate change is the biggest environmental public health threat of our time, and its direct and indirect impacts on human health and wellbeing are worsening. By implementing the new strategic approach, CDC aims to address this threat by detecting, investigating, forecasting, tracking, preventing, and responding to the public health threats of climate change, addressing health inequities, and strengthening community resilience.

KEYWORDS: Climate change; public health; health equity; climate resilience

O-SY-048 A new era in global climate change and human health research funding and action – EC

Tuomo Karjalainen
[1]*European Commission, Brussels, Belgium*

BACKGROUND: The European Commission has launched several recent initiatives on climate change and health. The European Climate and Health Observatory aims to support Europe in preparing for and adapting to the impacts of climate change on human health by providing access to relevant information and tools. Additionally, the EU Mission Adaptation to Climate Change was recently launched with the goal to support European regions and communities towards climate resilience by 2030.

METHODS: The Observatory aims to provide easy access to a wide range of relevant publications, tools, websites, and other resources related to climate change and human health. The Observatory is a partnership between the European Commission, the European Environment Agency (EEA) and several other organizations. It contributes to the European Green Deal and the EU4Health vision for a healthier European Union.
The Mission will foster the development of innovative solutions to adapt to climate change and encourage regions, cities and communities to lead the societal transformation.
Large-scale demonstrators, a key element of the Mission, will feature examples of breakthrough innovations implemented in real life such as floodplain restoration, vertical farming, or prototyping of insurance approaches. Regions, cities and local authorities will steer the process to build climate resilience “on the ground” in an inclusive way, engaging with local stakeholders, the civil society, the business community, industry, research organizations, and citizens.

RESULTS: The Mission will foster the development of innovative solutions to adapt to climate change and encourage regions, cities and communities to lead the societal transformation.
Large-scale demonstrators, a key element of the Mission, will feature examples of breakthrough innovations implemented in real life such as floodplain restoration, vertical farming, or prototyping of insurance approaches. Regions, cities and local authorities will steer the process to build climate resilience “on the ground” in an inclusive way, engaging with local stakeholders, the civil society, the business community, industry, research organizations, and citizens.

CONCLUSIONS: The EU Mission support will be provided in different ways by helping European regions and communities better understand, prepare for and manage climate risks and opportunities; working with at least 150 European regions and communities to accelerate their transformation toward climate resilience, and delivering at least 75 large-scale demonstrators of systemic transformations on the ground. The Observatory already includes the 38 EEA Member and cooperating countries and hundreds of resources from 1988 through present.

SYMPOSIUM 11: Impact of exposure measurement error (ME) on the health effect estimates: quantification and correction

O-SY-049 Impact of exposure measurement error (ME) on the health effect estimates: introduction

Klea Katsouyanni[1,2], Dimitris Evangelopoulos[2,3]
[1]*National and Kapodistrian University of Athens, Athens, Greece,* [2]*MRC Centre for Environment and Health, Environmental Research Group, Imperial College London, London, UK,* [3]*NIHR Health Protection Research Unit on Environmental Exposures and Health at Imperial College, London, London, UK*

BACKGROUND/AIM: Although it is widely accepted that air pollution exposure, at least to pollutants of ambient origin, has adverse health effects, the quantitative effect estimates incorporate considerable uncertainty, especially because the relevant exposure (namely individual or population exposure to pollutants of ambient origin) is so difficult to measure accurately. The resulting exposure Measurement Error (ME) is a neglected but potentially important problem resulting in bias and loss of accuracy in health effect estimates. This Symposium will focus on recently published results on the bias in effect estimates due to exposure measurement error.

METHODS: Measurements of air pollutants concentrations from fixed site monitors or ad-hoc campaigns have been used in epidemiological studies assessing the associations between exposure to pollutants and multiple health outcomes, and also models (statistical, dispersion or hybrid) have been extensively developed and applied. The magnitude and direction of bias resulting from ME in exposure estimation has mainly been evaluated in simulation or validation studies.

RESULTS: Recent publications show that bias from ME of commonly applied exposure models is mainly towards the null and can be substantial. Only under specific and relatively rarely observed values of correlations and variance ratios upward bias is observed. Other studies which use more sophisticated “hybrid” models show smaller bias.
CONCLUSION: In this Symposium we will attempt to quantify the importance of exposure ME in the valid estimation of health effects of air pollutants. We will present results from recent studies which quantified the impact of various types of exposure measurement error on the effect estimates for health outcomes and evaluated correction methods.

O-SY-049a Identifying determinants and characterizing the type of exposure measurement error in association with different error-prone exposure assessment methods

Dimitris Evangelopoulos[1,2], Hanbin Zhang[1,2], Dylan Wood[1,2], Ben Barratt[1,2], Heather Walton[1,2], Klea Katsouyanni[1,2,3]
[1]MRC Centre for Environment and Health, Environmental Research Group, Imperial College London, London, UK, [2]NIHR HPRU in Environmental Exposures and Health, Imperial College London, London, UK, [3]Department of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

BACKGROUND/AIM: In air pollution epidemiology, error-prone exposures are used to investigate the health effects of exposure to outdoor pollution. This leads to measurement error (ME) bias of varying size and direction. We seek to quantify ME magnitude, type (classical/Berkson/mixture), and determinants, to be able to use the most appropriate methods for error correction. Personal exposure to pollution from ambient origin has been defined as the true exposure and ME as the difference between the latter and any surrogate exposure.

METHODS: Within the MELONS project, we collected personal data from multiple monitoring campaigns in London for $PM_{2.5}$, NO_2, O_3 and BC. We compared those with measurements from the monitoring network, modelled concentrations at fine spatial scales or methods incorporating indirect adjustment of these estimates for the time-activity patterns in the postcode sector of the participants. Individual- and area-level characteristics, e.g. age, sex, socioeconomic status, temperature, were assessed as potential ME determinants.

RESULTS: Preliminary analysis using long-term exposure estimates has shown that personal exposure from outdoor sources to $PM_{2.5}$ and NO_2 (Mean (SD): 6.4 (3.0) μg/m³ and 7.1 (4.2) μg/m³ respectively) was largely overestimated when surrogate exposures were used (up to 9.9 (2.2) μg/m³ and 39.5 (11.0) μg/m³ respectively). Indirect time-activity adjustment for the nearest monitor estimates reduced ME magnitude and variability substantially. The types of error also varied by the surrogate used. Age and proximity to the nearest monitor were found to drive ME. Day-to-day ME variation and potential time-varying error determinants will also be examined.

CONCLUSIONS: The use of surrogate exposures for the investigation of the health effects of long-term exposure to outdoor air pollution can distort the epidemiological estimates. Information about the ME structures and its determinants can be used for correction and the identification of the true exposure-response functions.

O-SY-050 Accounting for space and time in measurement error corrections

Joel Schwartz

Measurement error is endemic in epidemiology and arguments over the direction of bias persist. Modern high-accuracy models of ambient concentrations of air pollutants have reduce error. We illustrate the use of machine learning algorithms to estimate the spatial and temporal variation of exposure error in simulation studies to estimate the direction and extent of bias in air pollution epidemiology using linear, nonlinear, and threshold relationships. We also illustrate the use of regression calibration models that account for differences in calibration across space. We also discuss the parallel between using ambient instead of personal exposure and intention to treat analyses.

O-SY-051 Using SIMEX and regression calibration to correct for mixtures of classical and Berkson measurement error

Barbara Nicholas (nee Butland)[1], Evangelia Samoli[2], Dimitris Evangelopoulos[3,4], Klea Katsouyanni[2,3,4]
[1]Population Health Research Institute, St George's, University of London, London, UK, [2]Department of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, [3]MRC Centre for Environment and Health, Environmental Research Group, School of Public Health, Imperial College London, London, UK, [4]NIHR HPRU in Environmental Exposures and Health, Imperial College London, London, UK

BACKGROUND AND AIM: Measurement error in modelled air pollution data is complex consisting of classical and Berkson error components. As part of the MELONS project, we investigated the adequacy of regression calibration and SIMEX in correcting health effect estimates when measurement error contains both components and may also be spatially correlated.

METHODS: In a simulation study of 5,000 subjects, we considered scenarios based on the amount of total measurement error (either 20% or 40% of the variance in the true annual average pollutant concentrations); the proportion of error that was classical (0%,20%,40%,60%, 80% or 100%); and whether total measurement error was homoscedastic or heteroscedastic. Within each simulation, we obtained a dataset of true, and error prone annual average pollutant concentrations and outcome data linked to the true by a hazard ratio of 1.041 per 10μg/m³. The error prone pollutant concentrations were then used as the exposure variable in a Cox regression, and for error correction, a 5% hypothetical validation sub-sample of the data were randomly selected and used to estimate the classical and Berkson error variances. Based on 1,600 simulations per scenario we investigated mean percent bias in the estimated log hazard ratio and the ability of regression calibration and SIMEX to correct for this bias.

RESULTS: Mean percent bias in the uncorrected log hazard ratio was typically negative (i.e., towards the null) ranging from -27.4% to +2.0% across scenarios. Mean percent bias in the corrected estimates ranged from -4.0% to +5.7% for regression calibration and -6.0% to +4.2% for SIMEX.

CONCLUSIONS: Across a range of scenarios varying the mix of classical and Berkson error and allowing total measurement error to vary spatially, SIMEX and regression calibration produced corrected log hazard ratios with relatively small mean percent bias.

KEYWORDS: Measurement Error, SIMEX, Regression Calibration

O-SY-052 Empirical measurement error bias correction for the effects of functions of the exposure history: cumulative average PM2.5 in relation to all-cause mortality

Donna Spiegelman

Cohort studies in air pollution epidemiology construct the exposure metric as a cumulative average over a pre-determined time window. We present valid methods for empirically estimating the time window, and simultaneously estimating the exposure effect from this complex variable that is a function of multiple exposure measurements over time, correcting for exposure measurement error bias using validation data. Air pollution validation studies will be briefly presented. Then, methods will be illustrated in the Nurses' Health Study's investigation of PM2.5 on all-cause mortality. Valid confidence interval construction will be considered, and publicly available software for conducting these analyses will be shown.

SYMPOSIUM 12: The project EXHAUSTION – Heat and air pollution effects on cardiopulmonary mortality and morbidity: geographical variability and vulnerable groups in Europe

O-SY-053 Short-term heat effects and effect modification by ambient air pollution on cardiovascular and respiratory mortality across 148 cities from 13 European countries – Results of the EXHAUSTION project

Masna Rai[1,2], Massimo Stafoggia[3], Francesca De'Donato[3], Antonio Gasparrini[4], Pierre Masselot[4], Envangelia Samoli[5], Sofia Zafeiratou[5], Klea Katsouyanni[5], Shilpa Rao[6], Liliana Vazquez Fernandez[6], Siqi Zhang[1], Kristin Aunan[7], Annette Peters[1,8], Alexandra Schneider[1], Susanne Breitner[1,8]

[1]Helmholtz Zentrum München - German Research Center for Environmental Health, Institute of Epidemiology, Neuherberg, Germany, [2]LMU Munich, Institute for Medical Information Processing, Biometry, and Epidemiology - Pettenkofer School of Public Health, Munich, Germany, [3]Lazio Regional Health Service - ASL ROMA 1, Department of Epidemiology, Rome, Italy, [4]London School of Hygiene & Tropical Medicine, Department of Public Health, Environments and Society, London, UK, [5]National and Kapodistrian University of Athens, Medical School - Department of Hygiene, Epidemiology and Medical Statistics, Athens, Greece, [6]Norwegian Institute of Public Health, Department of Air Pollution and Noise, Oslo, Norway, [7]CICERO - Center for International Climate Research, Oslo, Norway, [8]LMU Munich, IBE-Chair of Epidemiology, Neuherberg, Germany

BACKGROUND AND AIM: Epidemiological evidence on the potential interactive effects of high air temperature and air pollution on cause-specific mortality remains inconclusive and limited to selected locations. We investigated the effects of temperature on cardiovascular and respiratory mortality and its effect modification by particulate matter with a diameter ≤ 2.5 µm [$PM_{2.5}$] and ozone [O_3] during summer months (May-September) in 148 cities across 13 European countries.

METHODS: for these cities, we obtained daily counts of cardiovascular and respiratory mortality and daily exposure data between 2000 and 2018. We used location-specific confounder-adjusted Quasi-Poisson regression with a tensor product between air temperature and the air pollutant. We extracted temperature estimates at low, medium, and high levels of pollutants defined as the 5th, 50th, and 95th percentile of location-specific air pollutant concentrations. A random-effects multilevel meta-analytical model was used to derive the country-specific and overall estimates.

RESULTS: High summer temperatures were associated with increased cardiovascular and respiratory mortality. We further observed modification of the heat effects by elevated levels of $PM_{2.5}$ and O_3 in most locations, with stronger effects for respiratory than cardiovascular mortality. for example, the percent increase in respiratory mortality per increase in the 2-day average summer temperature from the 75th to the 99th percentile was 9.2% (95% Confidence Interval [CI] 8.9-9.4), 13.0% (95% CI 12.8, 13.2), and 19.8% (95% CI 19.5, 20.2) at low, medium, and high levels of $PM_{2.5}$, respectively.

CONCLUSION: We observed significant modification of the heat effects by elevated levels of $PM_{2.5}$ and O_3 leading to an increased risk of cardiovascular and respiratory mortality. With both temperature and air pollutant concentrations foreseen to increase considering climate change, targeted adaptation and mitigation measures are crucial to enhance resilience and sustainable development in alignment with EU climate change policies.

O-SY-054 Age standardized heat and cold related mortality impacts across European cities

Pierre Masselot[1], Malcolm Mistry, Jacopo Vanoli, Rochelle Schneider, Tamara Iungman, David Garcia-Leon, Juan-Carlos Ciscar, Luc Feyen, Hans Orru, Aleš Urban, Susanne Breitner, Veronika Huber, Alexandra Schneider, Evangelia Samoli, Massimo Stafoggia, Francesca de'Donato, Shilpa Rao, Ben Armstrong, Mark Nieuwenhuijsen, Ana Maria Vicedo-Cabrera, Antonio Gasparrini, MCC Collaborative Research Network, EXHAUSTION Project
[1]*London School of Hygiene & Tropical Medicine, London, UK*

BACKGROUND AND AIM: Heat and cold are important environmental risk factors for mortality with apparent geographical differences in vulnerability. Factors such as the local climate, topology, demography or the socio-economic situation can all affect the mortality burden of heat and cold. This study aims to comprehensively assess of the heat- and cold-related mortality in European cities, including less represented areas such as Scandinavia and Eastern Europe while accounting for the different demographic and vulnerability factors.

METHODS: We performed a mortality impact assessment related to heat and cold in 801 European cities through a three-stage analysis. First, in a selection of 191 cities, we assessed the exposure-response functions of temperature on mortality for different age groups. Second, these functions were pooled in a meta-analysis model with meta-predictors, including a regional background, age, and 22 vulnerability factors, reduced into a handful of composite indices. Third, this model was used to infer the exposure-response function to the whole 801 city sample, and to compute age-standardized excess mortality rates.

RESULTS: Across all examined European cities, we estimated an overall annual age-standardize excess mortality of 116 deaths (95%CI: 104-132) per 100,000 persons due to cold and 15 deaths (95%CI: 13-17) per 100,000 persons due to heat. The burden widely varied across Europe, being lower in western countries and higher in Eastern Europe for both heat and cold. at the same time, southern countries also experienced an important heat-related burden.

CONCLUSIONS: This study provides a high-resolution assessment of the heat and cold mortality burden across Europe. Results indicate important geographical differences with high vulnerability in the easternmost locations of the continent. These results might give valuable input for designing adaptation policies across Europe.

O-SY-055 Analysis of short-term heat effects on cardiopulmonary mortality using national and regional small area data – Results of the EXHAUSTION project

Massimo Stafoggia[1], Susanne Breitner[2], Francesca de' Donato[1], Alfonso Diz-Lois Palomares[3], Antonio Gasparrini[4], Pierre Masselot[4], Shilpa Rao[3], Evangelia Samoli[5], Liliana Vazquez Fernandez[3], Sofia Zafeiratou[5], Siqi Zhang[6], Kristin Aunan[7], Alexandra Schneider[6], EXHAUSTION Collaborative Group

[1]Lazio Region Health Service - Asl Roma 1, Rome, Italy, [2]Institute for Medical Information Processing, Biometry, and Epidemiology, LMU Munich, Munich, Germany, [3]Norwegian Institute of Public Health, Oslo, Norway, [4]Department of Public Health, Environments and Society, London School of Hygiene & Tropical Medicine, London, UK, [5]Department of Hygiene, Epidemiology and Medical Statistics, Medical School, University of Athens, Athens, Greece, [6]Institute of Epidemiology, Helmholtz Zentrum München (HMGU), Neuherberg, Germany, [7]CICERO Center for International Climate Research, Oslo, Norway

BACKGROUND AND AIM: The adverse effects of extreme air temperatures on mortality have been widely documented in major cities, while little is known about suburban or rural areas. We investigated the association between high air temperature and all-cause and cardiopulmonary mortality in the warm period (May-September) by small area levels in five European countries.

METHODS: We applied a novel two-stage design with two hierarchical aggregation levels, assigning mortality counts and air temperature at the finer level and performing the statistical analyses by using multiple series at the coarser level. The finer level was defined as municipalities in four countries (Norway, Germany, Italy and Greece) and as Lower Layer Super Output Area (LSOA) in England and Wales. The coarser level was defined as provinces (four countries) or Middle Layer Super Output areas (MSOA) (England and Wales). In each country, we applied area-specific Distributed Lag Nonlinear Models Poisson regression. Exposure was modelled at lag 0-1 days. Then, area-specific estimates were pooled in random-effects meta-analysis to obtain national and multi-country effects.

RESULTS: The pooled relative risk (RR) of mean temperature increases from the 75th to 99th percentile on all-cause mortality was 1.15 (95% confidence interval (CI): 1.08, 1.23) with RRs ranging from 1.05 (CI95%. 1.03-1.08) in Norway to 1.22 (95%CI. 1.21-1.24) in Italy. In Norway, England and Wales, and Greece, we detected much higher associations with respiratory mortality. Cause-specific analyses in Germany and Italy are ongoing. We also evaluated effect modification by age and sex, and found a greater risk among the elderly (75+ years, RR: 1.19, 95%CI: 1.10-1.28) and females (RR: 1.20, 95%CI: 1.09-1.32).

CONCLUSIONS: We found evidence of adverse effects of high temperatures on cardiopulmonary mortality in five countries using an innovative approach. Differentials urban/rural are object of current investigation.

O-SY-056 Long-term effects of air temperature on cardiopulmonary outcomes in prospective European cohort studies

Siqi Zhang[1], Susanne Breitner[2], MSc. Masna Rai[1], Massimo Stafoggia[3], Francesca de' Donato[3], Shilpa Rao[4], MSc. Alfonso Diz-Lois Palomares[4], Antonio Gasparrini[5], MSc. Jacopo Vanoli[5], Kristin Aunan[6], Annette Peters[1,2], Alexandra Schneider[1]

[1]Institute of Epidemiology, Helmholtz Zentrum München - German Research Center for Environmental Health, Neuherberg, Germany, [2]Institute for Medical Information Processing, Biometry, and Epidemiology, Ludwig Maximilian University of Munich, Munich, Germany, [3]Department of Epidemiology, Lazio Regional Health Service - ASL Roma 1, Rome, Italy, [4]Norwegian Institute of Public Health, Oslo, Norway, [5]Department of Public Health, Environments and Society, London School of Hygiene & Tropical Medicine, London, UK, [6]Center for International Climate Research, Norway

BACKGROUND AND AIM: Short-term health effects of air temperature have been well recognized. However, little is known about the effects of prolonged exposure to non-optimal air temperatures, particularly at the individual level. This study assessed long-term temperature effects on cardiopulmonary (CPD) outcomes using data collected in four prospective European cohorts.

METHODS: Participants of the KORA (Augsburg, Germany), RoLS (Rome, Italy), CONOR (Norway), and UK Biobank (UK) cohorts were included in the current analysis. Their vital status and incident diseases were identified through death and disease registries as well as follow-up surveys. Annual mean and standard deviation (SD) of air temperature were calculated for each participant and follow-up year based on the daily mean air temperature at residences estimated by spatial-temporal models. We applied cohort-specific Cox proportional hazard models with adjustment for individual characteristics and time trends, using the distributed lag non-linear model approach, to assess the associations of long-term air temperature with CPD mortality and morbidity. Random-effects meta-analysis was used to pool the cohort-specific estimates.

RESULTS: In the RoLS cohort, we observed a monotonically increasing risk for cardiovascular mortality associated with increasing annual mean and SD of temperature. for an increment from the 75th to the 95th percentile in the annual mean and SD, the hazard ratios for cardiovascular mortality were 1.055 (95% CI: 1.029, 1.081) and 1.151 (95% CI: 1.060, 1.251), respectively. Besides, increasing annual SD showed an indication of being associated with increased respiratory mortality risk. In the KORA cohort, no effects were observed for annual mean temperature or SD on CPD mortality and morbidity. Cohort-specific analyses in Norway and UK and the meta-analysis are ongoing.

CONCLUSIONS: This study provides evidence for long-term air temperature effects on CPD outcomes but also indicates heterogeneity in such effects among four European cohorts.

KEYWORDS: Air temperature, long-term, cardiopulmonary mortality, cohorts

O-SY-057 Heat and health prevention in European Region under a changing climate: the urgent need for a faster roll-out of Heat-Health Action Plans (HHAPs)

Gerardo Sanchez Martinez[1], Vladimir Kendrovski, Francesca de'Donato
[1]*Danish Technical University, Lyngby, Denmark,* [2]*European Environment Agency, Copenhagen, Denmark*

BACKGROUND AND AIM: adverse health effects from extreme heat remain a major risk, bound to increase in a changing climate. This paper assesses the status of heat impacts on health and their prevention in the European Region and discusses successes, failures and necessary action.

METHODS: results are based on a survey among the WHO European Region member states, a series of literature reviews intended to inform the update of the WHO Heat Health Action Planning guidance from 2008, and a review of the EEA Climate and Health observatory and Climate Adapt database.

RESULTS: though urbanization, population ageing and climate change are increasing heat vulnerability, heat-related mortality has decreased in several European countries. Heat health action plans (HHAP) progressively adopted since 2003 may have contributed to that reduction, although so far only 17 of the 53 member states of the WHO European Region have a HHAP, most (14) of them EU countries. All plans implemented basic core elements like alert systems and information plans, but most lack M&E, real time surveillance or influence over urban planning to reduce heat exposure. Involvement of subnational authorities remains low, and many plans are inadequately resourced and infrequently reviewed. Despite HHAPs being a prime example of climate change adaptation, their explicit presence in national adaptation plans and strategies in member states is far from generalized.

CONCLUSIONS: our findings suggest limited progress in the adoption and rollout of HHAPs, with many European countries lacking one, particularly outside the EU. Many core HHAP elements are still insufficiently implemented and only better M&E will clarify their effectiveness and allow for improvements. The EU Mission on Adaptation could support progress in HHAPs and contribute to attaining the objectives of the EU climate change adaptation strategy and the WHO Ostrava Declaration.

SYMPOSIUM 13: Advancing air pollution epidemiology in India: building capacity locally to address questions of context, policy relevance and methodological robustness

O-SY-058 Reconciling methodolatry and policy relevance in air pollution epidemiology: reflections from India

Bhargav Krishna[1]
[1]*Centre for Policy Research, New Delhi, India*

Indians experience some of the highest exposures to air pollution both within and outside the home, and Indian cities feature prominently on the list of most polluted places on the planet. The most recent sub-national burden of disease estimates note that approximately 1.7 million deaths were associated with household and ambient air pollution exposure in 2019, the highest of any country in the world. However, the evidence base continues to remain relatively scant for a country the size of India.

Recent efforts to strengthen the evidence base in India have involved the use of data from government sources. Examples of such sources in India include registry data and survey data from large-scale representative surveys conducted nationally. However, the use of these data in analyses for air pollution epidemiology presents fundamental challenges including:

1. Access and availability – data are either unavailable in a timely fashion to make meaningful inferences, or their public release involve several layers of complex bureaucracy
2. Quality – registry data are often incomplete and even when complete are replete with coding errors especially related to aspects such as cause of death
3. Periodicity – large-scale surveys are meant to be conducted with a pre-defined periodicity, but this has varied with gaps between iterations ranging from 4-10 years

These challenges are layered with an additional complication for early-career environmental epidemiologists – going the "quick and dirty" route of using tried and tested methods that may be contextually relevant but dated or aligning your methods to appeal to a field in environmental epidemiology that has made rapid advances in recent years.

This talk will focus on these challenges with examples from the author's own perspective as an early-career researcher, and outline steps needed to strengthen the policy-relevant evidence base locally.

O-SY-060 Bootstrapping air pollution epidemiology in the Indian context

Pallavi Pant[1]
[1]*Health Effects Institute, Boston, USA*

Air pollution is among the largest contributors to the overall burden of disease in India. Very few studies in India to date have assessed the effects of long-term exposure to air pollution on all-cause or cause-specific mortality, at the center of large health burdens and economic costs of air pollution. Furthermore, there is limited geographic coverage to date, and several outcomes with significant health burden in India are often not included in analyses. It is understood that epidemiologic studies of exposures to air pollution and their effects on health are critical to characterize the health burden for India's population and to motivate air quality progress. While the need for rapidly building the evidence base as well as research competencies in the field of air pollution science in India has been discussed in detail, there has been limited discussion regarding practical opportunities to effect this change.

I will discuss concrete examples and models for conduct of research studies based on available data and operating within constraints in the context of low- and middle-income countries. The talk will draw largely on ongoing work in India, including the establishment of a new research network focused on air pollution and health. I will also discuss possible roles for professional societies, funding organisations and experts, especially in the context of improving representation within ISEE and in the field of environmental health.

O-SY-061 Strengthening the evidence base on global air pollution epidemiology: the case for collaboration and engagement

Cathryn Tonne[1]
[1]*Isglobal, Barcelona, Spain*

Increasing interest in expanding the scope of environmental epidemiology to more adequately reflect the diversity of global contexts is converging with calls for reforming global health. This presentation will examine some of the drivers of these converging trends and offer reflections on the key components of sustainable, mutually beneficial research collaborations to support global air pollution epidemiology.

I will discuss the important role of capacity building at the organizational, project, and individual-level for strengthening the evidence base on air pollution epidemiology globally, drawing from the experience of the ISEE Capacity Building and Education Committee (CAPE) and specific projects including the Cardiovascular health effects of Air pollution in Telangana, India (CHAI) project. I will provide an overview of the guiding principles applied in the CHAI project to build capacity of new researchers in India, and increase their participation in international publications and professional networks.

I will reflect on current barriers to publication of environmental exposure science and epidemiology research from low- and middle-income country (LMIC) authors in journals. Finally, I will provide an overview of innovative strategies to facilitate publication of high quality LMIC-led research, including as an example, the CAPE Peer Editing Program.

SYMPOSIUM 14: Perfluoroalkyl and polyfluoroalkyl substances (PFAS) in Indigenous communities: a case of environmental injustice

O-SY-062 Contamination of country foods by perfluoroalkyl acids in the Arctic

Amira Aker[1,2], Pierre Ayotte[1,2,3], Élyse Caron-Beaudoin[4], Amila De Silva[5], Marie-Josée Gauthier[6], Amelie Bouchard[6], Mélanie Lemire[1,2,7]

[1]Axe santé des populations et pratiques optimales en santé, Centre de recherche du CHU de Québec-Université Laval, Quebec, Canada, [2]Département de médecine sociale et préventive, Université Laval, Québec, Quebec, Canada, [3]Centre de Toxicologie du Québec, Institut National de Santé Publique du Québec, Quebec, Canada, [4]Department of Health and Society University of Toronto Scarborough, Toronto, Canada, [5]Aquatic Contaminants Research Division, Water Science Technology Directorate, Environment and Climate Change Canada, Burlington, Canada, [6]Nunavik Regional Board of Health and Social Services, Kuujjuaq, Canada, [7]Institut de biologie intégrative et des systèmes, Université Laval, Quebec, Canada

BACKGROUND AND AIM: Perfluoroalkyl acids (PFAAs) are synthetic chemicals used in industrial and consumer applications. They are exceptionally stable and highly mobile in the environment, and have been detected in high concentrations in Nunavik Inuit adults. The study's objectives were to study the associations between dietary profiles in Nunavik and PFAAs concentrations, and the associations between specific foods and PFAAs concentrations.

METHODS: The study used data from the Qanuilirpitaa? 2017 Nunavik Inuit Health Survey. Nine PFAAs congeners were measured in plasma samples, including perfluorooctane sulfonate (PFOS), perfluorohexane sulfonate (PFHxS), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), perfluorodecanoic acid (PFDA) and perfluoroundecanoic acid (PFUdA). Dietary profiles were identified using latent profile analysis. Multiple linear regression models regressed log-transformed PFAAs concentrations against the dietary profiles, adjusting for sociodemographic variables. Elastic net was used to look at associations between PFAAs and dietary variables.

RESULTS: We identified strong associations between the dietary profile defined by frequent country food consumption and all PFAAs congeners (PFOA, PFNA, PFDA, PFUdA, PFHxS, and PFOS) compared to the dietary profile defined by frequent market food consumption. Individuals with low consumption of all foods also had higher concentrations of all PFAAs congeners compared to individuals with frequent market food consumption. The associations were stronger with profiles defined by more frequent country food consumption, and particularly those with increased marine mammal consumption. Elastic net identified marine mammal products (seal liver, beluga misirak), wild birds (ptarmigan, goose eggs), Arctic char and fish roe as main exposure sources.

CONCLUSIONS: Increased country food consumption was strongly associated with higher PFAAs concentrations, particularly PFOS and long-chain PFAAs congeners. The results provide further evidence that Arctic communities are disproportionately impacted by PFAAs, and further national and international regulations are required to protect the exceptional quality of country foods.

KEYWORDS: PFAS; exposure; food; Indigenous

O-SY-063 Elevated exposure to long-chain perfluoroalkyl and polyfluoroalkyl substances (PFAS) in Inuit from Nunavik, Arctic Canada: a call for global action

Lucy Grey[1], Amira Aker[2,3], Melanie Lemire[2,3], Elyse Caron-Beaudoin[4], Gauthier Marie-Josee[5], Amila DeSilva[6], Pierre Ayotte[2,3,7]

[1]Makivik Corporation, Kuujjuaq, Canada, [2]Axe santé des populations et pratiques optimales en santé, Centre de recherche du CHU de Québec-Université Laval, Quebec, Canada, [3]Département de médecine sociale et préventive, Université Laval, Quebec, Canada, [4]Department of Health and Society, University of Toronto Scarborough, Toronto, Canada, [5]Nunavik Regional Board of Health and Social Services, Kuujjuaq, Canada, [6]Environment and Climate Change Canada, Ottawa, Canada, [7]Centre de Toxicologie du Québec, Institut National de Santé Publique du Québec, Quebec, Canada

BACKGROUND AND AIM: The Inuit of Nunavik are exposed to perfluoroalkyl acids (PFAAs) via long-rang transport from southern to northern latitudes and biomagnification of PFAAs in Arctic food webs. Our objective was to document plasma PFAAs levels and compare them to previously documented levels and the general Canadian population.

METHODS: The study included 1326 Nunavimmiut aged 16-82 years from the population representative survey, Qanuilirpitaa? 2017 Nunavik Inuit Health Survey. Concentrations of nine PFAAs were assessed, including perfluorooctane sulfonate (PFOS), perfluorohexane sulfonate (PFHxS), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), perfluorodecanoic acid (PFDA) and perfluoroundecanoic acid (PFUdA). Concentrations were compared to Nunavik levels in 2004, other Arctic regions, and the Canadian Health Measures Survey (CHMS) Cycle 5 2016-2017. Multiple linear regression analyses compared concentrations by demographics and lifestyle.

RESULTS: There were elevated concentrations of various PFAAs congeners compared to CHMS, including PFOS, and long-chain PFAS congeners, PFNA, PFDA, and PFUnDA. PFNA and PFUdA concentrations were 7-fold higher than the CHMS concentrations, and PFDA concentrations were almost 4-fold higher than the CHMS concentrations. Short-chain congeners were largely undetected. Concentrations differed by sex, age, region, and indicators of seafood and marine mammal consumption. Males had higher concentrations of PFOA and PFHxS, whereas females had higher concentrations of PFDA and PFUdA. PFAAs concentrations increased with age and were highest among those aged 50+ years, such that serum PFOS concentrations were 2.5 times higher in those aged 50+ years compared to those aged 16-29 years. PFNA concentrations followed a U-shaped curve with increasing age.

CONCLUSIONS: Our findings indicate a decrease in older PFAAs, but concentrations of many PFAAs in Nunavik remain several-fold higher compared to the general Canadian population. Evidence also points to an increase in exposure to long-chain PFAAs, which are an emerging public health concern in the Arctic.

O-SY-064 Exposure to PFAS in two Alaska Native Communities

Sam Byrne[1], Vi Waghiyi, Pamela Miller, Samarys Seguinot-Medina, Frank von Hippel, C. Loren Buck, David Carpenter, Amina Salamova
[1]*Middlebury College, Middlebury, USA*

BACKGROUND: Many Arctic Indigenous communities are disproportionately exposed to persistent bioaccumulative toxicants due to global distillation and traditional diets. There is relatively little known about sources of exposure to PFAS in Arctic Indigenous Communities. Aim: The aim of this study was to assess exposure to, and health effects of, PFAS in two Arctic Indigenous communities on Sivuqaq (St. Lawrence Island), Alaska.

METHODS: Working within an established community-based participatory research program we assessed exposure to PFAS using human serum samples, indoor dust, traditional foods, as well as sentinel fish species.

RESULTS: Community members on Sivuqaq have broadly similar PFAS exposures to the U.S. population as measured by NHANES; however, select long chain PFAS such as PFNA and PFUNA appear elevated among Sivuqaq residents. Several PFAS are associated with circulating thyroid hormone concentrations in this this population. PFAS are present in traditional food animals as well as sentinel fish species collected in Sivuqaq. Sentinel fish suggest some aspect of the built environment acts as a point source of PFAS. Fish data also suggest strong species level effects in accumulation of PFAS. Dust concentrations of PFAS are on the low end of those reported and suggest the indoor environment may be a comparatively minor contributor to serum PFAS in this population.

DISCUSSION: Alaska Native communities are exposed to PFAS through multiple routes of exposure. This may result in elevated exposure for select PFAS. Serum PFAS are associated with measures of thyroid function.

O-SY-065 PFAS exposure and immunotoxic effects in children from Greenland

Amalie Timmermann[1], Henning Sloth Pedersen, Pál Weihe, Peter Bjerregaard, Flemming Nielsen, Carsten Heilmann, Philippe Grandjean
[1]*University of Southern Denmark, Copenhagen, Denmark*

BACKGROUND AND AIM: Perfluoroalkyl substances (PFAS) have been in production for more than half a century and is still used in numerous consumer products. Humans are exposed to PFAS through contaminated food and water as well as dust from treated materials. These chemicals bioaccumulate and are widespread in the environment, and populations relying on a marine diet are thus often more exposed. The aim of this study was to examine the association between Greenlandic children's exposure to major environmental chemicals and their concentrations of diphtheria and tetanus vaccine antibodies after vaccination.

METHODS: The study is based on cross-sectional data from Greenlandic children aged 7–12 years examined during 2012–2015. Among 175 children with known vaccination records, 169 provided a serum sample with sufficient volume to measure PFAS and specific antibodies against diphtheria and tetanus. Associations were examined in linear and logistic regression models.

RESULTS: We found higher serum-PFAS concentrations to be associated with lower diphtheria antibody concentrations after vaccination and with increased odds of having diphtheria antibody concentrations below the protective level. for each 1 ng/mL increase in serum concentrations of perfluorohexane sulfonic acid (PFHxS), perfluorooctane sulfonic acid (PFOS), perfluorononanoic acid (PFNA), and perfluorodecanoic acid (PFDA), odds of not having protective levels of diphtheria antibodies were increased 6.44 times (95 % CI: 1.51–27.36), 1.14 times (95 % CI: 1.04–1.26), 1.96 times (95 % CI: 1.07–3.60), and 5.08 times (95 % CI: 1.32–19.51, respectively.

CONCLUSIONS: Our findings emphasize the risk of immunotoxicity associated with PFAS exposure also in this Arctic population.

KEYWORDS: PFAS, Children, Vaccine antibodies, Immunotoxicity, Greenland

O-SY-066 Determinants of polyfluoroalkyl substances and perfluoroalkyl substances (PFAS) biomarkers in First Nations Communities of the Northwest Territories and Yukon

Brian Laird[1], Ashlyn Simpson[1], Joshua Garcia-Barrios[1], Mallory Drysdale[1]
[1]*University of Waterloo, Waterloo, Canada*

BACKGROUND AND AIM: Polyfluoroalkyl substances and perfluoroalkyl substances (PFAS) include numerous anthropogenic chemicals used in firefighting foams, non-stick cookware, food packaging, and waterproof clothing. Research has shown some PFAS exposures appear to be decreasing in the general population of Canada. In contrast, prior to a human biomonitoring research completed in Old Crow, Yukon and the Mackenzie Valley, Northwest Territories, much less was known on exposure patterns for Dene and Gwich'in populations. This research aims to describe exposure patterns among these populations by identifying determinants and potential sources of PFAS exposure for participants.

METHOD: Nine PFAS (including: perfluorooctanoic acid (PFOA), perfluorooctane sulphonic acid (PFOS), perfluorohexane sulphonic acid (PFHxS), perfluorononanoic acid (PFNA), perfluorodecanoic acid (PFDA), and perfluoroundecanoic acid (PFUdA), perfluorobutanoic acid (PFBA), perfluorohexanoic acid (PFHxA), and perfluorobutane sulphonic acid (PFBS)) were quantified using liquid chromatography mass spectrometry in blood samples collected in Old Crow (n=54) and the Dehcho Region, Northwest Territories (n=125).

RESULTS: This research showed that, for most PFAS, levels in Old Crow and the Dehcho Region, Northwest Territories were similar or lower to those observed in the Canadian Health Measures Survey. The key exception to this was perfluorononanoic acid (PFNA) which, relative to the CHMS (0.51 µg/L), was approximately 1.8 times higher in Old Crow (0.94 µg/L) and 2.8 times higher in Dehcho (1.42 µg/L) than observed in the general Canadian population. This presentation will report results describing the associations, using multivariable logistic regression, between PFAS levels and consumption of traditional food, lifestyle factors, and demographics.

CONCLUSIONS: The results highlight the importance of expanding PFAS analytical suites beyond PFOS and PFOA for both human biomonitoring as well as environmental sampling in northern environments.

O-SY-067 Indigenous lifeblood in land, water, and natural resources: the unknown threat of PFAS contamination

Whitney Gravelle[1]
[1]*Bay Mills Indian Community, Brimley, USA*

Bay Mills has a long-standing and critical interest in the waters of the Great Lakes. As a signatory to the 1836 Treaty of Washington, Bay Mills and other Tribal Nations ceded territory to the United States, but in exchange, Bay Mills reserved the right to fish, hunt, and gather throughout the territory, which has been upheld by federal courts.

This treaty right was carefully protected in order to preserve the traditional lifeways of our people – the Anishinaabe of the Great Lakes - and their reliance on the environment's natural resources for food, shelter, medicines, and for trade. Our ancestors understood that by protecting the relationship with land, water, and natural resources, they were also protecting the cultural and spiritual resources of Bay Mills Indian Community as well. Commercial and subsistence fishing continue to be the primary occupation of citizens of the Bay Mills Indian Community. Over half our citizen households rely on fishing for all, or a portion of their annual income. These lifebloods and lifeways are central to an indigenous way of life that goes back to time immemorial for Tribal Nations across the United States, and create a foundation of understanding who we are as a people and how we pass teachings on from elder to child.

In the last few years, PFAS/PFOS contamination has become a growing concern of Bay Mills Indian Community, as well as the impacts PFAS/PFOS will have on fish and wildlife, water, traditional food systems, medicines, and other traditional practices of citizens of Bay Mills Indian Community. Bay Mills Indian Community in partnership with several State agencies has undergone study of water tributaries near reservation, as well as study of the Great Lakes themselves to find point source pollution from PFAS/PFOS so that it can be mitigated and stopped altogether.

SYMPOSIUM 15: Location, Location, Location! The importance of geospatial exposure constructs to assess pesticide exposures and related adverse health outcomes in agricultural settings

O-SY-068 Geographic and record-based pesticide exposure assessment, biologic exposure signatures, and chronic disease modelling in California

Beate Ritz[1]
[1]*UCLA, Topanga, USA*

BACKGROUND AND AIMS: for the past 50 years, California has been recording agricultural pesticide applications in a pesticide use reports (PUR) database; i.e. documenting use for several hundred pesticide active ingredients. These data can be employed in exposure assessment purposes targeting specific pesticides and pesticide mixtures and study a range of adverse health outcomes.

METHODS: In collaboration with M. Cockburn at USC, my team at UCLA has generated a geographic information system tool that uses these records in conjunction with land use data to generate spatio-temporal exposure measures for the California population living near agricultural applications. Over the past 2 decades we have used this tool kit to estimate pesticide related health effects including studies of adverse birth outcomes, autism, cerebral palsy, childhood brain cancers, Parkinson's and Alzheimer's disease.

RESULTS: I will present and discuss common as well as special challenges for exposure assessment and the results of the studies we conducted in the past 2 decades. Furthermore, we investigated whether long- or shorter-term exposures to agricultural use pesticides assessed with the PUR tools generate exposure signals in biological systems and bio-fluids, i.e. relying on human blood samples from older adult residents of central California to examine metabolomic patterns, methylation changes, and influences that certain pesticides have on the gut microbiome. Using integrative omics analyses, we also examined overlap between pesticide-associated biologic pathways and pathways known to be perturbed in certain diseases.

CONCLUSIONS: These studies help to systematically identify physiologic responses to chronic pesticide exposures. Eventually this will help to better understand how low-level chronic pesticide exposures may contribute to chronic brain diseases in real world exposure scenarios.

KEYWORDS: pesticides, exposure assessment, Parkinson's disease, neurodevelopment, multi-omics

O-SY-069 Geospatial determinants of urinary insecticide concentrations and internalizing disorders in Ecuadorian adolescents

Briana Chronister[1], Marta M. Jankowska[2], Georgia Kayser[1], Jose Suarez-Torres[3], Sheila Gahagan[1], Harvey Checkoway[1], Jose R. Suarez Lopez[1]

[1]University of California San Diego, La Jolla, USA, [2]City of Hope, Los Angeles, USA, [3]Fundación Cimas del Ecuador, Quito, Ecuador

BACKGROUND: Depression and anxiety are top 5 contributors of increased disability-adjusted life years. Pesticide exposure has been linked to increased depression and anxiety; evidence in adolescents is limited. This study assesses clustering patterns of mental health symptoms and urinary pesticide metabolites, and their relationships with home proximity to floricultural crops in an Ecuadorean agricultural county.

METHODS: We assessed 514 adolescents (11-17 years) who lived in the 5 parishes of Pedro Moncayo County, Ecuador. We measured 8 urinary metabolites for neonicotinoid, pyrethroid and organophosphate pesticides, and assessed depression and anxiety symptoms using standardized questionnaires. Getis-Ord Gi* evaluated spatial clustering to identify hot and cold spots of pesticide metabolites, depression symptoms and anxiety symptoms. The association between home distance to floricultural greenhouses and anxiety/depression scores were tested using generalized estimating equations, adjusting for confounders.

RESULTS: The floricultural surface areas (% of total land) across parishes were: Tocachi: 0.12 km2 (0.001%), La Esperanza: 0.43 km2 (0.01%), Malchingui: 0.04 km2 (0.05%), Tupigachi: 5.36 km2 (12.5%), and Tabacundo: 9.36 km2 (13.2%). The average scores for anxiety (53.0 [SD=9.31]) and depression (58.8 [SD=9.61]) were in the anticipated range. We observed hotspots for anxiety and depression symptoms in Tupigachi (95-99%C [confidence]) and Tabacundo (90-95%C). There were hotpots for organophosphate and pyrethroid metabolites in Tupigachi, coinciding with anxiety and depression hotspots (malathion dicarboxylic acid [90%-99%C], para-nitrophenol [95%], 2-isopropyl-4-methyl-6-hydroxypyrimidine, trans-3-(2,2-Dichlorovinyl)-2,2-dimethylcyclopropane carboxylic acid [90%C], and 3-phenoxybenzoic acid [95%C]). Additionally, greater proximity to greenhouses was associated with greater depression (βper100m=0.94 [95%CI: 0.53, 1.36]) and anxiety (βper100m= 0.32 [95%CI: 0.11, 0.54]) scores.

CONCLUSIONS: We observed hotspots in Tupigachi for both anxiety, depression, and multiple organophosphate/pyrethroid metabolites. Throughout the county, residential proximity to floricultural crops was associated with higher anxiety and depression symptoms. This suggests that off-target pesticide drift from crops may be a contributor to increased internalizing behaviors.

KEYWORDS: Pesticides

O-SY-070 Residential exposure to pesticides and birth outcomes using the Dutch birth registry

Mariana Simões[1], Anke Huss[1], Roel Vermeulen[1,3], Nicole Janssen[2]
[1]IRAS Utrecht University, Utrecht, Netherlands, [2]RIVM - National Institute for Public Health and the Environment, Utrecht, Netherlands, [3]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands

BACKGROUND AND AIM: To explore associations between residential exposure to specific pesticides and birth outcomes using individual level exposure and pregnancy/birth data.

METHODS: From all singleton births from 2009-2013 in the Dutch birth registry we selected mothers >16 years-old living in non-urban areas that had complete address history and changed addresses at most once during pregnancy (N=325,435). We selected 12 active ingredients (AIs) with some evidence of reproductive toxicity and that were used in the Netherlands according to a farmers' survey from 2008 and explored a further 127 AIs. We estimated amount used (kg) within buffers of 50, 100, 250 and 500 meters around each mother's home during pregnancy. We used generalized linear models to investigate associations between AIs and gestational age, birth weight, low birth weight (LBW), small for gestational age (SGA), large for gestational age (LGA), still births/infant mortality, and prematurity, adjusting for individual and area-level confounders. We further used minimax concave penalty with a stability selection step to identify which AIs could further be related to the birth outcomes among the 12 and the additional 127 AIs.

RESULTS: Maternal residential exposure to linuron was associated with increased birth weight [β [95% confidence interval] 296.49 [56.07, 536.90], 74.32 [27.92, 120.72], 13.87 [6.86, 20.88] and 1.93 [0.56, 3.30], in 50m, 100m, 250m and 500m buffers) and higher odds of LGA babies (OR [95% CI] 5.72 [1.04, 31.58], 1.49 [1.06, 2.08], 1.07 [1.02, 1.13], 1.01 [1.00, 1.02], respectively). Variable selection also yielded the same associations, and further identified signals for a relationship between fluroxypir-meptyl and gestational age, picoxystrobin and LGA, and glufosinate and LBW.

CONCLUSIONS: Residential proximity to linuron during pregnancy was associated to increased birth weight and being large for gestational in babies. Other possible associations were identified that need further investigation.

KEYWORDS: residential pesticide exposure, birth registry

O-SY-071 Residential proximity to agricultural pesticide use and respiratory health in the CHAMACOS study

Robert Gunier[1], Rafael Buralli[2], John Balmes[3], Brenda Eskenazi[1], Kim Harley[1]
[1]UC Berkeley, School of Public Health, Berkeley, USA, [2]Brazilian Ministry of Health, Rio de Janeiro, Brasil, [3]UC San Francisco, Division of Occupational and Environmental Medicine, San Francisco, USA

BACKGROUND AND AIM: We previously observed associations in the Center for the Assessment of Mothers and Children of Salinas (CHAMACOS) cohort study between pesticide exposure (including organophosphate metabolites in children's urine and residential proximity to agricultural sulfur use) and respiratory symptoms and lung function at 7-years of age. In the current analysis, we examined respiratory health in relation to residential proximity to agricultural use of manganese (Mn) containing pesticides while accounting for other pesticide exposures previously associated with these outcomes in this cohort.

METHODS: Our population includes participants with pesticide exposure estimates available that completed the 7-year assessment. We evaluated agricultural use of Mn pesticides within 1 and 3 km of residences during pregnancy, early life (birth to 6y of age) and the year prior to the assessment (6 to 7y of age) using a Geographic Information System to link residential histories with California's Pesticide Use Reporting data. We assessed probable asthma from maternal report of symptoms and conducted lung function measurements using spirometry. The number of participants ranged from 276 – 330 for probable asthma and 204 – 265 for lung function measurements. We adjusted regression models for potential confounders and exposures that have been associated with these outcomes in this cohort.

RESULTS: We observed an association between residential proximity to Mn pesticide use and probable asthma. A two-fold increase in use within 1 km during the year prior to the assessment was associated with a relative risk for probable asthma of 2.1 (95% confidence interval = 1.4, 3.1) after adjusting for other exposures previously related to this outcome in this cohort. We did not observe any associations with proximity to use and lung function impairment at 7-years of age.

CONCLUSIONS: We observed a higher risk of probable asthma with residential proximity to higher Mn pesticide use.

O-SY-072 Residential proximity to pesticide sprayed sites and sex and adrenal hormones in Ecuadorian adolescents

Georgia Kayser[1], Jasen Zhang[1], Jenny Wei[1], Briana Chronister[1], Jose Suarez-Lopez[1]
[1]*University of California, San Diego, La Jolla, CA, USA*

BACKGROUND: Pesticides frequently used in agriculture, including organophosphates, glyphosate or 2,4-D, have endocrine disrupting potential. We previously found that residential proximity to agricultural crops (pesticide spray sites) can increase the potential for chronic pesticide exposure of children and adolescents, but little is known about whether residential proximity to crops can affect their hormone levels.

METHODS: We examined 523 adolescents (12-17 years, ESPINA cohort) living in Pedro Moncayo, Ecuador, where ~21% of the adult population works in floriculture. Using multiple linear regression, we analyzed the association of hormones (DHEA, testosterone, estradiol, and cortisol) with residential proximity to floricultural greenhouses and greenhouse areas near homes. Multiple linear regression models were stratified by whether participants lived closer or farther than 300m from the nearest plantation.

RESULTS: We found that 10 percent increases in crop areas within 150m and 200m residential buffer regions were associated with reduced concentrations of testosterone by -0.66 (95%CI: -1.27, -0.06) percent and -0.76 (-1.28, -0.23) precent, respectively. Crop areas within 150m and 500m were also significantly associated with lower estradiol, measured in boys only, by -1.21 (-2.27, -0.14) percent and -0.64 (-1.28, -0.01) percent, respectively. Cortisol was significantly associated with areas within 300m among boys but not girls. Residential proximity to crops within 150m and 200m was inversely associated with testosterone among boys.

CONCLUSIONS: This is the first study to evaluate geospatial determinants of off-target pesticide drift from crops to nearby homes, including residential proximity to crops and crop surface areas, in relation to hormone alterations. Endocrine disruption of adolescents growing up in agricultural settings is of concern.

KEYWORDS: Geospatial, drift, agriculture, pesticides, hormones.

O-SY-073 Geospatial analyses as a tool to monitor the implementation of regulation on aerial pesticide spraying in Matina County, Costa Rica

Luis Diego Palomo Cordero[1], Reichel Rodríguez[1], ScD. Jane Hoppin[1,2], Berna van Wendel de Joode[1]
[1]fants' Environmental Health Program (ISA), Central American Institute for Studies on Toxic Substances (IRET), Universidad Nacional, Heredia, Costa Rica, Heredia, Costa Rica, [2]Center for Human Health and the Environment, North Carolina State University, Raleigh, North Carolina, USA., Raleigh, NC 27695, USA, [3]Department of Biological Sciences, North Carolina State University, Raleigh, NC, USA., Raleigh, NC 27695, USA

BACKGROUND AND AIM: Worldwide, governmental agencies define buffer zones to protect agricultural populations from off-target pesticide drift, but its implementation is often unclear, particularly in low- and middle-income countries (LMIC).
In Costa Rica, a 100 meters buffer zone is established for aerial spraying, reduced to 30 meters if a natural barrier is present. Also, windspeed should be less than 15 km/h and workers cannot be in the field during aerial spraying. We aimed to identify potential noncompliance of this regulation by banana companies in Matina County, Costa Rica.

METHODS: Using geographical information systems, field observations and bystanders' reports (n=58), we created maps of Matina County Costa Rica, indicating where regulations for aerial spraying were probably disrespected. We informed an interinstitutional committee that supervises agricultural aerial spraying activities, governmental agencies, as well as community organizations about results, to promote corrective measures.

RESULTS: We identified 44 kilometers (km) of agricultural frontier without buffer zones at less than 100 meters from public areas with reported aerial spraying, of which 55% (24 km) near roads and 45% (20 km) near houses. Twelve out of the 20 km were in more densely populated towns (≥ 128 houses/km2). In three of these towns, aerial spraying was reported at ≤ 30 meters' distance which coincided with information collected by GIS. More than half of bystanders (59%, n=34) reported aerial spraying in windy conditions and 48% (n=28) reported to have observed workers inside banana fields during aerial spraying during the last month. Five community members denounced incompliance, which resulted in corrective actions by the interinstitutional committee for agricultural aerial spraying.

CONCLUSIONS: Our results suggest banana companies only partly fulfil Costa Rica aerial pesticide spraying regulation, that may result in increased environmental exposures from drift. GIS forms a useful tool to monitor the implementation of environmental legislation over time.

SYMPOSIUM 16: Toxicity of air pollutant mixtures: overcoming the toxic mixture of spatial misalignment, collinearity, and measurement error

O-SY-074 Measurement errors in Gaussian mixture models using high-dimensional air pollution constituents data

Xin Zhou[1], Li Xu[2], Junhan Fang[1], Donna Spiegelman[1]
[1]Yale School of Public Health, New Haven, USA, [2]Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: An active area of current interest in air pollution epidemiology is characterizing the impact of air pollution constituents on health outcomes. Statistical analysis of air pollution data suffers from bias due to measurement error of these exposures, and this bias is exacerbated when the exposures are high-dimensional. It is well known that exposure to fine particles (PM2.5) can cause adverse health effects. However, the independent effects of PM2.5 constituents have not been as well investigated.

METHODS: In this work, we develop a novel approach to correcting for the bias due to measurement errors associated with multiple correlated air pollutants with a complex correlated error structure through the use of Gaussian mixture models under the main / external validation design framework. The clusters are corrected for measurement error and then analyzed in a Cox model to investigate the impacts of different air pollutant profiles on time to even outcomes, such as all-cause mortality and cancer incidence.

RESULTS: Extensive simulation studies are carried out to investigate the performance of the proposed method, and to explore sensitivity to departures from Gaussian assumptions. The method is illustrated in a study of air pollutants on all-cause mortality in the Nurses' Health Study, with exposures validated in the RIOPA and MESA studies.

O-SY-075 Impact of exposure measurement error in multi-pollutant models: a simulation study in the time-series framework

Dimitris Evangelopoulos[1,2], Klea Katsouyanni[1,2,3], Joel Schwartz[4], Heather Walton[1,2]

[1]MRC Centre for Environment and Health, Environmental Research Group, Imperial College London, London, UK, [2]NIHR HPRU in Environmental Exposures and Health, Imperial College London, London, UK, [3]Department of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, [4]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Exposure measurement error in air pollutants can lead to biased health effect estimates and effect transfer from more poorly to better measured exposures. While some studies have estimated the impact of error in single-exposure models we aimed to quantify the effect of measurement error in multi-pollutant models, specifically in time-series analysis of $PM_{2.5}$, NO_2, and mortality using simulations, under various plausible scenarios for exposure errors.

METHODS: Measurement error was defined as the difference between ambient concentrations and personal exposure from outdoor sources. Error-free exposures with their consequent health outcome and error-prone exposures of various error types (classical/Berkson/mixture) were generated using information from the literature. Bias was quantified as the relative difference in effect estimates of the error-free and error-prone exposures.

RESULTS: NO_2 was assumed to be more prone to error than $PM_{2.2}$, based on separate work, and, thus, its mortality effect estimates were more affected by measurement error bias. The observed bias was up to 37% towards the null, when low ratios of the true exposure variance over the error variance were assumed. Higher ratios resulted in smaller, but still substantial health effect underestimation, up to 19% for both pollutants. Significant effect transfer was observed from NO_2 to $PM_{2.5}$ as the general underestimation due to measurement error was worsened for the former and lessened for the latter compared to single-pollutant model estimates.

CONCLUSIONS: Our results indicated an underestimation of true independent health effects of multiple exposures due to measurement error. Effect transfer showed that less precise measurements for one pollutant yield more bias, while the co-pollutant associations were found closer to the true. Using error parameter information in future epidemiological studies should provide more accurate concentration-response functions for health impact assessment.

KEYWORDS: Air pollution, Measurement error, Mixture error, Effect transfer, Simulations

O-SY-076 Predictive clustering methods to identify differential toxicity of air pollutant mixtures

Joshua Keller[1]
[1]*Colorado State University, Fort Collins, USA*

BACKGROUND AND AIM: Spatial misalignment between the relatively small number of locations where air pollution mixtures are measured and the locations of cohort members poses a challenge to assessing health effects. This talk presents a clustering-based approach to defining multipollutant exposure profiles that can be well predicted at unobserved locations.

METHODS: Clusters are defined by combining multipollutant measurements with spatial and spatiotemporal characteristics of the monitoring location in a Gaussian mixture model. Cluster membership for cohort locations and times are then predicted using parametric and machine learning classification algorithms.

RESULTS: We demonstrate this approach using PM2.5 components on a national scale and on-road multipollutant measures (including ultrafine particles and volatile organic compounds) on a regional scale. We identify mixtures associated with differing effects of air pollution exposure on atherosclerosis, blood pressure, and cancer risk.

CONCLUSIONS: Cluster-based approaches for defining pollution mixtures provide an effective approach to assessing multipollutant exposures using spatially misaligned data. Incorporating location characteristics can improve predictive accuracy and power for assessing differences in health effects of ambient air pollution exposure.

KEYWORDS: ambient air pollution, fine particulate matter, k-means, multipollutant exposures, spatiotemporal statistics

O-SY-077 Impact of long-term exposures of PM2.5 components and sources on cause-specific mortality in a US Medicare cohort: results from two-stage residual analysis

Helen Suh[1], Fatemeh Kazemiparkouhi, Trent Honda, Ki-Do Eum, Justin Manjourides
[1]*Tufts University, Medford, USA*

BACKGROUND: Our understanding of the impact of long-term exposures to PM2.5 constituents and sources on mortality is limited due in large part to the often strong correlations between individual PM2.5 constituent concentrations.

METHODS: We examined associations between long-term exposures to PM2.5 constituents and sources and cause-specific mortality in US older adults using a two-stage residual method. We did so using demographic and mortality data for 15.4 million Medicare beneficiaries living within the conterminous United States (US) between 2000 and 2008. We assessed PM2.5 constituents exposures for each beneficiary and used factor analysis and residual-based methods to characterize PM2.5 sources and mixtures, respectively. In age-, sex-, race- and site-stratified Cox proportional hazard models adjusted for neighborhood socio-economic status (SES), we assessed associations of individual PM2.5 constituents, sources, and mixtures and cause-specific mortality and examined modification of these associations by participant demographics and location of residence.

RESULTS: Hazard ratios (HR) were highest for all causes of death, except COPD, for coal-related PM2.5 constituents and sources. We found Pb, nitrate, Si, and metal-, traffic-, and soil-related components to be significantly associated with increased HR for most causes of death. Using residual-based methods, we found attenuation in HRs to be greatest for all causes of death when variability from sulfate, Se, or coal-related PM2.5 was removed from the PM2.5 mixture. While attenuated, HRs for mortality from all-cause, CVD, and IHD remained statistically significant and positive when variability from NO3–, OC, Si, and traffic- and soil-related PM2.5 were removed from the analyses. Removal of variability due to oil and metal-related sources had no discernable effect on HRs.

DISCUSSION: PM2.5 components related to coal combustion, traffic, and to a lesser extent, soil were strongly associated with mortality from CVD, respiratory disease, and cancer.

SYMPOSIUM 17: Two-way road: how has the environment affected the Covid-19 pandemic and how the pandemic response affected the environment in the Latin America and Caribbean Region

O-SY-079 Air pollution and post-Covid-19 syndrome

Nelson Gouveia[1], Juliana Carvalho Ferreira, Tiana Carla Lopes Moreira, Adriana Ladeira de Araújo, Geraldo Busatto-Filho, Thais Mauad
[1]*University of Sao Paulo Medical School, Sao Paulo, Brazil*

BACKGROUND AND AIM: Evidence exists linking exposure to air pollution with increased COVID-19 incidence, severity and mortality. However, little is known about the role of air pollution in persisting symptoms among recovering patients. We designed a cohort study of hospitalized COVID-19 survivors in São Paulo, Brazil, to examine whether ambient air pollution is associated with post-COVID-19 syndrome.

METHODS: Patients hospitalized between March to August 2020 who were alive six months after hospitalization were included. We collected individual and clinical characteristics during hospitalization and at follow-up assessed ten symptoms with standardized scales, 19 yes/no symptoms, a functional status and a quality-of-life scale and performed four clinical tests. Individual exposure to air pollution was assessed by averaging satellite gridded estimates of annual mean levels of PM2.5 in a 300 m buffer around each participant´s residential address. We also considered greenspace and neighborhood sociodemographic factors in generalized linear mixed models.

RESULTS: We included 749 patients with a median follow-up of 200 (IQR 185 - 235) days, and 618 (83%) had at least one of the ten symptoms measured with scales. Pain (41%), fatigue (38%) and post-traumatic stress disorder (35%) were the most frequent. Individual exposure to PM2.5 was associated with higher dyspnea and fatigue scores and lower functional status. Clinical and sociodemographic factors exhibited associations with different symptoms while greenspace and neighborhood sociodemographic factors did not show any significant association.

CONCLUSIONS: We identified a high frequency of persistent symptoms among COVID-19 survivors that were associated with clinical and sociodemographic factors. Ambient levels of air pollution were associated with persistent dyspnea, increased fatigue, and lower functional status at follow-up. Potential mechanisms involving oxidative stress and systemic inflammation can explain these associations but further studies are needed to confirm this novel impact of air pollution on health.

KEYWORDS: Air pollution, COVID-19; persistent symptoms

O-SY-080 Built environment, transport, and Covid-19

David Rojas-Rueda[1]
[1]Colorado State University, Fort Collins, USA, [2]Colorado School of Public Health, Fort Collins, USA

BACKGROUND: The COVID-19 pandemic has impacted daily-life activities around the world. Multiple countries and cities are implementing different mitigation strategies to reduce transmission (e.g., physical distancing, stay-at-home orders, avoiding large gatherings).

AIM: Describe the evidence and a framework linking COVID-19 mitigation strategies, the built environment, and transport to health determinants and outcomes.

METHODS: Scoping review

RESULTS: COVID-19 mitigation strategies, in addition to helping reduce disease transmission, have also decreased urban road transport, resulting in indirect benefits on air quality, traffic noise, and traffic incidents. On the other hand, the same mitigation strategies have negatively impacted physical activity, mental health, home isolation, and access to transport options, among others. COVID-19 mitigation strategies are an opportunity to test and implement built environment and transport interventions aimed to maximize health equity and minimize health risks. National and local authorities should systematically integrate a long-term urban health equity vision when designing and implementing COVID-19 mitigation strategies.

CONCLUSIONS: COVID-19 offers an opportunity to rethink the built environment and transport infrastructure to support short-term mitigation strategies and reduce long-term urban health inequities.

KEYWORDS: COVID-19. Built environment. Transport. Equity. Environmental health

O-SY-081 SARS-CoV-2 in wastewater: studies in Latin America

Astrid Schilmann[1]
[1]*National Institute of Public Health, Cuernavaca, Mexico*

BACKGROUND AND AIM: Wastewater (WW) based epidemiology has proven a useful epidemiological surveillance tool for the early detection of SARS-CoV-2 outbreaks and for the population-wide and specific area surveillance and has been also used to track the variants of concern. This review aims to summarize the research about SARS-CoV-2 in WW in Latin American countries.

METHODS: We performed a scoping review to examine the literature on the results for SARS-CoV-2 in WW in Latin American countries. We identified relevant studies through an electronic database search (language English), adding other publications identified in reference lists and hand searches.

RESULTS: Results have been published from Argentina, Brazil, Ecuador and Mexico. Different virus concentration and extraction methods have been selected and compared in some cases. All studies used RT-qPCR to detect and quantify genomic copies in most cases using the oligonucleotides targeting N1 and N2 regions, but also S and RdRp regions. SARS-CoV-2 has been detected and quantified in environmental samples from influent and sludge in WW treatment plants, river water from urban and rural areas without sewage collection, sewer network in cities, effluents from specific population areas. The virus was not detected in groundwater from Quintana Roo, Mexico.

CONCLUSIONS: It is necessary to move from pilots to scale to establish a complementary early warning surveillance system to inform the public health actions. Thus, the health sector must be aware of WBE as a useful tool and leader its implementation as a regular surveillance tool for SARS-CoV-2 and also for other biological and chemical agents.

KEYWORDS: SARS-CoV-2, wastewater, surveillance, Latin America

O-SY-082 Covid-19 related waste management in the LAC region

Agnes Soares da Silva[1]
[1]*PAHO/WHO, Washington DC, USA*

Globally, the health sector responds to approximately five 5% of carbon dioxide emissions and there is an increasing pressure to reduce its carbon footprint and minimize the amount of waste sent to landfills. However, 3 out of 10 healthcare facilities lack systems to segregate waste and less than 1 in 3 healthcare facilities have a basic healthcare waste management service.

Most countries in the Latin America and the Caribbean (LAC) region do not have data on waste management in healthcare facilities. Data collected in five countries (12% of the LAC population) shows large differences among them related to segregation (from 16% in Haiti to 97% in Peru), and treatment (from 23% in Paraguay to 74% in Nicaragua) of healthcare waste, though wastes could be segregated and not treated and treated without segregation.

COVID-19 has exposed long-lasting weaknesses of healthcare facilities in the management of healthcare wastes. 30% of solid waste generated in LAC ends up in uncontrolled dumpsites, and the increased amount of healthcare waste due to the response to the pandemic became an urgent public health problem. In response to that, some countries are purchasing incinerators as a solution to reduce the volume being disposed of. However, in most countries, there is limited or inexistent capacity to monitor and control hazardous emissions of incineration.

Filling data gaps and setting baselines for healthcare waste generation is a priority for LAC countries. To increase the resilience of the health sector, national emergencies preparedness plans should include waste management as a core public health component. Using the opportunity for a green recovery from the COVID-19 pandemic as proposed by WHO, sustainable solutions should include minimization of waste by imposing rules for the procurement and purchasing processes, and training and implementation of waste segregation and treatment in all healthcare facilities.

O-SY-083 Association between air pollution in Lima and the high incidence of Covid-19: findings from a post hoc analysis

Gustavo Gonzales[1], Mag Bertha Vasquez-Apestegui[1], Mag Enrique Parras-Garrido[1], Mag Vilma Tapia[1], Mag Valeria Paz-Aparicio[1], Jhojan P. Rojas[2], Odón R. Sanchez-Ccoyllo[3], Mag Diego Fano-Sizgorich[1]
[1]Universidad Peruana Cayetano Heredia, Lima, Perú, [2]SENAMHI, Lima, Perú, [3]Universidad Nacional Tecnológica de Lima Sur, Lima, Perú

BACKGROUND: Coronavirus disease (COVID-19) was originated in the People's Republic of China in December 2019. Thereafter, a global logarithmic expansion of the cases occurred and was declared a pandemic by the World Health Organization (WHO) in march 2020. Since some countries had a higher rate of infections despite the early implementation of quarantine, it was suggested that air pollution could be related to the high susceptibility to the virus and the associated case-fatality rates (deaths/cases*100). In June 2020, Lima, Peru has the second-highest incidence of COVID-19 in Latin America, and it is also one of the cities with the highest levels of air pollution in the Region.

METHODS: This study investigated the association of outdoor PM2.5 exposure between 2010 and 2016 in 24 districts of Lima with positive cases, deaths, and case-fatality rates of COVID-19 occurred between March 6 to June 12, 2020. Multiple Linear regression analysis was used to evaluate this association controlled by age, sex, population density, and the number of food markets per district.

RESULTS: On June 12, 2020, there were in Lima 128,700 positive cases, and 2,382 deaths due to COVID-19. The case-fatality rate was 1.93%. Previous exposure to PM2.5 (years 2010—2016) was associated with number of COVID-19 positive-cases (β=0.07; 95% CI: 0.034 – 0.107) and deaths (β = 0.0014; 95% CI: 0.0006 – 0.0.0023), but not with case-fatality rate.

CONCLUSIONS: the higher rates of COVID-19 in Metropolitan Lima are attributable, among others, to the increased PM2.5 exposure in the previous years after adjusting for age, sex, and the number of food markets. Reduction of air pollution since a long-term perspective and social distancing are needed to prevent the spread of virus outbreaks.

SYMPOSIUM 18: Understanding the link between the urban exposome and health

O-SY-084 Characterizing the urban exposome in Europe

Kees de Hoogh[1,2], Maria GM Pinho[3], Joline WJ Beulens[3], Joreintje D Mackenbach[3], Youchen Shen[4], Alonso Bussalleu[1,2], Benjamin Flückiger[1,2], Michelle Kelly-Irving[5], Cyrille Delpierre[5], Raphaële Castagné[5], Payam Dadvand[6], Mark Nieuwenhuijsen[6], Marta Cirach[6], Jelle Vlaanderen[4], Roel Vermeulen[4], Gerard Hoek[4]

[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]University of Basel, Basel, Switzerland, [3]Amsterdam University Medical Centers, Location VU University, Epidemiology and Data Science, Amsterdam, The Netherlands, [4]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands, [5]CERPOP UMR 1295, Université Toulouse III Paul Sabatier, INSERM, Toulouse, France, [6]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain

BACKGROUND AND AIM: The EXPANSE project studies the effects of the internal and external exposome on cardiometabolic-pulmonary health of more than 55 million Europeans. The external exposome consists of different environments (built, physico-chemical, social and food) and we aim to apply advance modelling approaches and evaluate and validate geographical data to characterise these different external environments.

METHODS: The latest advances in mapping and modelling are employed to characterise the external exposome at a fine spatiotemporal resolution across Europe. Geospatial, machine learning and propagation methods are being applied; the most recent remote sensing data are being obtained; validation performed and variables extracted.

RESULTS: We completed a first phase of producing several physico-chemical (NO2, PM10, PM2.5 and O3) and built (green, blue, and grey spaces, light at night, and walkability) variables at a high spatiotemporal resolution for 27 EU countries. Specifically, we developed new monthly and annual average concentration maps at a 25*25m resolution between 2000 and 2019, using updated methods to account for spatial heterogeneity improving previous models; built initial models for temperature. Validation of the food environment data showed strong correlation between exposures derived from different data sources, but further quality assessments are still needed. An evaluation of the availability of common social environment variables across Europe is ongoing; we developed a deprivation index at a national level and for some countries at municipality level (Netherland).

CONCLUSIONS: A range of external exposome variables are available to be assigned to the cohorts included in EXPANSE using the geocoded address location and matching the data of the analysed health event in the different EXPANSE working groups investigating cardio-metabolic and pulmonary health outcomes. The external exposome data will be made publically available at a later stage through the purposely built online tool, Exposome Maps, to facilitate and stimulate exposome research across Europe.

O-SY-085 Statistical methods for quantifying the link between the urban exposome and health

Marc Chadeau-Hyam

BACKGROUND AND AIM: High-resolution molecular profiles using omics technologies represent an unprecedented source of information to explore the effective biological effects of external stressors and detect determinants of subsequent risk drivers. In parallel, technological advances in exposure monitoring have enabled the reliable measurement of a large range of exposures at the individual level in large populations.

METHODS: The Exposome concept has been developed as a necessary complement to the genome to better understand the determinants of health and of the risk of chronic diseases. The external exposome combines a large range of external stressors (i.e. non-genetic) factors potentially impacting human health from conception onwards. These external exposures (i) are heterogeneous in nature, scale, and variability, (ii) feature complex correlation patterns and (iii) may operate as mixtures. The internal exposome can be defined as the way these exposures are embodied and its exploration relies on the screening and integration of high-resolution molecular data. While methods for omics data analyses are established, their application in an exposome context is raising specific methodological challenges including the analysis of complex and correlated exposures. Furthermore, the isolated exploration of an omic profile offers the possibility to capture stressor-induced biological/biochemical alterations, potentially impacting individual risk profiles, but this may only yield a fractional picture of the complex molecular events involved, therefore limiting our understanding of the effective mechanisms mediating the effect of the exposome.

RESULTS: Taking examples from real-life exposome projects we will illustrate the use of statistical and machine learning techniques to (i) identify 'expo-types' as defined by pools of co-occurring exposures contributing to population stratification, (ii) explore the links between these and cardiometabolic outcomes, and (iii) investigate the (multi)-omic response to these sets of exposures.

CONCLUSION: This presentation will describe sets of approaches methods (and their extensions) enabling such ambitious explorations of the internal and external exposome to provide novel insights into exposome-triggered molecular mechanisms affecting health.

O-SY-086 Exploring the exposome across the life-course; air pollution, metabolomics and lung function

Olena Gruzieva[1,2], Ayoung Jeong[3,4], Shizhen He[1], Zhebin Yu[1], Jeroen de Bont[1], Maria GM Pinho[5], Ikenna C. Eze[3,4], Sara Kress[6], Craig E Wheelock[7,8,9], Annette Peters[10], Jelle Vlaanderen[11], Kees de Hoogh[3,4], Augustin Scalbert[12], Marc Chadeau-Hyam[11,13], Roel C H Vermeulen[11], Ulrike Gehring[11], Nicole Probst-Hensch[3,4], Erik Melén[14,15]

[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Centre for Occupational and Environmental Medicine, Region Stockholm, Stockholm, Sweden, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]University of Basel, Basel, Switzerland, [5]Department of Epidemiology & Data Science, Amsterdam Public Health, Amsterdam UMC, location VUmc, Amsterdam, The Netherlands, [6]IUF-Leibniz Research Institute for Environmental Medicine, Düsseldorf, Germany , [7]Division of Physiological Chemistry 2, Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden, [8]Department of Respiratory Medicine and Allergy, Karolinska University Hospital, Stockholm, Sweden, [9]Gunma University Initiative for Advanced Research (GIAR), Gunma University, Maebashi, Gunma, Japan, [10]Institute of Epidemiology, Helmholz Zentrum München - German Research Center for Environmental Health, Neuherberg, Germany, [11]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands, [12]Nutrition and Metabolism Branch, International Agency for Research on Cancer (IARC/WHO), Lyon, France, [13]Imperial College London, London, UK, [14]Department of Clinical Science and Education Södersjukhuset, Karolinska Institutet, Stockholm, Sweden, [15]Sachs Children's Hospital, Stockholm, Sweden

BACKGROUND AND AIM: Previous studies have explored relationships of air pollution and metabolic profiles with lung function. However, the metabolites linking air pollution and lung function and associated mechanisms have not been reviewed from a life-course perspective. Accordingly, causal inference regarding health effects of single exposures or mixtures remains limited.

METHODS: We conducted a narrative review summarizing recent evidence on the associations of metabolic profiles with both air pollution exposure and lung function taking different stages of life into consideration (linking metabolites to exposure and outcome).

RESULTS: Thirty-two studies were included with 10 studies analyzing air pollution-related metabolic profiles, and 22 analyzing lung function-related metabolic profiles. A wide range of metabolites were identified being associated with short- and long-term exposure, partly overlapping with those linked to lung function in the general population and respiratory diseases such as asthma and COPD, including compounds of amino acid and lipid metabolism. The existing studies show that metabolomics offers potential to identify biomarkers linked to both environmental exposures and respiratory outcomes, which can improve exposure assessment, causal understanding, and identification of individuals at risk. However, many studies suffer from small sample size, cross-sectional designs, preponderance on adult lung function, heterogeneity in exposure assessment, lack of confounding control and omics integration.

CONCLUSIONS: Studies with prospectively and repeatedly collected biological samples and harmonized exposure assessment are needed to get insights into mechanisms and causality of life-long respiratory effects of air pollution. The ongoing EXposome Powered tools for healthy living in urbAN Settings (EXPANSE) project aims at addressing some of the shortcomings of earlier studies by combining biospecimens from large European cohorts covering different age groups, along with harmonized air pollution exposure and exposome data.

KEYWORDS: metabolomics, lung function, spirometry, Chronic obstructive pulmonary disease (COPD), air pollution

O-SY-087 The urban exposome and mortality: an analysis of European administrative cohorts

Evi Samoli[1], Massimo Stafoggia[2], Konstantina Dimakopoulou[1], Federica Nobile[2], Klea Katsouyanni[1,3], Danielle Vienneau[4,5], Cathryn Tonne[6], Sergio Olmos[6], Johan N Sommar[7], Nicole Janssen[8], Dorina Ibi[9], Jelle Vlaanderen[9], Roel CH Vermeulen[9]

[1]Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Athens, Greece, Athens, Greece, [2]Department of Epidemiology, Lazio Region Health Service, Rome, Italy, Rome, Italy, [3]b.MRC Centre for Environment and Health, Environmental Research Group, Imperial College London, UKNIHR HPRU in Environmental Exposures and Health, Imperial College London, London, UK., London, UK, [4]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, Allschwil, Switzerland, [5]University of Basel, Basel, Switzerland, Basel, Switzerland, [6]ISGlobal, Barcelona, Spain, Barcelona, Spain, [7]Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden, Umeå, Sweden, [8]National Institute for Public Health and the Environment, Bilthoven, the Netherlands, Bilthoven, Netherlands, [9]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, the Netherlands, Utrecht, Netherlands

BACKGROUND: EXPANSE collects multiple European cohorts data and applies standardized protocols for exposure assessment to investigate urban exposome effects on health. We evaluated associations of environmental stressors on all-cause mortality in adult administrative cohorts in Greece, Rome, Switzerland, Catalonia, Sweden and the Netherlands.

METHODS: We linked exposures to geocoded residential addresses of >20.9million adult participants followed between 2011 to 2019 including exposure to:PM2.5, NO2, BC, warm season O3, NDVI, distance to water and impervious surfaces and the mean and standard deviation of annual/warm /cold season temperature. We applied Cox proportional hazard models accounting for several cohort-specific individual and contextual variables. We evaluated the associations through single and multi-exposure models considering deviations from linearity, correlations of exposures and interactions between exposures.

RESULTS: In the Greek, Swiss, Rome and Catalan cohorts we observed >1.35million deaths out of ~107,000,000 person-years. High correlations were observed between NO2 and BC, and between temperature variables. Deviations from linearity were indicated for associations with the variance measures of temperature. Increased mortality was associated with increases in PM2.5, NO2, BC and mean temperature exposures. Decreased mortality was associated with increases in NDVI (all but the Catalan cohort) and distance from water (Greece and Rome). PM2.5 and NDVI presented the most consistent adverse associations following co-exposures' adjustment (HRs ~ 1.03 and 0.98 respectively per IQR increase). PM2.5 effects were modified by NDVI levels in a non-consistent pattern between cohorts. The cumulative risk index for air pollutants was ~ 1.03 per IQR in Greece and Rome.

CONCLUSIONS:The wealth of exposure data and the large administrative cohorts in EXAPNSE provide a powerful tool to investigate complex associations between environmental exposures and mortality. Initial results support the consistent effects of particulate pollution irrespective of the interplay with other environmental exposures.

O-SY-088 Urban labs – The personalized building block of exposome research

Ayoung Jeong[1,2], Klea Katsouyanni[3,4], Evangelia Samoli[3], Kinga Polanska[5], Roel Vermeulen[6], Jelle Vlaanderen[6], Anke Huss[6], Cathryn Tonne[7], Nicole Probst-Hensch[1,2]

[1]Swiss TPH, Allschwil, Switzerland, [2]University of Basel, Basel, Switzerland, [3]Department of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, [4]School of Population Health & Environmental Sciences, King's College London, London, UK, [5]Department of Environmental Epidemiology, Nofer Institute of Occupational Medicine, Lodz, Poland, [6]Utrecht University, Utrecht, Netherlands, [7]IS Global, Barcelona, Spain

BACKGROUND AND AIM: The EXPANSE project will provide evidence-based data for urban planners, policy makers, and European citizens on approaches for maximizing health and wellbeing in a modern urban environment. The embedded Urban Labs allow deep phenotyping of the urban exposome as well as assessing its use and perception. The Urban Labs aim to a) improve and personalize CMPD risk prediction by improving exposure assessment and by identifying mediating and modifying behavior/lifestyle factors of importance, b) quantify changes in the urban external exposome from residential relocation, and c) link the urban exposome to intermediate CMPD endpoints including blood biomarkers, BMI, sleep quality, and happiness.

METHODS: The Urban Labs involves 5000 individuals from five diverse urban areas spread across Europe (Amsterdam-Rotterdam area, Barcelona, Basel, Lodz, and Athens). Over a period of 2 years, participants answer to repeated bi-monthly questionnaires as well as to additional exposure-specific challenges over an engaging data capturing Mobile Phone App (ExpanSeeker). Two-week personalized measurement covering different seasons are rolled out over the course of the 1st year and will be repeated post-movement in a subsample of movers. Measurements include tracking of spatial-temporal activity patterns, sensor-based environmental and behavioral measurements, and minimally invasive biological sample collection for metabolomics and (epi-) genetic analyses.

RELEVANCE OF EXPECTED RESULTS: As a downstream goal, the embedded Urban Labs contributes to offering the following opportunities for individual citizens: based on a current or future residential address, based on answers to additional personalized questions on lifestyle/behavior including use and perception of their residential environment, and based on residential relocation plans to predict their expected level of happiness and CMPD risk.

KEYWORDS: Exposome, Urban Health, Cardiovascular Diseases, Diabetes, Respiratory Diseases

SYMPOSIUM 19: Scientist connections with Environmental Justice Communities

O-SY-089 Indigenous community environmental challenges and needs

Mi'sel Joe[1]
[1]*Miawpukek Mi'kamawey Mawi'omi, Conne River, Canada*

Canadian Indigenous research in the past had had a history of deception. However, the European settlers later acknowledged the injustice committed in research and now actively engaged and respect their perspectives. Miawpukek First Nation (MFN) community in Newfoundland and Labrador is considered one of Canada's most well-administered Indigenous communities due to strong leadership and pragmatism in every developmental activities, including research.

MFN has integrated indigenous perspectives in the health and wellbeing of the community. In the health care center, they did not put indigenous medicines into the modern-day clinic. They did not discourage it, but indigenous medicines were done through focusing on the land with hunting and gathering to make these indigenous medicines.

There are many different kinds of health care. The Indigenous people prefer to walk through the woods to gather natural medicines. The community has integrated lighted walking trails, a gym, weight rooms and a community garden to help with their well-being and mental health. They are trappers and hunters and live off the land. Therefore, prefer this way of life over modern medicine when able.

The climate change and planetary health crisis in the world is affecting everyone and everything, lands, oceans and animal migration are all being affected. The Indigenous communities used to do their fishing in the winter when the ice froze but because of the climate change there is no ice to fish on. The animals moved further south, for example, the polar bears to find food as well the fish farms are dying off. Everyone must play their part and work more towards green energy.

O-SY-090 Engagement of communities is critical to environmental health: lessons from some remote Canadian communities

Atanu Sarkar[1]
[1]*Memorial University of Newfoundland, St. John's, Canada*

INTRODUCTION: Indigenous communities in Canada live in the poorest living conditions. Due to the historical legacy of racism and mistrust, their hesitancy in collaborating in research is understandable. However, continuous dialogue and acknowledging their concern and sensitivity can bring the community and researchers closer and ensure a long-term relationship. The current presentation will highlight two research projects (uranium exploration and mine development and water and sanitation) in Labrador Inuit communities and their proactive roles in research design, data collection, data analysis, and knowledge translation.

METHODS: The objective of the first study was to measure the possible radioactive contamination in the local ecosystem surrounding an abandoned uranium development site on Indigenous land in Labrador (Canada). It was an initiative by the Indigenous community, since the Indigenous people regularly visited the mine site for hunting, foraging traditional food and spiritual activities, they were very much concern for their safety. The community leaders contacted the university researchers for exploring the extent of environmental contamination and public safety. The second study explored the water insecurity, coping strategies and associated health risks in a small and isolated sub-Arctic Indigenous (Inuit) community in Canada. The community-based participatory survey was conducted.

RESULTS: Except the surrounding areas of the mining site, the rest of the land was safe for the Indigenous people. The community did not have any piped water supply. Their regular sources of water consisted of several un-monitored local streams, brooks, and ponds. The public water system was not affordable to the majority of community members who solely depended on government aid. Water insecurity has put the community at risk of multiple serious adverse health outcomes.

CONCLUSION: Integration of western science and Indigenous knowledge can yield more effective solutions for the communities.

O-SY-091 Partnering with the community to advocate for clean air: a case study from the South Bronx, NYC

Jenni Shearston[1], Mychal Johnson[2], Diana Hernández[3], Marianthi-Anna Kioumourtzoglou[1], Steven Chillrud[4], Markus Hilpert[1]

[1]Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [2]South Bronx Unite, Bronx, USA, [3]Department of Sociomedical Sciences, Columbia University Mailman School of Public Health, New York, USA, [4]Lamont-Doherty Earth Observatory of Columbia University, Palisades, USA

BACKGROUND/AIM: Improving urban air quality at the neighborhood level benefits from working closely with communities to identify air pollution sources and levers for change. We partnered with South Bronx Unite, a community organization that advocates for environmental justice in the Mott Haven and Port Morris (MHPM) neighborhoods of New York City, and a local middle and high school, to conduct hyper-local air monitoring campaigns.

METHODS: We intermittently measured traffic and air pollution in MHPM from 2017 onwards at several residential, business, and community locations. at select locations, traffic radar devices were collocated with continuous black carbon monitors to assess street-level traffic and pollution. To assess changes in neighborhood-scale traffic congestion, we analyzed crowd-sensed traffic data. We also partnered with a local middle and high school to teach students how to program Arduino electronics platforms to build air quality monitors. A web platform was built to store the student-collected measurements and share them with the public.

RESULTS: Our monitoring campaigns allowed us to quantify increases in traffic and air pollution following the opening of an online grocery delivery warehouse in 2018. Analysis of the crowd-sensed traffic data showed significant increases in traffic congestion in the period 2017-2019 in mixed-use and residential areas, with the greatest increases overnight and in the morning. South Bronx Unite currently uses these data to advocate for measures to mitigate the adverse health impacts of the heavy-truck traffic in MHPM, e.g., improved waterfront access and green buffers. Students were able to build air quality monitors using the Arduino devices; efforts to measure air quality in their communities are underway.

CONCLUSIONS: Partnerships between academic institutions and community organizations are critical for environmental justice work; such relationships promote community ownership and capacity building and can generate powerful tools for advocacy.

KEYWORDS: community-based research; traffic; air pollution; citizen science

O-SY-092 A Community-centered approach to inform change: the Assessing Imperial Valley Respiratory Health and the Environment Study

Yoshira Ornelas Van Horne[1], Shohreh F. Farzan[1], Elizabeth M. Kamai[1], Brandyn C. Ruiz[1], Esther Bejarano[2], Luis Olmedo[2], Jill E. Johnston[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [2]Comite Civico del Valle, Brawley, USA

BACKGROUND AND AIM: The Assessing Imperial Valley Respiratory Health and the Environment (AIRE) study is an on-going community-academic collaboration with Comité Civico del Valle (CCV) to study the role of exposures to air pollution, drying of a saline lake, pesticides, and agricultural burning on children's respiratory health in the rural U.S/Mexico border community of Imperial Valley, California, USA. Changing weather patterns, droughts and competing water demands are dramatically altering the landscape and creating conditions conducive to the production of wind-blown dust and dust storms. Residents of this predominantly low-income, Mexican-American community have expressed growing concern about the health impacts of these environmental changes.

METHODS: With this community-driven effort we are focusing on the cumulative burden of multiple types of pollutants on children's respiratory health. To date we have leveraged a local air monitoring network to assess particulate matter exposures, we are utilizing publicly available pesticide use registry data to geospatially assess exposure to pesticides and have requested agricultural burning permit data to further assess additional sources of air pollution. Through our partnership with local promotoras and schools we are collecting information on children's respiratory health.

RESULTS: To date, the AIRE cohort has successfully enrolled over 700 elementary school-aged children from seven different schools across five cities in the northern Imperial Valley and identified high rates of asthma and respiratory symptoms.

CONCLUSIONS: Through this multi-partnership effort that is incorporating the principles of environmental justice we are linking multiple environmental pollutants to respiratory health outcomes, centering community members, involving them in the research process, collectively determining the environmental exposure issues of highest concern, creating dissemination plans and discussing sustainable interventions and implementation strategies.

KEYWORDS: Environmental justice, children's health, cumulative burden

O-SY-093 Providing expert witness testimony regarding affected Community impacts of natural gas pipeline proposals

George Thurston[1]
[1]*New York University School of Medicine, New York, USA*

BACKGROUND AND AIM: Today, most energy project development decisions involve scientific and health impact considerations. Vested interests usually have the financial and scientific resources to support their petitions, but affected communities, and especially underserved minority communities, often lack such experts to counter vested interests' consultants. In this presentation, Thurston will provide case studies of his recent experiences working with public interest groups by providing input to decision-makers and courts.

METHODS: Case studies are presented of real-world examples where expert technical reports and board testimony were provided regarding the adverse human health effects of proposed energy projects.

RESULTS: Processes and outcomes of decision-making proceedings regarding proposed natural gas pipelines are presented and discussed, along with more general insights into effective participation by scientists in providing a balanced consideration of scientific facts in regulatory and policy decision-making settings. This includes written and in-person participation in permit proceedings for natural gas pipeline extensions proposed near underserved minority communities in Virginia. Evidence for the occurrence of adverse health effects from such projects, even at prevailing air pollution levels within the ambient air quality standards, is also presented.

CONCLUSIONS: Significant adverse health impacts can occur from a proposed project that would result in the emission of additional air pollution, even in a locality that presently meets the ambient particulate matter air quality standards. By providing expert reports and testimony, scientists can "level the playing field" between vested interests and communities, enabling more balanced and equitable policy-making decisions.

KEYWORDS: civic engagement, underserved communities, equity, litigation

SYMPOSIUM 20: Epidemiological studies for preparedness and response to public health and environmental crises and disasters

O-SY-094 Lessons learnt from past nuclear accidents

Elisabeth Cardis[1], Liudmila Liutsko[1]
[1]*Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain*

The organization of the follow-up of populations after the Chernobyl and Fukushima accidents was very different, as was the scale of the accidents in terms of likely direct somatic effects of radiation. The size of the exposed population and the levels of doses were, fortunately for the residents of Fukushima prefecture, considerably lower than after the Chernobyl accident.

While Chernobyl brought new knowledge about radiation induced somatic effects, both accidents have taught us invaluable lessons about other important health effects of the accidents, including: avoidable loss of life among the evacuated elderly and severely ill patients; and the psycho-social consequences resulting from the response to the accident, evacuations and relocations/resettlements, remediation actions and the presence of radiation. These include serious mental health problems that, in addition to affecting the populations' wellbeing are a large burden on medical services.

Based on a review of the lessons learnt, the SHAMISEN project drew recommendations related to a) evacuation; 2) identification of affected persons and importance of dose assessment and communication at all phases of the accident (including the importance of citizen measurements in order to empower affected populations); 3) need to adapting/designing epidemiological and health surveillance strategies that address the concerns, needs and expectations of affected populations going beyond simple health monitoring and meeting the broader objectives of improving living conditions of affected populations, ideally including engagement of affected populations; 4) improving professional support of affected populations, including training/education of health professionals on radiation effects, post-traumatic stress syndromes, and risk communication; 5)desirability of developing common core epidemiological and surveillance protocols in the preparedness phase that can readily be adapted to different crises when they occur.

Many of the lessons learnt are applicable to the COVID-19 situation and to Public Health and Environmental Crises and Disasters in general.

O-SY-096 Beirut Blast August 2020: lessons learned for environmental epidemiology in low-resource settings

Iman Nuwayhid[1,2], Rima R Habib[1], Najat Aoun-Saliba[1]
[1]American University of Beirut, Beirut, Lebanon, [2]Yale University, New Haven, USA

BACKGROUND AND AIM: On August 4, 2020, Beirut experienced one of the worst non-nuclear explosions in modern history. The Blast happened in the midst of the COVID-19 pandemic and a protracted political and financial crisis. This presentation describes the immediate response to the disaster, shares initial environmental assessments, and proposes a cohort study to assess the environmental and health impacts of the Blast. Obstacles to conducting environmental epidemiology studies are discussed.

METHOD: Within a few days, a handful of professors established Khaddit Beirut (KB, Beirut Shakeup). The Environmental Health team under KB observed the safety measures followed by the respondents to the Blast, collected soil samples for asbestos and air samples for particulate matter, and established a Consortium of environmental health experts to propose a population-based epidemiological study to assess the environmental and health impact of the Blast.

RESULTS: Thousands of young volunteers and poorly-equipped professionals rushed to the site of destruction to support the residents and clean the rubble. Safety measures were not followed. The KB team produced multiple safety guidelines. Environmental assessments by international teams were not accessible. Our assessment showed elevated particulate matter in the affected area as compared to a non-affected area. Soil samples analyzed outside Lebanon were negative for asbestos. The long-term health impacts of the Blast are yet to be assessed through a longitudinal cohort study of residents in the affected areas, as proposed by the Consortium.

CONCLUSIONS: The magnitude of the explosion suggests serious environmental exposures and potentially multiple respiratory, neurological, and mental health outcomes. It will be amiss if the impacts of the Blast are not documented. So far, immediate humanitarian needs are prioritized over funding a study on long-term health effects. Conducting such studies in low-resourced settings requires international action and support and the development of an equitable framework for collaboration.

O-SY-097 Emerging preparedness for major accidents: updates about the 9/11 health consequences and more recent events.

Roberto Lucchini[1,2], Leslie London[3], Rajen Naidoo[4]
[1]Florida International University, Miami, USA, [2]University of Brescia, Brescia, Italy, [3]University of Cape Town, Cape Town, South Africa, [4]University of Kwazulu Natal, Durban, South Africa

BACKGROUND AND AIM: Response to disasters and the investigation of their immediate and long-term impact on health population health differ by the social, economic, and political contexts. We analyze three different events and extract key lessons for emergency preparedness and disaster management.

METHOD: This presentation reviews the response to the 9/11 disaster in 2001 and provides updates from the World Trade Center Health Program (WTCHP). It also analyzes two events occurred in: i) Miami Beach, Florida, where the Champlain Tower residential building collapsed on June 24, 2021; ii) Durban, South Africa, where a fire caused by protest-related arson caused a large chemical warehouse to burn down on July 12, 2021.

RESULTS: The WTCHP is revealing emerging impacts on cognitive decline among the responders, signaling the need for long term follow up. Across the three disasters, prevention, response and environmental monitoring was suboptimal. No action has been taken to investigate and control the physical and mental health consequences among responders and impacted community in the aftermath of the chemical fire in Durban, where access to critical exposure information needed to identify risk has been denied. In Florida, there was also some suboptimal preparedness in terms of recognizing the immediate threat posed by exposure to airborne pollutants. The scientific and health communities may be still missing important exposure-outcome relationships needed to address these recent disasters.

CONCLUSIONS: The observation of the health consequences from the WTCHP strengthen the need of long-term health surveillance in populations impacted by disasters. It also reinforces the need of adequate emergency preparedness, which is still largely insufficient, if not ignored, as shown by the cases of most recent disasters.

O-SY-098 Standardized epidemiological protocols for assessment of health impacts in eruption crises

Claire Horwell[1], Will Mueller[2], Hilary Cowie[2], John Cherrie[2], Damien McElvenny[2], Peter Baxter[3], Mark Booth[4], Paul Cullinan[5], Debbie Jarvis[5], Ciro Ugarte[6], Hiromasa Inoue[7]

[1]Durham University, Durham, UK, [2]Institute of Occupational Medicine, Edinburgh, UK, [3]University of Cambridge, Cambridge, UK, [4]Newcastle University, Newcastle, UK, [5]Imperial College, London, UK, [6]Pan American Health Organization, Washington DC, USA, [7]Kagoshima University, Kagoshima, Japan

BACKGROUND AND AIM: Volcanoes produce airborne emissions of ash and gas which may impact public health. Many epidemiological studies have been conducted following eruption crises but they often miss critical periods of highest exposures at eruption onset whilst methodological protocols are being developed and approved. Hence, we still have little understanding of the acute impact of volcanic emissions, particularly on respiratory health. In response to this need, the International Volcanic Health Hazard Network (www.ivhhn.org) developed and published* two standardized epidemiological protocols.

METHODS: Two workshops were held to develop the protocols. The first focused on technical aspects and content of the protocols, ensuring that they were comprehensive and jargon-free. The second, to present and discuss the protocols, took place after peer review and assessed issues of practical implementation.

RESULTS: We developed a 'basic' study protocol to assess the respiratory (and other) health impacts from acute exposures by tallying hospital/clinic visits. This is designed to be used during and/or immediately following a volcanic eruption, at the population level, where syndromic surveillance is not already in place or cannot be adapted for the outcomes expected from exposure to volcanic emissions. We also developed a protocol for a more detailed 'cross-sectional' survey of individuals, to be undertaken if the basic study or syndromic surveillance indicate adverse health effects, to assess the extent to which volcanic exposures may have been causal.

CONCLUSIONS: Advising relatively simple and inexpensive methods, the protocols are applicable in all volcanic contexts, regardless of resource availability or health records systems. The data collection forms included in the protocol can be integrated into, or merged with, existing response protocols, for efficiency and to minimize duplication. Standardized protocols will maximize the opportunity for rapid assessments. Consistent use will generate a strong and comparable evidence base of the health impacts of eruptions.

SYMPOSIUM 21: Is access to environmental public health monitoring and surveillance an equity and justice issue in low- and middle-income countries?

O-SY-100 Strengthening environmental health surveillance in low- and middle-income countries

Sumi Mehta[1], Daniel Kass[1]
[1]*Vital Strategies, New York, USA*

We will describe work to develop and implement actionable frameworks for measuring progress of actions to promote children's environmental health. Active health sector engagement to ensure the use of local data to inform policies and implementation will be described to underscore the value of ensuring sustained investments in surveillance, rather than one-off studies, to direct limited health resources. Applied examples will include 1) integrating and enhancing routinely collected data to quantify the impact of clean air policies in Indonesia and 2) targeting surveillance efforts to identify populations most at risk for increased blood levels in India and the Philippines.

O-SY-101 Interventions to reduce lead (Pb) exposure and value of a broad environmental health monitoring capacity

Ekaterine Ruadze[1], Irma Khonelidze[1], Lela Sturua[1]
[1]*The National Center for Disease Control and Public Health of Georgia, Tbilisi, Georgia*

BACKGROUND AND AIMS: In recent years, reports of lead (Pb) contamination have dramatically increased in Georgia. In 2018, 41% of the children who participated in the Multiple Indicator Cluster Surveys (MICS), a nationally representative among 2 to 7 years old children (n=1578), had blood Pb levels (BLL) above 5 microgram/dL. The National Centre for Disease Control and Public Health of Georgia (NCDC&PH) implemented written and verbal advice on how to reduce Pb exposure, and a state program of clinical follow-up was implemented. A significant reduction of BLL in children over a relatively short period has been documented. We aimed to identify the most relevant sources of Pb exposure contributing to elevated blood Pb in MICS children.

METHODS: In collaboration with UK Health Security Agency, British Geological Survey, and Georgian agencies, NCDC&PH conducted a Pb isotope ratio study in 36 purposefully selected children from MICS. Environmental samples collected for each included household included dust, soil, paint, spices, milk, drinking water, and toys. Pb isotope ratio analyses were conducted on both blood and environmental samples. Analyses included household level and group level ranking of environmental sources as an explanation of exposure to Pb represented by BILL.

RESULTS: Preliminary results indicate that drinking water and milk are not among Pb exposure sources of concern, while the precise ranking of other Pb sources varies between children and regions of Georgia.

CONCLUSIONS: It is expected that these data will support the design of more detailed public health interventions to reduce exposure to key sources of Pb, thus leading to further reduction of Pb-induced health effects in Georgia. In addition, this experience will clarify elements of ongoing monitoring of environmental factors such as an Environmental Public Health Tracking system, to support the national capacity to manage the risks to public health.

KEYWORDS: Lead, intervention, health surveillance

O-SY-102 The role of field epidemiology in strengthening public health capacity for chemical and environmental hazards in Ghana and Zambia

Giovanni Leonardi[1,2], Benduri Basil Kaburi[3], Elizabeth Peacocke[4], Caesar Nyadedzor[5], Ernest Kenu[3], Edwin A Afari[6], Joseph Pett[7], Nyambe Sinyange[8], Nicholas Brooke[1], Lydia Izon-Cooper[1], Rebecca Hams[1,9], Neelam Iqbal[1], Eirian Thomas[1], Helen Crabbe[1]

[1]Chemical and Environmental Effects Department, Radiation, Chemical and Environmental Hazards Directorate, UK Health Security Agency (UKHSA), Chilton, UK, [2]Department of Public Health, Environments and Society, London School of Hygiene and Tropical Medicine, London, UK, [3]Ghana Field Epidemiology and Laboratory Training Programme (GFELTP), University of Ghana, Accra, Ghana, [4]Norwegian Institute of Public Health, Oslo, Norway, [5]Ghana Poison Control Centre, Occupational and Environmental Health Unit, Ghana Health Service, Accra, Ghana, [6]School of Public Health, University of Ghana, Accra, Ghana, [7]Zambia Team, Global Public Health, UK Health Security Agency (UKHSA), Lusaka, Zambia, [8]Zambia National Public Health Institute (ZNPHI), Lusaka, Zambia, [9]East of England Health Protection Unit, Health Protection Operations, UK Health Security Agency (UKHSA), Mildenhall, UK

BACKGROUND AND AIM: The International Health Regulations (IHR, 2005) require that each country is prepared and able to detect, respond and undertake surveillance for public health risks, irrespective of origin or source. Gaps in relevant capacity can be identified via Joint External Evaluation. Field Epidemiology Training Programmes (FETP) are established in many countries and provide capacity to respond to infectious disease outbreaks and establish appropriate surveillance. Field epidemiology skills are required to assess, respond to, and mitigate the health impact of environmental and chemical hazards. Our training aimed to support capacity building in field environmental epidemiology in Ghana and Zambia.

METHODS: At the request of public health agencies in Ghana and Zambia, an environmental epidemiology module was developed as part of FETP programmes. The design of this module was based on the experience of providing a similar module to FETP trainees in the UK, and adapted to address local objectives and context for each country. The main educational theory underlying the design of the module was problem-based learning. Learning needs assessment identified topics to be prioritised for inclusion in the module.

RESULTS: Between 2018 and 2022, a week-long module in environmental epidemiology was delivered to cohorts of FETP fellows and environmental health practitioners in Ghana and Zambia. Topics addressed included preparedness in relation to chemical hazards, strategies for exposure assessment, risk assessment and communication, choice of design, and surveillance. The evaluation showed that participants consider case-studies in environmental epidemiology as a key element for training in this area, and field visit very valuable.

CONCLUSIONS: An environmental epidemiology module was developed for inclusion in FETP curriculum.
Workforce competencies in field environmental epidemiology for surveillance and response to chemical and environmental hazards were built, and their contribution to global health security and IHR capacity discussed.

KEYWORDS: Field epidemiology, training

O-SY-103 Inequalities in the environmental public health funding in the European region

Ariana Zeka[1], Helen Crabbe[1]
[1]*College of Health, Medicine and Life Sciences, Brunel University London, London, UK*

BACKGROUND AND AIM: Many societies in low- and middle-income (LMICs) countries face increasing environmental challenges, while also have minimal capacities to monitor and assess their impacts on population health, and therefore to inform decision making and policy. The European Union (EU) has supported the research in Environment and Health (EH) for more than 3 decades through its Framework Programmes of Research and Innovation, resulting in over 500 research projects, and investing close to €2 billion until 2020. The aim was to examine in detail the distribution of such funding across the European region and internationally, and in supporting EH capacities.

METHODS: An analysis of EU Horizon 2020 (2014-20) was carried out initially, assessing 269 funded projects linked to EH, totalling to €1.1 billion. The distribution of funding by country, institution, coordination, provisions for supporting research and policy capacities and capabilities, and how these have changed overtime were examined for EH domains (i.e. air pollution, urban health, climate change, EH Policy).

RESULTS: In all EH funding domains, the majority of the funding and coordination went to just a handful of countries (Spain, UK, Netherlands, Germany, France, Italy) and institutions. Societal Challenges 1 (SC1) and SC5, and Scientific Excellence received 77%, while the Spreading Excellence and Widening Participation projects aimed at building and strengthening capacities in EH only 3% of this funding. There was little indication that the majority of these projects contributed to EH capacity building in LMICs.

CONCLUSIONS: Inequalities in the EU funding distribution for EH research and policy capacities remain stark and persistent overtime. It is difficult to understand how the EU informs strategies to addressing such inequalities, but potential lack of attention to addressing these can lead to environmental and health justice issues across the region and beyond.

KEYWORDS: environment, health, funding, capacities, inequality, justice

O-SY-104 International Network for Public Health and Environmental Tracking (INPHET) and its role to Environmental Epidemiology

Paolo Lauriola

BACKGROUND AND AIM: INPHET was formed by a community of environmental public health practitioners to address common interests and activities that advance environmental public health surveillance (EPHS) and data systems, and their uses to inform public health actions. Our aim is to show how this has supported environmental epidemiology practice.

METHODS: A “Community of Practice”, INPHET main goals focus on sharing experiences and expertise; addressing common challenges to implementation and enhancing the science of EPHS/tracking; improving understanding of the link between the environment and health; and providing the appropriate evidence that informs public policy.

RESULTS: The network, initiated in ISEE meetings in 2012-13 and formally launched in Modena, Italy in 2014, has carried out several activities which aim at sharing expertise and learning from different models of environmental and health data integration and surveillance systems that directly inform policy. These include Twinning cooperation with Euro-Asian and Balkan countries and sharing of expertise with African Public Health Agencies. Some experiences are presented in this Symposium (Georgia, Ghana, Zambia), and highlight the EPHS/Tracking (EPHT) model adopted by several national public health agencies. It promotes that such integration and uses of environmental and health data is key for EPHS, including their accessibility and usability for communities of public health researchers, practitioners and policy makers.

CONCLUSIONS: Environment and health monitoring and information systems are fundamental infrastructure for evidence provision for policy making. INPHET aims to address the vast inequalities across countries and communities in their ability to monitor, assess, inform and mitigate environmental and health issues. Its objectives and work support environmental epidemiology in its role as the pillar science that provides evidence for decision making and intervention aimed at reducing and preventing environmental related diseases, and contributes to an overall vision for public health.

SYMPOSIUM 22: Climate change, heat and maternal health: estimating current and future burdens

O-SY-105 Associations between ambient temperature and risk of preterm birth in Sweden: a comparison of analytical approaches

Jeroen De Bont[1], Massimo Stafoggia[1,2], Britt Nakstad[3,4], Shakoor Hajat[5], Sari Kovats[5], Chérie Part[5], Matthew Cherisch[6], Stanley Luchters[7,8,9], Veronique Filippi[10], Olof Stephansson[11], Petter Ljungman[1,12], Nathalie Roos[11]

[1]Institute of Environmental Medicine, Karolinska Institutet, Sweden, Stockholm, Sweden, [2]Department of Epidemiology, Lazio Region Health Service, Rome, Italy, [3]Division Paediatric Adolescent Medicine, Inst Clinical Medicine, University of Oslo, Oslo, Norway, [4]Department Paediatrics and Adolescent Health, University of Botswana, Botswana, [5]Centre on Climate Change and Planetary Health, London School of Hygiene & Tropical Medicine, UK, [6]Wits Reproductive Health and HIV Institute, Faculty of Health Science, University of the Witwatersrand, Johannesburg, South Africa, [7]Institute of Human Development, Aga Khan University, Nairobi, Kenya, [8]Department of Public Health and Primary Care, Ghent University, Ghent, Belgium, [9]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia, [10]Faculty of Epidemiology and Population Health, London School of Hygiene and Tropical Medicine, London, UK, [11]Clinical Epidemiology Division, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [12]Department of Cardiology, Danderyd University Hospital, Stockholm, Sweden

BACKGROUND AND AIM: Evidence indicates that high temperatures are a risk factor for preterm birth. However, the large heterogeneity of study designs and statistical methods across previous studies complicate comparisons. We investigated associations of short-term exposure to ambient temperature with preterm birth in Sweden, applying three complementary analytical approaches.

METHODS: We included 560,615 singleton live births between 2014-2019, identified in the Swedish Pregnancy Register. We estimated at residential address weekly mean temperatures at 1-km² spatial resolution using a spatiotemporal model. The main outcomes of the study were gestational age in weeks (GW) and subcategories of preterm birth (<37GW): extremely preterm birth (<28GW), very preterm birth (from 28 to <32GW), and moderately preterm birth (from 32 to<37GW). Case-crossover, quantile regression and time-to-event analyses were applied to estimate the effects of short-term exposure to ambient temperature during the week before birth on preterm births. Furthermore, distributed lag nonlinear models (DLNM) were applied to identify susceptibility windows of exposures throughout pregnancy in relation to preterm birth.

RESULTS: A total of 1,924 births were extremely preterm (0.4%), 2,636 very preterm (0.5%), and 23,664 moderately preterm (4.2%). Consistent across all three analytical approaches (case-crossover, quantile regression and time-to-event analyses), higher ambient temperature (95th vs 50th percentile) demonstrated increased risk of extremely preterm birth, but associations did not reach statistical significance. In DLNM models, we observed no evidence to suggest an increased effect of high temperature on preterm birth risk. Even so, a suggested trend was observed of a higher risk of extremely preterm birth with higher temperature during the last week before birth.

CONCLUSIONS: In Sweden, with high quality data on exposure and outcome, we did not find an association between high ambient temperatures and preterm births. Results were consistent across three complementary analytical approaches.

KEYWORDS: Preterm births; ambient temperature; case-crossover; quantile regression; time-to-event analyses

O-SY-106 Ambient temperature during pregnancy and risk of maternal hypertensive disorders: a time-to-event study in Johannesburg, South Africa

Cherie Part[1], Jean le Roux[2], Matthew Chersich[2], Shobna Sawry[2], Véronique Filippi[1], Nathalie Roos[3], Lee Fairlie[2], Britt Nakstad[4,5], Jeroen de Bont[3], Petter Ljungman[3,6], Massimo Stafoggia[7], Sari Kovats[1], Stanley Luchters[8,9,10], Shakoor Hajat[1]

[1]London School of Hygiene & Tropical Medicine, London, UK, [2]University of the Witwatersrand, Johannesburg, South Africa, [3]Karolinska Institutet, Stockholm, Sweden, [4]University of Oslo, Norway, [5]University of Botswana, Gaborone, Botswana, [6]Danderyd Hospital, Stockholm, Sweden, [7]Lazio Regional Health Service, Rome, Italy, [8]Aga Khan University, Nairobi, Kenya, [9]Ghent University, Belgium, [10]Monash University, Australia

BACKGROUND AND AIM: Hypertensive disorders in pregnancy are a leading cause of maternal and perinatal mortality. We evaluate the effects of ambient temperature on risk of maternal hypertensive disorders throughout pregnancy.

METHODS: We used birth register data for all singleton births (22-43 weeks' gestation) recorded at a tertiary-level hospital in Johannesburg, South Africa, between July 2017-June 2018. Time-to-event analysis was combined with distributed lag non-linear models to examine the effects of mean weekly temperature, from conception to birth, on risk of (i) high blood pressure, hypertension, or gestational hypertension, and (ii) pre-eclampsia, eclampsia, or HELLP (hemolysis, elevated liver enzymes, low platelets). Low and high temperatures were defined as the 5th and 95th percentiles of daily mean temperature, respectively.

RESULTS: of 7986 women included, 844 (10.6%) had a hypertensive disorder of which 432 (51.2%) had high blood pressure/hypertension/gestational hypertension and 412 (48.8%) had pre-eclampsia/eclampsia/HELLP. High temperature in early pregnancy was associated with an increased risk of pre-eclampsia/eclampsia/HELLP. High temperature (23°C vs 18°C) in the third and fourth weeks of pregnancy posed the greatest risk, with hazard ratios of 1.76 (95% CI 1.12-2.78) and 1.79 (1.19-2.71), respectively. High temperatures in mid-late pregnancy tended to protect against pre-eclampsia/eclampsia/HELLP. Low temperature (11°C) during the third trimester (from 29 weeks' gestation) was associated with an increased risk of high blood pressure/hypertension/gestational hypertension, however the strength and statistical significance of low temperature effects was reduced with model adjustments.

CONCULSIONS: Our findings support the hypothesis that high temperatures in early pregnancy increase risk of severe hypertensive disorders, likely through an effect on placental development. This highlights the need for greater awareness around the impacts of moderately high temperatures in early pregnancy through targeted advice, and for interventions that reduce heat exposure among pregnant women. The potential ameliorating effects of high temperature in mid-late pregnancy requires further exploration.

O-SY-107 Climate and extreme weather impacts on health service delivery in sub-Saharan Africa: a systematic review

Sari Kovats[1], Amanda Quintana[1]
[1]*London School of Hygiene and Tropical Medicine, London, UK*

BACKGROUND AND AIMS: Health systems experience shocks and stresses related to climate events. Seasonal weather extremes also disrupt access to and delivery of services. There is very little information on the overall burden of extreme weather to health service disruption.

METHODS: We conducted a systematic review of the impact of weather events (heatwaves, heavy rainfall, flooding) on health service disruption (including access and travel time to services, damage to health facilities) in sub-Saharan Africa, from the six databases [CINAHL, Embase, Global Health; Web of Science; SCOPUS; ECONLIT; DESASTRUS].

RESULTS: We found 26 papers that met our criteria. 15 papers were quantitive analyses of the impacts of rainfall and weather events health service access, accessibility and use. The vast majority of there papers addressed the impacts of heavy rainfall, flooding and windstorms. 11 papers were qualitative studies of barriers to health service access and use that identified particular vulnerable groups and settings. The majority of papers reported a negative impact of weather but in many settings extreme weather is not a barrier to accessing health care. Few papers examined the impact of heatwaves on hospitals, clinics or health services.

CONCLUSIONS: Improving access to quality health services is a recognised factor in reducing maternal mortality. A resilient health care facility is structurally and functionally able to withstand extreme weather events and climate hazards. More research is needed to map and model the impacts of extreme weather on health service delivery in sub-Saharan Africa.

O-SY-108 The effect of high and low ambient temperature on infant health: a systematic review

Darshnika Pemi Lakhoo[1], Helen Blake[2,3], Matthew Chersich[1], Britt Nakstad[4], Sari Kovats[2]
[1]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [2]London School of Hygiene and Tropical Medicine, London, UK, [3]Royal College of Surgeons of England, London, UK, [4]Institute of Clinical Medicine, Centre of Global Health, University of Oslo, Oslo, Norway

BACKGROUND: Climate change poses grave dangers to the health of children. Among infants, in particular, there are physiological, anatomical, immunological, and behavioural factors that could increase vulnerability to temperature extremes. To inform public health strategies for addressing heat and cold risks, we performed a systematic review to explore the association between acute adverse infant outcomes and exposure to high and low ambient temperatures.

METHODS: MEDLINE (Pubmed), Embase, CINAHL Plus and Global Health were searched in July 2020 alongside reference lists of key papers. We included published studies in English that assessed adverse infant outcomes related to short-term ambient temperature exposure. Titles and abstracts of 2396 studies were screened using the inclusion and exclusion criteria. This resulted in a review of 64 full text articles, of which 26 studies were found to be eligible. Data were extracted, appraised using a modified quality appraisal tool, and synthesised using a narrative approach.

RESULTS: Outcomes assessed included: infant mortality (n=9), sudden infant death syndrome (n=5), hospital visits or admissions (n=5), infectious disease (n=5), and other neonatal conditions like jaundice (n=2). Higher temperatures were associated with increased infant mortality, hospital admissions, and hand, foot, and mouth disease. Several studies identified associations between lower temperatures and infant mortality and respiratory disease. Findings on temperature links with sudden infant death syndrome were inconsistent. of the 26 studies, 14 had a probably or definitely high risk of bias, with many studies scoring poorly due to misclassification of temperature exposure. Only five studies were conducted in low- or middle-income countries, where people are most vulnerable to changes in climate; further research here is required.

CONCLUSIONS: Rising global temperatures will have serious health implications for infants, again highlighting the need for major emissions reductions and urgent adaptation interventions.

KEYWORDS: climate change, infant health, neonatal health, heat exposure, cold exposure, heatwaves

O-SY-109 Past and projected climate change impacts on heat-related child mortality in Africa

Sarah Chapman[1], Cathyrn Birch[1], John Marsham[1], Cherie Part[2], Shakoor Hajat[2], Matthew Chersich[3], Kristie Ebi[4], Stanley Luchters[5], Britt Nakstad[6], Sari Kovats[2]

[1]Leeds University, Leeds, UK, [2]London School of Hygiene and Tropical Medicine, London, UK, [3]Wits University, Johannesburg, South Africa, [4]University of Washington, Seattle, USA, [5]Aga Khan University, Nairobi, Kenya, [6]University of Oslo, Oslo, Norway

BACKGROUND AND AIM: Climate change is likely to impact on the health of children. Children under 5 years are vulnerable to hot weather due to their limited ability to thermoregulate, and because high temperatures can exacerbate other health conditions. We estimated the impacts of past and future anthropogenic warming on child mortality due to higher temperatures.

METHODS: We estimated heat-related child mortality using a linear threshold model. Scenario-based estimates were generated using the CMIP6 global climate scenarios. We estimated heat-related child mortality for the period 1995–2020 in Africa, and apportioned the observed temperature increases to natural variability and anthropogenic climate change (from the DAMIP experiment of CMIP6). We estimated the future burden of child mortality for the period 2020–2050 for three emission scenarios (SSP119, SSP245 and SSP585), and a single scenario of population growth.

RESULTS: By 2009, heat-related child mortality was double what it would have been without climate change. Further, this climate change-related increase was greater than the reduction in heat-related child mortality from improvements in health and development. Under a high emission scenario (SSP585) heat-related child mortality was projected to double by 2049 compared to 2005-2014. If 2050 temperature increases are kept to the Paris target of 1.5ºC (SSP119), approximately 4,000–6,000 heat related child deaths could be avoided annually in Africa, compared with the SSP585 scenario.

CONCLUSIONS: Our findings support the need for urgent mitigation and adaptation measures to save lives now and in the future. Estimating heat related child mortality in Africa is complex due to a lack of epidemiological evidence about how heat effects child mortality across the continent.

SYMPOSIUM 23: The use of epidemiology in risk assessment: challenges and innovations in translating human health research

O-SY-110 Introduction to applying dose-response modeling from epidemiological data to derive toxicity values

Thomas Bateson[1]

[1]U.S. Environmental Protection Agency, Washington, USA, [2]Disclaimer: This work does not necessarily represent EPA views or policy.

BACKGROUND AND AIM: EPA derives toxicity values based on exposure-response functions from studies meeting adequately reported study quality criteria. EPA rarely has individual-level epidemiology data to model and therefore uses slopes extracted from published studies.

METHODS: EPA selects a benchmark response (BMR) based on biological and statistical considerations to identify points-of-departure (PODs) from the exposure-response functions. for cancer, the POD is often the exposure concentration associated with 1% extra risk of cancer (the BMR) and is identified using the upper-bound of published exposure-response functions (e.g., hazard ratio) and vital statistics data to account for competing causes of death. for an inhaled exposure, the toxicity value is the inhalation unit risk derived as the BMR/POD when the expectation that extra cancer risk is linear at low doses is appropriate. Noncancer effects are assumed to occur above a threshold level of exposure. for non-cancer effects, the POD can be estimated as the lower bound of the benchmark dose (i.e., the BMDL) using the upper-bound on the exposure-response functions for a specific BMR. A reference concentration (RfC) is derived as the POD divided by the product of uncertainty factors.

RESULTS: Challenges may arise over questions of the best-fitting shape of exposure-response functions and unintended consequences regarding low-dose extrapolations of log-transformed exposures. Many published exposure-response functions are only assessed for fit at the mean exposure while toxicity values are derived at the low end of the distribution. Sometimes publications do not provide information on the low end of the exposure distribution to allow EPA to see where estimated PODs may fall within the distribution.

CONCLUSIONS: A better general understanding of how EPA applies exposure-response functions from the epidemiological literature may allow investigators to anticipate some challenges EPA can face when deriving toxicity values, and thus make those publications more impactful for assessing health risks.

O-SY-111 Developments in benchmark modeling of epidemiological data

Esben Budtz-Jorgensen[1], Philippe Grandjean[2]
[1]University of Copenhagen, Copenhagen, Denmark, [2]University of Southern Denmark, Odense, Denmark

Using the benchmark dose (BMD) approach, we have explored joint data from multiple studies of prenatal fluoride exposure and IQ. We also analyzed data from birth cohort studies of children exposed to different perfluorinated alkylate substances (PFASs) at different ages in regard to immunotoxicity in later childhood. We calculated individual and joint study BMDs and their lower confidence bounds (BMDLs) using different curve shapes and including covariate adjustments and mutual adjustments for major PFASs. Health effects of multiple PFASs were modeled by creating exposure indices where the weight of each PFAS was estimated using quantile sum regression.

O-SY-112 Benchmark dose estimation using covariate-controlled epidemiology estimates

Matthew Wheeler[1]

[1]*National Institute of Environmental Health Sciences, Research Triangle Park, USA*

Traditionally, benchmark dose (BMD) estimation and dose-response modeling has focused on modeling exposure-response curves in toxicology experiments. Due to experimental randomization, additional factors that may bias the dose-response are controlled. These factors cannot be controlled using randomization in an observational epidemiologic study, where participants are not randomized. In this situation, their impact is controlled through covariates analyses, and normalized population estimates, adjusted for confounders, of the exposure-response are often reported. Based upon the WHO update of chapter 5 of "Principles and methods for the risk assessment of chemicals in food," or EHC 240, we apply the BMD methodology using Bayesian monotone splines to these normalized estimates to produce covariate controlled for estimates of the BMD to human populations.

O-SY-113 Advances in the meta-regression of heterogeneous studies: lessons learned from EPA's analysis of inorganic arsenic

Alexandra Larsen[1], Allen Davis[1], Bruce Allen[2], Jeff Gift[1]

[1]U.S. Environmental Protection Agency - Washington, DC, Research Triangle Park, USA, [2]Independent Consultant, Carrborro, USA

Challenges can arise when analyzing a group of published epidemiology studies due to heterogeneity in how effect measures are reported, exposure metrics, and other methodological issues. In this presentation, we will discuss techniques developed in the context of exposure or dose-response modeling of inorganic arsenic (iAs) exposure to facilitate meta-analyses in the presence of heterogeneous study designs and reporting. These methods include (1) effective count derivation, where covariate-adjusted relative risks and odds ratios are used to estimate the counts of cases and controls that would have been observed if covariates in all exposure groups were the same as those in the referent group, i.e., the "effective counts"; (2) dose conversion to convert various study-specific iAs exposure metrics into a uniform measure of intake; and (3) meta-analytic dose response methods, including both Bayesian hierarchical modeling for bladder cancer and categorical regression, where health outcomes are grouped into severity categories to facilitate meta-analysis, for diseases of the circulatory system (DCS). These approaches allow us to maximize the set of studies eligible for inclusion in meta-analysis. However, while these methods successfully address issues arising from heterogeneous reporting, use of such approaches can introduce uncertainty in the analysis. This presentation will discuss how improved reporting in published epidemiology studies can decrease such uncertainty and enhance the utility of meta-analyses across studies. Disclaimer: The views expressed are those of the authors and do not necessarily represent the views or policies of the US EPA.

O-SY-114 Estimation of the exposure response relation by combining epidemiological, human biomarker and animal data in a Bayesian meta-regression model

Roel Vermeulen[1], Bernice Scholten[2], Anjoeka Pronk[2], Rob Stierum[2], George Downward[3], Jelle Vlaanderen[1]
[1]Utrecht University, IRAS, Utrecht, Netherlands, [2]Nederlandse Organisatie voor Toegepast Natuurwetenschappelijk Onderzoe, Utrecht, Netherlands, [3]UMCU, Utrecht, Netherlands

INTRODUCTION: The importance of integrating various datatypes such as human disease, biomonitoring and animal data into the risk assessment process of chemicals has been emphasized in several risk assessment guideline. So far attempts have been mainly qualitative.

MATERIAL AND METHODS: We developed a Bayesian data augmentation approach and tested this on the evidence domain of benzene and acute myeloid leukemia. The benefit of our approach is that it facilitates the use of non-linear regression models and therefore provided more flexibility in assessing the shape of the benzene induced ERC of AML.

RESULTS: Combining epidemiological, animal and human biomonitoring data in a Bayesian meta-regression model resulted in more precise risk estimates in comparison to using only evidence from human benzene-AML studies.

DISCUSSION: With the current analyses we demonstrated that in the case of deriving the benzene and AML ERC, quantitatively combining animal- and biomarker studies with epidemiological studies was feasible and worthwhile, though came at the cost of making strong assumptions that in the end may hamper the interpretation of the derived ERC.

SYMPOSIUM 24: Chemical exposures and children's health in the United States: results from the NIH Environmental influences on Child Health Outcomes (ECHO) Program

O-SY-115 Solution-oriented research for chemical exposures and children's health: the ECHO Program

Jessie Buckley[1]
[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, USA*

BACKGROUND: The National Institutes of Health's Environmental Influences on Child Health Outcomes (ECHO) Program launched in 2016 with the goal to advance understanding of environmental influences on childhood disease. With rich chemical bioassay data for hundreds of chemicals, ECHO is uniquely suited to address gaps in exposure assessment and risk characterization of chemical exposures during pregnancy and early life.

METHODS: We overview ECHO data related to 1) chemical exposures, including available information from bioassays, place-based measures, and questionnaires; and 2) children's health outcomes, including ECHO's focus areas of pre-, peri-, and postnatal; respiratory; obesity; neurodevelopment; and positive health.

RESULTS: ECHO consists of more than 50,000 mother-child pairs from 69 cohorts with diverse geography and demographic characteristics. ECHO cohorts have measured a vast array of chemicals in pregnancy samples, including phthalates, environmental phenols, organophosphate ester flame retardants, per- and polyfluoroalkyl substances, and metals/trace elements. Leveraging large sample sizes, diverse cohorts, and rich data, ECHO investigators are conducting innovative epidemiologic studies to address key gaps in children's environmental health research. Importantly, the ECHO data platform will be made publicly available to the broader research community to facilitate high impact environmental epidemiology research. ECHO's rich data can be used to address multi-faceted problems such as co-pollutant mixtures; interactions with social, physical, and behavioral stressors; gene-environment interactions; health disparities; effects of cumulative exposures during early life; and periods of heightened susceptibility.

CONCLUSION: ECHO, the largest ever study of children's health in the United States, is an unprecedented data resource for addressing urgent environmental health questions to improve child health in the US and around the world.

O-SY-116 Organophosphate ester flame retardant exposure and perinatal outcomes

Deborah Bennett[1]
[1]*UC Davis Public Health Sciences, Belvedere Tiburon, USA*

BACKGROUND AND AIMS: Following a phase out of PBDE flame retardants in the mid-2000s due to concerns about toxicity, exposure to organophosphate ester (OPFRs) flame retardants increased, leading to increasing concerns regarding the toxicity of OPFRs. We hypothesize that prenatal exposure to OPFRs adversely affects outcomes at birth. Our overarching hypothesis is that prenatal exposure to OPFRs flame retardant chemicals adversely affects outcomes at birth. We propose to quantify prenatal exposure to a suite of flame retardants utilizing maternal urine collected during pregnancy to address our specific aims: 1) examine exposure trends over calendar time, and 2) investigate associations with perinatal outcomes, specifically low birth weight, preterm birth, and small for gestational age.

METHODS: We quantify prenatal exposure utilizing a single maternal urine collected during pregnancy, quantifying 9 OPFRs: Dipropyl phosphate (DPRP), Dibutyl phosphate + Di-isobutyl phosphate (DBUP_DIBP), bis(butoxyethyl) phosphate (BBOEP), bis(2-ethylhexyl) phosphate (BEHP), Bis(2-chlorethyl) phosphate (BCETP), Bis(1-chloro-2-propyl) phosphate (BCPP), Bis(1,3-dichloro-2-propyl) phosphate (BDCPP), Diphenyl phosphate (DPHP), and bis(2-methylphenyl) phosphate (BMPP). The study sample includes over 7000 pregnancies from 19 ECHO cohorts over 9 states. Outcomes include gestational age (continuous and categorized to consider preterm birth), birth weight (continuous and categorized to consider low birth weight), birthweight for gestational age (continuous and categorized to consider small for gestational age). Key confounders expected to be associated with both exposures and outcomes based on prior literature include cohort, maternal age, socioeconomic status (measured by education, marital status, income, or related variables), race/ethnicity, BMI, and year of birth.

RESULTS: The following compounds were detected in over 85% of the samples: BDCPP, DBUP_DIBP, and DPHP, while BBOEP, BCETP, and BCPP were detected in over 50% of samples. DPHP had the highest geometric mean concentration of 1.0 ng/mL, followed by BDCPP (0.86 ng/mL). Analysis of associations between exposures and outcomes is underway.

O-SY-117 Prenatal exposures to bisphenols and phthalates, gestational length and birth weight in the US: a national longitudinal study

Leonardo Trasande[1], Akram Alshawabkeh[2], Emily Barrett[3], Dana Dabelea[4], Anne Dunlop[5], John Meeker[6], Craig Newschaffer[7], Amy Padula[8], Nigel Paneth[9], Megan Romano[10], Doug Ruden[11], Sheela Sathyanarayana[12], Susan Schantz[13], Anne Starling[4], Morgan Nelson[14], Jessie Buckley[15], Ghassan Hamra[15]

[1]Nyu Grossman School of Medicine, New York, [2]Northeastern University College of Engineering, Boston, USA, [3]Rutgers School of Public Health, Piscataway, USA, [4]Colorado School of Public Health, Denver, USA, [5]Emory University School of Medicine, Atlanta, USA, [6]University of Michigan School of Public Health, Ann Arbor, USA, [7]Penn State College of Health and Human Development, Hershey, USA, [8]University of California San Francisco, San Francisco, USA, [9]Michigan State University, East Lansing, USA, [10]Dartmouth Geisel School of Medicine, Hanover, USA, [11]Wayne State University, Detroit, USA, [12]Seattle Children's Research INstitute, Seattle, USA, [13]University of Illinois, Urbana-Champaign, USA, [14]Research Triangle Institute, Cary, USA, [15]Johns Hopkins University Bloomberg School of Public Health, Baltimore, USA

Phthalates are synthetic chemicals used in personal care products, cosmetics and food packaging. Because they disrupt sex hormones and promote oxidant stress, they have the potential to disrupt fetal growth. Multiple longitudinal studies suggest consistent relationships of prenatal phthalate exposures with decreased gestation, but they have typically measured 1–2 spot samples during pregnancy, which introduces exposure imprecision and limits insight into effects that depend on the stage of fetal development. We therefore leveraged the NIH Environmental Influences on Child Health Outcomes (ECHO) Program to study the effects of prenatal phthalate exposure on gestational length and birth weight.

O-SY-118 Exposures to environmental phenols and asthma risk

Rachel Miller[1], Yuyan Wang[2], Annemarie Stroustrup[3], Rachel Kelly[4], Mengling Liu[2]
[1]Icahn School of Medicine at Mount Sinai, New York, USA, [2]NYU Grossman School of Medicine, New York, USA, [3]Zucker School of Medicine at Hofstra/Northwell, New Hyde Park, USA, [4]Harvard Medical School, Boston, USA

BACKGROUND: Prenatal exposure to bisphenol (BP) A has been associated with asthma. While the mechanisms underlying these associations are poorly understood, altered endocrine disruption, upregulated allergic immune response, altered response to oxidative stress, and mitochondrial dysfunction have been implicated in the adverse respiratory effects. As a result of these associations, the use of BPA has been banned in certain materials (i.e. baby bottles), although exposure remains prevalent. In many cases, BPA has been replaced with structurally similar chemicals, including BPF and BPS, despite the uncertain safety of these compounds.

METHODS: We assessed whether prenatal exposure to BPA and analogues BPF and BPS among mothers participating in the Environmental Influences on Child Health Outcomes (ECHO) study was associated with respiratory and allergic outcomes among their offspring. Exposure measures (adjusted for urinary dilution using the Boeniger method), outcomes, and covariates (including sex, race, child BMI, mode of delivery, maternal smoking status, income, education, parental asthma history, sibling and pet ownership) were harmonized across ECHO cohorts, and asthma was assessed in children ages 5-9 years. Multivariable logistic regression was applied to estimate associations between exposure and outcome.
Results/

CONCLUSIONS: In the ECHO consortium, we evaluated 830,645, and 771 mother-child pairs for analysis of associations between BPA, BPF, and BPS, and asthma. Preliminary results did not suggest associations between prenatal BPA, BPF, or BPS with asthma, but child BMI and parental history of asthma showed significant associations with child asthma. Ongoing analyses will examine: 1) the impact of additional harmonized covariates including season, 2) variation across cohorts in the relationship between prenatal phenol exposure and asthma diagnosis, and 3) associations between BPA, BPF, and BPS on additional outcomes such as rhinitis, wheeze phenotypes, asthma phenotypes, and atopic dermatitis.

O-SY-119 Associations of gestational perfluoroalkyl substances exposure with early childhood BMI Z-scores and risk of overweight/obesity: results from the ECHO cohorts

Jamie Yun Liu[1], Adaeze C Wosu[2], Ghassan B Hamra[2], Abby F. Fleisch[3], Anne L. Dunlop[4], Anne P. Starling[5,6], Assiamira Ferrara[7], Dana Dabelea[6], Emily Oken[8], Jessie P. Buckley[2], Leda Chatz[9], Margaret R. Karagas[10], Megan E. Romano[10], Susan Schantz[11], Thomas G O'Connor[12], Tracey J. Woodruff[13], Yeyi Zhu[7], Joseph M Braun[1]

[1]Brown University, Providence, USA, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, USA, [3]Maine Medical Center and Maine Medical Center Research Institute, Portland, USA, [4]Emory University School of Medicine, Atlanta, USA, [5]University of North Carolina at Chapel Hill, Chapel Hill, USA, [6]University of Colorado Anschutz Medical Campus, Aurora, USA, [7]Kaiser Permanente Northern California, Oakland, USA, [8]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA, [9]University of Southern California, Los Angeles, USA, [10]Dartmouth College, Hanover, USA, [11]University of Illinois at Urbana-Champaign, Urbana, USA, [12]University of Rochester, Rochester, USA, [13]University of California, San Francisco, San Francisco, USA

BACKGROUND AND AIM: Gestational per- and polyfluoroalkyl substances (PFAS) exposure may be associated with adiposity and increased risk of obesity among children and adolescents. However, results from prospective cohort studies evaluating associations between gestational PFAS and child adiposity are inconsistent. We estimated the associations of PFAS concentrations in pregnancy with child BMI z-scores and risk of overweight/obesity.

METHODS: We used data from 1,391 mother-child pairs that enrolled in eight Environmental Influences on Child Health Outcomes (ECHO) cohort studies. We quantified concentrations of seven PFAS in maternal plasma or serum in pregnancy. We measured child weight and height between ages 2-5 years and calculated age- and sex-specific body mass index (BMI) z-scores. We estimated associations of individual PFAS and their mixture with repeated child BMI z-scores and risk of overweight/obesity using linear mixed models, modified Poisson regression models, and two Bayesian approaches for mixtures. We explored whether child sex modified these associations.

RESULTS: Overall, gestational PFAS were associated with slightly higher BMI z-scores and risk of overweight/obesity. for instance, adjusting for covariates, each doubling in perfluorohexane sulfonic acid concentrations was associated with higher BMI z-scores at age 2-5 years (β=0.06, 95%CI: 0.01, 0.11). Each doubling in perfluroundecanoic acid (RR=1.10, 95%CI: 1.04, 1.16) and N-methyl perfluorooctane sulfonamido acetic acid (RR=1.06, 95%CI: 1.00, 1.10) were associated with increased risk of overweight/obesity, with some evidence of a monotonic dose-response relation. We found no mixture effect of PFAS on child BMI z-scores or the risk of being overweight/obese. These associations did not differ by child sex.

CONCLUSIONS: In eight US-based prospective cohorts, higher gestational concentrations of PFAS were associated with subtly higher childhood BMI z-score and risk of overweight or obesity. Future ECHO studies should evaluate the associations between PFAS concentrations in pregnancy and related cardiometabolic health outcomes in children.

Drexel Autism Institute, Drexel University, Philadelphia, USA, [10]Department of Epidemiology, Human Genetics, and Environmental Sciences, The University of Texas Health Science Center, Austin, USA, [11]School of Public Health, University of California, Berkeley, Berkeley, USA, [12]Department of Psychiatry, University of Rochester, Rochester, USA, [13]Program on Reproductive Health and the Environment, Department of Obstetrics, Gynecology and Reproductive Sciences, University of California, San Francisco, San Francisco, USA

BACKGROUND AND AIM: Epidemiological evidence linking prenatal exposure to per- and polyfluoroalkyl substances (PFAS) with altered neurodevelopment is inconclusive, and few large studies have focused on autism-related outcomes. This study investigates whether blood concentrations of PFAS in pregnancy are associated with child autism-related outcomes.

METHODS: Ten cohorts from the National Institutes of Health (NIH)-funded Environmental influences on Child Health Outcomes (ECHO) Program were included (n=1318). Fourteen PFAS analytes were measured in maternal serum or plasma collected during pregnancy. We assessed quantitative autism-related traits in children aged 2.9-18.0 years via parent report on the Social Responsiveness Scale (SRS). In multivariable linear models, we examined relationships of each PFAS with SRS scores. We further considered PFAS as a complex mixture using a Bayesian shared mean model and Bayesian Weighted Sums (BWS). We also examined modification of these relationships by child sex.

RESULTS: Higher blood concentrations of perfluorononanoic acid (PFNA) (adj-β [95% CI]=3.6 [-0.5, 7.8]) and perfluorooctane sulfonate (PFOS) (adj-β [95% CI]=3.4 [-0.8, 7.6]) were associated with higher total raw SRS scores. Adjustments for co-pollutants in the Bayesian shared mean model strengthened the point estimate for PFOS (adj-β [95% Highest Posterior Density [95% HPD]]=5.8 [-0.5, 12.3]. The BWS summed mixture, which included PFAS detected in >98% of participants, was associated with a small increase in total raw SRS scores (adj-β [95% HPD]=2.3 [-2.7, 7.3]). Sex-stratified estimates were imprecise but suggested that some PFAS (e.g., NMFOSAA, PFDA, and PFOS) may be associated with higher autism-related traits in girls only.

CONCLUSIONS: We found limited evidence that prenatal PFAS blood concentrations are associated with autism-related outcomes in children. Future work should continue to examine the relationship between exposures to both legacy and emerging PFAS and additional dimensional, quantitative measures of child neurodevelopment and neurobehavior.

KEYWORDS: PFAS; neurodevelopment; prenatal exposure

SYMPOSIUM 25: Global perspectives on harmonizing chemical risk assessments: current status and future needs

O-SY-121 Towards 'one substance-one assessment': an analysis of European chemical registration and environmental risk assessment frameworks

Joanke Van Dijk[1,2], Mikael Gustavsson[3], Stefan C. Dekker[1], Annemarie P. van Wezel[2]
[1]Copernicus Institute of Sustainable Development, Utrecht University, Utrecht, Netherlands, [2]Institute for Biodiversity and Ecosystem Dynamics, University of Amsterdam, Amsterdam, Netherlands, [3]Department of Mathematical Sciences, Chalmers University of Technology, Gothenburg, Sweden

BACKGROUND AND AIM: The registration and risk assessment of chemicals on the European market is currently fragmented across different legal frameworks, dependent on the chemical's use. A 'one-substance one-assessment' (OS-OA) approach has been proposed in order to better protect human and environmental health, and increase harmonisation and consistency across these different legal frameworks. We reviewed the five main European chemical registration frameworks and their risk assessment procedures for the freshwater environment, covering 1) medicines for human use, 2) veterinary medicines, 3) pesticides, 4) biocides and 5) industrial chemicals in order to provide an understanding of the differences between these chemical legislations and analyse how a shift towards an OS-OA approach might be realised.

RESULTS: Overall, the function of the current frameworks is similar, but important differences exist between the frameworks' environmental protection goals and risk assessment strategies. These differences result in inconsistent assessment outcomes for similar chemicals. Chemicals are also registered under multiple frameworks due to their multiple uses, and chemicals that are not approved under one framework are in some instances allowed on the market under other frameworks. In contrast, an OS-OA will require a uniform hazard assessment between all different frameworks. In addition, we show that industrial chemicals are the least hazardous for the freshwater environment, whilst biocides seem the most toxic following current regulatory assessment schemes. Finally, in order to facilitate a successful move towards an OS-OA approach we recommend a) harmonisation of protection goals and risk assessment strategies, b) that emission, use and production data should be made publicly available and that data sharing becomes a priority, and c) an alignment of the criteria used to classify problematic substances.

O-SY-122 Environmental health assessment in the United States

Rachel Shaffer[1]
[1]*U.S. Environmental Protection Agency, Washington, USA*

In the United States, chemical evaluations and assessments are conducted by several federal agencies responding to distinct statutory requirements and focusing on different exposure scenarios. This presentation will highlight a novel infographic depicting more than 30 different evaluation and assessment processes conducted by federal agencies for chemicals found in the environment, workplace, consumer products, hazardous waste sites, food, and/or cosmetics. This infographic illustrates the opportunity and need for further intra- and interagency collaboration and coordination – including a particular focus on aggregate risk assessment, given that the population regularly experiences exposures from multiple sources crossing agency domains.

O-SY-123 Advancing coordination of systematic review

Kristina Thayer[1]
[1]*US Environmental Protection Agency, Research Triangle Park, USA*

Systematic review is resource- and time-intensive, yet it is an essential part of the chemical assessment process. Alignment of systematic review (SR) approaches can allow for sharing of intermediate products (e.g., systematic evidence map (SEM)), which has the potential to minimize duplication and increase efficiency and collaboration between and within agencies. This presentation will provide updates on efforts to improve coordination of SR, including 1) collaboration across EPA; 2) development of an SEM template; 3) software applications to facilitate date re-use; and 4) unified ontologies.

O-SY-124 Evaluating chemical hazard on a global scale

Tracey Woodruff

Approaches to address the growing burden of chemical related diseases globally has not kept pace with this increasing human health threat. Policy and regulatory structures for addressing chemical exposures vary globally, but all incorporate elements of scientific evidence collection and evaluation. More transparent, consistent methods for hazard identification including systematic reviews have been implemented and adopted by various countries and global agencies. This talk will discuss opportunities to standardize and improve hazard identification that can be shared between high resource and low resource countries. More consistent approaches that incorporate contemporary scientific principles for robust data evaluation will improve the basis for health-related decision making.

ORAL PRESENTATIONS SESSIONS

Monday, September 19

ORAL PRESENTATIONS SESSION 01: Air pollution, diabetes and cardiometabolic outcomes

O-OP-001 Long-term air pollution exposure and diabetes risk in American older adults: a national cohort study

Maayan Yitshak Sade[1], Liuhua Shi[2], Elena Colicino[1], Heresh Amini[3], Joel Schwartz[4], Qian Di[5], Robert Wright[1]
[1]ICAHN School of Medicine at Mount Sinai, New York, USA, [2]Emory University, Atlanta, USA, [3]University of Copenhagen, Copenhagen, Denmark, [4]Harvard T.H. Chan School of Public Health, Boston, USA, [5]Tsinghua University, Beijing, China

BACKGROUND AND AIM: Type 2 diabetes is a major public health concern. Studies show that both genetics and environmental exposures play a significant role in developing the disease. We assessed the association between air pollution and first documented diabetes occurrence in a national U.S. cohort of older adults to estimate diabetes risk.

METHODS: We included all Medicare enrollees 65 years and older in the fee-for-service program, part A and part B, in the contiguous United States (2000-2016). Participants were followed annually until the first recorded diabetes diagnosis, end of enrollment, or death (264,869,458 person-years). We obtained annual estimates of fine particulate matter (PM2.5), nitrogen dioxide (NO2), and warm-months ozone (O3) exposures from highly spatiotemporally resolved prediction models. We assessed the simultaneous effects of the pollutants on diabetes risk using survival analyses. We repeated the models in cohorts restricted to ZIP codes with air pollution levels not exceeding the national ambient air quality standards (NAAQS) during the study period.

RESULTS: We identified 10,024,879 diabetes cases of 41,780,637 people (3.8% of person-years). The hazard ratio (HR) for first diabetes occurrence was 1.074 (95% CI 1.058; 1.089) for 5 µg/m3 increase in PM2.5, 1.055 (95% CI 1.050; 1.060) for 5 ppb increase in NO2, and 0.999 (95% CI 0.993; 1.004) for 5 ppb increase in O3. Both for NO2 and PM2.5 there was evidence of non-linear exposure-response curves with stronger associations at lower levels (NO2 ≤ 36 ppb, PM2.5 ≤ 8.2 µg/m3). Furthermore, associations remained in the restricted low-level cohorts. The O3-diabetes exposure-response relationship differed greatly between models and require further investigation.

CONCLUSIONS: Exposures to PM2.5 and NO2 are associated with increased diabetes risk, even when restricting the exposure to levels below the NAAQS set by the U.S. EPA.

KEYWORDS: Air pollution; diabetes; PM2.5, NO2, O3

O-OP-002 Air pollution exposure and glucose and lipids levels among the World Trade Center Health Program General Responder cohort

Pablo Knobel[1], Allan C. Just[1], Elena Colicino[1], Susan Teitelbaum[1], Mary Ann McLaughlin[2], Heresh Amini[3], Maayan Yitshak-Sade[1]

[1]Icahn School of Medicine at Mount Sinai, Department of Environmental Medicine and Public Health, New York, USA, [2]Division of Cardiology, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Department of Public Health, University of Copenhagen, Copenhagen, Denmark

BACKGROUND AND AIM: Several studies found associations between fine particulate matter (PM2.5) and glucose and lipids, but evidence of the effects of extreme air-pollution events is scarce. Furthermore, studies investigating the cardiometabolic risk associated with World Trade Center (WTC) related exposures are mixed. We aimed to assess the simultaneous association of WTC-related exposure and subsequent PM2.5 exposure and blood glucose and total cholesterol levels among responders who participated in the clean-up, rescue, and recovery mission after the WTC disaster.

METHODS: This retrospective cohort study includes 22,447 members of the WTC Health Program (2004-2019). WTC-exposure was derived from a questionnaire applied upon recruitment to the cohort. Daily mean PM2.5 levels were derived from a satellite-based model. We assessed the simultaneous effects of WTC-related and PM2.5 exposures on glucose and total cholesterol (mg/dL) levels obtained during each cohort monitoring visit.

RESULTS: We included 96,155 cholesterol and 82,015 glucose blood test results. We observed a 0.53% (95% CI 0.16%;0.9%) increase in glucose and a 0.82% (95% CI 0.46%;1.18%) increase in cholesterol levels associated with an interquartile range increase in PM2.5 averaged six months before the test. Comparing to the lowest WTC-exposure, an intermediate exposure was associated with a 0.51% (95% CI 0.14%;0.87%) increase in cholesterol, and the highest exposure was associated with a 0.63% (95% CI 0.16%;1.1%) increase in glucose levels. Most associations were larger among people with diabetes. PM2.5-related cholesterol increases were largest among individuals with the highest WTC-exposure. PM2.5-related glucose increases among the lowest and highest WTC-exposure, were equally smaller than the effect observed among the intermediate WTC-exposure.

CONCLUSIONS: We found that WTC-related exposure and subsequent PM2.5 exposure were independently associated with increases in glucose and cholesterol levels. Associations were more substantial among people with Diabetes. Our findings suggest possible interactions between the two exposures, which requires further research.

O-OP-003 Longitudinal associations between metabolites and long-term exposure to ambient air pollution: results from the KORA cohort study

Yueli Yao[1,2], Alexandra Schneider[2,3], Kathrin Wolf[2,3], Siqi Zhang[2], Rui Wang-Sattler[2,3], Annette Peters[1,2,3,4], Susanne Breitner[1,2]

[1]Institute for Medical Information Processing, Biometry and Epidemiology – IBE, Ludwig-Maximilians-Universität München (LMU), Munich, Germany, [2]Institute of Epidemiology, Helmholtz Zentrum München – German Research Center for Environmental Health (GmbH), Neuherberg, Germany, [3]German Center for Diabetes Research (DZD), Munich-Neuherberg, Germany, [4]German Centre for Cardiovascular Research (DZHK), Partner Site Munich, Munich, Germany

BACKGROUND AND AIM: Long-term exposure to air pollution is associated with a vast number of adverse health outcomes, while the underlying mechanisms remain unclear. Therefore, this study aimed to investigate changes in serum metabolites associated with long-term exposure to air pollution in a longitudinal study design.

METHODS: We used data from the German population-based Cooperative Health Research in the Region of Augsburg (KORA) S4 survey (1999-2001) and two follow-up examinations (F4: 2006-08 and FF4: 2013-14). Mass-spectrometry-based targeted metabolomics was used to quantify metabolites among serum samples. Only participants with repeated metabolites measurements were included in current analysis. Land-use regression models were used to estimate annual average concentrations of ultrafine particles, particles with a diameter < 10 µm, coarse particles (PMcoarse), fine particles, PM2.5 absorbance (a proxy of elemental carbon related to traffic exhaust, PM2.5abs), nitrogen oxides (NO2, NOx), and ozone at individuals' residences. We applied covariate-adjusted linear mixed-effects regression models to examine associations between long-term exposure to air pollution and metabolites.

RESULTS: Among 9,620 observations from 4,261 KORA participants, we included 5,772 (60.0%) observations from 2,583 (60.6%) participants in this analysis. Out of 108 metabolites that passed stringent quality control among these study waves, we identified nine significant negative associations between phosphatidylcholines (PCs) and PM2.5abs, PMcoarse, and NO2, at a Benjamini-Hochberg false discovery rate (FDR) corrected p-value < 0.05. The strongest association was seen for an increase of 0.27 µg/m3 (interquartile range) in PM2.5abs and decreased phosphatidylcholine acyl-alkyl C36:3 (PC ae C36:3) concentrations [percent change in the geometric mean: -2.5% (95% confidence interval: -3.6%, -1.5%)].

CONCLUSIONS: Our study suggested that long-term exposure to air pollution is associated with metabolic alterations, particularly in PCs with unsaturated long-chain fatty acids. These findings might provide new insights into potential mechanisms for air pollution-related adverse health outcomes.

KEYWORDS: long-term air pollution, targeted metabolomics, phosphatidylcholine

O-OP-004 Exposure to air pollution, road noise and surrounding green space and risk for type 2 diabetes: a multi-exposure study covering Denmark

Mette Sørensen[1], Aslak Poulsen[1], Matthias Ketzel[2], Ole Raaschou-Nielsen[1]
[1]Danish Cancer Society Research Center, Copenhagen O, Danmark, [2]Department of Environmental Science, Aarhus University, Roskilde, Denmark

BACKGROUND AND AIM: Air pollution, road noise and lack of greenness coexist in urban environments and have all been associated with type 2 diabetes (T2D). We aimed to identify how air pollutants, road noise and greenness were associated with T2D risk in a multi-exposure perspective.

METHODS: We estimated 5-year time-weighted exposure to PM2.5, ultrafine particles (UFP), elemental carbon (EC), NO2 and road traffic noise for all persons living in Denmark in 2005–2017 (HERMES study). for each air pollutant, we estimated the total contribution together with the traffic and non-traffic contributions. We estimated road noise at the most and least exposed façade and address-specific greenness (150m and 1000m radius). In total, 1.9 million persons aged >50 years were included, and 128,358 developed T2D during follow-up. Using Cox proportional hazards models, we conducted single-, two- and multi-pollutant analyses, with adjustment for individual and area-level sociodemographic co-variates.

RESULTS: In single-pollutant models, all air pollutants and road noise were associated with increased risk and green space with reduced risk of T2D. In two-pollutant models, HRs for NO2 total and UFP total were robust to further air pollution adjustment, besides when mutually adjusted, where HR for UFP total was markedly reduced. for air pollution originating from traffic, only UFP traffic was robust to adjustment for the other air pollutants. In models with mutual air pollution-noise adjustment, both air pollution and road noise were associated with higher T2D risk. HRs for green space remained virtually unchanged in all two-pollutant models. In a multi-pollutant analysis including both air pollution, noise and green space, HRs of all exposures but PM2.5 total and EC total remained associated with T2D.

CONCLUSIONS: Air pollution, road noise and green space were independently associated with risk for T2D in the Danish population.

KEYWORDS: Air pollution, road noise, greenness, type 2 diabetes, multi-pollutant

O-OP-005 Air pollution, metabolomic response, and bone mineral density among Women's Health Initiative participants

Diddier Prada[1], Kathryn Rexrode, Vrinda Kalia, Charles Kooperberg, Alex Reiner, Raji Balasubramanian, Gary Miller, Carolyn J. Crandall, Duanping Liao, James D. Stewart, Eric A. Whitsel, Andrea A. Baccarelli
[1]*Mailman School of Public Health - Columbia University, New York City, USA*

BACKGROUND AND AIM: Ambient air pollution has been associated with bone damage. However, no studies have evaluated the metabolomic changes linked to air pollutants and their potential influence on bone damage in postmenopausal women.

METHODS: We analyzed data available among Woman's Health Initiative (WHI) participants. We used log-normal, ordinary kriging to estimate daily mean concentrations of PM10 (µg/m3) and NOx, NO2, and SO2 (ppm) at their geocoded addresses. We averaged the means over 1-, 3-, and 5-year periods before metabolomic assessments. We measured whole-body, total hip, femoral neck, and spine bone mineral density (BMD) via dual-energy X-ray absorptiometry. We processed 2,129 plasma samples using liquid chromatography-tandem mass spectrometry (LC-MS) to estimate the concentration of approximately 500 metabolites. We used multivariable linear models adjusted for age, body mass index, ethnicity, education, and coronary heart disease to identify metabolome-wide significant cross-sectional associations between air pollutants, metabolites, and BMD at an FDR-corrected threshold of 0.05. We then used a hypergeometric enrichment test hosted on Metaboanalyst to conduct pathway analysis with the KEGG metabolic map as reference.

RESULTS: The mean (standard deviation) age of participants was 67.0 (7.1) years. Air pollutants were associated with several metabolite concentrations. for example, 1-year mean NOx exposure was associated with 104 metabolites after adjusting for multiple comparisons, including homoarginine, sphingosine-1-phosphate, uridine diphosphate glucose (UDP), UDP-galactose, alpha-glycerophosphate, kynurenine, cytidine monophosphate, malonylcarnitine, docosatrienoic acid, carboxybuprofen, and others. These NOx-associated metabolites enriched the arachidonic acid, purine, glycerophospholipid, and arginine metabolic pathways. Likewise, 17 metabolites were significantly associated with BMD, particularly total hip and whole body. Homoarginine was associated with both NOx and BMD.

CONCLUSIONS: This initial study of air pollutant-associated metabolites and bone mineral density in the Women's Health Initiative highlights potential metabolomic mechanisms by which air pollution may negatively affect bone health among postmenopausal women.

KEYWORDS: Air pollution, Metabolomics, BMD, Postmenopausal, Women.

O-OP-006 Exposure to household and outdoor air pollution and fasting plasma glucose as a marker of diabetes risk in Chinese adults

BACKGROUND AND AIM: Household air pollution (HAP) from solid fuel stoves is a widespread environmental exposure. Exposure to outdoor air pollution can increase risk of diabetes but studies of HAP and diabetes are limited.

METHODS: We modelled the relation of personal exposure to two HAP components – fine particulate matter (P2.5) and black carbon (BC), and stationary measures of outdoor PM2.5, with fasting plasma glucose (FPG) as a marker of diabetes risk in a cross-sectional study of 663 adults (40-79 years) in three provinces of China. We applied linear mixed regression models with a village-level random intercept to assess associations between pollutants and FPG levels in the same season as blood collection (winter) and for annual weighted mean exposure estimated across two seasons, adjusted for covariates.

RESULTS: We observed higher FPG (mmol/L) with winter outdoor PM2.5 (2.4%, 95% CI 0.2 to 4.5% per 100µg/m3 increase), driven by an increase in the southern non-heating province of Guangxi (10.5%, 95% CI -2.6% to 23.6% per 100µg/m3 increase). We observed higher FPG in association with winter and annual outdoor PM2.5 among participants with no hypertension and among those with BMI below the median (<25.1kg/m2). We found no association with winter or annual personal PM2.5 and BC exposures, however in sub-group analyses excluding those taking diabetes treatment, we found higher FPG levels with personal winter BC exposure (0.8%, 95% CI -0.2% to 1.7% per 1µg/m3 increase), an association that was stronger among participants with a BMI below the median (1.9%, 95% CI 0.7% to 3.1% per 1µg/m3 increase).

CONCLUSIONS: We found some evidence of detrimental associations between air pollutants and FPG levels. Longitudinal investigations of HAP exposure and markers of diabetes risk are needed in settings where solid fuels are an important energy source for cooking and heating.

KEYWORDS: air pollution, diabetes

O-OP-007 Heavy metals and diminished ovarian reserve: single-exposure and mixture analyses amongst women consulting in French fertility centres

Maximilien Génard-Walton[1], Charline Warembourg[1], Solène Duros[2], Martine Ropert-Bouchet[3], Tiphaine Lefebvre[4], Anne Guivarc'h[5], Marie-Thérèse Le Martelot[6], Bénédicte Jacquemin[1], Cécile Chevrier[1], Nathalie Costet[1], Luc Multigner[1], Ronan Garlantézec[7]

[1]Univ Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) - UMR_S 1085, Rennes, France, [2]Unité d'Assistance Médicale à la Procréation, CHU Rennes, Rennes, France, [3]CHU Rennes, Univ Rennes, Numecan (Nutrition, métabolismes et cancer) - UMR 1241, Rennes, France, [4]Reproductive Medicine, CHU Nantes, Nantes, France, [5]Reproductive Medicine, Clinique de La Sagesse, Rennes, France, [6]Reproductive Medicine, CHU Brest, Brest, France, [7]Univ Rennes, CHU Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) - UMR_S 1085, Rennes, France

BACKGROUND AND AIM: Diminished ovarian reserve (DOR) is one of the most frequent pathology diagnosed in women consulting for infertility. Animal studies have reported impacts of some heavy metals on the ovarian function but research on the ovarian reserve in humans is limited.

METHODS: We included 139 cases and 153 controls between 2016-2020. The participants were aged 18-40 and consulted for couple infertility in one of four fertility centres in western France. Cases of DOR were defined as women with an antral follicle count < 7 and/or anti-müllerian hormone (AMH) levels ≤ 1.1 ng/ml. Controls were frequency matched on age and centre and were women with normal ovarian reserve evaluations, no malformations, and regular menstrual cycles. Four heavy metals (lead, mercury, cadmium and chromium) were measured in whole blood at inclusion. Single-exposure associations were examined with multivariable logistic regressions adjusted on potential confounders. Mixture effects were investigated with quantile g-computation and bayesian kernel machine regression (BKMR).

RESULTS: All metals were detected in over 85% of control samples. We observed non-significant increased risks of DOR for chromium (OR = 1.24 [0.65 - 2.39] for the second tercile of exposure and OR = 1.77 [0.84 - 3.70] for the tercile) and cadmium (OR = 1.89 [0.98 - 3.67] for the second tercile of exposure and OR = 1.18 [0.55 - 2.52] for the tercile). Quantile g-computation and BKMR both yielded a non-significant increased risk of DOR for the mixture of metals, with no evidence of interaction.

CONCLUSIONS: We detected weak signals that some heavy metals could be associated with DOR. These findings should be replicated in other studies.

Chan School of Public Health, Boston, USA, [3]Department of Obstetrics and Gynecology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, USA, [4]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Solar and geomagnetic activity have been previously shown to suppress melatonin, which is an important hormone for fetal development. We explored whether solar and geomagnetic activity were associated with fetal growth.

METHODS: We included singleton births with routine ultrasounds at an academic medical center in Eastern Massachusetts from 2011 through 2016. Sunspot number (SSN), interplanetary magnetic field (IMF), and Kp index were obtained from the NASA Goddard Space Flight Center. Three exposure windows were considered, including the first 16 weeks of pregnancy, one month prior to fetal growth measurement, and conception until fetal growth measurement (cumulative). Ultrasound scans from which we extracted biparietal diameter (BPD), head circumference (HC), femur length (FL), and abdominal circumference measurements were categorized as anatomic (<24 weeks' gestation) or growth scans (≥24 weeks' gestation). Ultrasound parameters and birth weight were standardized, and linear mixed models adjusted for seasonality, long-term trends, meteorological factors, and maternal characteristics were fitted.

RESULTS: Among 9,428 pregnancies, prenatal exposure was negatively associated with ultrasound parameters among growth scans. Associations varied by exposure window, solar metric, and fetal growth parameter. Cumulative exposure to solar and geomagnetic activity was important across exposure metrics, where an interquartile range (IQR) increase in SSN was associated with a -0.20 (95% CI: -0.30, -0.11), -0.28 (95% CI: -0.39, -0.17), and -0.16 (95% CI: -0.26, -0.06) difference in average BDP, HC, and FL z-scores, respectively. Cumulative IMF and Kp index were also associated with reduced average HC, -0.23 (95% CI: -0.36, -0.10) and -0.14 (95% CI: -0.24, -0.03) z-score difference per IQR increase, respectively.

CONCLUSIONS: Solar and geomagnetic activity were associated with reduced fetal growth. Future studies are needed to better understand the impact of these natural phenomena on clinical endpoints.

KEYWORDS: fetal growth, solar activity, pregnancy

O-OP-009 A prospective study of cadmium concentrations and uterine fibroid incidence

Kristen Upson[1], Quaker E. Harmon[2], Alicia K. Kusaka[1], Robert O. Wright[3], Lauren A. Wise[4], Ganesa Wegienka[5], Ruth J. Geller[4], Amelia K. Wesselink[4], Birgit Claus Henn[6], Janet E. Hall[7], Erik J. Tokar[8], Donna D. Baird[2]

[1]Department of Epidemiology and Biostatistics, College of Human Medicine, Michigan State University, East Lansing, USA, [2]Epidemiology Branch, National Institute of Environmental Health Sciences, NIH, Research Triangle Park, USA, [3]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [4]Department of Epidemiology, Boston University School of Public Health, Boston, USA, [5]Department of Public Health Sciences, Henry Ford Health System, Detroit, USA, [6]Department of Environmental Health, Boston University School of Public Health, Boston, USA, [7]Clinical Research Branch, National Institute of Environmental Health Sciences, NIH, Research Triangle Park, USA, [8]Mechanistic Toxicology Branch, Division of the National Toxicology Program, National Institute of Environmental Health Sciences, NIH, Research Triangle Park, USA

BACKGROUND AND AIM: Although uterine fibroids are common, etiology of these smooth muscle tumors remains unclear. Mounting data suggest genetic mutations are an early event in fibroid development, with hormonal signaling promoting tumor growth. Cadmium exhibits mutagenic and hormonal properties, yet prior human studies of cadmium and fibroids have yielded discrepant results, and none were prospective investigations.

METHODS: The Study of Environment, Lifestyle & Fibroids is a cohort study of 1,693 Black women ages 23-35 years, based in Detroit, Michigan. Participants underwent transvaginal ultrasound at baseline and every 20 months for 5 years to detect fibroids ≥0.5 cm in diameter. Among 1,123 fibroid-free participants at baseline, we quantified baseline whole blood and creatinine-corrected urinary cadmium concentrations in 1,027 and 1,119 participants, respectively. We conducted Cox regression to estimate adjusted hazard ratios (aHRs), and 95% CIs for the association between cadmium and fibroid incidence, adjusting for urinary creatinine and time-varying factors of parity, years since last birth, years since last depot medroxyprogesterone acetate use, body mass index, smoking, and education.

RESULTS: Urinary cadmium was not associated with fibroid incidence. However, we observed elevated incidence estimates with blood cadmium (quartile 3 vs. 1: aHR 1.49, 95% CI: 1.07,2.08; quartile 4 vs. 1: 1.17, 95% CI: 0.75,1.84). Considering the short half-life of cadmium in blood (3 months), we repeated the analyses restricting follow-up to 20 months and observed a stronger association (quartile 3 vs. 1: aHR 1.79, 95% CI: 1.03,3.10; quartile 4 vs. 1: aHR 1.42, 95% CI: 0.67,2.99).

CONCLUSIONS: We found suggestive evidence of an association between blood cadmium concentrations and fibroid incidence. While urinary cadmium represents long-term exposure over prior decades, urinary excretion may come directly from kidney storage rather than blood circulation, which is the component available to the uterus. Future analyses will examine blood cadmium and fibroid growth.

O-OP-010 Associations between phenols and phthalates and placental weight in a mother-child cohort with improved exposure assessment

Nicolas Jovanovic[1], Vicente Mustieles[1], Anne Couturier-Tarrade[2], Cathrine Thomsen[3], Amrit Kaur Sakhi[3], Azemira Sabaredzovic[3], Isabelle Pin[4], Rémy Slama[1], Philippat Claire[1]

[1]Team of Environmental Epidemiology applied to Reproduction and Respiratory Health, Institute for Advanced Biosciences (IAB), Inserm U1209, CNRS UMR 5309, Université Grenoble Alpes, Grenoble, France, [2]National Research Institute for Agriculture, Food and Environment, Jouy-en-Josas, France, [3]Norwegian Institute of Public Health, Oslo, Norway, [4]Pediatric Department, Grenoble University Hospital, La Tronche, France

BACKGROUND AND AIM: The placenta plays a key role in assuring a normal foetal development and growth. Few epidemiological studies have investigated the effects of phenols and phthalates on placental function. We aimed to explore whether maternal exposure to phenols and phthalates during the second and third pregnancy trimesters are associated with changes in placental weight at birth and placental-to-birth weight ratio (PFR).

METHODS: We relied on a subsample of 357 women from the French SEPAGES cohort with placental and birth weights assessed, and for whom 8 phenols (4 parabens, 2 bisphenols, triclosan and benzophenone-3), 13 phthalate metabolites and 2 non-phthalate plasticizer metabolites were measured in within-subject pools of repeated urine samples collected at second and third pregnancy trimesters (median= 21 samples/trimester). Adjusted linear regressions were used to evaluate the associations between each compound and placental weight or PFR.

RESULTS: Each ln-unit increase in urinary monobenzyl phthalate (MBzP) concentrations at the second and third trimesters was associated with a mean placental weight decrease of 19.67 g (95%CI: -37.94; -1.4) and 16.71 g (95%CI: -33.08; -0.33), respectively. A decrease in PFR was also observed with MBzP exposure at the second (β: -0.51; 95%CI: -0.99; -0.04) and third trimester (β: -0.46; 95%CI: -0.88; -0.03). Children born to mothers with detected/quantified bisphenol S (BPS) in the second trimester showed a significantly lower PFR compared to mothers with undetected BPS (β: -0.83, 95%CI: -1.57; -0.09). No associations were observed with the remaining compounds.

CONCLUSIONS: This is the first study exploring the effect of BPS maternal exposure on placental function in humans. Our MBzP results are consistent with a previous study that found a similar negative association on placental function in girls, whereas three other studies relying on spot urine samples reported null associations.

KEYWORDS: placental weight, phenols, phthalates, pfr, prenatal exposure

O-OP-011 Exposure to perfluoroalkyl substances at preconception in association with fertility outcomes in women from Singapore

Nathan Cohen[1], Meizhen Yao[1], Vishal Midya[1], Sandra India-Aldana[1], Tomer Mouzica[1], Syam Andra[1], Manish Arora[1], Srinivasan Narasimhan[1], Jerry Kok Yen Chan[2,3], Shiao-Yng Chan[4,5], Youssef Oulhote[6], Jonathan Huang[4,7], Damaskini Valvi[1]

*[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, USA, [2]Department of Reproductive Medicine, KK Women's and Children's Hospital, Singapore, [3]Academic Clinical Program in Obstetrics and Gynaecology, Duke-NUS Medical School, Singapore, [4]Singapore Institute for Clinical Sciences (SICS), Agency for Science, Technology, and Research (A*STAR), Singapore, [5]Department of Obstetrics and Gynaecology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, [6]Department of Biostatistics and Epidemiology, School of Public Health and Health Sciences, University of Massachusetts at Amherst, USA, [7]Centre for Quantitative Medicine, Duke-NUS Medical School, Singapore*

BACKGROUND AND AIM: Exposure to perfluoroalkyl substances (PFAS) may affect fertility, but human studies are scarce. We assessed associations between PFAS concentrations and probability of pregnancy and live birth in women in Singapore.

METHODS: In a case-control study nested within the Singapore Preconception Study of Long-Term Maternal and Child Outcomes, we measured PFAS in preconception serum from 382 women of reproductive age (328 who became pregnant and 54 who failed to conceive or miscarried). We used logistic and weighted quantile sum (WQS) regression respectively to assess the associations between concentrations of seven individual PFAS and the PFAS mixture with the odds of pregnancy or live birth. We calculated time-to-pregnancy based on the number of menstrual cycles over 12 months of follow up and used Cox regression to estimate fecundability ratios (FR). We used inverse probability weighting to account for the nested case-control design. All models were adjusted for batch, age, ethnicity, education, household income, and parity.

RESULTS: Higher PFAS mixture exposure was associated with reduced odds of pregnancy (WQS: OR [95% CI] per PFAS quartile increase=0.67 [0.44, 1.02]) and live birth (0.71 [0.48, 1.07]), with PFOA and PFOS being the major contributors to the mixture associations. In individual PFAS analyses, the strongest associations were observed for PFOA (OR [95% CI]=0.58 [0.35, 0.96] for pregnancy and 0.62 [0.39, 1.00] for live birth) compared to other PFAS. Higher concentrations of PFOA (FR [95% CI]=0.87 [0.75, 1.02]), PFOS (0.84 [0.68, 1.03]), and PFHpA (0.76 [0.59, 0.98]) were associated with lower fecundability. Associations for PFHxS, PFDA, and PFHpS were in the same direction but more attenuated. There was no association between PFNA and the fertility outcomes.

CONCLUSIONS: Higher PFAS exposures may decrease fertility in women from Singapore. These findings need further investigation in larger populations.

KEYWORDS: Perfluoroalkyl substances; Endocrine disrupting chemicals; Fertility; Pregnancy outcomes.

O-OP-012 Water fluoridation and birth outcomes in California

Dana Goin[1], Amy Padula[1], Tracey Woodruff[1], Rachel Morello-Frosch[2]
[1]University of California, San Francisco, San Francisco, USA, [2]University of California, Berkeley, Berkeley, USA

BACKGROUND AND AIM: Evidence suggests fluoride exposure may affect neurodevelopment among children. A portion of this effect may be operating via adverse birth outcomes, but there is a lack of research on the relationship between water fluoridation and pregnancy outcomes.

METHODS: We linked California birth records from 2010-2018 to annual average fluoride levels by community water system. Fluoride levels were collected from consumer confidence reports. Births were geocoded to the address at delivery and the fluoride level in the year of pregnancy was determined, using a weighted average if the pregnancy spanned multiple years. We estimated the effects of a hypothetical intervention reducing water fluoride levels to 0.7 ppm and 0.5 ppm on birthweight and gestational age using G-computation. We used a linear regression model with a natural cubic spline to allow for non-linearity in the effects of fluoride. Individual covariates included maternal age, race/ethnicity, insurance type, educational attainment, and the month and year of conception. Area-level covariates included water system size, county-level unemployment, income inequality, temperature and urbanicity. Inference was calculated using a clustered bootstrap with Wald-type confidence intervals.

RESULTS: There was no estimated effect of the hypothetical intervention to reduce fluoride levels to 0.7 ppm on birthweight (-1.6 g, 95% CI -4.1, 0.8). We did observe a negative association of the hypothetical intervention to reduce fluoride level to 0.5 ppm (-7.6 g, 95% CI -12.6, -2.6). We also observed no effect for either the 0.7 or 0.5 ppm intervention on gestational age (-0.007 weeks, 95% CI -0.017, 0.003 and -0.023 weeks, 95% CI -0.050, 0.003, respectively).

CONCLUSIONS: We found a negative association of a hypothetical intervention of reducing fluoride levels to 0.5 ppm on birthweight, but no association for reducing fluoride levels to 0.7 ppm. We did not observe associations for either intervention with gestational age.

ORAL PRESENTATIONS SESSION 03: Noise exposure and health

O-OP-013 Associations between aircraft noise exposure and adiposity in the U.S.-based prospective Nurses' Health Studies

Matthew Bozigar[1], Francine Laden[2], Jaime Hart[3], Susan Redline[4], Tianyi Huang[5], Elizabeth Nelson[6], Stephanie Grady[1], Jonathan Levy[1], Junenette Peters[1]

[1]Boston University School of Public Health, Boston, MA, USA, [2]Departments of Environmental Health and Epidemiology, Harvard T. H. Chan School of Public Health; Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School; Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [4]Brigham and Women's Hospital and Harvard Medical School; Department of Epidemiology, Harvard T. H. Chan School of Public Health; Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, USA, [5]Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [6]College of Arts and Sciences, Boston University, Boston, USA

BACKGROUND AND AIM: Aircraft noise exposure is increasingly linked to cardiovascular disease risk. But intermediate pathways such as adiposity, which is biologically influenced by stress and sleep disruption, lack attention. This study investigates associations between aircraft noise exposure and general obesity in two prospective Nurses' Health Studies (NHS I and II).

METHODS: Aircraft day-night average noise levels (DNL) were estimated at geocoded participant residential addresses from noise contours modeled using the Aviation Environmental Design Tool for 90 U.S. airports from 1995-2015 in 5-year intervals. Biennial surveys from 1994-2017 provided information on body mass index (BMI) and potential confounding factors. Categorical BMI (18.5-24 (reference), 25-29, >=30 kg/m2) was modeled against multiple cut-points of aircraft noise exposure (45, 55, and 65 A-weighted decibels: dB(A)) using repeated multinomial logistic regression and generalized estimating equations to evaluate the odds of an increased BMI category from elevated aircraft noise exposure (dichotomous or ordinal). Multivariable models adjusted for age, race, socioeconomic status (SES), region, menopausal status, hormone replacement therapy, parity, diet, physical activity, smoking status, alcohol use, and neighborhood SES.

RESULTS: at baseline, the 78,154 pooled female participants averaged 50.2 years old. of these participants, 83.0%, 14.7%, 2.2% and 0.1% were exposed to <45 (reference), 45-54, 55-64, and >=65 dB(A) of aircraft noise, respectively. While all multivariable models indicated increased odds of reporting BMIs 25-29 or >=30 kg/m2 for each aircraft noise exposure cut-point, the largest increased odds were at the 55 dB(A) threshold (16.6% [95% CI: 6.8%, 27.3%]; 16.0% [95% CI: 4.0%, 29.4%], respectively). Increasing ordinal exposure was associated (ptrend<0.001) with each respective BMI group above 25 kg/m2.

CONCLUSIONS: In the NHS cohorts, higher aircraft noise exposure groups were associated with higher BMI categories. The relationship was independent of multiple factors influencing BMI over time, suggesting the importance of an adiposity pathway for noise-health effects.

O-OP-014 Long-term exposure to source-specific transportation noise and diabetes mellitus mortality: a national cohort study

Danielle Vienneau[1,2], Benedikt Wicki[1,2], Benjamin Flückiger[1,2], Beat Schäffer[3], Jean-Marc Wunderli[3], Martin Röösli[1,2]
[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]University of Basel, Basel, Switzerland, [3]Empa, Swiss Federal Laboratories for Materials Science and Technology, Dübendorf, Switzerland

BACKGROUND AND AIM: Long-term exposure to transportation noise is related to cardio-metabolic diseases. Identified as an important health outcome in the 2018 WHO environmental noise guideline systematic reviews, the body of evidence supporting an association between noise and diabetes mellitus incidence is growing. This study aimed to evaluate the association between road traffic, railway and aircraft noise exposure and diabetes mortality.

METHODS: Over 4.1 million adults in the Swiss National Cohort were followed from 2001-2015. Accounting for residential history, source-specific noise calculations were performed for residential locations. During follow-up over 73000 deaths identified diabetes mellitus on death certificates as the primary cause (~20%), or as a concomitant, consecutive or initial disease. Multipollutant, time-varying Cox regression with age as timescale was applied to evaluate the risk of mortality (hazard ratios, HR and 95% confidence intervals). Models included each noise source (road traffic, railway and aircraft Lden), and were incrementally adjusted for individual and area-level covariates and air pollution. HRs stratified by sex and age were also derived.

RESULTS: HR in the adjusted model (including PM2.5) were 1.061 (1.051-1.071), 1.022 (1.015-1.030) and 1.004 (0.991-1.018) per 10dB Lden road traffic, railway and aircraft noise, respectively. Substituting PM2.5 with NO2 did not change the associations with noise. The relative risk of mortality was higher in males compared to females (1.076 [1.062-1.090] vs. 1.045 [1.031-1.059] per 10dB road traffic noise), and higher in younger compared to older adults.

CONCLUSIONS: Though cautious interpretation is warranted due to the lack of adjustment for important lifestyle factors, this study provides new evidence that death with diabetes mellitus may be associated with road traffic and railway noise exposure. Given similar findings in incidence studies, the increasing diabetes prevalence and the large disease burden, further research on this association is of great public health interest.

KEYWORDS: metabolic disease; noise; transport

O-OP-015 Impact of road traffic noise on annoyance and preventable mortality in European cities: a health impact assessment

Sasha Khomenko[1,2,3], Marta Cirach[1,2,3], Jose Barrera-Gómez[1,2,3], MPH Evelise Pereira-Barboza[1,2,3], MPH Tamara Iungman[1,2,3], Natalie Mueller[1,2,3], Maria Foraster[1,2,3,4], Cathryn Tonne[1,2,3], Meelan Thondoo[1,2,3], Calvin Jephcote[5], John Gulliver[5], James Woodcock[1,6], Mark Nieuwenhuijsen[1,2,3]

[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Department of Experimental and Health Sciences, Universitat Pompeu Fabra (UPF), Barcelona, Spain, [3]CIBER Epidemiología y Salud Pública (CIBERESP), Barcelona, Spain, [4]PHAGEX Research Group, Blanquerna School of Health Science, Universitat Ramon Llull (URL), Barcelona, Spain, [5]Centre for Environmental Health and Sustainability (CEHS), University of Leicester, Leicester, UK, [6]MRC Epidemiology unit, University of Cambridge School of Clinical Medicine, Cambridge, UK

BACKGROUND AND AIM: Road traffic noise is one of the main environmental risks to health and wellbeing. We aimed to provide an in-depth assessment of available road traffic noise data and to estimate population exposure and health impacts for cities in Europe.

METHODS: We analyzed 724 cities and 25 greater cities in 25 European countries. We retrieved strategic noise maps delivered under the Environmental Noise Directive (END) or available from local sources. We employed the 24h day-evening-night noise level indicator (Lden) and estimated the health impacts of compliance with the World Health Organization (WHO) recommendation for road traffic noise (53 dB Lden) for adults aged 20 and over (n=123,966,346). Two primary health outcomes were assessed: high noise annoyance and Ischemic Heart Disease (IHD), using mortality from IHD causes as indicator.

RESULTS: Strategic noise map data varied in formats, noise ranges and levels of exposure categorization. The majority of noise maps (83.2%) were considered of moderate or low quality. Almost 60 million adults were exposed to road traffic noise levels above 55 dB Lden, equating to a median of 42% of the adult population. Approximately 11 million adults were highly annoyed by road traffic noise and 3608 deaths from IHD (95% CI: 843-6266) could be prevented annually.

CONCLUSIONS: A considerable number of adults are exposed to road traffic noise levels harmful for health. Efforts to standardize the strategic noise maps and to increase data availability at the city level are needed. These would allow for a more accurate and comprehensive assessment of the health impacts and further help local governments to address the adverse health effects of road traffic noise.

KEYWORDS: health impact assessment; road traffic noise; preventable mortality; ischaemic heart disease; annoyance; European cities.

O-OP-016 Transportation noise exposure, insulin resistance and diabetes: what is the role of sleep?

Noemie Letellier[1], Clemence Cavailles[2], Gabriel Carrasco Escobar[3], Steven Zamora[1], Marta Jankowska[4], Tarik Benmarhnia[1]

[1]Scripps Institution of Oceanography, UC San Diego, USA, [2]Institute for Neurosciences of Montpellier INM, INSERM Montpellier, University of Montpellier, Montpellier, France, [3]Health Innovation Laboratory, Institute of Tropical Medicine "Alexander von Humboldt", Universidad Peruana Cayetano Heredia, Lima, Peru, [4]Population Sciences, Beckman Research Institute, City of Hope, 1500 E Duarte Rd, Duarte, CA, USA

BACKGROUND AND AIM: Adverse health effects of noise, especially on cardiovascular health, are well identified; however, the mechanisms and sleep patterns underlying such effects remain unclear. The aim of this study is to understand whether exposure to road noise is associated with insulin resistance and diabetes and quantify the contribution of sleep in these associations.

METHODS: Among the Community of Mine Study, in San Diego County, insulin resistance and type 2 diabetes were assessed. Exposure to road noise was calculated based on the participant's census tract of residence and categorized according to WHO guidelines (>53dBA). Sleep was characterized by 3 variables: alertness, efficiency, and duration (from actigraphy). Associations of noise with insulin resistance or diabetes were quantified using generalized estimating equation models adjusted for sex, age, race/ethnicity, income and NO2. We conducted causal mediation analyses using Inverse Odds Ratio Weighting method, considering multiple sleep mediators. All analyses were stratified by neighborhood poverty levels coupled with heterogeneity tests (Cochran Q test).

RESULTS: Among 573 participants (mean age 58.7 years), individuals living in poorer neighborhoods were more vulnerable to the effect of noise on insulin resistance (p-Cochran=0.09) and diabetes (p-Cochran=0.03). An exposure to road noise equal to or greater than 53dBA was associated with higher level of insulin resistance (β, 95% Confidence Interval [CI]: 0.19, 0.01-0.37) and increased risk of diabetes (Odds Ratio [OR], 95%CI:3.05, 1.26-7.42), only for participants living in poorer neighborhoods. Among these participants, when decomposing the noise-diabetes association, we observed a Natural Indirect Effect (NIE) of 1.01 (95%CI:0.65-1.45) for sleep alertness, 1.00 (95%CI:0.62-1.52) for sleep efficiency and 1.00 (95%CI:0.63-1.42) for sleep duration. Similar findings were observed with insulin resistance.

CONCLUSIONS: In this population, neighborhood income is an important effect modifier for the associations between noise and insulin resistance or diabetes. Sleep does not seem to contribute to these associations.

O-OP-017 Associations between residential exposure to aircraft noise, cardiovascular disease, and all-cause mortality in the Nurses' Health Studies

Stephanie Grady[1], Jaime Hart[2,3], Francine Laden[3,2,4], Daniel Nguyen[1], Matthew Bozigar[1], Elizabeth Nelson[1], Jonathan Levy[1], Junenette Peters[1]

[1]Boston University School of Public Health, Boston, USA, [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [4]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Aircraft noise is hypothesized to increase cardiovascular disease (CVD) risk and mortality through multiple pathways; however, there is limited evidence. We aim to examine associations between aircraft noise, CVD, and all-cause mortality in the prospective US-based Nurses' Health Studies (NHS/NHSII).

METHODS: Between 1994 and 2014, we followed 109,432 participants from NHS and 114,746 from NHSII free of CVD at baseline. Aircraft noise was estimated for 90 US airports in 5-year intervals and linked to geocoded residential addresses. Time-varying Cox proportional hazards models were used to assess relationships between dichotomized (< vs. ≥45 dB(A)) day-night average sound level (DNL) and each outcome, adjusting for race/ethnicity, spouse's education, region, fine particulate matter (PM2.5), neighborhood socioeconomic status (nSES), population density, lifestyle factors, menopausal status, and family history of CVD. We assessed effect modification by duration at current residence, nSES, PM2.5, and population density.

RESULTS: Over 20 years of follow-up, there were 8,730 CVD cases and 28,312 deaths in NHS as well as 1,482 CVD cases and 2,471 deaths in NHSII. Approximately 7% of participants were exposed to DNL ≥45 dB(A). In CVD models, we observed adjusted hazard ratios (aHRs) of 0.95 (95% CI: 0.88, 1.04) in NHS and 0.99 (95% CI: 0.81, 1.21) in NHSII comparing exposed and unexposed participants. Similarly, for all-cause mortality, we observed aHRs of 0.99 (95% CI: 0.94, 1.03) and 1.00 (95% CI: 0.86, 1.16) in NHS and NHSII, respectively. We only observed evidence of effect modification by nSES on noise and all-cause mortality in NHS, with greater adverse effects of noise among those living in areas of higher nSES.

CONCLUSIONS: We did not find associations between noise and CVD or all-cause mortality overall. Unexpectedly, we found associations between aviation noise and all-cause mortality among those living in more affluent areas.

KEYWORDS: aircraft, noise, CVD

O-OP-018 A nationwide cohort study on transportation noise and tinnitus: expanding current knowledge on the adverse health effects of noise pollution

Manuella Lech Cantuaria[1,2], Ellen Raben Pedersen[1], Aslak Harbo Poulsen[2], Jesper Hvass Schmidt[1,3], Mette Sørensen[2,4]

[1]University of Southern Denmark, Odense, Denmark, [2]Danish Cancer Society Research Center, Copenhagen, Denmark, [3]Odense University Hospital, Odense, Denmark, [4]Roskilde University, Roskilde, Denmark

BACKGROUND AND AIM: Transportation noise is a major contributor to the environmental burden of disease worldwide and has been consistently linked to several non-auditory health outcomes. However, there is a clear lack of studies investigating transportation noise and auditory outcomes, such as tinnitus, even though these are considered critical outcomes for the development of public health guidelines. We aimed to investigate the association between transportation noise exposure and incident tinnitus in a nationwide cohort from Denmark.

METHODS: Our study population included all adults ≥ 30 years old living in Denmark between 2000 and 2017. Road traffic and railway noise were modelled at the most and least exposed façades of all Danish addresses for the period 1990-2017, enabling us to calculate 10-year time weighted mean noise exposure for all cohort members. We used data from health and administrative national registers to retrieve individual-level information on tinnitus diagnosis, address history and socioeconomic factors. Analyses were based on Cox Proportional Hazard models, with adjustment for potential individual and area-level confounders, and air pollution.

RESULTS: We identified 40,692 cases of tinnitus. Ten-year mean residential exposure to road traffic noise (per 10 dB) at the most and least exposed façades were positively associated with tinnitus, with respective hazard ratios of 1.018 [95% CI 1.005 – 1.032] and 1.056 [95% CI 1.037 – 1.075]. Associations between road noise at the least exposed façade and tinnitus followed a linear and positive exposure-response relationship throughout the entire exposure range. No associations were found between railway noise and risk of tinnitus.

CONCLUSIONS: We found road traffic noise to be associated with a higher risk of tinnitus, thus suggesting transportation noise may also affect the auditory system.

KEYWORDS: Transportation noise; road traffic; railway; tinnitus; auditory outcomes

O-OP-019 Characterization of urban built and natural environments with high-resolution satellite images and unsupervised deep learning

Antje Barbara Metzler[1], Ricky Nathvani[1], Viktoriia Sharmanska[2], Wenjia Bai[1], Emily Muller[1], Simon Moulds[3], Charles Agyei-Asabere[4], Dina Adjei-Boadi[4], Elvis Kyere-Gyeabour[4], Jacob Doku Tetteh[4], George Owusu[4], Samuel Agyei-Mensah[4], Jill Baumgartner[5], Brian E Robinson[5], Raphael E Arku[6], Majid Ezzati[1,4]

[1]Imperial College London, London, UK, [2]University of Sussex, Brighton, UK, [3]University of Oxford, Oxford, UK, [4]University of Ghana, Accra, Ghana, [5]McGill University, Montreal, Canada, [6]University of Massachusetts, Amherst, USA

BACKGROUND AND AIM: Cities in the developing world are expanding rapidly and undergoing changes to their roads, housing and other buildings, vegetation, and land use characteristics. Timely data are needed to ensure that urban change enhance health, wellbeing and sustainability.

METHODS: We characterise, as mutually exclusive clusters, the complex, multidimensional, built and natural environments in cities with high-resolution satellite images and unsupervised deep clustering. We apply our approach to Accra, Ghana, one of the fastest growing cities in the developing world, and contextualise the resultant clusters with demographic and environmental data that were not used for clustering.

RESULTS: We show that image-based clusters captured distinct features of the urban built environment (building count, size, density, and orientation; length and arrangement of roads), vegetation, water, and population, either as a unique defining characteristic (e.g., bodies of water or dense vegetation) or in combination (e.g., buildings surrounded by vegetation or sparsely populated areas intermixed with roads). Clusters that were based on single defining characteristics were robust to the spatial scale of analysis and choice of cluster number, whereas those based on a combination of defining characteristics changed based on scale and number of clusters.

CONCLUSIONS: The results demonstrate that satellite data and unsupervised deep learning provide a cost-effective interpretable and scalable approach for real-time tracking of sustainable urban development, especially where traditional environmental and demographic data are limited and not frequently updated. Our approach has multiple urban environmental applications, such as providing ground data for tracking and measuring urban health, air- and noise pollution, urban connectivity and road traffic, as well as city growth in cities across Africa and beyond.

KEYWORDS: Big data, satellite imagery, deep learning, built environment; urban growth, unsupervised machine learning

O-OP-020 Diarrhea in children under 5 years and extreme precipitation in Nigeria

Athicha Uttajug[1], Kayo Ueda[1], Xerxes Tesoro Seposo[1], Asura Arai[1]
[1]*Department of Hygiene, Graduate School of Medicine, Hokkaido University, Sapporo, Japan*

BACKGROUND AND AIM: Extreme precipitation events are expected to increase in frequency and intensity due to climate change. Understanding the potential links between extreme weather events and infectious disease in Nigeria is important to reduce the future burden disease, particularly for the vulnerable population. We examined the association between extreme precipitation and diarrhea in children younger than 5 years in Nigeria.

METHODS: We obtained the survey data collected in 2018 from Demographic and Health Survey (DHS) survey for Nigeria with GPS coordinated of each household cluster. We used these data with monthly high-resolution precipitation data from Climate Hazard group InfraRed Precipitation with Station data (CHIRPS) for year 2005-2020. Extreme precipitation was defined when the rainfall in the month of DHS survey (30 days prior to the survey) higher than 90th percentile of the entire data. We used multivariable logistic regression in examining the diarrhea and extreme precipitation association, after adjusting for the covariates of temperature and sanitation variables. Stratified analysis by different climate zones was subsequently performed.

RESULTS: Among the 33,924 children under 5 years of age included in the survey (in 2018), approximately 12% reported having diarrhea within the 2 weeks prior to the survey. Extreme precipitation was associated with under-5 diarrhea in Nigeria [Odds Ratio (OR) = 1.30 (95% Confidence Interval (CI): 1.17-1.44)]. We found that improved water drinking source, toilet facilities, and living in urban area reduced the risk of under-5 diarrhea. Stratified analysis revealed a variation in the extreme precipitation and under-5 diarrhea association across the country.

CONCLUSIONS: Our findings show that extreme precipitation can affect the risk of diarrhea in young children in Nigeria. The health burden of climate-sensitive disease such diarrhea can be protected by encouraging to access safe water drinking and sanitation infrastructure.

KEYWORDS: Diarrhea, children, extreme precipitation

O-OP-021 The protective effect of green space on heat-related respiratory hospitalization among children under five years of age in Hanoi, Vietnam

Tran Ngoc Dang[1], Nguyen Tuong Vien[2], Doan Quang Van[3], Ngoc Nguyen Tran[4], Ly Thi Mai Luong[5], Pham Minh Chinh[6], Thai Khanh Phong[7], Dung Phung[8], Le Huynh Thi Cam Hong[1]

[1]University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh City, Vietnam, [2]Pham Ngoc Thach University of Medicine, Ho Chi Minh, Vietnam, Vietnam, [3]Center for Computational Sciences, the University of Tsukuba, Japan, [4]School of Information and Communication Technology, Hanoi University of Science and Technology, Hanoi, Vietnam, [5]Faculty of Environmental Sciences, VNU University of Science, Vietnam National University, Hanoi, Vietnam, [6]Faculty of Environmental Engineering, National University of Civil Engineering, Hanoi, Vietnam, [7]Queensland Alliance for Environmental Health Sciences, The University of Queensland, Brisbane, QLD, 4102, Australia, [8]7School of Medicine and Dentistry, Griffith University, Gold Coast, Australia,

BACKGROUND AND AIM: Combined effects of global warming and rapid urbanization replaces green spaces with urban facilities. Children in urban areas are at a higher risk of heat-related adverse health effects. Our study aimed to examine the protective effect of urban green space on heat-related respiratory hospitalization among children under five years of age in Hanoi, the capital city of Vietnam.

METHODS: We estimated district-specific meteorological conditions from 2010 to 2014 by using a dynamic downscaling approach with a fine-resolution numerical climate model. The green space in each district was calculated using satellite data. The attributable fraction of heat-related respiratory hospitalization was estimated using a two-stage model, including a distributed lag non-linear model (DLNM) coupled with multivariate meta-analysis. The association between heat-related respiratory hospitalization and green spaces at the district level was explored using a linear regression model.

RESULTS: The central districts were more crowded and hotter, with less green spaces than the outer districts. at temperatures > 34oC (extreme heat threshold), the hospitalizations in the central districts increased significantly; however, in the outer districts, the hospitalization rate was insignificant. On average, extreme heat attributed 0.33% to citywide hospitalization, 0.35% in the center, and 0.32% in the outer region. Every 1% increase in the greenspace fraction will reduce heat-related respiratory hospitalization risk by 3.8%.

CONCLUSIONS: Heat significantly increased the risk of respiratory hospitalization among children under five years in Hanoi, Vietnam. These findings are valuable for authorities to consider strategies to protect children's health against the effects of heat, including increasing greenspace.

KEYWORDS: Greenspace, the heat-related hospitalisation, children under five years old, Vietnam

O-OP-022 Pesticide exposure assessment in farmers from Malaysia, Uganda, and the UK: an analysis of urinary biomarker concentrations

Will Mueller[1], Kate Jones[2], Anne-Helen Harding[2], Andrew Povey[3], Martie van Tongeren[3], Ioannis Basinas[3], Hans Kromhout[4], Samuel Fuhrimann[4], Zulkhairul Naim Bin Sidek Ahmad[3], Aggrey Atuhaire[5], Karen Galea[1]

[1]Institute of Occupational Medicine, Currie, UK, [2]Health & Safety Executive (HSE), Buxton, UK, [3]Centre for Occupational and Environmental Health, School of Health Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, UK, [4]Utrecht University, Utrecht, Netherlands, [5]Uganda National Association of Community and Occupational Health (UNACOH), Kampala, Uganda

BACKGROUND AND AIM: More robust exposure data are needed for epidemiological studies of pesticide exposure, particularly in low and middle income countries. The aim of our study was to examine pesticide exposure in farmers based on urinary biomarkers.

METHODS: We used data from three cohorts of pesticide applicators in Malaysia, Uganda, and the UK. Participants completed questionnaires and provided same day urine samples for pre- and post-direct handling and spraying of pesticides. We analysed urinary biomarkers based on the reported use of active ingredients, including 3PBA (pyrethroids), DCVA (cypermethrin/cyfluthrin), ETU (mancozeb), TCPyr (chlorpyrifos), and Glyph (glyphosate). We report biomarker results where post-activity concentrations were less than the limit of quantification (LoQ) in <50% of samples.

RESULTS: There were 81, 84, and 106 participants from the Malaysia, Uganda, and UK cohorts, respectively, who provided a total of 758 urine samples. Several biomarkers included post-activity urine concentrations with ≥50% of samples above the LoQ in multiple studies, including 3PBA (16/32 [50%] in the UK to 67/73 [92%] in Malaysia), Glyph (100/192 [52%] in Uganda to 86/106 [81%] in the UK), and TCPyr (23/32 [72%] in the UK to 62/62 [100%] in Malaysia). of these same three biomarkers, median post-activity concentrations (in nmol/L) in Uganda and Malaysia were greatest for TCPyr: 2.66 (Interquartile Range [IQR]: 1.00-5.99) and 6.38 (IQR: 0.76-28.8), respectively. However, in the UK, median concentrations were highest for Glyph: 1.25 (IQR: 0.61-2.26).

CONCLUSIONS: Preliminary findings suggest distinct exposure patterns and pesticide use in Malaysia, Uganda, and the UK based on objective indicators. We will continue our analysis using linear mixed effects regression with multiple imputation to assess the importance of different exposure modifying factors for a suite of urinary biomarkers.

O-OP-023 Occupational heat stress induced renal health impacts – A field study on outdoor workers in Southern India

Vidhya Venugopal[1], Rekha Shanmugam[1], PK Latha[1]
[1]*Sri Ramachandra Institute of Higher Education and Research, Porur, India*

BACKGROUND AND AIM: Temperature increases have been linked to large increases in heat-related illnesses as a result of global climate change. Heat stress, strenuous labour, and dehydration are all known to be major risk factors for kidney disease in workers who toil in heat. The goal of this study was to fill in the gaps in data on heat stress impacts on renal health among outdoor workers in India.

METHODS: During the summer and winter seasons of 2018-2019, three unorganised outdoor sectors were surveyed. The ACGIH standards and TLV-WBGT°C were used to establish job-specific workloads. Tympanic temperatures (Ttemp), Sweat Rates (SwR), Serum creatinine, and urine dipstick were all measured in ~550 workers, and heat-strain symptoms were assessed using questionnaires. The estimated Glomerular Filtration Rate (eGFR) was calculated using the CKD-EPI formula.

RESULTS: The mean WBGT temperature in summer and winter was 30.1±2.4°C and 27.0±2.5°C, respectively. While 86% of workers did heavy work, the remaining 14% had moderate job profiles. 65.3% of workers (N =364) were exposed to excessive heat, and they reported 2.8-times the number of heat-related illnesses/symptoms. Heat-exposed workers showed cross-shift increases in Ttemp > 1°C (17%), USG (36%), and SwR (30%). Even after controlling for confounders such as age, gender, and behavioural aspects, 36% of the workers had eGFRs < 90 mL/min/1.73m2 (AOR: 2.7; 95%CI: 1.8-4.2) and 8% of the workers had eGFRs < 60 mL/min/1.73m2 (AOR: 2.6; 95% CI: 1.2-6.2) that were significantly associated with heat exposure.

CONCLUSIONS: Excessive heat exposure, physical activity, dehydration, and reduced kidney function among outdoor workers warrant further in-depth investigation to develop workplace interventions and implementation of protective labour legislation and welfare measures for these workers.

KEYWORDS: Occupational heat stress, WBGT, heat strain, outdoor workers, reduced kidney function.

ORAL PRESENTATIONS SESSION 05: Challenges in health studies of chemicals: from methods to policy

O-OP-024 The relative importance of faecal and urinary excretion of PFAS and implications for epidemiological studies

Tony Fletcher[1], Axel Andersson[2], Ying Li[2], Yiyi Xu[2], Christian H Lindh[3], Anna Kärrman[4], Kristina Jakobsson[2]
[1]London School of Hygiene & Tropical Medicine, London, UK, [2]University of Gothenburg, Gothenburg, Sweden, [3]Lund University, Lund, Sweden, [4]Orebro University, Orebro, Sweden

BACKGROUND AND AIM: Some per- and polyfluoroalkyl substances (PFAS) are persistent with long half-lives. Elimination rates and half-lives for PFAS have been described in animal and human studies, but there is little data on the importance of different routes of excretion, and many reviews have assumed that the renal route is primary.
The aim is therefore to address the magnitude of faecal vs renal excretion for PFAS in a population highly exposed to PFAS.

METHODS: Municipal drinking water contaminated with PFAS was distributed to many households in Ronneby, Sweden. The source was firefighting foam used nearby since the mid-1980s. Clean water was provided from December, 2013. Faeces and urine samples have been collected from over 200 participants in the serum biomonitoring programme with parallel measurements of multiple PFAS, including: perfluorooctanoic acid (PFOA), perfluorohexane sulfonate (PFHxS), linear perfluorooctane sulfonate (L-PFOS) and branched PFOS.
This study will estimate the distribution of individual excretion rates by the two routes in this population based on concurrent measured PFAS in serum, blood, and faeces. Preliminary data presented here are for 51 subjects with repeated blood measurements between 2014 and 2018, in a half-life study.

RESULTS: for PFOA median concentrations were 10 ng/ml in serum, 0.02 ng/ml in urine and 0.6 ng/g dry weight in faeces, corresponding to estimated elimination rates of 28 and 17 ng/day via urine and faeces respectively. Faecal elimination was generally less than urinary, median ratio 0.45. Equivalent median faecal/urinary daily elimination ratios were 0.18 for PFHxS and 3.65 for PFOS.

CONCLUSIONS: Faecal elimination is important and for some PFAS, eg L-PFOS, far outweighs renal elimination. This has implications for epidemiological studies using serum concentration, as measured levels are sensitive to gut excretion rates, and variation in this rate has the potential to confound associations with some outcomes studied.

KEYWORDS: PFAS, Biomonitoring

O-OP-025 Associations between perfluoroalkyl substances and lipid profile in a highly exposed adult community in the Veneto Region: a comparison of mixture-based statistical approaches

Erich Batzella[1], Maryam Zare Jeddi[2], Cristina Canova[1], Gisella Pitter[3], Tony Fletcher[5], Francesca Russo[4]
[1]Unit of Biostatistics, Epidemiology and Public Health, Department of Cardio-Thoraco-Vascular Sciences and Public Health, Padua, Italy, [2]RIVM-National Institute for Public Health and the Environment, Bilthoven, the Netherlands, [3]Screening and Health Impact Assessment Unit, Azienda Zero-Veneto Region, Padua, Italy, [4]Directorate of Prevention, Food Safety, and Veterinary Public Health-Veneto Region, Venice, Italy, [5]London School of Hygiene and Tropical Medicine, London, Italy

BACKGROUND AND AIM: Residents of a large area in the Veneto Region were exposed to drinking water contaminated by perfluoroalkyl substances (PFAS) for decades. Combined exposures to multiple PFAS has been poorly investigated for serum lipid profile and highly exposed populations. We will compare results across statistical methods specifically developed to examine the association between mixtures of chemicals and their effects, in order to identify the impact of PFAS mixture on lipid parameters.

METHODS: Cross-sectional data from the Regional health surveillance program (34,633 individuals aged 20-64 years) were used to assess the association between the mixture of four serum PFAS namely, PFOA, PFOS, PFNA, PFHxS and total cholesterol (TC), high-density-lipoprotein cholesterol (HDL-C) and low-density-lipoprotein cholesterol (LDL-C). Given that no statistical mixture method is considered the gold standard, both Weighted Quantile Sum (WQS) regression, Quantile-based G-computation (Q-Gcomp) and Bayesian Kernel Machine Regression (BKMR) were selected based on their ability to handle highly correlated chemicals.

RESULTS: Each quartile increased in the WQS index was associated with an increase in the levels of TC (β:4.09, 95%CI:3.47-4.71), HDL-C (β:1.13, 95%CI:0.92-1.33), and LDL-C (β:3.14, 95%CI:2.65-3.63). Q-Gcomp estimated that a quartile increase in the PFAS mixture was associated with increased TC, HDL-C and LDL-C (ψ:4.04, 95%CI:3.5-4.58; ψ:1.07, 95%CI:20.87-1.27; ψ:2.71, 95%CI:2.23-3.19). In the BKMR analysis, the effect of PFAS mixture on serum lipids increased significantly when their concentrations were at their 75th percentiles or above compared to those at their median. All the three methods revealed a major contribution of PFOS and PFNA, although the main exposure was due to PFOA.

CONCLUSIONS: The PFAS mixture was positively associated with lipid parameters, regardless of the applied method. Very similar results obtained from the three methods may be attributed to the linear positive association with the outcomes and no interaction between each PFAS

KEYWORDS: combined exposure; mixture; PFAS; lipid.

O-OP-026 The Devil they knew: chemical documents analysis of industry influence on PFAS Science

Tracey Woodruff[1], Lisa Bero[2], Nadia Gaber[1]
[1]*University of California San Francisco, San Francisco, USA,* [2]*University of Colorado Anschutz Medical Campus, Aurora, USA*

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) are widely-used persistent and bio-accumulative chemicals of global health concern. PFAS have been produced since the 1940s, but their toxicity wasn't publicly established until late 1990s. We use established methods to evaluate the role of the chemical industry in delaying public information on PFAS toxicity using previously undisclosed industry documents.

METHODS: We reviewed a collection of previously secret industry documents archived at the UCSF Chemical Industry Documents Library. We analyzed PFAS industry documents using well-established document analysis methods, identifying themes through deductive or inductive reasoning and grouping them. Our deductive codes were adapted from White and Bero, evaluating six strategies (Manipulating the research question; funding and publishing research supporting industry interests; suppressing unfavorable research; distorting public discourse about research; changing or setting scientific standards to serve corporate interests; and disseminating favorable research directly to decision makers and the public, bypassing normal channels of scientific discourse) six industries. We also conducted a literature review to establish when scientific information on the health effects of PFAS became public.

RESULTS: We found companies knew PFAS was "highly toxic when inhaled and moderately toxic when ingested" by 1970, forty years before the public health community. The industry used several strategies common to tobacco, pharmaceutical and other industries to influence science and regulation – notably, suppressing unfavorable research and distorting public discourse. We did not find evidence in this archive of funding favorable research or targeted dissemination of those results.

CONCLUSIONS: Lack of transparency in industry-driven research on industrial chemicals has significant legal, political and public health consequences. Illuminating industry strategies to suppress scientific research findings or early warnings about the hazards of industrial chemicals help guides future prevention.

KEYWORDS: PFAS, chemical policy, environmental health, commercial determinants, industry documents, research ethics

O-OP-027 Associations between organochlorine pesticide mixtures and sex steroid hormones modified by age, gender and body mass index in the US 2011-2016: a quantile-based g-computation approach

Juwel Rana[1,2,3], Angela Nyamekye Osei[2], Divine-Favour Ofili[2], Edgar Ortiz-Brizuela[2], Rakibul Islam[3,4], Alexander Keil[5]
[1]North South University, Dhaka, Bangladesh, [2]McGill University, Montreal, Canada, [3]South Asian Institute for Social Transformation (SAIST), Dhaka, Bangladesh, [4]Monash University, Clayton, Australia, [5]National Cancer Institute, Bethesda, USA

BACKGROUND AND AIM: Toxicological studies have shown adverse effects of organochlorine pesticides on reproductive function in animals; however, human studies are limited and mostly on a single pesticide. This study, therefore, examined the combined effects of lipid-adjusted serum concentrations of organochlorine pesticides and sex hormones in the US and to what extent these associations vary by age, gender, and body mass index (BMI).

METHODS: We have used six years of repeated cross-sectional data that consist of three consecutive National Health and Nutrition Examination Survey (NHANES) cycles from 2011 to 2016. Serum concentrations of seven organochlorine pesticides (β-hexachlorocyclohexane, hexachlorobenzene, oxychlordane, p,p'-dichlorodiphenyltrichloroethene, p,p'-dichlorodiphenyltrichlorethane, trans-Nonachlor, and Mirex) were used as mixtures. The sex hormones considered were testosterone in nmol/L (n=798), estradiol in pmol/L (n=528 in), sex hormone-binding globulin -SHBG in nmol/L (n=497), and testosterone/estradiol in pg/mL (n=528). Quantile-based g-computation method was used for mixture effects, adjusting for potential confounders, and survey design.

RESULTS: Results showed that lipid-adjusted pesticide mixtures had an inverse association with testosterone (β=-1.02, 95% CI: -1.81, -0.23; p= 0.012), estradiol (β= -663.16, 95% CI: -1232.09, -94.23, p= 0.022), SHBG (β= -14.62, 95% CI: -32.00, 2.77, p=0.100) and testosterone/estradiol (β= -3.06, 95% CI: -17.41, 11.29, p= 0.676). These associations were modified by gender with higher precisions for testosterone (Male: -1.90, 95% CI: -3.46, -0.35, pint= 0.003; Female: -0.79, 95% CI: -1.60, 0.02, p= 0.003). Moreover, age and BMI also significantly modified the effects of pesticide mixtures on sex hormones with higher precision in testosterone and estradiol.

CONCLUSIONS: Our study suggests that pesticide mixture is inversely associated with sex hormones in the US population aged 12-80 years old, and these associations are modified by age, gender, and BMI. Intervention should be focused on reducing pesticide mixture exposures focusing on vulnerable communities.

KEYWORDS: Pesticides; Mixture; Testosterone; Hormones; Quantile g-computation

O-OP-028 Prenatal endocrine disrupting chemical exposure and child IQ: accounting for uncertainty in pattern identification in a two-stage health analysis

Elizabeth Gibson[1], Robbie Parks[2], Sebastian Rowland[2], John Paisley[3], Jeff Goldsmith[2], Pam Factor-Litvak[2], Julie Herbstman[2], Marianthi-Anna Kioumourtzoglou[2]

[1]Harvard University T. H. Chan School of Public Health, Boston, USA, [2]Columbia University Mailman School of Public Health, New York, USA, [3]Columbia University Data Science Institute, New York, USA

BACKGROUND AND AIM: A growing body of evidence links prenatal endocrine disrupting chemicals (EDCs) with adverse neurodevelopment in children, and previous research has analyzed the impact of environmental mixtures of EDC classes on health outcomes. Here, we investigate the relationship between EDC exposure patterns in pregnant women and their children's neurodevelopment.

METHODS: We measured exposure to 17 phenols and phthalates in 343 pregnant women in a mother-child cohort and full-scale IQ in children at seven years of age. We designed a two-stage Bayesian hierarchical model to estimate health effects of environmental exposure patterns while incorporating the uncertainty of pattern identification. In the first stage, we identified EDC exposure patterns using Bayesian non-parametric non-negative matrix factorization (BN²MF). In the second stage, we included individual pattern scores and their distributions as exposures of interest in a linear regression model, with child IQ as the outcome, adjusting for potential confounders. We present sex-specific results.

RESULTS: BN²MF identified two underlying patterns of exposure. One pattern expressed exposure to phthalates and bisphenol A (BPA). One standard deviation increase in this pattern was associated with a decrease of 3.2 IQ points (95% credible interval: -6.4, -0.2), on average, in female children but not in males (-0.6 IQ points, 95% CrI: -2.7, 1.5). The second pattern represented exposure to phenols and di-ethyl phthalate. We found no associations between this pattern and child neurodevelopment.

CONCLUSIONS: The two BN²MF-identified patterns of EDC exposure in pregnant mothers corresponded with diet and personal care product use as potentially separate sources or behaviors leading to exposure. Phthalates and BPA found in food packaging and can linings formed a pattern of EDC exposure associated with decreases in full-scale IQ in female children. Results may be used to inform interventions designed to target modifiable behavior or regulations to act on dietary exposure sources.

O-OP-029 Data quality evaluation criteria for systematic review of epidemiology studies under the Toxic Substances Control Act (TSCA): refinement through practical application in risk evaluation

Leora Vegosen[1], Amy Benson[1], Stanley Barone[1]
[1]*Office of Chemical Safety and Pollution Prevention (OCSPP), U.S. Environmental Protection Agency (EPA), Washington, USA*

BACKGROUND AND AIM: The 2016 Frank R. Lautenberg Chemical Safety for the 21st Century Act and the 2017 Procedures for Chemical Risk Evaluation under the Amended Toxic Substances Control Act (TSCA) require the U.S. Environmental Protection Agency (EPA) to conduct risk evaluations using the best available science and weight of the scientific evidence. Therefore, EPA has developed systematic review methods including data quality evaluation criteria to evaluate scientific studies in specific disciplines including epidemiology. EPA has aimed to refine these criteria for practical application in risk evaluation of high-priority chemicals under TSCA.

METHODS: EPA considered the pros and cons of multiple existing systematic review frameworks and guidance documents and drew upon these methodologies to develop data quality evaluation domains, metrics, and criteria for the systematic review of epidemiology studies under TSCA. EPA refined these domains, metrics, and criteria through practical application to add specificity to increase consistency among evaluators and to harmonize with the evaluation of animal toxicology studies under TSCA.

RESULTS: EPA adopted aspects of methods including the National Toxicology Program (NTP) Office of Health Assessment and Translation (OHAT) and EPA's Integrated Risk Information System (IRIS) methods, but also aimed to be consistent with other disciplines and to address TSCA scientific standards.

CONCLUSIONS: EPA has further refined data quality evaluation criteria for systematic review of epidemiology studies under TSCA in response to comments from peer reviewers, the public, the National Academies, and the TSCA Science Advisory Committee on Chemicals (SACC). Systematic review of epidemiology studies is a critical component of protecting human health under TSCA.
DISCLAIMER: The views expressed in this presentation are solely those of the authors and do not represent the policies of EPA. Mention of trade names or commercial products should not be interpreted as an endorsement by EPA.

BACKGROUND AND AIM: Late-life disability is a common endpoint of the chronic health conditions that affect people as they age. Although fine particulate matter (PM2.5) is associated with chronic conditions that contribute to disability, associations with disability itself are understudied, and the most toxic emission sources have yet to be identified. We evaluated the association between long-term exposure to PM2.5 from specific emission sources and disability.

METHODS: We used biennial survey data between 2006 and 2016 on Activities of Daily Living (ADL) from participants >65 years of the Health and Retirement Study. Using a spatiotemporal prediction model, we estimated 10-year PM2.5 concentrations at participants' residences and multiplied these values by spatially-resolved fractions of PM2.5 from sources including agriculture, energy production, industry, transportation, fires, and windblown dust, derived from a chemical transport model. We used Cox models to estimate the risk of incident ADL disability per 1-μg/m³ source-specific PM2.5, adjusting for individual- and area-level confounders, time, geography, and sampling weights.

RESULTS: Among 11,782 adults (72±6.8 years), 37% reported a new disability during follow-up. Overall, both total PM2.5 and source-specific PM2.5 were associated with increased incident of ADL disability. A 1-μg/m³ increment in total PM2.5 corresponded to a 2% (95% CI: 1.00, 1.04) greater hazard of ADL. In single-sector models, PM2.5 from each source was also positively associated with incident ADL. After adjusting for PM2.5 from other sources, associations with agriculture, non-road and road transportation, non-coal energy production, and windblown dust PM2.5 remained, whereas no associations were observed for the other sources.

CONCLUSIONS: We found evidence that higher levels of PM2.5 from some but not all sources were associated with increased risk of disability, suggesting that selective interventions could be effective at improving health and function in late-life.

KEYWORDS: Air Pollution, emission sources, Activities of Daily Living, PM2.5

O-OP-031 Investigation on associations between long-term air pollution exposure and osteoporotic fracture using nationwide cohort study data in South Korea

Seulkee Heo[1], Honghyok Kim[1], Sera Kim[2], Seung-Ah Choe[3], Garam Byun[2], Jong-Tae Lee[2], Michelle Bell[1]
[1]School of the Environment, Yale University, New Haven, USA, [2]Interdisciplinary Program in Precision Public Health, Department of Public Health Sciences, Graduate School of Korea University, Seoul, South Korea, [3]College of Medicine, Korea University, Seoul, South Korea

BACKGROUND AND AIM: Bone health is a major concern for aging populations globally. Human and animal studies have suggested biological mechanisms for osteoporosis and bone density associated with air pollution, but less is known about the impacts of air pollution on osteoporotic fracture. We examined the associations between long-term air pollution exposure and risk of osteoporotic fracture in adults in seven large Korean cities.

METHODS: We used Cox proportional hazard models to estimate hazard rations (HRs) of time-varying moving window of past exposures of particulate matter (PM_{10}), sulfur dioxide (SO_2), carbon monoxide (CO), nitrogen dioxide (NO_2), and ozone (O_3) for osteoporotic fracture in Korean adults (age ≥50 years) in the National Health Insurance Service-National Sample Cohort data, followed 2002 to 2015. HRs were calculated for an interquartile range (IQR) increase of 3-year moving average concentration of each pollutant. Data of 56,467 participants over 535,481 person-years of follow-up were used. The model adjusted for individual-level confounders (comorbidity, prescription for osteoporosis, age, sex, body mass index, health behaviors, income).

RESULTS: Linear and positive exposure-response associations were found for SO_2, while PM_{10} and NO_2 showed nonlinear associations. SO_2 was associated with osteoporosis-related fracture with marginal significance (HR for an IQR [2 ppb] increase = 1.04, 95% CI: 1.00–1.09). The SO_2 HR estimates were robust in analyses applying various moving windows of exposure (from one to three years of past exposure) and two-pollutant models. The O_3 HR estimate was positive but not significant (HR for 0.007 ppm increase = 1.01, 95% CI: 0.97–1.06). PM_{10}, CO, and NO_2 did not show associations. Vulnerable groups by sex, age, exercise, and income varied across air pollutants and there was no evidence of effect modifications.

CONCLUSIONS: Long-term exposure to SO_2 was associated with increased osteoporotic fracture risks in Korean adults.

KEYWORDS: Air pollution, bone fracture, cohort studies, osteoporosis.

O-OP-032 Shortened leucocyte telomere length is associated with increased daily air temperature: KORA F3 and KORA F4

Wenli Ni[1,2], Kathrin Wolf[1], Susanne Breitner[1,2], Siqi Zhang[1], Nikolaos Nikolaou[1,2], Cavin K Ward-Caviness[3], Melanie Waldenberger[1,4,5], Christian Gieger[1,4], Annette Peters[1,2,5,6], Alexandra Schneider[1]

[1]Institute of Epidemiology, Helmholtz Zentrum München - German Research Center for Environmental Health (GmbH), Ingolstädter Landstraße 1, Neuherberg, Germany, [2]Institute for Medical Information Processing, Biometry, and Epidemiology, Pettenkofer School of Public Health, LMU Munich, München, Germany, [3]Center for Public Health and Environmental Assessment, US Environmental Protection Agency, Chapel Hill, NC, USA, [4]Research Unit of Molecular Epidemiology, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany, [5]German Centre for Cardiovascular Research (DZHK), Partner Site Munich Heart Alliance, Munich, Germany, [6]German Center for Diabetes Research (DZD), München-Neuherberg, Germany

BACKGROUND AND AIM: Climate change endangers human health and well-being in numerous ways. Increased air temperature is associated with increased age-related morbidity and mortality, but the mechanisms are not yet fully understood. We aimed to assess the short-term effects of air temperature on leucocyte telomere length, a clinical gauge for age-related disease risk, among an adult population.

METHODS: This population-based study involved 5,864 participants from the KORA F3 (2004-2005) and F4 (2006-2008) cohort studies, conducted in Augsburg, Germany. Leucocyte telomere length was assessed by a quantitative PCR-based method. We estimated air temperature at each participant's residential address by a highly resolved spatio-temporal model using satellite, meteorological and land-use data. We conducted cohort-specific generalized additive models to explore the short-term effects of air temperature on leucocyte telomere length at lags 0-1, 2-6, 0-6, and 0-13 days separately and pooled the estimates by fixed-effects meta-analysis. We investigated potential effect modification by including interaction terms for individual characteristics, season and ozone.

RESULTS: A 1°C increase in daily air temperature was associated with decreased leucocyte telomere lengths at lags 0-1, 2-6, 0-6 and 0-13 days [%changes (95% confidence interval): -0.28 (-0.42; -0.13), -0.28 (-0.45; -0.11), -0.42 (-0.62; -0.22), and -0.72 (-0.99; -0.46), respectively]. Only participants examined in the cold season showed a stronger effect of air temperature on leucocyte telomere length at lags 0-1 days, compared to participants examined in the warm season. There was no indication for other effect modification.

CONCLUSIONS: This meta-analysis of two cohort studies showed that increased daily air temperature was associated with shortened leucocyte telomere length. Our findings add to the burgeoning evidence of how increases in air temperature can adversely impact human health. This abstract does not necessarily represent the policies of the US EPA.

KEYWORDS: short-term effects, air temperature, telomere length

O-OP-033 Ambient exposure and fetal black carbon load in association with telomere length in cord blood

Charlotte Van Der Stukken[1], prof.Tim Nawrot[1,2], Eva Bongaerts[1], Prof.Marcel Ameloot[3], Dries Martens[1]
[1]Centre for Environmental Sciences, Hasselt University, Diepenbeek, België, [2]Department of Public Health & Primary Care, University of Leuven, Leuven, België, [3]Biomedical Research Institute, Hasselt University, Diepenbeek, België

BACKGROUND AND AIM: Ambient particulate matter (PM) is an important factor that is associated with telomere length (TL) at birth. A recent study has shown that translocation of black carbon (BC), one of the most toxic components of PM, towards the fetus is possible, but it is not yet linked to biological outcomes. In this study, we investigated whether 1) ambient BC is associated with cord blood TL, 2) fetal BC load relates to ambient BC exposure and 3) fetal BC load is related to newborn TL.

METHODS: In 247 mother-newborn pairs from the ENVIRONAGE (Environmental Influence On Early Ageing) study, which is a population-based birth cohort study located in Limburg, Belgium, maternal residential exposure to BC during pregnancy was estimated using a spatial-temporal interpolation model. BC particles were detected in cord blood by the generation of white-light under femtosecond pulsed laser illumination. Cord blood TL was measured using qPCR. We applied Pearson correlations and distributed lag models to associate BC exposure with cord blood TL.

RESULTS: An IQR increment (0.85 µg/m3) in ambient BC was associated with a -12% (95% CI: −21% to −2.8%) decrease and a 20% (95% CI: 7.6% to 34%) increase in cord blood TL during the second and third trimester of pregnancy respectively. Secondly, fetal BC load showed the highest correlation with ambient BC during trimester 3 ($r=0.28$, $p<0.0001$). Thirdly, fetal BC load was positively correlated with TL in cord blood ($r=0.15$, $p=0.023$).

CONCLUSIONS: Our findings show that mothers with a higher exposure to ambient BC had more BC particles in cord blood. The positive correlation between both ambient and fetal BC exposure during trimester 3 and cord blood TL may suggest the possibility of an acute protective response, but additional studies are needed to investigate the underlying mechanisms.

O-OP-034 Role of sleep quality in the acceleration of biological aging and its potential for preventive interaction on air pollution insults: findings from the UK Biobank cohort

Xu Gao[1]
[1]*Peking University, Beijing, China*

BACKGROUND AND AIM: Sleep has been associated with aging and relevant health outcomes, but the causal relationship remains inconclusive. Additionally, air pollution is a critical environmental exposure that could advance aging and affect sleep quality, but no studies yet evaluated whether the sleep quality could modify the adverse effects of air pollution on biological aging or vice versa.

METHODS: We investigated the associations of sleep behaviors with biological ages (BAs) among 363,886 middle and elderly adults from UK Biobank. A sleep index (0[worst]-6[best]) was retrieved from six sleep behaviors: snoring, chronotype, daytime sleepiness, sleep duration, insomnia, and difficulties in getting up. Two BAs, the KDM-biological age and PhenoAge, were estimated using clinical traits, and their residual discrepancies with chronological age were defined as age accelerations (AAs). Annual averaged ambient levels of PM2.5, PMcoarse, PM10, NO2, and NOx of the participants were estimated using Land Use Regression model.

RESULTS: We first observed negative associations between the sleep index and the two AAs, and demonstrated that the change of AAs could be the consequence of sleep quality using Mendelian randomization with genetic risk scores of sleep index and BAs. Particularly, a one-unit increase in sleep index was associated with 0.104- and 0.119-year decreases in KDM-biological age acceleration and PhenoAge acceleration, respectively. We further observed significant independent and joint effects of sleep and air pollution (PM2.5 and NO2) on AAs. Sleep quality also showed a modifying effect on the associations of PM2.5/NO2 with accelerated AAs. for instance, an interquartile range increase in PM2.5 level was associated with 0.009-, 0.044-, and 0.074-year increase in PhenoAge acceleration among people with high (5-6), medium (3-4), and low (0-2) sleep index, respectively.

CONCLUSIONS: Our findings elucidate that better sleep quality could lessen accelerated biological aging resulting from air pollution.

O-SY-127 Association of environmental chemical exposure during pregnancy with subsequent breast cancer risk

Young-Mi Go[1], Sami Teeny[1], Piera Cirillo[2], Nickilou Krigbaum[2], Barbara Cohn[2], Dean Jones[1]
[1]Clinical Biomarkers Laboratory, Emory University School of Medicine, Atlanta, USA, [2]Child Health and Development Studies, Public Health Institute, Oakland, USA

BACKGROUND AND AIM: Breast cancer became the most common cancer globally as of 2021, accounting for 12% of all new annual cancer cases worldwide, according to the World Health Organization. Despite epidemiologic studies establishing a number of risk factors for breast cancer, additional research is needed to elucidate environmental exposures that increase breast cancer risk. In this study, we used highly informative, existing pregnancy cohort biospecimens with an untargeted high-resolution mass spectrometry (HRMS) approach to discover possible environmental chemical exposures associated with subsequent breast cancer occurrence.

METHODS: Archived pregnancy samples, collected between 1959-1967, from the Child Health and Development Studies in California, one of the largest prospective pregnancy cohorts, were analyzed and searched against the Toxic Exposome Database (T3DB). The samples included 2nd (T2) and 3rd (T3) trimester archival samples of 182 women who subsequently developed breast cancer, compared to T2 and T3 samples from 384 women who did not develop breast cancer. Metabolites and environmental chemicals extracted from 50 µL aliquots of thawed pregnancy serum (n=1,148) were analyzed by HRMS with liquid chromatography followed by advanced data extraction, annotation and pathway enrichment analysis.

RESULTS: A large number of mass spectral features differed between cases and controls at $p<0.05$. Annotation of the discriminatory metabolites with T3DB showed increased abundance of accurate mass matches (within 5 ppm) to methylmercury and the organophosphate insecticide, tebupirimfos, in both T2 and T3 breast cancer cases compared to controls ($P<0.05$). Additional verification of chemical identities is ongoing. Available literature is mixed for mercury association with breast cancer; however, methylmercury has been found to stimulate proliferation of breast cancer cells in culture.

CONCLUSIONS: In addition to a significant metabolic disruption, exposure to methylmercury or/and organophosphate insecticide during pregnancy is associated with subsequent breast cancer risk.

KEYWORDS: Breast cancer, environmental chemical exposure, metabolic disruption, high-resolution metabolomics, pregnancy.

ORAL PRESENTATIONS SESSION 07: Exposure assessment for chemicals and PFAs

O-OP-035 Exposure assessment of per- and polyfluoroalkyl substances (PFAS) and disinfection by-products (DBPs) in drinking water during pregnancy

Dora Cserbik[1,2,3], Cintia Flores[4], Alexandra Paraian[4], Ioar Rivas[1,2,3], Payam Dadvand[1,2,3], Jordi Sunyer[1,2,3,5], Cristina M. Villanueva[1,2,3,5]

[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [3]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [4]Mass Spectrometry Laboratory/Organic Pollutants, Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Barcelona, Spain, [5]IMIM (Hospital del Mar Medical Research Institute), Barcelona, Spain

BACKGROUND AND AIM: Prenatal exposure to per- and polyfluoroalkyl substances (PFAS) and disinfection by-products (DBPs) have been linked to multiple adverse birth outcomes in epidemiological studies. The aim of this study was to comprehensively assess exposure to these chemicals in drinking water during pregnancy in the Barcelona Life Study Cohort (BiSC).

METHODS: A total of 1086 pregnant women living in the Barcelona Metropolitan area were recruited at the first trimester of pregnancy and followed by surveys until delivery (2018-2021). Water ingestion habits were ascertained at the first and third trimesters through questionnaires. Tap water samples were collected in a subset (N=105) during the 3rd trimester to analyze 35 PFAS. Routinely monitored DBPs (trihalomethanes, THMs) were obtained from the local public health authority for the pregnancy period (N=183). PFAS and DBPs concentrations were modelled based on geolocation and temporal variation to predict concentrations in the residential water supply of each participant from conception until delivery.

RESULTS: 5/35 PFAS were detected, namely perfluoropentanoic acid (PFPeA), perfluorohexanoic acid (PFHxA), perfluoroheptanoic acid (PFHpA), perfluorobutane sulfonic acid, (PFBS), and perfluorooctane sulfonic acid (PFOS), at median (Interquartile range; IQR) concentrations (ng/L), respectively, of 5.7(4.3-8.3), 12.0(10.5-12.0), 3.4(2.5-4.7), 8.3(7.2-10.5), and 13.0(11.8-14.0). Median (IQR) concentrations (µg/L) of THMs were 18.6(7.3-27.6) for chloroform, 9.4(5.6-12.4) for dibromochloromethane, 6.4(2.9-10.3) for bromodichloromethane, and 26.1(16.2-36.0) for bromoform. Drinking water consumed at home was bottled (64.8%), filtered (22.9%), and tap water (12.3%). Water used for cooking was from tap (78.4%), filtered (15.7%), and bottled water (0.6%). Individual exposure estimates by trimester and for the whole pregnancy will be calculated using residential levels multiplied by amount and type of water consumed.

CONCLUSIONS: The study population is exposed to relatively low concentrations of PFAS in drinking water, and THMs have a significant component of brominated species.

KEYWORDS: drinking water; PFAS; disinfection byproducts; exposure assessment.

O-OP-036 An assessment of health risks posed by consumption of pesticide residues in fruits and vegetables among residents in the Kampala Metropolitan Area in Uganda

Charles Ssemugabo[1], Asa Bradman[2], John Ssempebwa[1], Fenna Sille[3], David Guwatudde[4]

[1]Department of Disease Control and Environmental Health, School of Public Health, Makerere University College of Health Sciences, Kampala, Uganda, Kampala, Uganda, [2]Department of Public Health, School of Social Sciences, Humanities and Arts; University of California Merced, Merced, CA 95343, USA, Merced, USA, [3]Department of Environmental Health and Engineering, The Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD 21205, USA, Baltimore, USA, [4]Department of Epidemiology and Biostatistics, School of Public Health, Makerere University College of Health Sciences, Kampala, Uganda, Kampala, Uganda

BACKGROUND AND AIM: Pesticide use for fruits and vegetable production in Uganda may result in presence of residues on produce which may pose health risks to consumers. This research aimed at conducting a health risk assessment of presence of pesticide residues in fruits and vegetables in Kampala Metropolitan Area, Uganda.

METHODS: Pesticides were measured in 160 fruits and vegetables samples were analysed using liquid chromatography-tandem mass spectrometry. Fruit and vegetable consumption information was collected from 2,177 people. Pesticide concentrations were compared with European Union maximum residual limits (MRLs). Mean values of pesticide concentrations; and fruits and vegetables intake and body weight were used to calculate the estimated daily intake (EDI) of pesticide residues. EDI values were compared with acceptable daily intakes (ADI) to calculate the hazard quotient by age group, and stage of consumption along the chain.

RESULTS: Concentrations of fonofos, fenitrothion and fenhexamid were above the European Union MRLs in some samples. Hazard quotients based on dietary ingestion scenarios for eighteen pesticides, including dichlorvos (444) alanycarb (314), fonofos (68), fenitrothion (62), dioxacarb (55) and benfuracarb (24) and others, were above 1, indicating the possibility of chronic health risk to consumers. Chronic health risk decreased with age but was stable for stage at which consumption happens along the food chain. The number of pesticides with EDI greater than the ADI decreased with increase in age; with 18, 13, 9, 11, 8, 9, and 9 pesticides for age groups <5, 5-12, 13-19, 20-25, 36-49 and ≥50 respectively.

CONCLUSIONS: Chronic dietary pesticide exposures to Ugandans are likely common, and for some pesticides results in exposure exceeding health-based benchmarks. Risks were highest for younger participants. There is urgent need to increase monitoring and regulation of pesticides in fruits and vegetables in order to protect consumers, especially children who are more vulnerable to adverse health effects.

O-OP-037 Incorporating land use and wind direction in assessment of residential exposure to agricultural herbicides

Jessica Madrigal[1], Robert Gunier[2], Rena Jones[1], Abigail Flory[3], Catherine Metayer[4], John Nuckols[5], Mary Ward[1]
[1]Occupational and Environmental Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, USA, [2]Center for Environmental Research and Children's Health (CERCH), University of California, Berkeley, School of Public Health, Berkeley, USA, [3]Westat, Inc., Rockville, USA, [4]University of California, Berkeley, School of Public Health, Berkeley, USA, [5]Colorado State University, Fort Collins, USA

ORAL PRESENTATIONS SESSION 07: Exposure assessment for chemicals and PFAs, MC3.3 Hall, September 19, 022, 1:15 PM - 2:45 PM

BACKGROUND AND AIM: Few studies have incorporated land use or wind direction in agricultural pesticide exposure metrics. Using the California Pesticide Use Reporting (PUR) database, we evaluated agricultural herbicide applications and herbicide concentrations in carpet dust before and after accounting for land use and wind direction.

METHODS: We measured concentrations (ng/g) of 2,4-dichlorophenoxyacetic acid (2,4-D), trifluralin, simazine, and glyphosate (µg/g) in carpet dust samples from 598 California homes. We determined PUR use (reported at ~1 mile²) within 0.5-, 1-, 2-, and 4-km radial buffers around homes and calculated density of use (kg/km²) 30-, 60-, 180-, and 365-days before sampling. for land use metrics, we apportioned herbicide applications to the land area of crop fields within the buffers. for wind metrics, we weighted applications by the proportion of days between application and dust collection that the home was 90° downwind of the application. We modeled natural-log transformed dust concentrations using Tobit regression adjusting for season/year, occupation, and home/garden uses.

RESULTS: Detections were 60% for trifluralin and >90% for 2,4-D, simazine, and glyphosate. for each herbicide, we found similar increases in dust concentrations with increasing densities for all time periods and buffers and comparing the PUR metric to the land use and wind metrics. The highest tertiles of glyphosate use (365-days) were associated with ~2-fold higher dust concentrations compared to homes without applications within 0.5km (PUR-365-day eβ=2.02, 95%CI=1.34-3.04; land use: eβ=1.51, 95%CI=0.95-2.39; wind: eβ=2.25, 95%CI=1.50-3.37) and 4km (eβ=2.09, 95%CI=1.53-2.85; land use: eβ=2.20, 95%CI=1.60-3.05; wind: eβ=1.94, 95%CI=1.43-2.65). Compared to homes without applications, the highest tertiles of 2,4-D, simazine, and trifluralin applications within 4km (365-days) were associated with 2-, 3.5-, and 6.8-fold higher concentrations, respectively; the magnitude for each was similar across all metrics.

CONCLUSIONS: Agricultural herbicide use was an important determinant of indoor contamination up to 4km from homes.

O-OP-038 Pilot study of consumer product chemicals measured using silicone wristband monitors

Peter Paul Egeghy[1], Timothy J. Buckley[1], Daniel M. Stout II[1], Kyla W. Taylor[2], Steven E. Prince[1], Raquel A. Silva[3], Lillian Alston[1], Richard Walker[1], José Zambrana[1]

[1]U.S. EPA Office of Research and Development, Research Triangle Park, USA, [2]National Institute of Environmental Health Sciences, National Institutes of Health, Research Triangle Park, USA, [3]ICF International, Inc., Durham, USA

BACKGROUND AND AIM: The assessment of human exposure to chemical constituents of personal and household care products is an enormous challenge. It is hindered by the vast array of products, considerable variability in formulations, and ubiquitous use. The U.S. Environmental Protection Agency's Office of Research and Development partnered with the National Institute of Environmental Health Sciences to evaluate effective exposure assessment strategies, with an emphasis on novel and non-traditional methods.

METHODS: The consumer product use of nine female, nonsmoking participants was monitored over a 10-day period. Biological and environmental samples were collected, including silicone wristbands used as personal monitors. A suite of chemicals, including many commonly associated with consumer products, was measured via a contract with Oregon State University (OSU). Wristbands were extracted using thermal and liquid methods, and a wide range of analytes were measured using GC/MS, including 1400 chemicals using OSU's multiple analyte quantitative screening method.

RESULTS: Only about 60 compounds out of more than 1400 were detected using the quantitative screening method. However, among the compounds with at least one detected measurement were phthalates, personal care product ingredients, and flame retardants, which were detected at frequencies of 52%, 41%, and 32%, respectively.

CONCLUSIONS: Wristband samplers hold considerable promise as a personal and low-burden sampling method that identifies a broad swath of chemicals to which we are exposed. However, to realize this potential, careful consideration needs to be given to sampling duration. Despite far fewer compounds being detected using silicone wristband samplers over a ten-day period than expected, several compounds associated with personal care products were measured with relatively high detection frequencies. Moreover, as several of these compounds are not typically measured in exposure studies, these results are expected to inform future studies of exposure to chemical constituents of consumer products. This abstract does not reflect EPA policy.

O-OP-039 A healthy and diverse diet and the association with perfluoroalkyl acids (PFAA) concentrations in Swedish adolescents

Jennifer Nyström[1], Jonathan P Benskin[2], Merle Plassmann[2], Oskar Sandblom[2], Anders Glynn[1], Erik Lampa[3], Irina Gyllenhammar[4], Sanna Lignell[4], Lotta Moraeus[4]

[1]Swedish University of Agricultural Sciences, Uppsala, Sweden, [2]Stockholm University, Stockholm, Sweden, [3]Uppsala University, Uppsala, Sweden, [4]Swedish Food Agency, Uppsala, Sweden

BACKGROUND AND AIM: Food is a major exposure source of perfluoroalkyl acids (PFAA) for adult populations, yet said relationship has rarely been studied in adolescent populations. Considering the role of a healthy diet as a major positive influence on health and consequent development, we studied the association between legacy PFAA concentrations in serum and a healthy eating index (SHEIA15) and diet diversity score (RADDS) amongst Swedish adolescents.

METHODS: Serum samples of adolescents (age 10-21, n=1098), from the nationally representative dietary survey Riksmaten Adolescents 2016-17 (RMA), were analysed by liquid chromatography tandem-mass spectrometry. Consumption of individual food groups and composited dishes were captured using both food frequency questionnaires and dietary registrations. The associations were analysed by fitting the cumulative probability model using ordinal regression.

RESULTS: Median concentrations of <1 ng/g serum were observed for perfluorononanoic acid (PFNA), perfluorodecanoic acid (PFDA), perfluoroundecanoic acid (PFUnDA), linear (lin) perfluorohexanesulfonic acid (PFHxS) and branched (br) perfluorooctanoic acid (PFOS), and ranging between 1-2 ng/g serum for lin-perfluorooctanoic acid (PFOA) and lin-PFOS (n=1098). Those adhering to a healthier, as well as a more diverse diet as suggested by SHEIA15 and RADDS, had significantly higher serum PFNA, PFDA, PFUnDA and lin-PFOS concentrations. Given the correlation between SHEIA15/RADDS and habitual consumption of fish and seafood, as well as the positive association between fish consumption and serum PFNA, PFDA, PFUnDA and lin-PFOS, seafood consumption was likely a major driver behind the observed associations. The lack of association for br-PFOS and both SHEIA15/RADDS suggest isomeric differences in PFOS exposure sources.

CONCLUSIONS: We conclude that more research is needed for understanding the relationship between healthy eating and the corresponding health implications from a PFAA exposure perspective.

KEYWORDS: Human biomonitoring, dietary index, fish, healthy diet, PFAS

O-OP-040 Cumulative risk assessment and exposure characteristics of parabens in the general Taiwanese using multiple hazard indices approaches

Jung-Wei Chang[1], Po-Chin Huang[2], Hsin-Chang Chen[3], WC Chou[4], Hui-Wen Lin[1], Wan-Ting Chang[2]
[1]National Yang Ming Chiao Tung University, Taipei 112, Taiwan, [2]National Health Research Institutes, Miaoli county 350, Taiwan, [3]Tunghai University, Taichung 407224, Taiwan, [4]University of Florida, USA

BACKGROUND AND AIM: Parabens, a group of endocrine disrupting chemicals (EDCs), are well known preservatives in personal care products (PCPs). However, studies on parabens exposure and their cumulative effects in Asian population are limited. This study aimed to identify the exposure characteristics, like PCPs, and estimate the cumulative risk of four parabens in the general Taiwanese.

METHODS: We used urine samples, included 271 adults (18–97 yrs old) and 95 minors (7–17 yrs old), from Taiwan Environmental Survey for Toxicants 2013, and analyzed for four urinary parabens including methyl (MeP)-, ethyl (EtP)-, propyl (PrP)-, and butylparaben (BuP) by using UPLC-MS/MS. The health-based guidance value (HBGV) and the antiandrogenic-based of parabens were used to calculate the hazard index (HI) for cumulative risk.

RESULTS: MeP and PrP were most abundant compounds and startlingly higher than those in other countries. Adults had a higher geometric mean level of four parabens than minors (adults: MeP, 381.7; PrP, 108.6; EtP, 39.6 and BuP 6.3 ng/mL; minors: MeP, 65.7; PrP, 7.9, EtP, 2.6 and BuP 2.2 ng/mL). Participants who used a higher number of personal care products had a significantly higher risk with higher concentrations of PrP (above 75th %tile) [adjusted odds ratio (aOR): 1.78, 95% CI: 1.01–3.15] and BuP [aOR: 1.80, 95% CI: 1.04–3.11]. The median and 95th %tile HI (the sum of the HQs of each paraben) was as 1.10 and 4.39-fold higher than acceptable cumulative threshold (HI <1) and PrP accounted for 90% of the HI.

CONCLUSIONS: Our results indicate omnipresent exposure to parabens among the Taiwanese, which might cause certain level of concerns. These significant increasing trends of HI with age dependence were observed, which mainly driven by PPCPS used. Routine survey of parabens in PPCPs and continued biomonitoring needs to be urgently addressed.

KEYWORDS: personal care products; hazard index; cumulative risk assessment

ORAL PRESENTATIONS SESSION 08: Child health and exposure to phthalates

O-OP-041 Mixtures of phthalates and phthalate replacements in relation to size-for-gestational age in the LIFECODES Fetal Growth Study

Paige Bommarito[1], David Cantonwine[2], Thomas McElrath[2], Kelly Ferguson[1]
[1]National Institute of Environmental Health Sciences, Durham, USA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, USA

BACKGROUND AND AIM: Phthalate exposure has been previously associated with reductions in fetal growth, including small-for-gestational age (SGA) births. Little is known about how phthalate replacements may be associated with adverse growth outcomes, including changes at both the small and large ends of the growth spectrum. Thus, we estimated joint associations between phthalates and their replacements with size-for-gestational age, including both SGA and large-for-gestational age (LGA) births.

METHODS: Using the LIFECODES Fetal Growth Study, a case-cohort of 249 SGA, 411 appropriate-for-gestational age (AGA), and 241 LGA births, we measured concentrations of metabolites for 13 phthalates and 4 phthalate replacements at three timepoints during pregnancy. We used quantile g-computation as a multipollutant approach to estimate the joint association between phthalates or phthalate replacements and the odds ratios (OR) (95% confidence intervals [CI]) of an SGA or LGA birth.

RESULTS: of the metabolites analyzed, 12 phthalate and 2 phthalate replacements were detected frequently (> 70% of participants). The highest correlations were observed within chemical classes. Phthalate replacement metabolites were negatively correlated with phthalate metabolites. A simultaneous one-quartile increase in the concentrations of all phthalate replacement metabolites was associated with higher odds of an SGA birth (OR: 1.33, 95% CI: 1.13, 1.57) and inverse, though null, associations were observed for phthalate metabolites (OR: 0.82, 95% CI: 0.64, 1.07). Associations with LGA births were generally inverse or null. Single-pollutant models were consistent with our mixtures results. for example, an interquartile range-increase in concentrations of the phthalate replacement metabolite mono-2-ethyl 5-carboxypentyl terephthalate (OR: 1.64, 95% CI: 1.25, 2.15) was associated with higher odds of an SGA birth.

CONCLUSIONS: Phthalate replacements were associated with higher odds of an SGA birth. Given the increasing prevalence of exposure to phthalate replacements, further research should continue to examine their health impacts.

KEYWORDS: phthalates, phthalate replacements, fetal growth, mixtures

O-OP-042 Associations of pregnancy and early childhood phthalate exposures with adolescent lipid levels and insulin resistance: The HOME Study

Taylor Etzel[1], Jordan Kuiper[1], Xiaboin Wang[1], Noel Mueller[1], Antonia Calafat[2], Kim Cecil[3,4], Aimin Chen[5], Bruce Lanphear[6], Heidi Kalkwarf[3,4], Kimberly Yolton[3,4], Joseph Smith[7], Jessie Buckley[1]

[1]Johns Hopkins University Bloomberg School of Public Health, Danville, USA, [2]Division of Laboratory Sciences, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, USA, [4]University of Cincinnati College of Medicine, Cincinnati, USA, [5]University of Pennsylvania, Philadelphia, USA, [6]Simon Fraser University, Burnaby, Canada, [7]Brown University, Providence, USA

BACKGROUND AND AIM: Early-life phthalate exposures may disrupt metabolism, but few prospective studies have assessed their association with cardiometabolic outcomes during adolescence. We investigated associations of pregnancy and childhood urinary phthalate biomarker concentrations with serum lipids and insulin resistance at age 12-years.

METHODS: We used data from 183 mother-adolescent pairs in a prospective cohort study that enrolled pregnant women in Cincinnati, OH from 2003-2006. We quantified nine phthalate metabolites in spot urine samples collected twice from mothers during pregnancy and up to seven times from children at ages 1-5, 8, and 12 years. at age 12 years, we assessed triglycerides, high-density (HDL) and low-density (LDL) lipoprotein cholesterol, insulin, and glucose from fasting serum samples and calculated homeostatic model assessment of insulin resistance. Using a multiple informant model, we estimated covariate-adjusted associations between phthalate concentrations at each time period and cardiometabolic biomarkers at age 12 years and assessed modification by child sex.

RESULTS: Overall, we observed weak or null associations of phthalate biomarker concentrations with lipid levels and insulin resistance. Urinary Monoethyl (MEP), Mono-n-butyl (MnBP), Mono-isobutyl (MiBP), and Monobenzyl (MBzP) biomarkers were generally associated with lower LDL at age 12 years. for example, a 10-fold increase in 4- and 12-year MEP was associated with -15.3 mg/dL (95% CI: -27.5, -3.13 mg/dL) and -11.8 mg/dL (-22.0, -1.51 mg/dL) lower levels of 12-year LDL, respectively. Inverse associations were generally stronger in females than males. for example, a 10-fold increase in 3-year MEP concentrations was associated with 12.0 mg/dL (95% CI: -7.11, 31.1 mg/dL) higher LDL levels in males and -30.4 mg/dL (95% CI: -50.9, -9.83 mg/dL) lower LDL levels in females.

CONCLUSIONS: Early-life phthalate concentrations may be associated with exposure period- and sex-dependent differences in LDL during early adolescence in this cohort.

KEYWORDS: Children’s health, metabolic disruptors, phthalates, insulin resistance, lipids

O-OP-043 Parental Exposure to Phthalates and Children's Behavior: Results from the PEACE Study

Jordana Leader[1], Lidia Mínguez-Alarcón[2], Paige L. Williams[3], Jennifer B. Ford[1], Alexandra Azevedo[1], Ramace Dadd[1], Emily Oken[4], Russ Hauser[1,5], Joseph M. Braun[6]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [2]Channing Division of Network Medicine, Harvard Medical School & Brigham and Women's Hospital, Boston, USA, [3]Departments of Biostatistics and Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [4]Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA, [5]Department of Obstetrics, Gynecology and Reproductive Biology, Harvard Medical School, Boston, USA, [6]Department of Epidemiology, Brown University, Providence, USA

BACKGROUND AND AIM: Emerging evidence suggests that preconception environmental exposures, including phthalates, affect offspring health. There are few studies examining associations of paternal and maternal preconception phthalate exposure with children's neurodevelopment, as most focus on maternal prenatal exposures. This study aims to explore this window of exposure.

METHODS: Since 2019, children whose parents attended a Boston fertility clinic were recruited in the Preconception Environmental exposure and Childhood health Effects (PEACE) study. for 12 phthalate metabolites, we calculated specific gravity-adjusted geometric-means in the preconception (mother and father) and prenatal periods (mother only). We used linear regression to estimate covariate-adjusted differences in Behavioral Assessment System for Children-3 (BASC-3) Externalizing, Internalizing, and Behavioral Symptom Index (BSI) scores per log e increase in specific gravity standardized urinary phthalate metabolite concentrations. Higher BASC-3 scores indicate more problematic behaviors.

RESULTS: As of March 2022, 112 children aged 6-11 years (mean: 9.7 years) and their 187 parents enrolled in the ongoing PEACE study. They all completed BASC-3 questionnaires and provided preconception and/or prenatal urines. Men and women provided a median of 1 preconception sample, and women provided a median of 2 prenatal samples. Higher maternal preconception MBP, MBzP and MiBP concentrations were associated with 2.3 (95% CI: 0.3, 4.3), 2.3 (95% CI: 0.7, 3.9) and 2.5 (95% CI: 0.8, 4.1) point increases in externalizing scores, respectively. Higher maternal preconception MBzP (β: 2.0; 95% CI: 0.51,3.4) and MiBP (β: 2.2; 95% CI: 0.6, 3.8) concentrations were also associated with higher BSI scores. Higher maternal urinary MBzP during pregnancy was associated with a 2.9 (95% CI: 1.2, 4.6) point increase in externalizing scores. Paternal preconception phthalate metabolites were not associated with BASC-3 scores.

DISCUSSION: Women's preconception and prenatal concentrations of some phthalates were associated with more problematic child behaviors. Paternal preconception concentrations of phthalate metabolites were not associated with children's behavior.

O-OP-044 Associations between bisphenols and onset of puberty: the Hokkaido Study

Atsuko Ikeda-Araki[1], Yu Ait-Bamai[1], Celine Gys[2], Maarten Roggeman[2], Yoshinori Ikenaka[1], Takeshi Yamaguchi[1], Hideyuki Masuda[1], Akie Nakamura[1], Takeya Kitta[1,3], Chihiro Miyashita[1], Atsushi Manabe[1], Nobuo Shinohara[1], Adrian Covaci[2], Reiko Kishi[1]

[1]Hokkaido University, Sapporo, Japan, [2]University of Antwerp, Antwerp, Belgium, [3]Asahikawa Medical University, Asahikawa, Japan

BACKGROUND AND AIM: Bisphenols are class of chemicals with concern about endocrine disrupting properties. Associations between bisphenol levels with children's timing of puberty as well as reproductive and steroid hormone levels at pubertal age are not well known. The aim of this study is to assess bisphenol levels in urine and their association with puberty onset and reproductive hormones at pubertal age.

METHODS: The Hokkaido Study is an ongoing birth cohort. at age 9-11 children living in Sapporo area were asked to visit pediatrician for face-to-face health check-up, and blood and urine samples were collected. Seven bisphenols in urine were measured by GC/MSMS, 14 steroid hormones in plasma by LC/MSMS, and reproductive hormones by ELISA, respectively. Onset of puberty were determined according to LH levels, testosterone and estradiol levels, or menarche (girls only). Specific gravity corrected bisphenols with associations between onset of puberty, having menarche, and hormone levels were examined by logistic regression models, and linear regression models. Both bisphenols and hormones were log-natural transformed and adjusted for age and BMI after stratified by sex.

RESULTS: In this study, 230 boys and 197 girls were included. Median levels of BPA, BPS, and BPF were 514, 81.0, and 42.0 pg/mL, respectively, with their detection frequency >65%. None of bisphenols was associated with onset of puberty, nor menarche. Among boys, positive associations were found between BPA and androstenedione, BPS and corticosterone, whereas BPA and FSH, and BPS and inhibin B were inversely associated. Among girls, BPA was positively associated with 11-deoxycortisol and corticosterone.

CONCLUSIONS: Although a few significant associations suggest bisphenols' hormone-disrupting effects, bisphenols are unlikely to affect the phenotypic timing of secondary sexual onset. The results should be interpreted with caution, as the study has a cross-sectional design.

KEYWORDS: bisphenols, puberty, reproductive hormones, steroid hormones

O-OP-045 Effects of Prenatal Phthalate Exposure on Early Childhood Expressive Language Development Trajectories

Justin Yu[1], Amy Kalkbrenner[1], Cheng Zheng[2], Bonita Klein-Tasman[1], Kristen Lyall[4], Craig Newschaffer[4], Daniele Fallin[3], Lisa Croen[5], Rebecca J. Schmidt[6], Irva Hertz-Picciotto[6], Heather Volk[3]

[1]University of Wisconsin - Milwaukee, Milwaukee, USA, [2]University of Nebraska Medical Center, Omaha, USA, [3]John Hopkins University, Baltimore, USA, [4]Drexel University, Philadelphia, USA, [5]Kaise Permanente Division of Research, Oakland, USA, [6]University of California Davis, Davis, USA

BACKGROUND AND AIM: Phthalates are common endocrine disruptors that can impair neurodevelopment. We investigated potential links between prenatal exposure to phthalates and child language development trajectories given prior inconsistent evidence across individual phthalates.

METHODS: We investigated fourteen urinary phthalate metabolites, measured in maternal urine during pregnancy, and child expressive language scores from the Mullen Scales of Early Learning (MSEL) at 6, 12, 24, and 36 months in 231 children from an enhanced autism-risk cohort (19% with autism): Early Autism Risk Longitudinal Investigation (EARLI), born 2009 - 2013 from California, Maryland, and Pennsylvania. We used multiple imputation to handle missingness in MSEL (~37%) and phthalates (~9%), and assigned children to six distinct expressive language trajectories after selecting the latent class growth analysis model with best goodness-of-fit measures. We estimated relative risk ratios (RRR) of being in different language trajectories ("high growth" as reference) associated with two-fold change in creatinine adjusted phthalates using multinomial logistic regression with Firth correction, adjusting for child sex, birth season, income, and maternal age, race, and education.

RESULTS: Some low molecular weight phthalates were associated with sub-optimal language trajectories, e.g. RRRs of 1.33 or higher for mono-2-hydroxy-iso-butyl phthalate, peaking at 1.51 (1.02, 2.24) for the delayed growth low trajectory. In contrast, some high molecular weight phthalates exhibited protective effects for delayed growth trajectories but adverse effects for plateau and tracking trajectories: e.g. mono-isononyl phthalate with RRR 0.72 (0.59, 0.89) with delayed growth low but 1.29 (1.08, 1.53) with the tracking low trajectory. Some phthalates exhibited null patterns.

CONCLUSIONS: Prenatal phthalate exposure may impact the trajectory of expressive language development in early childhood, with differences by individual phthalates, perhaps by molecular weight group. We observed adverse and protective influences of phthalates that may be influenced by small numbers in each trajectory class.

KEYWORDS: phthalates, language development, trajectory analysis

ORAL PRESENTATIONS SESSION 09: Climate change: Health Impact Assessment and intervention policies

O-OP-046 Extreme Heat Public Health Preparedness Planning and Response Activities in the Most Populous Jurisdictions in the United States: Survey

RESULTS: Jeremy Hess[1], Cat Hartwell[1], Juliette Randazza[1], Quinn Adams[2], Amruta Nori-Sarma[2], Keith Spangler[2], Yuantong Sun[2], Kate Weinberger[3], Gregory Wellenius[2], Nicole Errett[1]
[1]University of Washington, Seattle, USA, [2]Boston University, Boston, USA, [3]University of British Columbia, Vancouver, Canada

BACKGROUND AND AIM: Extreme heat causes more deaths each year than any other type of extreme weather in the U.S. Urban populations can experience heightened heat risk as a result of hazard amplification from the built environment and other factors. Climate change is increasing extreme heat exposure, prompting the need for adaptation measures at all levels of governance. Our study aimed to assess the level and type of heat preparedness and response activities occurring in U.S. jurisdictions with populations of 200,000.

METHODS: We developed and administered an online survey to public health and emergency management agencies in 99 jurisdictions representing municipalities and counties in the US with populations of at least 200,000 people. Survey questions explored heat adaptation activity implementation, including presence or absence of a written heat action plan (HAP), timing of HAP development and updates, critical HAP components, and facilitators and barriers surrounding heat activities.

RESULTS: 38.4% (38) jurisdictions responded to the survey. of those, 60.5% reported having a formal HAP. There was considerable variability in the prevalence of various prevention activities. Jurisdictions with HAPs reported higher engagement in several heat-related activities, including communications about extreme heat, surveillance of heat-related health conditions, and providing climate-controlled shelter for populations experiencing homelessness, compared to jurisdictions without HAPs. The most prevalent communication and outreach modalities were social media, news alert, and internet, which may be less likely to reach populations identified as the most vulnerable to extreme heat (low income, elderly, and people experiencing homelessness).

CONCLUSIONS: Jurisdictions with formal HAPs broadly reported more engagement in heat adaptation activities. Results indicate reliance on lower-cost outreach strategies that may not adequately reach some at-risk populations. Health departments and emergency agencies should consider establishing HAPs as temperatures rise.

KEYWORDS: Extreme heat, climate change, adaptation, public health preparedness

O-OP-047 A Novel Decision-Support Tool for Estimating Local Climate Change Health Risks: Current and Projected Heat-Related Risks in Washington State

Timothy Sheehan[1,4], Alyssa Miller[1], Jeremy Hess

[1]Department of Environmental and Occupational Health Sciences, School of Public Health, University of Washington, Seattle, USA, [2]Department of Emergency Medicine, School of Medicine, University of Washington, Seattle, USA, [3]Department of Global Health, Schools of Medicine and Public Health, University of Washington, Seattle, USA, [4]Environmental Sciences Program, Oregon State University, Corvallis, USA

BACKGROUND AND AIM: Climate change presents a variety of health risks. These risks are location-specific and determined substantially by population vulnerability. There is a need to develop and validate risk assessment and management tools tailored to individual geographies and hazards. Therefore, the UW Center for Health and the Global Environment (CHanGE) has collaborated with local partners to create an interactive tool for estimating current and future health risk associated with climate-sensitive hazards. The approach is piloted using heat in Washington State (WA) which has emerged as an important priority following the unprecedented Pacific Northwest 2021 heat dome.

METHODS: Predicted census-tract heat-health risk (PHHR) is modeled using fuzzy logic. Heat vulnerability indicators were selected from published literature and constructed into a hierarchical model using fuzzy logic conversions and operators. Heat hazards are modeled for 1979-2020 and 2045-2055. Modeled PHHR in WA is compared against established WA environmental hazard indices using rank correlation analysis.

RESULTS: The CHanGE tool displays public-facing, interactive maps alongside associated fuzzy logic models enabling users to visualize distributions of PHHR for historic and projected hazards and determine local PHHR drivers. Historically, high PHHR tracts are concentrated in central WA. Given the predicted rise in temperature, PHHR increases statewide in our projections. Initial findings from a comparison against established hazard indices indicate the CHanGE tool outputs similar risk patterns across WA; however, hazard specific indicators may modify risk locally.

CONCLUSIONS: The CHanGE tool's ability to support transparent, flexible visualizations and allow users to interactively explore local drivers of PHHR fills a gap in climate risk assessment and decision-support. Future development will be focused on model validation and calibration against observed data, and expansion to other hazards and geographies. Recent updates and additions to the tool will also be presented.

O-OP-048 Inequalities in drought effects on non-external, circulatory, and respiratory mortality in the population of macro urban areas of Brazil

Coral Salvador[1,2,3], Ana M. Vicedo-Cabrera[2,3], Renata Libonati[4,5], Ana Russo[5], Beatriz N. Garcia[4], Liz Barreto C. Belem[4], Luis Gimeno[1], Raquel Nieto[1]

[1]Centro de Investigación Mariña, Universidade de Vigo, Environmental Physics Laboratory (EPhysLab), Ourense, Spain, [2]Institute of Social and Preventive Medicine (ISPM), University of Bern, Bern, Switzerland, [3]Oeschger Center for Climate Change Research, University of Bern, Bern, Switzerland, [4]Departamento de Meteorologia, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [5]Instituto Dom Luíz (IDL), Faculdade de Ciências, Universidade de Lisboa, Lisbon, Portugal

BACKGROUND AND AIM: Drought poses a threat to the health, safety, and livelihood of many populations worldwide. The urban population of Brazil is especially vulnerable to drought exposure but the effect of this phenomenon on mortality risk across the population is unknown. Our objective was to assess the drought impact on non-external, circulatory, and respiratory mortality in the urban population of Brazil exploring the populations at potential risk.

METHODS: A two-stage time-series analysis was conducted in 13 macro urban areas of Brazil between 2000 and 2019. We applied quasi-Poisson regression models adjusted by temperature to assess the short-term association between drought (measured by the Standardized Precipitation Evapotranspiration Index) and weekly non-external, circulatory, and respiratory mortality in each location. Then, we fitted independent multivariate meta-analytical models for each cause of death to pool individual estimates and obtain overall risks. We also included stratified analysis by sex and age groups (0-9, 10-44, 45-64, 65-74, ≥75). Relative risks (RRs) and attributable fractions were calculated for different drought severity levels.

RESULTS: Overall, a positive but no significant association between drought exposure and mortality risk was found in the total population with RRs varying from 1.003 [95%CI: 0.999-1.007] to 1.010 [0.996-1.025] for non-external mortality associated with moderate and extreme drought, respectively; 1.002 [0.997-1.007] to 1.008 [0.991-1.026] for circulatory mortality; and 1.004 [0.995-1.013] to 1.013 [0.983-1.044] for respiratory mortality. However, a significant positive association was found in females for all causes of death analysed. According to age groups, we found strong effects in the elderly and children. Moreover, heterogeneity was observed between Brazilian locations.

CONCLUSIONS: Our findings suggest that drought affects the urban population of Brazil unequally, disproportionately affecting females, the elderly, and children. However, action measures should be designed ad hoc according to the specific characteristics of each region.

KEYWORDS: drought; mortality; Brazil, urban population; gender assessment

O-OP-049 The impact of climate change on agricultural labour productivity: implications for human mobility and poverty

Andreas Flouris[1], Leonidas Ioannou[1], Jack Liang[2], Lydia Tsoutsoubi[1], Konstantinos Mantzios[1], Giorgos Gkikas[1], Gerasimos Agaliotis[1], Yiannis Koutedakis[1], Glen Kenny[3], George Havenith[4], David García-León[5], Matthias Otto[6], Tord Kjellstrom[7], Lars Nybo[8], Costas Arkolakis[2]

[1]FAME Laboratory, Department of Physical Education and Sport Science, University of Thessaly, Trikala, Greece, [2]Department of Economics, Yale University, New Haven, USA, [3]Human and Environmental Physiology Research Unit, School of Human Kinetics, University of Ottawa, Ottawa, Canada, [4]Environmental Ergonomics Research Centre, Loughborough Design School, Loughborough University, Loughborough, UK, [5]European Commission, Joint Research Centre, Seville, Spain, [6]Climate Heat Impact Research Program, Health and Environment International Trust, Mapua, New Zealand, [7]Center for Technology Research and Innovation, CETRI, Nicosia, Cyprus, [8]Department of Nutrition, Exercise and Sports, August Krogh Building, University of Copenhagen, Copenhagen, Denmark

BACKGROUND AND AIM: Working in hot or cold environments causes discomfort, fatigue, and cognitive impairment, raising the risk for health complications. The present study developed a new model to estimate the impact of ambient conditions on labour productivity based on field data and applied this model to predict the welfare implications of climate change by estimating the labour productivity change between the years 2000 and 2040.

METHODS: In total, we monitored 1,260 hours of work performed by 194 (men=123; women=71) experienced and acclimatized agriculture workers from 10 nationalities. Time-motion analysis using video recordings was used to extract detailed information on each worker's activities during their work shift. Sine orthogonal distance regression was used to generate the labor loss functions for WBGT and air temperature. Using this model, we projected the welfare implications across the globe of climate change by estimating the labour productivity change between the years 2000 and 2040, using an extended unified general equilibrium framework combining labour mobility and trade interactions between locations.

RESULTS: Our findings reveal an inverted U-shaped relationship with the highest labour productivity observed at 15 °C WBGT or ambient temperature (R2 0.95-0.98). By applying this model to project global welfare implications, we found that the ongoing climate change is expected to impair agricultural labour productivity, promoting significant labour mobility and wealth redistribution across the globe. In contrast to cold regions, which are projected to have average gains up to 6.3%, regions located close to the equator, where poverty is widespread, will face average losses up to 1.2% in productivity and wealth.

CONCLUSIONS: Our projections show larger labour productivity losses in countries where poverty is widespread and the economy is heavily dependent on the agricultural sector. This creates concerns over whether the 1st Sustainable Development Goal involving eradication of poverty can be achieved by 2030.

ORAL PRESENTATIONS SESSION 10: Air pollution and neurobehavioural outcomes

O-OP-050 Lifetime Residential Air Pollution Exposure, Amygdala Volumes, and Emotional Function in Young Adults

Karl O'Sharkey[1], Claire Campbell[1], Kimberley Felix[1], Joel Schwartz[2], Fred Lurmann[3], Nathan Pavlovic[3], Rob McConnell[1], Rima Habre[1], Megan Herting[1]

[1]University of Southern California, Los Angeles, USA, [2]Harvard University, Cambridge, USA, [3]Sonoma Technology, Petaluma, USA

BACKGROUND AND AIM: Air pollution (AP) exposure at differing timepoints across life has been linked to adverse mental health conditions. However, the effects of lifetime exposure to AP on emotional behavior and related functional regions of the brain are not well understood. Therefore, we investigated the effect of lifetime AP exposure on emotional behaviors and associated amygdala volumes in young adults.

METHODS: We recruited 39 participants in a follow up to the Children's Health Study. We performed structural brain Magnetic Resonance Imaging (MRI) and assessed emotional behavior using the Achenbach System of Empirically Based Assessment Adult Self Report questionnaire. Lifetime exposure to particulate matter with aerodynamic diameter <2.5µm ($PM_{2.5}$) and <10µm (PM_{10}), ozone (O_3), and nitrogen dioxide (NO_2) were assessed using inverse distance square weighted interpolation from ambient monitoring data and the Di et al. (2019, 2020) and Requia et al. (2020) spatiotemporal models. We fit linear regression models to estimate the association between lifetime AP exposure (from birth to ~21 years at MRI scan) and emotional behaviors and amygdala volumes, adjusting for key covariates.

RESULTS: Participants were largely Hispanic (38%) and Non-Hispanic White (44%), with a mean (SD) age of 21.6 (0.9) years. We found a SD increase in $PM_{2.5}$,sptmp was associated with a 100.60 mm^3 (95% CI: 13.76 –187.45) increase in total amygdala volume after accounting for total cranial volume, which remained after adjustment for O_3,sptmp. Additionally, a SD increase in O_3,sptmp (β = 12.53, 95% CI: 5.31 -19.74; p =0.001), PM_{10} (β = 17.01, 9.67 –24.34; p <0.001), and $PM_{2.5}$ (β = 11.58, 4.20 –18.96; p =0.003) was significantly associated with greater total emotional problems.

CONCLUSIONS: Lifetime exposure to ambient air pollution is linked to both structural differences in the key emotional brain region of the amygdala as well as greater impairments in emotional functioning in early adulthood.

O-OP-051 Metals mixture is associated with cognitive function in older U.S. adults: the National Health and Nutrition Examination Survey (NHANES) 2011–2014

Habyeong Kang[1], Xin Wang[1], Kelly Bakulski[1], Sung Kyun Park[1,2]
[1]Department of Epidemiology, University of Michigan School of Public Health, Ann Arbor, USA, [2]Department of Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, USA

BACKGROUND AND AIM: Non-essential metals (e.g., cadmium and lead) have adverse effects and essential metals (e.g., selenium) have protective effects on cognitive function. Mixture effects, including interactions and non-linear relationships, have rarely been evaluated. We examined the association of blood metal markers with cognitive function in older U.S. adults using mixture approaches.

METHODS: We examined 1825 participants aged ≥60 years who had complete data on blood metal, cognitive function tests, and covariates in the National Health and Nutrition Examination Survey 2011-2014. Lead, cadmium, total mercury, manganese, and selenium measured in whole blood were included. Four measures of cognitive function (Consortium to Establish a Registry for Alzheimer's Disease (CERAD) word learning, CERAD recall, animal fluency, digit symbol substitution test) were standardized and averaged to create a composite cognitive z-score. Bayesian kernel machine regression (BKMR) was the primary approach for assessing the overall mixture effects. Quantile g-computation was used to evaluate the robustness of the mixture effects. for both approaches, mixture effects were estimated of increasing octiles of lead, cadmium, mercury, and manganese concentrations and decreasing octiles of selenium concentrations.

RESULTS: In BKMR adjusted for covariates, the relationship between cadmium and cognitive z-score was a non-linearly decreasing curve, while selenium showed a non-linearly increasing curve [change in z-score per interquartile increase (95% CI): -0.03 (-0.06, 0.00) and 0.02 (-0.01, 0.05), respectively]. No significant interactions between the exposures were observed. In the mixture analysis, a quantile increase in lead, cadmium, mercury, and manganese and a quantile decrease in selenium simultaneously were associated with lower cognitive z-scores [change in z-score per interquartile change (95% CI): -0.06 (-0.11, -0.01)]. Similar mixture effects were observed in quantile g-computation.

CONCLUSIONS: Exposure to higher levels of cadmium and lower levels of selenium may be associated with lower cognitive function in older adults.

KEYWORDS: cadmium, selenium, cognitive decline, BKMR

O-OP-052 Early life metal exposure is associated with reduced fractional anisotropy in the corpus callosum in children

Elza Rechtman[1], Christine Austin[1], Paul Curtin[1], Azzurra Invernizzi[1], Demetrios M. Papazaharias[1], Michelle A. Rodriguez[1], Libni A. Torres-Olascoaga[2], Luis Bautista[2], Sandra Martínez-Medina[3], Rafael Lara-Estrada[4], Erika Proal[2], Viviana Villicaña-Muñoz[2], Chris Gennings[1], Cheuk Y. Tang[5], Martha M Téllez-Rojo[2], Robert O. Wright[1], Manish Arora[1], Megan K. Horton[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Center for Nutrition and Health Research, National Institute of Public Health, Mexico, [3]National Institute of Perinatology, Mexico, [4]National Research Laboratory in Imaging and Medical Instrumentation, Universidad Autónoma Metropolitana, Mexico, [5]Department of Diagnostic, Molecular, and Interventional Radiology, Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: The corpus callosum (CC) is the largest white matter structure in the brain, connecting the left and right hemispheres into functional networks subserving cognition and behavior. Neuroimaging studies demonstrate rapid CC development during the first years of life. During these early-life critical windows, the CC is vulnerable to perturbation by neurotoxicants including heavy metals. Most environmental studies consider single neurotoxicant exposures at a single time point, potentially missing the effects of joint exposure across a developmental stage. Here, we investigated associations between early life metal mixture exposure and CC white matter microstructure integrity in children.

METHODS: In a preliminary analysis of 47 children (8-13 years; 22 females) enrolled in a neuroimaging substudy within the Programming Research in Obesity, Growth, Environment and Social Stressors (PROGRESS) study, we estimated weekly exposure (22nd-week gestation through 43rd week postnatal) to manganese (Mn), zinc (Zn), and lead (Pb) using laser ablation-inductively coupled plasma-mass spectrometry of teeth. We estimated CC white matter microstructure integrity using fractional anisotropy (FA) from diffusion tensor imaging (DTI) acquired in a 3T Siemens scanner. We used lagged weighted quantile sum (lWQS) regression to estimate the time-varying mixture effect on FA in the CC.

RESULTS: A higher metal mixture index in the 24th-43rd postnatal weeks was associated with decreased FA in the CC genu, body, and splenium (maximum β = -0.65 [95% CI -0.25, -1.07]), driven mainly by Zn and Pb.

CONCLUSIONS: The CC may demonstrate a postnatal critical window to metals, with higher exposure to Zn and Pb associated with reduced FA. These results may help understand the role of exposure timing in driving neurodevelopmental outcomes, pointing to future optimal and timely public health interventions.

O-OP-053 Prenatal/Early-Life Exposure to Polycyclic Aromatic Hydrocarbons (PAHs) and Adverse Neurodevelopment Outcomes in Children: A Systematic Review and Meta-Analysis

Barbara Hudson-Hanley[1], Ellen Smit[1], Adam Branscum[1], Perry Hystad[1], Molly Kile[1]
[1]*Oregon State University, Corvallis, USA*

BACKGROUND AND AIM: Research indicates prenatal/early-life exposure to PAHs may be associated with adverse neurodevelopment outcomes, but there are conflicting research results. A weight of evidence approach is needed.
OBJECTIVE: Summarize eligible evidence of prenatal/early-life PAH exposure on neurodevelopment outcomes in children.

METHODS: Using a priori search strategy, we conducted a systematic review (SR) to identify eligible peer-reviewed studies in English, in PubMed, Wed of Science, and Google Scholar. Eligible studies modeled or measured PAH exposure during pregnancy or at least six months prior to neurodevelopment assessment, with no limits on study time-period or geography. Two reviewers, working independently, followed PRISMA protocol. Risk of bias assessment followed Navigation Guide protocol. of 613 studies identified, 26 were included in final meta-analysis. Outcomes were grouped into either dichotomous (summary effect measure: odds ratio) or continuous outcomes (Cohen's d). We report the summary effect size of each outcome, 95%CI, and I2.

RESULTS: We found a statistically significant positive association in dichotomous outcomes between prenatal/early-life PAH exposure and anxiety/depression (OR: 1.36; 95%CI:1.10,1.68; p=0.005; npooled=4,989; I2=73.6%), and in neurodevelopment delay (1.07; 95%CI: 1.01, 1.14; p =0.028; npooled = 1,113; I2 = 30.2%). We found a marginal positive association with attention problems (OR: 1.81; 95%CI:0.96,3.43; p=0.068; npooled=2,997; I2=86.4%). In continuous outcomes, we found a statistically significant negative association in motor skills (Cohen's d: -0.371; 95%CI:-0.52,-0.22; p<0.001; npooled=1,372; I2=96.7%), and in adaptive behavior (-0.142, 95%CI:-0.25,-0.00; p=0.042; npooled = 1,128; I2=84.3%). We did not find an association in intelligence, language skills, social behavior, ADHD, or other behavior problems.

CONCLUSIONS: There is limited human evidence that prenatal/early-life PAH exposure adversely affects neurodevelopment. Between-study variance was low to high. However, limited human evidence of adverse neurodevelopment effects associated with prenatal/early-life exposure to common environmental pollutants is cause for concern.

ORAL PRESENTATIONS SESSION 11: Environmental exposures and emerging outcomes

O-OP-055 Associations between long-term air pollution and kidney diseases in the US Medicare population

Whanhee Lee[1,2,3], Seulkee Heo[3], Rory Stewart[3], Xiao Wu[4], Kelvin Fong[3], Ji-Young Son[3], Benjamin Sabath[4], Danielle Braun[4], Jae Yoon Park[5], Yong Chul Kim[6], Jung Pyo Lee[7], Joel Schwartz[4], Ho Kim[8], Francesca Dominici[4], Michelle Bell[3]
[1]Department of Environmental Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [2]Institute of Ewha-SCL for Environmental Health (IESEH), College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [3]Yale School of the Environment, Yale University, New Haven, USA, [4]Harvard T H Chan School of Public Health, Boston, USA, [5]Department of Internal Medicine, Dongguk University Ilsan Hospital, Ilsan, Republic of Korea, [6]Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea, [7]Department of Internal Medicine, Seoul National University Boramae Medical Center, Seoul, Republic of Korea, [8]Department of Public Health Science, Graduate School of Public Health, Seoul, Republic of Korea

BACKGROUND AND AIM A few studies have reported that long-term exposure to air pollution is associated with an increase in the risk of incident chronic kidney disease (CKD); however, the generalizability of these results was limited due to the non-representative nature of the study populations. This study aimed to provide quantitative evidence on the risk of air pollution on the development of kidney diseases using a nationwide Medicare longitudinal cohort.

METHODS: Over 61 million US Medicare fee-for-service beneficiaries and 34,849 ZIP codes across the continental United States (2000-2016) with data collected from the Medicare Part A fee-for-service (FFS). As exposure variables, annual averages of traffic-related pollutants (fine particles (PM2.5) and nitrogen dioxide (NO2)) were assigned according to the ZIP code of residence of each beneficiary with the use of well-validated prediction models. We estimated the association between long-term exposure to air pollution and first admission with diagnosis codes related to the total kidney disease or CKD, separately, using a two-pollutant Cox-equivalent re-parameterized Poisson model.

RESULTS: The average annual concentrations of air pollution were 9.8 μg/m3 for PM2.5 and 18.9 ppb for NO2. The total number of first admissions related to total kidney disease and CKD were around 19.0 and 5.9 (2000-2016). for total kidney disease, hazard ratios (HRs) were 1.1076 (95% CI: 1.071 to 1.081) for 5 μg/m3 increase in PM2.5 and 1.040 (1.036 to 1.043) for 10 ppb increase in NO2. for CKD, HRs were 1.106 (1.097 to 1.115) for 5 μg/m3 increase in PM2.5 and 1.013 (1.008 to 1.019) for 10 ppb increase in NO2. These positive association between PM2.5 and kidney outcomes persisted at concentrations below national health-based air quality standards.

CONCLUSIONS:We found that annual air pollution levels are associated with development of kidney diseases in the Medicare population.

KEYWORDS: Kidney disease, Air pollution, Medicare

O-OP-056 Chronic Kidney Disease (CKD) and Exposure to Fine Particulate Matter and Ozone: A Cross-Sectional Study Utilizing North Carolina Electronic Healthcare Records

David Dillon[1], Cavin Ward-Caviness[2], Joshua Moyer[2], Joel Schwartz[3], Qian Di[4], Anne Weaver[2]
[1]Oak Ridge Institute of Science and Education, Chapel Hill, USA, [2]United States Environmental Protection Agency, Durham, USA, [3]Harvard University, Boston, USA, [4]Tsinghua University, Beijing, China

BACKGROUND AND AIM: Chronic kidney disease (CKD) affects more than 38 million people in the United States, predominantly those over 65 years of age. While CKD etiology is complex, recent research suggests associations with certain environmental exposures. Additional studies are needed to understand the strength of associations. We examine estimated glomerular filtration rate (eGFR) using a random sample of North Carolina electronic healthcare records (EHRs) and potential relationships with $PM_{2.5}$ and O_3.

METHODS: Patient data came from a random sample of 7,065 EHRs within the EPA CARES resource, with recorded serum creatinine concentrations. Patients were seen at a University of North Carolina Healthcare System affiliated hospital or clinic from 2004-2017. We estimated eGFR using CKD-EPI equations. $PM_{2.5}$ data comes from a hybrid model using 1x1 km grids and O_3 data from CMAQ 12x12 km grids. Exposures were annual average $PM_{2.5}$ and O_3 based on the creatinine lab test date. We used multiple linear regression to estimate eGFR per IQR increase of $PM_{2.5}$ & O_3. We adjusted for patient sex, race, age, comorbidities, and 2010 census block group measures of sociodemographic and economic factors.

RESULTS: Patients averaged 55.3 (SD: 16.2) years of age, with 58.3% female. There were 1,001 patients (14.2%) diagnosed with CKD, identified by ICD-9 & 10 codes. Mean concentrations for the study period of $PM_{2.5}$ and O_3 were 9.92 (IQR: 1.61) $\mu g/m^3$ and 40.20 (IQR: 2.53) ppb respectively. eGFR decreased 8.45 mL/min/1.73m² (95% CI: 7.92, 8.98) per IQR increase of $PM_{2.5}$ and a more modest decrease of 0.66 mL/min/1.73m² (95% CI: -.08, 1.40) per IQR of O_3.

CONCLUSIONS: Annual average $PM_{2.5}$, and to a lesser extent O_3, were associated with lower (poorer) eGFR. Future work will examine the relationship between air pollution and onset of CKD and impaired renal function. This abstract does not reflect EPA policy.

O-OP-057 Combined effects of air pollution and neighborhood violence on epilepsy and seizures in children

Rachit Sharma[1], Jamie Humphrey[2], Ellen Kinnee[3], Perry Sheffield[4], Jane Clougherty[5]
[1]Department of Environmental and Occupational Health, Dornsife School of Public Health, Drexel University, Philadelphia, USA, [2]RTI International, Research Triangle Park, USA, [3]University Center for Social and Urban Research, University of Pittsburgh, Pittsburgh, USA, [4]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [5]Department of Environmental and Occupational Health, Dornsife School of Public Health, Drexel University, Philadelphia, USA

BACKGROUND AND AIM: Psychosocial stress and air pollution are being linked to multiple neurological disorders. However, research investigating their impact on epilepsy and seizures is scarce. We examined the combined effects of acute exposures to multiple pollutants and neighborhood violent crime (a critical urban psychosocial stressor) on epilepsy/seizure aggravation among children (0-4 years) in New York City.

METHODS: Using conditional logistic regression in a time-stratified, case-crossover design, we quantified percent excess risk of epilepsy/seizure event per 10-unit increase in daily exposures to PM2.5, NO2, SO2, and O3. Data on epilepsy/seizure cases (n = 28,385), presenting at NYC emergency departments, 2005 to 2011, was obtained from New York Statewide Planning and Research Cooperative System. for each case, residence-specific, year-round, daily average spatio-temporal pollution and temperature exposures were estimated using data from NYC Community Air Survey, and daily EPA pollution and NOAA weather data. Point-level NYPD crime data were aggregated to tract-level annual average rates. Separate models were fit for each pollutant for lag days 0 to 6, controlling for case-day effects of other pollutants, temperature, and humidity, after sensitivity-testing multiple co-pollutant adjustment strategies. Interactions with quintiles of crime rates were assessed.

RESULTS: Strongest main effects were observed for PM2.5 on lag day 1 [β = 2.93 (0.63, 5.28)], lag day 2 [β = 1.79 (-0.28, 3.90)], and lag day 3 [β = 2.47 (0.44, 4.54)]. NO2, SO2, and O3 effects were statistically non-significant. Violence modified PM2.5 effects in opposite-to-hypothesized direction; U-shaped exposure-response observed with violence quintiles 1 and 4 demonstrating the strongest associations across lag days 1-3.

CONCLUSIONS: Acute PM2.5 exposure may be associated with pediatric seizure risk. Greater apparent effects in the lowest and high violence communities need further investigation but could result, in part, from saturation effects in socio-environmental stressor synergism.

KEYWORDS: air pollution, stress, violence, epilepsy, seizure, children

O-SY-129 Metabolome-wide association study suggests antagonistic responses to cadmium and selenium in diseased human lungs

Dean Jones[1], Ryan Smith[2], Xin Hu[1], Jolyn Fernandes[3], Michael Orr[1], Joshua Chandler[4], Douglas Walker[5], Annette Esper[1], Lucian Marts[1], David Neujahr[1], Young-Mi Go[1]

[1]Division of Pulmonary Medicine, Emory University, Atlanta, USA, [2]Atlanta Department of Veterans Affairs Medical Center, Decatur, USA, [3]Department of Pediatrics, University of Oklahoma Health Sciences Center, Oklahoma City, USA, [4]Department of Pediatrics, School of Medicine at Emory University, Altanta, USA, [5]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: Cadmium (Cd) is a toxic environmental metal that binds selenium (Se) and contributes to many lung diseases. Humans have widespread exposures to Cd through diet and cigarette smoking, and studies in rodent models show that Se can protect against Cd toxicities. We performed metabolome-wide association study (MWAS) of Cd and Se in diseased and non-diseased human lungs to test for possible Cd-Se interactions.

METHODS: We analyzed tissue from 31 human lung explants, including 25 from patients with end-stage lung diseases, including idiopathic pulmonary fibrosis, cystic fibrosis, and chronic obstructive lung disease (COPD)/emphysema. We used ICP-MS (Inductively Coupled Plasma Mass Spectrometry) to measure Cd and Se, and liquid chromatography-high-resolution mass spectrometry (LC-HRMS) to conduct metabolomics analysis.

RESULTS: Metabolic pathway associations with Cd were similar to those previously observed in experimental models, including amino acid, lipid and energy-related pathways, many of which were also associated with Se. Two-way hierarchical cluster analysis (HCA) of metabolites associated with Cd revealed separation of individuals according to disease, with COPD/emphysema in the highest Cd cluster, and non-diseased individuals in the lowest Cd cluster. HCA of Se-associated metabolites revealed that COPD/emphysema also clustered by lower Se compared to others. More pathway associations occurred for the ratio of Cd:Se than either Cd or Se alone, suggesting an antagonistic relationship, and network analysis showed that most metabolites were associated with either Cd or Se. A relatively small number of polyunsaturated fatty acids and metabolites associated with inflammatory signaling had high Eigenvector centrality scores, suggesting a central mechanism of antagonistic interaction.

CONCLUSIONS: Overall, the data show that metabolic pathway responses in human lung vary with Cd:Se ratio in a pattern suggesting that Se is antagonistic to Cd toxicity.

KEYWORDS: Human lung disease, environmental metals, metabolic disruption, high-resolution metabolomics.

ORAL PRESENTATIONS SESSION 12: Health impact and risk assessment

O-OP-058 Cooling cities through urban green interventions: A health impact assessment in European cities

Tamara Iungman[1,2], Marta Cirach[1], Federica Marando[3], Evelise Pereira Barboza[1,2], Sasha Khomenko[1,2], Pierre Masselot[4], Marcos Quijal[1,2], José Urquiza[1], Antonio Gasparrini[4], Natalie Mueller[1], Mark Nieuwenhuijsen[1,2]
[1]Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Universitat Pompeu Fabra, Barcelona, Spain, [3]European Commission, Joint Research Centre (JRC), Ispra, Italy, [4]London School of Hygiene and Tropical Medicine (LSHTM), London, UK

BACKGROUND AND AIM: High ambient temperatures are associated with many health effects including premature mortality. Given the current warming trend due to climate change and the global built environment expansion, the intensification of urban heat islands (UHI) is expected, accompanied by adverse impacts on population health. Urban green interventions can reduce local temperatures. We aimed to estimate the mortality burden that could be attributed to the UHI and the mortality burden that would be prevented by increasing the urban tree cover (Tc) in 93 European cities.

METHODS: We conducted a quantitative health impact assessment (HIA) for the summer (June-August) of 2015 to estimate the impact of the UHI, on natural-cause mortality for adult residents in 93 European cities. In addition, we estimated the temperature reduction resulting by increasing the Tc to 30% for each city and estimated the number of deaths that could be potentially prevented as a result, with the aim of providing decision-makers with usable evidence to promote greener cities. We performed all analyses at a high-resolution grid-cell level (250m x 250m).
FINDINGS: The population-weighted-city-average daily UHI from June to August was 1.5°C (city range 0.5°C - 3.0°C). Overall, 7,053 (95% CI 5,961 - 8,135) premature deaths could be attributable to the UHI (ie, 4.6%, city range 0.2%-16.9% of summer mortality). Increasing the Tc up to 30% at 250m resolution resulted in an average city cooling of 0.4ºC (city range 0.0ºC-1.3ºC). We estimated that 2,597 (95% CI 2,451-2,728) premature deaths (ie, 1.9%, city range 0.0%-11.2% of summer mortality) could be prevented by increasing the average Tc in cities to 30%.
INTERPRETATION: Our results showed the impacts on mortality of the UHI and highlight the health benefits of green infrastructure to cool urban environments, while promoting more sustainable and climate-resilient cities.

KEYWORDS: urban heat island, urban green infrastructure, tree cover density, cooling, mortality, health impact assessment

O-OP-059 A quantitative burden of proof risk function to evaluate environmental risk factors in comparative risk assessments

Michael Brauer[1,2]

[1]The University of British Columbia, Vancouver, Canada, [2]Institute for Health Metrics and Evaluation, University of Washington, Seattle, USA

BACKGROUND AND AIM: Assessing strength and quantifying risk-outcome relationships is critical for public health prioritization, policy formulation, clinical guidance and to inform personal choices related to modifiable risk factors. While meta-analyses or meta-regressions are often used as an inputs, their use in decision making is often subjective. We introduce the quantitative burden of proof risk function in the context of the Global Burden of Disease comparative risk assessment framework.

METHODS: The burden of proof risk function combines meta-regression mean relationship between exposure and risk with unexplained between-study heterogeneity, adjusted for number of studies. We developed and applied a Bayesian meta regression framework to robustly estimate the mean and burden of proof risk function, allowing for non-linear relationships, and applied this to 197 behavioral, metabolic and environmental risk factor – outcome relationships. Relationships were summarized by a 'star-rating' where 1-star risks had a probability of no association after accounting for between-study heterogeneity, and 2, 3, 4, and 5-star risks indicated a 0-15%, >15-50%, >50-85% and >85% increase in risk, respectively, over the 15%-85% percentiles of exposures of included studies.

RESULTS: Environmental risk factors included in the Global Burden of Disease ranged from 4-star (e.g. sanitation-diarrheal disease) to 1-star (e.g. NO2 – asthma). Across all 197 included risk-outcome pairs, 4%, 7%, 25%, 42% and 23% were 5, 4, 3, 2, and 1-star, respectively. 81% of the 32 included environmental risk factor-pairs, were 2 or 3-star.

CONCLUSIONS: The burden of proof risk function is a cautious interpretation of evidence, incorporating both magnitude and uncertainty in relative risks. Higher risk scores indicate a larger effect and/or a lower probability of results driven by residual confounding or other bias. Risk-outcome pairs with low star ratings indicating substantial between-study heterogeneity may suggest a need for additional studies, especially where exposure and outcome prevalence are high.

O-OP-060 Methods for evaluating environmental health impacts at different stages of the policy process in cities

Jaime Benavides[1], Sebastian T. Rowland[1], Jenni A. Shearston[1], Yanelli Nunez[1], Darby W. Jack[1], Marianthi-Anna Kioumourtzoglou[1]
[1]*Dept. of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York City, USA*

BACKGROUND AND AIM: Evaluating the environmental health impacts of urban policies is critical for developing and implementing policies that lead to more healthy and equitable cities. This narrative review aims to (1) identify research questions commonly used when evaluating the health impacts of urban policies at different stages of the policy process, (2) describe commonly used methods, and (3) discuss challenges, opportunities, and future directions.

METHODS: We reviewed the scientific literature on methods to quantify the urban environmental health impacts of policies given research questions. We prioritized articles published in the last five years and included some relevant older papers to illustrate specific knowledge that complements the reviewed papers. Given the diversity of health impact evaluation studies, we separate our discussion by policy stage, following the policy process: diagnosis, design, pilot, implementation, operation, and dismantling.

RESULTS: In the diagnosis and design stages of the policy process, research questions aim to characterize environmental problems affecting human health and estimate the potential impacts of new policies. Simulation methods using existing exposure-response information to estimate health impacts predominate at these stages of the policy process. In subsequent stages, e.g., during implementation, research questions aim to understand the actual policy impacts. Simulation methods or observational methods, which rely on experimental data gathered in the study area to assess the effectiveness of the policy, are often applied at these stages.

CONCLUSIONS: The policy process consists of interdependent stages, from inception to end, but most reviewed studies focus on single stages, neglecting the continuity of the policy life cycle. Studies assessing the health impacts of policies using a multi-stage approach are lacking. Most studies investigate intended impacts of policies; focusing also on unintended impacts may provide a more comprehensive evaluation of policies.

KEYWORDS: Healthy cities, Urban policy, Environmental health, Impact evaluation, Policy process

O-OP-061 Cancer hazard Evaluations for Contemporary Needs: What's New at NIEHS

Ruth Lunn[1], Suril Mehta[1], Gloria Jahnke[1], Amy Wang[1], Mary Wolfe[1], Brian Berridge[1]
[1]*NIEHS, Research Triangle Park, USA*

BACKGROUND AND AIM: Primary prevention is an effective strategy for reducing the global cancer burden. To inform public health decisions and communicate hazards, the U.S. National Toxicology Program conducts cancer hazard evaluations for possible listing in the congressionally mandated Report on Carcinogens (RoC). The scientific community recognizes challenges with traditional cancer hazard evaluations that do not always address real-world experiences like exposure to complex mixtures that disproportionally affect certain racial and ethnic communities.
To increase the relevance and usefulness of our cancer hazard evaluations, we have enhanced our assessment methods and communication strategy.

METHODS: AND

RESULTS: We highlight advancements from recent and ongoing cancer hazard evaluations, encompassing the entire lifecycle of our review process – from substance selection to systematic review methods and hazard communication.
We have selected real-world exposures such as mixtures (e.g., wood smoke), non-traditional agents (e.g., light at night), complex exposure scenarios (e.g., night shift work), and chemical classes (e.g., polycyclic aromatic hydrocarbons) for review. Systematic review methodology improvements include (1) using evidence maps to inform the review approach, (2) implementing more structured approaches to identify and organize mechanistic data, (3) exploring read-across approaches to evaluate substances without human and animal cancer data, and (4) incorporating triangulation approaches for evidence integration. To improve hazard communication, we are contextualizing hazards (e.g., persistent night shift work), providing information on prevention (e.g., Helicobacter pylori), and presenting information in an interactive format. for example, our online platform allows the public to explore substance uses and specific human cancers associated with RoC listings. We are also exploring ways to emphasize and communicate environmental health disparities.

CONCLUSIONS: The RoC has a legacy of providing highly impactful information that significantly enables cancer prevention efforts. We are actively evolving our approaches to meet contemporary challenges.

ORAL PRESENTATIONS SESSION 13: Occupational exposures, mental health and other outcomes

O-OP-062 Consumption of Iron- and Protein-Rich Diets may Ameliorate the Effect of Metals-Induced Anemia among Informal Electronic Waste Recyclers in Ghana

Sylvia Takyi[1], John Arko-Mensah, Niladri Basu, Julius N. Fobil
[1]*University of Ghana, School of Public Health, Legon, Ghana*

BACKGROUND AND AIM: Environmental exposure to metals may play a role in the pathogenesis of anemia, yet, nutrition may ameliorate adverse effects of these metals on hemoglobin (Hb) levels in humans. Although informal electronic waste (e-waste) recycling processes have recently drawn attention as an important source of pollution, there is almost no empirical evidence on the relationship between diet, metals exposure and anemia among e-waste recyclers. Therefore, we evaluated possible ameliorating effects of diet on metal-induced anemia, as measured by Hb levels of e-waste recyclers and a reference population in Ghana.

METHODS: Study employed a repeated-measures design to collect whole-blood samples from e-waste recyclers (n=142) and a reference population (n=65) between March 2017 and October 2018. Blood was analyzed for the following metals: Cd, Pb, Rb, Tb & Eu using the ICP-MS®. Dietary intake parameters; proteins, folate, carbohydrates, Fe, Ca, Mg, Se, Zn and Cu were assessed using a 48-hour-recall. Blood Hb levels were measured using the URIT-810® semi-automatic biochemistry analyzer. Ordinary least-square regression models were used to estimate joint effects of metals and nutrients on Hb levels.

RESULTS: at baseline, mean Hb was lower among recyclers (12.99±3.17g/dL) than the reference group (13.02±2.37g/dL). Blood Pb, Cd, Rb, Eu and Tb were associated with significant decreases in Hb levels of e-waste recyclers. Dietary intake of proteins and Fe was associated with concomitant increase in Hb levels of both groups as well as when analysis was restricted to recyclers. Despite the high exposure of e-waste recyclers to a myriad of metals, consumption of Fe-rich diets seemed to ameliorate anemia and improved Hb levels (β=0.229; 95% CI: 0.013, 0.445; p=0.04).

CONCLUSIONS: Consumption of Fe and protein-rich foods was associated with significant increases in Hb levels of e-waste recyclers, even when exposed to high levels of these metals.

KEYWORDS: e-waste, hemoglobin, anemia, metals, diet

O-OP-063 Gendered precarious employment trajectories and self-reported health outcomes: a retrospective study in France

Hyunji Byun[1], Mélanie Bertin[2], Emilie Counil[1,3]

[1]French Institute for Demographic Studies (INED), Aubervilliers, France, [2]Univ Rennes, EHESP, CNRS, Inserm, Arènes - UMR 6051, RSMS (Recherche sur les Services et Management en Santé), Rennes, France, [3]Institut de Recherche Interdisciplinaire sur les Enjeux Sociaux - Sciences sociales, politique, santé, IRIS (UMR 8156 CNRS - EHESS - U997 INSERM), Aubervilliers, France

BACKGROUND AND AIM: As precarious employment has been prevalent since the mid-1970s in high-income countries, it emerged as a social determinant of health, with potentially different health consequences for men and women. In France, unemployment and temporary employment have been high since the early 2000s. Our objective was to investigate the gendered influence of precarious employment trajectories on health outcomes in the French context.

METHODS: We used a retrospective national survey (4445 men, 5371 women) to create patterns of employment trajectories by sex, using multiple correspondence analysis followed by hierarchical ascendant clustering. We considered five dimensions of precariousness: unemployment (%), inactivity (%), frequency of job changes, qualification trend, and versatility of duty. We then explored the associations between the trajectory patterns and four health outcomes (self-perceived health, chronic morbidity, activity limitations and depression) through multivariate logistic regression, taking the most continuous, stable, and skilled trajectories as the reference.

RESULTS: Five patterns of employment trajectories were observed in each sex, with some specificities. Highly precarious trajectories concentrated in one cluster in both men (19%) and women (10%) ; they were associated with worse self-perceived health (OR_men=1.34, 95%CI [1.00;1.80] ; OR_women=1.56, 95%CI [1.22;1.99]), and more activity limitations (OR_men=1.52, 95%CI [1.05;2.20] ; OR_women=1.40, 95%CI [1.05;1.88]) as compared to the stable pattern. In women, high precarity was also associated with depression (OR_women=1.37, 95%CI [1.09;1.73]), while those who experienced a sex-specific inactivity pattern (24% of women) or long-lasting low-skill pattern (22%) only reported worse self-perceived health. Men experiencing a sex-specific medium precarity pattern (15%) reported more chronic morbidity and activity limitations than in the stable trajectory.

CONCLUSIONS: Different patterns of employment trajectories were found in men and women. The precarious patterns were also associated with different adverse health outcomes depending on gender. Ongoing analysis will further address potential mediation through working conditions.

O-OP-064 Functional changes in neural mechanisms underlying post-traumatic stress disorder in World Trade Center responders

Azzurra Invernizzi[1], Elza Rechtman[1], Paul Curtin[1], Demetrios Papazaharias[1], Maryam Jalees[1], Alison Pellecchia[2], Evelyn Bromet[3], Roberto Lucchini[4,5], Benjamin Luft[2,6], Sean Clouston[7], Cheuk Tang[8], Megan Horton[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]World Trade Center Health and Wellness Program, Renaissance School of Medicine at Stony Brook University, New York, USA, [3]Department of Psychiatry, Renaissance School of Medicine at Stony Brook University, New York, USA, [4]Department of Environmental Health Sciences, Robert Stempel School of Public Health, Florida International University, Miami, USA, [5]Department of Medical Surgical Specialties, Radiological Sciences and Public Health, University of Brescia, Brescia, Italy, [6]Department of Medicine, Renaissance School of Medicine at Stony Brook University, New York, USA, [7]Program in Public Health and Department of Family, Population, and Preventive Medicine, Renaissance School of Medicine at Stony Brook University, New York, USA, [8]Department of Radiology and Psychiatry, Icahn School of Medicine at Mount Sinai, New York, USA

INTRODUCTION: World Trade Center (WTC) responders have high prevalence (23%) of persistent, clinically significant WTC-related post-traumatic stress disorder (PTSD). Recent structural magnetic resonance imaging (MRI) studies demonstrate anatomical differences between WTC responders with and without PTSD. We used resting state functional (rs-fMRI) to investigate neural mechanisms underlying WTC-PTSD and identify changes in local brain areas associated with WTC exposure.

METHODS: Using graph theory analysis of rs-fMRI data, we calculated eigenvector centrality (EC) to measure connectivity in 111 brain areas in WTC responders with PTSD (WTC-PTSD, n = 45) and matched responders without PTSD (non-PTSD, n = 51). Permutation statistics quantified EC differences; partial least squares discriminant analysis (PLS-DA) modeled the divergence in EC values between groups. Associations between WTC-exposure duration (months on site) and EC in identified brain areas were examined using general linear model (GLM) regression, adjusting for medication usage and comorbid depression. Generalized weighted quantile sum (WQS) regression was used to examine associations between an index of PTSD symptoms and EC values.

RESULTS: PLS-DA analysis of EC values enabled effective discrimination (auc: 0.749 (0.651-0.847)) of WTC-PTSD from non-PTSD; EC in nine brain regions (right/left anterior inferior temporal gyrus, right superior parietal lobule, right anterior parahippocampal gyrus (PHG), right anterior/posterior temporal fusiform cortex, right caudate nucleus, left amygdala (AMG) and brainstem) differed significantly and contributed the most to differentiate functional neuro-profiles between groups. The association between exposure duration and EC differed significantly between WTC-PTSD and non-PTSD in PHG and AMG (p= 0.010, 0.005, respectively). Within WTC-PTSD, the index of PTSD symptoms was positively associated with EC values in PHG and brainstem.

CONCLUSIONS: Our results confirm hypotheses about key brain areas associated with PTSD and extend our understanding of neural mechanisms linking WTC exposure with PTSD. Better understanding of neural mechanisms leading to WTC-PTSD would help guide intervention and treatment.

O-OP-065 Occupational Risk Factors of Prenatal Depression in Pregnant Women in the New York City Metropolitan Area

Venu Gopal Bangla[1], Michael Belingheri[1,2], Lynn C. Onyebeke[1], Demetrios M. Papazaharias[1], Omara Afzal[1], Marti Soffer[3], Roberto G. Lucchini[4], Yueh-Hsiu Mathilda Chiu[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, USA, [2]University of Milano-Bicocca, Monza, Italy, [3]Massachusetts General Hospital, Boston, USA, [4]Florida International University, Miami, USA

BACKGROUND AND AIM: Approximately 80% of women become pregnant at some point during their career in the United States. Prenatal depression (PD) has been associated with adverse health outcomes in pregnant women and their offspring, particularly in lower sociodemographic (SES) populations. We examined the occupational risk factors associated with PD in a population of lower SES pregnant workers in New York City.

METHODS: Analyses included 487 women aged ≥18 years visiting obstetrics and gynecology clinics during pregnancy or within 2 months of child delivery between March to September 2017, with employment status at the time or after January 2014, when the Pregnant Workers Fairness Act legislation was enforced in NYC. Detailed occupational and sociodemographic data were collected via in-person interviews. Women completed a 10-item Edinburgh Depression Scale (EDS); EDS score ≥13 was classified as probable PD. Scores for established subconstructs of EDS (anxiety, anhedonia, classical depression) were also calculated. Multivariable adjusted regressions were used to identify the occupational factors that predict higher scores of EDS and its subconstructs, adjusting for age, race/ethnicity, education, marital status, and manager status.

RESULTS: Majority of women were black and/or Hispanic (84%), reporting <$30,000 annual household income (64%). Unconventional work shifts (night/evening or rotating shiftwork) [adjusted odds ratio {aOR} (95% CI)=2.01(1.14-3.55)], higher perceived work stress [aOR=2.91(1.27-6.70)], and health, science, or technology-related industry [aOR=2.74 (1.07-7.03)] were independently associated with elevated EDS score. for EDS subconstructs, higher perceived stress level at job was significantly positively associated with all three subconstructs, while job duty of lifting/pulling heavy objects was significantly associated with classical depression subconstruct (all $p<0.05$).

CONCLUSIONS: As more women continue to work during pregnancy, workplace policies to decrease hours of unconventional work shifts or physically demanding duties may be particularly important for protecting pregnant women and their children's well-being.

KEYWORDS: pregnant worker, occupational factors, stress, depression

ORAL PRESENTATIONS SESSION 14: Respiratory disorders in children and adults

O-OP-066 Precipitation and lung health in children with asthma

Nicholas Nassikas[1], Sheryl Rifas-Shiman[2], Heike Gibson[3], Kelly Chen[1], Jeffrey Blossom[4], Emily Oken[2,3], Diane Gold[5], Mary Rice[1]

[1]Beth Israel Deaconess Medical Center, Boston, USA, [2]Department of Population Medicine, Harvard Medical School/Harvard Pilgrim Health Care Institute, Boston, USA, [3]Harvard T. H. Chan School of Public Health, Boston, USA, [4]Center for Geographic Analysis, Harvard University, Cambridge, USA, [5]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital, Boston, USA

BACKGROUND AND AIM: The frequency of heavy precipitation events is increasing in the northeastern United States (US) due to climate change, with potential implications for lung health. Thunderstorms and tropical cyclones have been associated with asthma exacerbations, potentially due to bioaerosol formation. We aimed to assess if short-term exposure to precipitation is associated with lung function and eosinophilic airway inflammation in children with asthma.

METHODS: Study subjects were adolescents with a history of asthma in a longitudinal cohort study based in the northeastern US state of Massachusetts (n=252). The mean age was 13.2y (SD 0.92). Daily precipitation estimates were based on an 800m resolution climate dataset linked to geocoded participant addresses. We used linear regression models adjusted for sex, age, height, race/ethnicity, household tobacco use, maternal education, season, study visit date, $PM_{2.5}$ and O_3 pollution, to evaluate associations of 1-, 2-, 3-, and 7-day moving averages of precipitation with forced expiratory volume in one second (FEV_1), forced vital capacity (FVC) and the natural log of fractional exhaled nitric oxide (FeNO).

RESULTS: Median daily precipitation for the 7 days preceding study visit was 2.08mm (IQR: 3.90mm). Median FeNO was 23ppb (IQR: 38.3ppb). Higher levels of precipitation were associated with lower FEV_1 and FVC. The association was statistically significant for previous-day precipitation and FVC: each 2mm increase in prior-day precipitation was associated with a 16.7 ml lower FVC (95% CI -29.3,-4.10). The 3- and 7-day moving averages of daily precipitation were associated with higher FeNO. Each 2mm higher 7-day moving average for precipitation was associated with an 8.55% (95% CI 1.22, 16.40) higher FeNO.

CONCLUSIONS: Short-term exposure to precipitation was associated with lower FVC and higher FeNO in children with a history of asthma.

KEYWORDS: Lung function, fractional exhaled nitric oxide, climate change

O-OP-067 Air pollution, lung function and mortality: survival and mediation analyses in UK Biobank

Anna Guyatt[1], Samuel Cai[1,2,3], Danny Doiron[4,5], Martin Tobin[1,6], Anna Hansell[1,2,3]
[1]Department of Health Sciences, University of Leicester, Leicester, UK, [2]Centre for Environmental Health and Sustainability, University of Leicester, Leicester, UK, [3]National Institute for Health Protection Research Unit in Environmental Exposures and Health, University of Leicester, Leicester, UK, [4]Respiratory Epidemiology and Clinical Research Unit, Research Institute of the McGill University, Montreal, Canada, [5]Centre for Outcomes Research and Evaluation, Research Institute of the McGill University Health Centre, Montreal, Canada, [6]National Institute for Health Research, Leicester Respiratory Biomedical Research Centre, Glenfield Hospital, Leicester, UK

BACKGROUND AND AIM: Air pollution is associated with lung function, and both are associated with premature mortality and cardiovascular disease (CVD). We performed mediation analysis to estimate the proportion of the relationship between air pollution and mortality or incident CVD explained by the association between air pollution and forced expiratory volume in 1 second (FEV1).

METHODS: We used data from the UK Biobank cohort (aged 40-69 years at baseline 2006-2010) with 8-year follow-up to mortality (N=208,998) and incident CVD (N=199,577). Exposures to PM10, PM2.5, and NO2 were assessed by land-use regression modelling to estimate exposures at baseline. Lung function (Forced Vital Capacity (FVC), FEV1) was measured by spirometry and transformed to Global Lung Function Initiative z-scores. Adjusted Cox proportional hazards and causal proportional hazards mediation analysis models were fitted, stratified by smoking status.

RESULTS: Long-term exposures to PM2.5 and NO2 (but not PM10) were associated with incident CVD, with similar effect sizes between ever-smokers and never-smokers (Hazard Ratio (HR) per IQR in ever-smokers, PM2.5: 1.05 [95%CI: 1.01, 1.09]; NO2: 1.04 [95%CI 1.00, 1.09]). PM2.5 was associated with CVD mortality in ever-smokers only (HR per IQR: 1.15 [95%CI: 1.02, 1.30]. Positive but non-significant associations were found with all-cause mortality. FEV1 and FVC were associated with all-cause, CVD mortality and incident CVD. Point estimates for the mortality outcomes were larger in ever-smokers than never-smokers. Mediated proportions of the air pollution—all-cause mortality estimates driven by FEV1 were 18% [95%CI: 2%-33%] for PM2.5, and 27% [95%CI: 3%-51%] for NO2. The estimated mediated proportions for air pollution—incident CVD were 9% [95%CI: 4%-13%] for PM2.5 and 16% [95%CI: 6%-25%] for NO2.

CONCLUSIONS: Lower FEV1 may mediate the effect of PM2.5 and NO2 on mortality and incident CVD outcomes, with more pronounced effects for NO2 than for PM2.5.

KEYWORDS: air pollution; lung function; mortality; mediation analysis; cardiovascular;

O-OP-068 Effects of long-term exposure to particle components on inpatient asthma hospitalizations among children and adults in the U.S. using Bayesian kernel machine regression (BKMR)

Bryan N. Vu[1], Xinye Qiu[1], Joel Schwartz[1]
[1]*Harvard University, Boston, USA*

BACKGROUND AND AIM: Particulate matter has been documented to adversely affect asthma exacerbation. However, few studies have investigated the long-term exposure of particle components in conjunction with PM2.5 and ozone to assess their individual and additive effects.
AIM: We aim to utilize a Bayesian Kernel machine regression (BKMR) to assess the individual and join effects of air pollutants including 15 different particle components such as organic carbon (OC), elemental carbon (EC), copper (Cu), and zinc (Z), along with PM2.5 and ozone, on counts of inpatient asthma hospitalizations for children ages 0 to 18 and adults ages 19 to 64 years.

METHODS: Inpatient records were collected from the State Inpatient Databases which included hospitals from 12 U.S. states ranging in years from 2000 through 2016. We also included temperature from Daymet and variables from the U.S. census to control for socio-economic status. All variables were aggregated to the annual level.

RESULTS: We observed an increase of 0.44 (95%CI: 0.28,0.59), 1.24 (95%CI: 1.07,1.40), and 2.35 (95%CI: 2.17,2.52) in the number of children asthma inpatient hospitalizations each year at the 25th, 50th, and 75th percentiles of pollutant mixture, respectively. In adults, we observed an increase of 0.84 (95%CI: 0.63,1.04), 1.98 (95%CI: 1.78,2.19), and 3.27 (95%CI: 3.06,3.48) in the number of asthma inpatient hospitalizations each year at the 25th, 50th, and 75th percentiles of the pollutant mixture, respectively.

CONCLUSIONS: Our results indicate that long-term exposure to pollutant mixtures result in increased asthma hospitalizations in both children and adults, and daily measurements of particle components data is needed to assess short-term exposure.

KEYWORDS: Asthma, PM Components, PM2.5, Ozone, BKMR

O-OP-069 Short-term exposure to livestock farm emitted endotoxin and acute effects on lung function in non-farming residents

Myrna De Rooij[1], Hans Erbrink[2], Lidwien Smit[1], Inge Wouters[1], Gerard Hoek[1], Dick Heederik[1]
[1]Utrecht University, Utrecht, Netherlands, [2]Erbrink Stacks Consult, Oosterbeek, Netherlands

BACKGROUND AND AIM: Livestock-related air pollution is known for long-term effects on respiratory health in non-farming residents. Previous research indicated endotoxin as a relevant component in farm emissions. Acute respiratory effects of livestock-related air pollution has been shown for NH3 and PM10, but have not yet been studied for endotoxin. We aimed to assess associations between lung function and short-term exposure to livestock emitted endotoxin in co-pollutant models with NH3 and PM10.

METHODS: Spirometry data was used of 2494 persons living in a livestock dense area in 2014/2015. Residential exposure to farm emitted endotoxin during the week prior to spirometry was predicted by dispersion modelling. The model was applied to geo-located individual barns within 10km of each home address using provincial farm data and local hourly meteorological conditions. Regional week-average measured concentrations of NH3 and PM10 were obtained by monitoring stations. Lung function parameters were expressed in %-predicted value based on GLI-2012. Exposure-response relations were analysed with linear regression modelling.

RESULTS: Week-average endotoxin exposure was negatively associated with FVC, independently from NH3 and PM10 exposure. A decline in FVC of 1.1% was estimated, corresponding to an increase of endotoxin exposure from 10th to 90th percentile. Stratified analyses showed a larger effect (3.2% decline) for participants with current asthma and/or COPD. for FEV1 a significant negative association with week-average endotoxin exposure was observed, which did not remain after co-pollutant adjustment. FEV1/FVC and MMEF, showed no significant associations with week-average endotoxin exposure.

CONCLUSIONS: Results indicated an adverse effect on lung function of short-term endotoxin exposure for non-farming residents. These effects related to short-term exposure to endotoxin seemed stronger than long-term exposure effects as assessed in previous research. Co-pollutant modelling indicated the probable relevance of microbial emissions from livestock farms for public health besides chemical exposures.

O-OP-070 The impact of exposure measurement error on the estimated concentration-response relationship between long-term exposure to PM2.5 and mortality

Yaguang Wei[1], Xinye Qiu[1], Mahdieh Yazdi[1], Alexandra Shtein[1], Liuhua Shi[2], Jiabei Yang[3], Adjani Peralta[1], Brent Coull[1], Joel Schwartz[1]

[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Emory University, Atlanta, USA, [3]Brown University, Providence, USA

BACKGROUND AND AIM: Exposure measurement error is a central concern in air pollution epidemiology. As studies have been using ambient air pollution predictions as proxy exposure measures, the potential impact of exposure error on health effect estimates needs to be comprehensively assessed. We aim to generate wide-ranging scenarios to assess direction and magnitude of bias caused by exposure errors under plausible concentration-response relationships between annual exposure to fine particulate matter (PM2.5) and all-cause mortality.

METHODS: We use daily PM2.5 predictions at 1-km spatial resolution to estimate annual PM2.5 exposures and their uncertainties for ZIP Codes of residence across the contiguous US between 2000–2016. We consider scenarios in which we vary the error type (classical or Berkson) and the true concentration-response relationship between PM2.5 exposure and mortality (linear, quadratic, or soft-threshold–i.e., smooth approximation to "hard-threshold" model). In each scenario, we generate numbers of deaths using error-free exposures and confounders of concurrent air pollutants and neighborhood-level covariates, and perform epidemiological analyses using error-prone exposures under correct specification or misspecification of concentration-response relationship between PM2.5 exposure and mortality, adjusting for the confounders.

RESULTS: We simulate 1000 replicates of each of 162 scenarios investigated. In general, both classical and Berkson errors can bias the concentration-response curve towards the null. The biases remain small even when using three times the predicted uncertainty to generate errors, and are relatively larger at higher exposure levels.

CONCLUSIONS: Our findings suggest that the causal determination for long-term PM2.5 exposure and mortality is unlikely to be undermined when using high-resolution ambient predictions since estimated effect is generally smaller than the truth. The small magnitude of bias suggests that epidemiological findings are relatively robust against exposure error. The use of ambient predictions with finer spatial resolution will result in smaller bias.

KEYWORDS: ambient air pollution prediction, exposure measurement error, concentration-response model

O-OP-071 Long-term exposure to source-specific fine particles and mortality – a pooled analysis of 14 European cohorts within the ELAPSE project

Jie Chen[1], Gerard Hoek[1], Kees de Hoogh[2,3], Zorana Andersen[5], Tom Bellander[6,7], Barbara Hoffmann[10], Petter Ljungman[6,13], Ole Raaschou-Nielsen[8,11], Evangelia Samoli[4], Massimo Stafoggia[6,9], Maciej Strak[1,12], Gudrun Weinmayr[14], Kathrin Wolf[15], Bert Brunekreef[1], George Thurston[16]

BACKGROUND AND AIM: Past studies on the health effects of long-term particle component exposure were mostly analyzed on a constituent basis and have resulted in inconsistent findings. We aimed to assess mortality risks associated with source-specific fine particles (PM2.5) in a pooled European cohort of 323,782 participants.

METHODS: We estimated source-specific PM2.5 exposures through a combination of principal component analysis (PCA) of elemental composition on collected samples, and Europe-wide land-use regression models. Exposure to 2010 annual average concentrations of source-specific PM2.5 was assessed at baseline residential addresses. We applied Cox proportional hazards models to estimate mortality hazard ratios (HRs) adjusting for a variety of covariates at individual- and area-level. Besides the single-source analysis, we also performed a multi-source analysis where all identified source-specific PM2.5 were included in the model simultaneously.

RESULTS: We identified five source-related PM2.5 principal components: traffic, residual fuel oil combustion, soil, biomass & agriculture, and industry. In single-source analysis, all identified sources were significantly positively associated with increased natural mortality risks. In multi-source analysis, associations with all sources attenuated, but remained statistically significant with traffic, oil, and biomass & agriculture. The highest association per interquartile increase was observed for the traffic-PM2.5 (HR 1.06; 95% CI: 1.04, 1.08 per 2.86-µg/m3 increase) across five identified sources. On a per 1-µg/m3 basis, the residual fuel oil-related PM2.5 had the strongest association (HR 1.13; 95% CI: 1.05, 1.22), which is about ten times higher than that for the generic PM2.5 mass, suggesting a larger impact per unit mass by fossil fuel combustion derived particulate matter. Source-specific associations with cause-specific mortality were in general consistent with findings for natural mortality.

CONCLUSIONS: Fine particles from multiple sources were associated with increased mortality risks.

O-OP-072 Health effects of long-term exposure to ultrafine particles around Schiphol airport

Nicole Janssen[1], Maciek Strak[1], José Jacobs[1], Alina Nicolaie[1], Jurriaan Hoekstra[1], Danny Houthuijs[1]
[1]*National Institute for Public Health and The Environment, Bilthoven, Netherlands*

BACKGROUND AND AIM: Studies have shown elevated concentrations of ultrafine particles (UFP) near airports. Little is known about the health effects of UFP, in particular from aviation (UFP-aviation). We evaluated the health effects of long-term exposure to UFP-aviation around Schiphol Airport, The Netherlands.

METHODS: We investigated a wide range of health outcomes, by linking modelled annual average residential concentrations of UFP-aviation to individual data from existing health registries and surveys. We conducted two longitudinal cohort studies, on mortality and incidence of medication use, and a cross-sectional study using survey data on self-reported health and lifestyle factors. The cohort studies included all residents of 31 municipalities in a 45x50 km area around Schiphol Airport (~1.3 million adults). Survey data was available for 90,880 adults. Effect estimates were adjusted for individual and neighborhood-level covariates and expressed per 3500 pts/cm3 (~p5-p95 increment across the three studies). We performed a number of sensitivity analyses to evaluate the robustness of the results, including adjustment for co-pollutants and noise. The combination of different databases and designs allowed us to evaluate consistency of the findings both within and across studies.

RESULTS: We found no clear or consistent associations between UFP-aviation and health outcomes related to general health, respiratory health, neurodegenerative disease, or mental health. for cardiovascular health, we found robust positive associations with incidence of medication use for heart disease [HR 1.03 (95%CI 1.00-1.05)] and mortality for arrhythmia [HR 1.08 (95%CI 0.98-1.02)], but not for incidence of medication use for hypertension or (total or other subclasses of) cardiovascular mortality. In the survey data, we found robust significant associations with prevalence of hypertension and self-reported heart attack and consistently elevated (non-significant) associations with self-reported stroke.

CONCLUSIONS: Exposure to UFP from aviation around Schiphol Airport was associated with cardiovascular health outcomes.

KEYWORDS: ultrafine particles, aviation, air pollution, mortality, morbidity

O-OP-073 Long-term Exposure to PM2.5 Components and Mortality among Medicare Beneficiaries

Mahdieh Danesh Yazdi[1], Heresh Amini[2,1], Yaguang Wei[1], Edgar Castro[1], Liuhua Shi[3], Joel Schwartz[1]
[1]Harvard TH Chan School of Public Health, Boston, USA, [2]University of Copenhagen, Copenhagen, Denmark, [3]Rollins School of Public Health at Emory University, Atlanta, USA

BACKGROUND AND AIM: PM2.5 has been linked to numerous adverse health outcomes. However, PM2.5 is a mixture made of many components. Identifying which components are most toxic is important in identifying sources and implementing mitigation measures.

METHODS: We looked at mortality among Medicare participants 65 years of age or older from 2000 to 2018 in response to changes in annual mean levels of 15 PM2.5 components, namely: organic carbon, elemental carbon, nickel, lead, zinc, sulfate, potassium, vanadium, nitrate, silicon, copper, iron, ammonium, calcium, and bromine. Data on exposure was derived based on high-resolution, validated spatio-temporal models which were then aggregated to each beneficiary's residential ZIP code. We aggregated the number of deaths in each ZIP code and year and used the rate of deaths in each ZIP code per year as the outcome of interest. Covariates included demographic, temperature, socioeconomic status, and access-to-care variables. We used a weighted quantile sum approach with a quasi-Poisson distribution to analyze the joint effects of PM2.5 components on mortality. We also ran single-pollutant models for comparison. We further looked at the effects of the components when PM2.5 mass levels were at concentrations below 8 µg/m3, and effect modification by temperature, socioeconomic status, and race.

RESULTS: Each decile increase in the PM2.5 mixture was associated with a 1.4% (95% CI: 1.4%-1.5%) increase in the rate of mortality among Medicare participants. The components which contributed the greatest weight to the mixture were organic carbon, nickel, lead, and zinc. at PM2.5 mass concentrations below 8 µg/m3, the increase in the rate of mortality per decile increase in PM2.5 components was 1.5% (95% CI: 1.5%-1.6%).

CONCLUSIONS: Increases in the concentration of PM2.5 components were associated with an increased rate of mortality among Medicare beneficiaries.

BACKGROUND AND AIM: Within the ELAPSE project, we found associations between natural-cause mortality and long-term exposure to fine particulate matter (PM2.5) and nitrogen dioxide (NO2 at concentrations lower than current European limit values. The current aim was to characterize the health effects of these pollutants for selected cut-off values in a causal modelling framework.

METHODS: We analyzed data from the ELAPSE pooled cohort, consisting of eight well-characterized adult cohorts from six European countries (enrolled 1985–2005; follow-up 2011–15), and seven population-based administrative cohorts of adults from Belgium, Denmark, England, the Netherlands, Norway, Rome (Italy), and Switzerland (enrolled 2000–11; follow-up 2011–17). Annual mean PM2.5 and NO2 concentrations from Europe-wide land use regression models were assigned to baseline residential addresses. We applied Cox proportional hazards models using inverse probability weights (truncated to 1-99% of the distribution) for selected cut-off levels of the pollutants (PM2.5: 10, 12 and 15 μg/m³; NO2: 20 and 40 μg/m³) to obtain causal risk estimates of long-term PM2.5 and NO2 exposure on natural-cause mortality.

RESULTS: of 325,367 and 28,153,138 participants in the pooled and administrative cohorts, 47,131 and 3,593,741 participants deceased from natural causes, respectively. When increasing PM2.5 exposure from levels below to above 15 μg/m³, the HR for natural-cause mortality was increased for the pooled (HR 1.224; 95% CI 1.195–1.254) and the majority of administrative cohorts. for an increase of NO2 levels below to above 20 μg/m³, the HR was 1.068 (95% CI 1.045–1.092) for the pooled cohort and ranged from 0.987 (0.972–1.003) to 1.098 (1.076–1.120) for the administrative cohorts.

CONCLUSIONS: Causal modeling showed mostly consistent associations for changes in exposure to PM2.5 and NO2 with increases in natural-cause mortality in the pooled and the administrative cohorts.

O-OP-075 A nationwide study of air pollution on the NCD related morbidity in an unselected population

Henriette Thisted Horsdal[2,3,9], Jørgen Brandt[4], Christian Erikstrup[3,5,6], Signe Frederiksen[1,3], Camilla Geels[4], Ulla Hvidtfeldt[7], Karin Rosenkilde Laursen[1,3], Cecilie Schmidt Østergaard[2,3], Ole Raaschou-Nielsen[7], Clive Sabel[3,8], Jörg Schullehner[1,3,9], Carsten Bøcker Pedersen[2,3,9], Torben Sigsgaard[1,3,9]

[1]Dept of Public Health, Aarhus University., Aarhus, Denmark, [2]National Centre for Register-Based Research (NCRR), Department of Economics and Business Economics, Aarhus University., Aarhus, Denmark, [3]Danish Big Data Centre for Environment and Health (BERTHA), Aarhus University, Aarhus, Denmark, [4]Dept. of Environmental Science, Aarhus University, Roskilde, Denmark, [5]Dept. of Clinical Immunology, Aarhus University Hospital, Aarhus, Denmark, [6]Dept. of Clinical Medicine, Aarhus University, Aarhus, Denmark, [7]Danish Cancer Society, Copenhagen, Denmark, [8]Health Research Institute, University of Canberra, Canberra, Australia, [9]Centre for Integrated Register-based Research (CIRRAU), Aarhus University, Aarhus, Denmark

BACKGROUND AND AIM: Very few studies of the effect of air pollution on national mortality exist. Even fewer studies have investigated the effect of air pollution on non-communicable disease (NCD) in the total population. Thus, this study aims to elucidate the burden of air pollution on the morbidity of the total unselected population.

METHODS: The study cohort consisted of all individuals age 50 years or older who were alive and resided in Denmark on their 50th birthday or 1st January 2004, whichever came later (entry date) (N=2,872,957).
All hospital contacts for cancer, type 2 diabetes, asthma, Chronic Obstructive Pulmonary Disease (COPD), Alzheimer's-, Parkinson's-, ischemic heart -, and cerebrovascular-disease, between 1st January 2004 and 31st December 2016 were identified. We defined all NCD incident onsets as the date of first contact.
For each case and 5 randomly selected controls, we modelled pollution ($PM_{2.5}$, PM10, SIA, NO_2, O_3, BC, $PPM_{2.5}$, Sea salt, and SOA) as personal average concentrations over the 20 years prior to the incident date.
We estimated IRRs with 95% CIs for a fixed increase in air pollution assuming a linear exposure response relationship, adjusted for age, gender, calendar time, and individual as well as area-level socio-economic status.

RESULTS: We found IRR (95% CI) per 5 µg/m³ increase in $PM_{2.5}$ and per 10 µg/m³ increase in NO_2 to be highest for asthma, Alzheimer's disease, type 2 diabetes, and COPD, table 1.

	IRR $PM_{2.5}$	IRR NO_2
Type 2 Diabetes	1.47 (1.41 - 1.52)	1.27 (1.24 - 1.30)
Alzheimer's Dis	1.76 (1.67 - 1.87)	1.30 (1.26 - 1.35)
Asthma	1.88 (1.76 - 2.01)	1.47 (1.42 - 1.53)
COPD	1.34 (1.30 - 1.39)	1.36 (1.33 - 1.39)

In conclusion we find key NCDs are associated to $PM_{2.5}$ and NO_2 even in a low exposure environment.

KEYWORDS: Air pollution, non-communicable diseases, Nationwide, Cohort.

[1]Div. Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, USA, [2]University of California Berkeley, Berkeley, USA, [3]Battelle Memorial Institute, Columbus, USA

BACKGROUND AND AIM: In prior analyses in the California Childhood Leukemia Study (CCLS), house dust concentrations of the herbicide dacthal were associated with acute lymphoblastic leukemia (ALL). Here, we estimated ALL risk with concentrations of glyphosate in homes.

METHODS: The CCLS is a population-based case-control study of childhood leukemia (<15 years) in 35 counties in the Central Valley/San Francisco Bay area. Among those <8-years (no move since diagnosis/reference date), we collected dust (2001-2007) from the room where the child spent the most time while awake and measured >40 pesticides. Three-to-eight years later, we collected a second sample from non-movers. We used Ultra-Performance Liquid Chromatography Tandem Mass Spectrometry to measure glyphosate (µg/g dust) for 181 ALL cases and 225 controls and for 45 cases/controls with a second dust sample. Odds ratios (ORs) and 95% confidence intervals (CI) were calculated for quartiles of the concentration (first sample) using unconditional logistic regression. We computed the intraclass correlation coefficient (ICC), the within-to-between home variance ratio, and bias in a true OR=2.0 based on one dust sample.

RESULTS: Glyphosate was frequently detected (cases: 98%; controls: 99%). Higher concentrations in homes were associated with occupational pesticide exposure among family members, nearby agricultural use, treatment for lawn weeds and bees/wasps, and season. Increasing concentrations in the homes were not associated with ALL risk (adjusted ORQ4vs.Q1=0.8 CI 0.4-1.4). We observed similar null associations for boys and girls, Hispanics and non-Hispanic whites, and among those who resided in their home since birth (76 cases/117 controls) or age two (130 cases/176 controls). The ICC was 0.32 and the variance ratio was 2.13, which would result in a biased OR=1.25 based on one sample.

CONCLUSIONS: Glyphosate concentrations in homes were not associated with risk of childhood ALL. Due to large within-home temporal variability in concentrations, a modest association cannot be ruled out.

O-OP-077 Cumulative exposure to per- and polyfluoroalkyl substances from pregnancy to age 12 years and bone health in early adolescence: the HOME Study

Jessie Buckley[1], Jordan Kuiper[1], Bruce Lanphear[2], Antonia Calafat[3], Kim Cecil[4,5], Aimin Chen[6], Yingying Xu[4,5], Kimberly Yolton[4,5], Heidi Kalkwarf[4,5], Joseph Braun[7]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, USA, [2]Simon Fraser University, Vancouver, Canada, [3]Centers for Disease Control and Prevention, Atlanta, USA, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, USA, [5]University of Cincinnati College of Medicine, Cincinnati, USA, [6]University of Pennsylvania, Philadelphia, USA, [7]Brown University, Providence, USA

BACKGROUND AND AIM: Per- and polyfluoroalkyl substance (PFAS) concentrations during pregnancy and childhood have been inversely associated with childhood bone mineral density (BMD). Because bone remodeling is ongoing throughout childhood, cumulative PFAS exposure may be more strongly related to bone accrual than measures at a single time point. We estimated associations of cumulative exposure to PFAS and their mixture from pregnancy through early adolescence with BMD at age 12 years.

METHODS: We quantified concentrations of perfluorooctanoate (PFOA), perfluorononanoate, perfluorohexanesulfonate, and perfluorooctanesulfonate in maternal serum collected at 16 weeks gestation and child serum collected at ages 3, 8, and 12 years among 222 mother-child pairs in the HOME Study (Cincinnati, OH; enrollment 2003-2006). for each PFAS, we estimated cumulative exposure as the area under the curve (AUC) of each participant's serial PFAS concentrations. at age 12 years, we measured BMD at six skeletal sites and calculated height-, age-, sex-, and race-specific Z-scores. We estimated covariate-adjusted differences and 95% confidence intervals (CIs) in Z-scores per interquartile range (IQR) increase in the AUC of each PFAS using linear regression and the PFAS AUC mixture using quantile g-computation. We explored sex differences using sex-stratified models.

RESULTS: We observed associations of the PFOA AUC and the PFAS mixture AUC with lower BMD at the 1/3rd distal radius. Differences in 1/3rd distal radius BMD Z-scores per IQR AUC increase were -0.19 (95% CI: -0.39, 0.00) for PFOA and -0.20 (95% CI: -0.42, 0.01) for the PFAS mixture. Associations were stronger for males [e.g., PFOA: -0.31 (95% CI: -0.55, -0.06)] than females [-0.08 (95% CI: -0.36, 0.20)]. Patterns of association were similar but generally weaker and not statistically significant at other skeletal sites (β range: -0.05 to -0.15).

CONCLUSIONS: Cumulative exposure to PFOA and PFAS mixtures from gestation through early adolescence were inversely associated with BMD, particularly among males.

O-OP-078 Latent profiles of early life perfluoroalkyl substances exposure and body composition at age 12 years: The Health Outcomes and Measures of the Environment (HOME) Study

Jordan Kuiper[1], Joseph Braun[2], Shelley Liu[3], Bruce Lanphear[4], Kim Cecil[5], Yingying Xu[6], Kimberly Yolton[6], Heidi Kalkwarf[6], Aimin Chen[7], Jessie Buckley[1]

[1]Department of Environmental Health and Engineering, Johns Hopkins University Bloomberg School of Public Health, Baltimore, USA, [2]Department of Epidemiology, Brown University, Providence, USA, [3]Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York, USA, [4]Faculty of Health Sciences, Simon Fraser University, Vancouver, Canada, [5]Department of Radiology, Cincinnati Children's Hospital Medical Center, University of Cincinnati College of Medicine, Cincinnati, USA, [6]Department of Pediatrics, Cincinnati Children's Hospital medical Center, University of Cincinnati College of Medicine, Cincinnati, USA, [7]Department of Biostatistics, Epidemiology and Informatics, University of Pennsylvania Perelman School of Medicine, Philadelphia, USA

BACKGROUND AND AIM: We used latent profile analysis (LPA) to identify subpopulations with distinct perfluoroalkyl substances (PFAS) exposure trajectories during early life, and assess their associations with body composition at age 12 years.

METHODS: Among 390 mother-child dyads enrolled in the HOME Study, we quantified serum concentrations of perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), perfluorohexane sulfonate (PFHxS), and perfluorooctanesulfonic acid (PFOS) at least once during pregnancy (mothers) or at ages 3, 8, and 12 years (children). We measured child's weight and height to calculate body mass index (BMI) and performed dual energy x-ray absorptiometry to measure fat mass index (FMI) and lean body mass index (LBMI) at age 12 years, and calculated age- and sex-standardized Z-scores for all measures. We performed an LPA of all log2-transformed PFAS measures, across all timepoints, using full information maximum likelihood to account for missing exposure data, and used likelihood ratio tests to assess model fit. We estimated adjusted associations (95% confidence intervals) for profile membership with body composition measures among 239 singletons with at least one outcome measure, and adjusted for parity, duration of breastfeeding (weeks), household income, and average maternal serum cotinine and blood lead concentrations during pregnancy.

RESULTS: A two-profile model fit best, with ~50% of the analytic sample in each profile. Relative to profile 1, geometric means of PFAS concentrations in profile 2 were higher at all timepoints, particularly at the 3-year visit. In adjusted analyses, membership in profile 2 was associated with a -0.49 (-0.94, -0.03) lower height Z-score, -0.46 (-0.89, -0.02) lower BMI Z-score, -0.22 (-0.58, 0.08) lower FMI Z-score, and -0.74 (-1.23, -0.24) lower LBMI Z-score.

CONCLUSIONS: Using LPA to model longitudinal PFAS biomarkers, we found evidence that higher PFAS exposure during early life affects adolescent stature and body composition.

Lurie Children's Hospital of Chicago, Chicago, USA, [6]Cincinnati Children's Hospital Medical Center, Department of Pediatrics, University of Cincinnati College of Medicine, Cincinnati, USA, [7]Center for Pediatric Obesity Medicine, University of Minnesota Medical School, Minneapolis, USA, [8]Division of Gastroenterology, Hepatology and Nutrition, Children's Hospital Los Angeles, Los Angeles, USA, [9]Department of Pediatrics, Baylor College of Medicine, Houston, USA, [10]Department of Environmental Toxicology, University of California, Davis, USA

BACKGROUND AND AIM: Ubiquitous exposure to per- and poly-fluoroalkyl substances (PFAS) may increase the risk of metabolic- and liver- related disorders, especially in children. In a cohort of adolescents with severe obesity, we investigated the association of plasma concentrations of PFAS and alanine aminotransferase (ALT), a predominantly hepatocellular, cytoplasmic enzyme that is a validated biomarker of liver damage.

METHODS: Adolescents undergoing bariatric surgery were enrolled in the Teen-Longitudinal Assessment of Bariatric Surgery (Teen-LABS, 2007-2012) study. Plasma measurements of six PFAS (PFHxS, PFHpS, PFOS, PFOA, PFNA, PFDA) were determined using liquid chromatography-mass spectrometry. for each PFAS, we generated linear models of PFAS and ALT controlling for covariates. We additionally evaluated the association of PFAS and ALT among those with histologically validated nonalcoholic fatty liver disease (NAFLD, including nonalcoholic fatty liver [NAFL] or nonalcoholic steatohepatitis [NASH]) and those without NAFLD.

RESULTS: of those enrolled, 129 individuals had available measures of plasma-PFAS and ALT measured preoperatively. NAFL (n=47) or NASH (n=27) was present in 74 (57.4%) of the 129 participants with severe obesity. Among all participants, positive associations were observed between plasma concentrations of PFOA and ALT (ß=4.0, 95% CI: 0.87, 7.1) measured prior to bariatric surgery. Among those with NAFLD, a significant association between PFOA and ALT was observed (ß=5.2, 95% CI:0.3, 10.2), which was not observed among those without NAFLD (ß=0.48, 95% CI: -2.6, 3.5). No associations were observed between ALT and other PFAS.

CONCLUSIONS: Higher plasma PFOA concentrations were found to be associated with higher concentrations of ALT in a cohort of adolescents with severe obesity, and among the subset with NAFLD in particular PFAS may be an important toxicant contributing to NAFLD progression.

O-OP-080 Metals, Perfluoroalkyl Substance, and Birth Outcomes in the New Hampshire Birth Cohort Study: Beyond Single-Class Mixture Approaches

Gyeyoon Yim[1], Glen McGee[2], Lisa Gallagher[1], Emily Baker[1], Brian Jackson[3], Diane Gilbert-Diamond[1,4,5,6], Margaret Karagas[1], Megan Romano[1], Caitlin Howe[1]

[1]Department of Epidemiology, Geisel School of Medicine at Dartmouth, Lebanon, USA, [2]Department of Statistics and Actuarial Science, University of Waterloo, Waterloo, Canada, [3]Department of Earth Sciences, Dartmouth College, Hanover, USA, [4]Department of Pediatrics, Geisel School of Medicine at Dartmouth, Hanover, USA, [5]Dartmouth-Hitchcock Weight and Wellness Center, Department of Medicine at Dartmouth-Hitchcock Medical Center, Lebanon, USA, [6]Department of Medicine, Geisel School of Medicine at Dartmouth, Hanover, USA

BACKGROUND AND AIM: Exposure to either metal or perfluoroalkyl substance (PFAS) mixtures during pregnancy has been associated with adverse birth outcomes. However, little is known about the potential joint effects of these two classes of chemicals. We aimed to investigate the joint, index-wise, and individual impacts of metals and PFAS exposures on birth outcomes in a prospective cohort study using both established and novel mixture modeling approaches.

METHODS: Study participants included 537 mother-child pairs from the New Hampshire Birth Cohort Study (NHBCS). Primary analyses included metals measured in maternal toenails collected six weeks postpartum, reflecting exposures during the prenatal period. PFAS were measured in maternal plasma collected during pregnancy. Birth weight (BW) and head circumference (HC) at birth were abstracted from medical records. Joint and individual associations between in utero metals and PFAS exposures and birth outcomes were evaluated using Bayesian Kernel Machine Regression (BKMR) and employing the recently developed Bayesian Multiple Index Models (BMIM) to additionally assess index-wise associations and interactions among the chemical classes (i.e. toxic metals, essential elements, and PFAS).

RESULTS: After controlling for potential confounders, the metals-PFAS mixture was associated with a larger HC at birth. This was driven by Mn (posterior inclusion probability [PIP]: 0.95). Similar associations were identified for the essential element group (including Mn) using BMIM (indexPIP: 0.95; posterior mean for Mn: 0.69; 95% credible interval: 0.00, 0.99). The positive relationship between Mn (essential element group) exposure and HC was stronger at higher levels of Hg (toxic metal group), consistently shown in both BKMR and BMIM. Prenatal co-exposure to metals and PFAS was not associated with BW.

CONCLUSIONS: Our findings highlight the importance of simultaneously investigating multiple chemical classes in environmental mixture studies.

O-OP-081 Dietary folate intake modifies the relationship between per- and polyfluoroalkyl substances and immune markers among U.S. adolescents

Yu Zhang[1], Vicente Mustieles[2], Yi-Xin Wang[1], Yang Sun[1], Carmen Messerlian[1,3]
[1]Harvard T.h. Chan School of Public Health, Boston, USA, [2]University of Granada, Center for Biomedical Research (CIBM), Spain. Instituto de Investigación Biosanitaria Ibs GRANADA, Spain. Consortium for Biomedical Research in Epidemiology and Public Health (CIBERESP)., Spain, [3]Massachusetts General Hospital Fertility Center, Department of Obstetrics and Gynecology, Boston, USA

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) are considered immunotoxic. Previous research found that folate was negatively associated with PFAS exposure. This study aimed to examine if dietary folate intake modifies associations between PFAS concentrations and immune markers in U.S. adolescents.

METHODS: The study included adolescents (12-19 years) from the National Health and Nutrition Examination Survey cycles 2007-2016 with measured serum concentrations of four prevalent PFAS compounds and immune markers (antibodies to measles and rubella (N=322), total white blood cell (WBC) and neutrophil counts (N=1564)). Study population was divided into lower vs. upper folate groups by the median dietary folate equivalent intake, estimated as the average of two 24-hr dietary recalls. for each folate group, we used linear regressions and quantile g-computation (QGC) to estimate covariate-adjusted associations of individual PFAS and PFAS mixtures with immune markers.

RESULTS: We observed negative associations between several PFAS compounds and measles and rubella antibody levels only in the lower (i.e., below the median) folate group, but not in the upper folate group. for example, serum perfluorononanoic acid concentration was associated with decreased rubella antibody levels in the lower folate group (percent change: -10.97%, 95%CI: -18.03%, -3.29%), while not in the upper folate group (percent change: 1.76%, 95% CI: -20.14%, 30.09%). Consistently, some PFAS concentrations were associated with higher WBC and neutrophil counts, again only in the lower folate group (p for interactions ranged 0.01-0.21). QGC models showed consistent patterns of associations between PFAS mixtures and immune markers, among adolescents with lower folate intake.

CONCLUSIONS: Associations between some PFAS and PFAS mixtures and immune markers were found in adolescents whose folate intake was below the population median level. These findings may have important implications for using diet as a mitigating measure to reduce PFAS related deleterious immune effects.

KEYWORDS: PFAS, folate, immune, mitigation, U.S.

ORAL PRESENTATIONS SESSION 17: Reproductive outcomes and various environmental exposures (2)

O-OP-082 Fetal and infant death associated with short-term ozone exposure

Sandie Ha[1], Erika Ramsey[1], Sandy Rubio[1], Valerie Martinez[1], Sneha Ghimire[1]
[1]*University of California, Merced, Merced, USA*

BACKGROUND AND AIM: Air pollution is linked to adverse pregnancy outcomes such as preterm births, but few studies evaluated its acute impact on fetal and infant mortality. We evaluated short-term impacts of warm-season ozone and cold-season fine particulate matter <2.5 microns (PM2.5) exposures on the risk of fetal death (>20 weeks) and infant mortality (live birth to one year).

METHODS: This time-stratified case-crossover analysis includes 1,880 singleton fetal deaths (2007-2011) and 3,229 singleton infant deaths (2007-2015) from the San Joaquin Valley (SJV), California. Daily ozone and PM2.5 were estimated by the SJV Air Pollution Control District and geospatially linked to maternal zip code at birth. Critical exposure windows of interest included the day of death (lag 0) up to 14 days before (lag 14). Conditional logistic regression models estimated the odds ratio (OR) and 95% confidence intervals (CI) for each 5 units increase in pollutant.

RESULTS: In warm season (May-October), a 5-ppb increase in ozone was associated with a 7% (95% CI: 2%-13%) increased risk of fetal death and 6% (95% CI: 2%-10%) increased risk of infant death within two weeks. The estimates were generally consistent from lag 0 to lag 14 for both mortality outcomes, with evidence of slightly stronger estimates for fetal death compared to infant death during certain lags. During lag 7, a 5-ppb increase in ozone was associated with a 9% increased risk in fetal death (95% CI: 5%-14%) and a 4% (95% CI: 1%-7%) increased risk in infant death. No associations were observed for cold-season PM2.5.

CONCLUSIONS: Ozone exposure is positively associated with short-term risk of fetal and infant mortality in the warm season. Given the ubiquitous nature of air pollution, these associations merit further investigation. Meanwhile, efforts to minimize exposures among pregnant women may be warranted.

KEYWORDS: pollution, infant mortality, fetal death, stillbirth, pregnancy, mortality, ozone

O-OP-084 Association of vitamin D and green space. Results from the GINIplus & LISA birth cohorts

BACKGROUND AND AIM: While there is increased awareness and a growing body of evidence for beneficial health effects of green space surrounding the home, underlying mechanisms are not yet fully understood. Here, we investigate vitamin D as a potential pathway linking greenness and health, including cardiometabolic, respiratory and mental health.

METHODS: 25-hydroxyvitamin D (25(OH)D) was measured at ages 10 and 15 years in the German birth cohort studies GINIplus and LISA. Greenness was measured using the Landsat-derived Normalized Difference Vegetation Index (NDVI) in a 500m buffer surrounding the home. We applied linear and logistic regression models at both time points adjusted for month of examination, sex, study area, study, parental education and BMI (N_10Y=2504, N_15Y=2613). In additional analyses, physical activity, time spent outdoors, urbanicity, and vitamin D-related genes were investigated as potential effect modifiers.

RESULTS: A 2-standard-deviation (SD) increase in NDVI was significantly associated with increased 25(OH)D values at ages 10 and 15 years (β_10y=2.41nmol/l, p=<0.01; β_15y =2.03nmol/l, p=0.02. In stratified analyses, the association was strongly attenuated in participants spending more than 5h/day outside in summer (β_10y=-2.39nmol/l, p=0.165; β_15y =-1.07nmol/l, p=0.675), having a high physical activity level (β_10y=0.62nmol/l, p=0.637; β_15y =1.71nmol/l, p=0.296), taking supplements (β_10y=-2.05nmol/l, p=0.386; β_15y =0.10nmol/l, p=0.296), or examined during winter season (β_10y=0.86nmol/l, p=0.352; β_15y =0.07nmol/l, p=0.970). In a subset with genetic data, a significant gene-environment interaction of NDVI with CYP2R1, an upstream gene in 25(OH)D synthesis, was observed.

CONCLUSIONS: We observed robust associations between greenness measured by NDVI and 25(OH)D levels in children and adolescents independent of other confounders and additionally supported by the presence of a gene-environment interaction. Effects were stronger in those having lower vitamin D levels due to genetically reduced 25(OH)D synthesis or due to their covariate profile.

O-OP-085 Exposure to ambient temperature extremes during peri-conception and fecundability

Carrie Nobles[1], Pauline Mendola[2], Sunni Mumford[3], Neil Perkins[4], Enrique Schisterman[3]
[1]University of Massachusetts Amherst, Amherst, USA, [2]University at Buffalo, Buffalo, USA, [3]University of Pennsylvania, Philadelphia, USA, [4]National Institutes of Health, Bethesda, USA

BACKGROUND AND AIM: Ambient temperature extremes, particularly high heat, have been associated with adverse pregnancy outcomes; however, fecundity has been little examined. We assessed the relationship of exposure to ambient temperature extremes during the menstrual cycle with fecundability.

METHODS: A total of 1,228 women enrolled in the EAGeR trial at study sites in Salt Lake City, Denver, Buffalo, and Scranton, USA. Analyses evaluated exposure to ambient temperature, obtained from local weather monitors during the first two menstrual cycles of follow-up, and pregnancy, assessed at the end of each menstrual cycle using urinary hCG. Mean daily temperature and hours per day above and below set thresholds (≥20°C, ≥25°C, ≥30°C, and <0°C) were calculated during the follicular phase (menses through ovulation), luteal phase (ovulation through next menses), ovulation (-5 to 0 days before ovulation), and implantation (6 to 10 days post-ovulation). Cox proportional hazards models calculated the fecundability odds ratio (FOR). Models were stratified by warm (Apr. 1-Sep. 30) versus cold (Oct. 1-Mar. 31) season and adjusted for participant characteristics.

RESULTS: A total of 2,147 cycles were observed. During the warm season, a 2°C increase in temperature across the menstrual cycle was associated with a trend of lower fecundability, though estimates were imprecise. Each additional hour per day of temperatures ≥30°C during ovulation and implantation was associated with lower fecundability (FOR 0.86, 95% CI 0.73-1.00 and FOR 0.89, 95% CI 0.78-1.01, respectively). During the luteal phase, overnight (10pm-6am) temperatures ≥25°C were most strongly associated with lower fecundability as compared to daytime temperature extremes (FOR 0.52, 95% CI 0.28-0.98 for each additional hour per night ≥25°C). No clear associations were observed during the cold season.

CONCLUSIONS: Exposure to high temperatures ≥30°C during ovulation and implantation and overnight temperatures ≥25°C during the luteal phase may reduce chance of pregnancy.

KEYWORDS: Temperature, Pregnancy, Fecundability

O-OP-086 Admission to neonatal intensive care in relation to satellite-based estimates of NO2 and PM2.5 in the United States, 2018

Pauline Mendola[1], Timothy Canty[2], Carrie Nobles[3], Jing Nie[1]
[1]University at Buffalo, Epidemiology and Environmental Health, Buffalo, USA, [2]University of Maryland, College Park, USA, [3]University of Massachusetts Amherst, Amherst, USA

BACKGROUND AND AIM: Prior work noted an increased risk of admission to neonatal intensive care units (NICU) associated with acute exposure to air pollution in 12 clinical centers across the US, 2002-2008. We aimed to assess chronic exposure in relation to NICU admission.

METHODS: We obtained 2018 birth certificate data for the US, including all counties with populations greater than 100,000. County-level air pollution data were derived from OMI (NO2), a combination of the MISR, MODIS, and SeaWIFS instruments (PM2.5) and downscaled CMAQ model data were assembled for ozone. We conducted both single and multi-pollutant logistic models for season of birth (winter: December to February; spring: March to May; summer: June to August; and fall: September to November). Exposure was characterized in quartiles with the lowest as reference. The risk of NICU admission among singletons (n=3,644,722) in relation to air pollution exposure was assessed using logistic regression with generalized estimating equations (to account for correlated data within county) and adjusted for maternal age, race, education, body mass index and infant sex.

RESULTS: NICU admission (8.1% of births) was significantly increased in relation to NO2 during all seasons in both single and multi-pollutant models. Adjusted odds ratios (OR) ranged from 1.21 to 1.28 for the highest quartile of exposure in single-pollutant models and 1.13 to 1.27 in multi-pollutant models. The highest quartile of PM2.5 was significantly associated with increased NICU risk in winter (single-pollutant OR=1.27, multi-pollutant OR=1.13), spring (single-pollutant OR=1.14) and summer (single-pollutant OR= 1.12). The highest quartile of ozone was associated with increased risk in the single pollutant model for summer (OR= 1.15) and reduced risk in fall and winter; all multipollutant models for ozone were non-significant.

CONCLUSIONS: Consistent with our prior work, ambient air pollutants, particularly NO2 and PM2.5, are associated with increased risk of NICU admission.

O-OP-087 Traffic-related air pollution and pregnancy loss in Eastern Massachusetts, USA

Michael Leung[1], Sebastian T Rowland[2], Anna M Modest[3,4], Michele R Hacker[1,3,4], Stefania Papatheodorou[1], Joel Schwartz[1], Brent A Coull[1], Ander Wilson[5], Marianthi-Anna Kioumourtzoglou[2], Marc G Weisskopf[1]
[1]Harvard Th Chan School of Public Health, Boston, USA, [2]Columbia University Mailman School of Public Health, New York, USA, [3]Beth Israel Deaconess Medical Center, Boston, USA, [4]Harvard Medical School, Boston, USA, [5]Colorado State University, Fort Collins, USA

BACKGROUND AND AIM: Prior studies that have examined associations with pregnancy loss have mostly relied on losses identified by medical records (i.e., a subset of all losses). Analyzing live birth-identified conceptions (LBICs) —the difference between the total number of conceptions and those lost for a given time window— can tell us about associations with pregnancy loss (including those undetected). Using this approach, we estimate the association between prenatal nitrogen dioxide (NO2) —a traffic emissions tracer— and pregnancy loss in a Massachusetts-based cohort.

METHODS: We used data on 21,204 live births from pregnancies conceived in 2003-2015 and that had their prenatal care at Beth Israel Deaconess Medical Center (Boston, USA). We used a distributed lag model coupled with g-computation to estimate the additive association between weekly NO2 during pregnancy and LBICs adjusted for temperature and time trends.

RESULTS: The mean number of LBICs per conception week was 30 (standard deviation [SD]: 6.5). Weekly NO2 concentrations (mean: 23.3 parts per billion [ppb], SD: 6.5 ppb) were below the USEPA annual standards. Higher NO2 in gestational weeks 5-19 was associated with fewer LBICs, and the strongest association was in week 11. A 10-ppb higher NO2 exposure sustained throughout weeks 5-19 was associated with 6.0 (95% CI: 1.3, 11.3) fewer LBICs. That is, out of 30 LBICs per conception week, 6 would be lost if average NO2 was 10-ppb higher in weeks 5-19.

CONCLUSIONS: We show through the analysis of LBICs that higher prenatal NO2 was associated with pregnancy loss with the critical exposure window in weeks 5-19. The described approach can quantify the change in the number of pregnancy losses per conception week as it is simply the complement of the change in live births from that week's conceptions.

KEYWORDS: air pollution, traffic, nitrogen dioxide, pregnancy loss, distributed lag models

O-SY-131 Reproductive health diseases among South Korean workers: the propensity score matching approach

Kayoung Park[1]
[1]*Occupational Safety and Health Research Institute, Ulsan, Republic of Korea*

BACKGROUND AND AIM: To explore the reproductive health problems that may arise from occupational exposure of productive workers' workplace hazard.

METHODS: A retrospective investigation was made on the Korean health and Nutrition Examination Survey(KNHANES) of the workers with occupational classification code from 2007 to 2015 for adults ages 20 and 49 years. First, we compared workers classified as workers who KNHANES Korean Standard Classification of Diseases (KCD) reclassification codes 211 to 233 (including diseases such as urogenital system and infertility) and 234 to 244 (including pregnancy, childbirth, and puerperium) with those who did not classify reproductive health diseases reclassification codes (211 to 233, 234 to 244). Then, the relationship between reproductive health diseases and heavy metal exposure according to gender was investigated using the propensity score matching method.

RESULTS: In consideration of age, gender, body mass index, and occupation, a 1:1 optimal matching method was used to match workers with genital and non-reproductive diseases. Before matching, there were 2,135 men and 3,838 women. After matching, 42 men and 382 women were reproductive health workers, and 42 men and 382 women were non-reproductive health workers. As a result of estimation by the PSM method, there was no significant difference in male reproductive health disease and exposure to lead, mercury, and cadmium, and there was no difference even after matching. There were significant differences in female reproductive health disease and lead and mercury exposure, but lead did not show a significant difference after matching. Also, there was no significant difference between reproductive disease and cadmium exposure before and after matching.

CONCLUSIONS: It was confirmed that exposure to mercury in female workers was sensitive to reproductive health diseases. Exposure to mercury in the workplace should be more cautious.

O-OP-088 Misclassification bias in the assessment of gene-by-environment interactions

Marc Weisskopf[1], Michael Leung[1]
[1]*Harvard Th Chan School of Public Health, Boston, USA*

BACKGROUND AND AIM: Misclassification bias is a common concern in epidemiologic studies. While there is good understanding of misclassification influences on main effects, general results for understanding when misclassification bias may affect studies involving gene-environment interactions have not yet been developed. Here, we address this issue using the example of a case-control study in which cases over-report exposures (reduced specificity of exposure classification among cases).

METHODS: We derive equations to assess the influence of recall bias on the identification of gene-environment interactions. Then, we numerically illustrate these results through simulating a case-control study of 500 cases and 1000 controls while varying several input parameters: exposure E prevalence (π_E), strength of E main effect (OR_E), exposure specificity among cases (level of recall bias), and strength of the gene-environment interaction (OR_INT). The prevalence of the genetic factor G and disease among those with G and E=0 were simulated to be low (0.2 and 0.01, respectively). Each scenario was simulated 1000 times.

RESULTS: In the absence of a true gene-environment interaction, the estimate is unbiased despite even large recall bias of OR_E under the assumptions of gene-environment and gene-recall independence. Further, if a true gene-environment interaction exists, the observed gene-environment interaction will always be biased towards the null. If gene-environment dependence exists (assessable among controls), observed results place bounds on possible gene-environment interaction. In simulations, we show that the impact of recall bias was attenuated with higher π_E and stronger OR_E. for example, when π_E=0.6, OR_E=2, the true OR_INT=2.5, and specificity=0.6, the observed OR_INT=2.33 (low bias) and coverage was appropriate (0.93).

CONCLUSIONS: Gene-environment interactions can be identified even in the presence of misclassification bias under the assumptions of gene-environment and gene-recall independence. This can greatly aid environmental studies when exposure recall is questionable.

O-OP-089 mpower – An R package for power analysis of exposure mixture studies

Phuc Nguyen[1], Stephanie M. Engel[2], Amy H. Herring[1]
[1]Department of Statistical Science, Duke University, Durham, USA, [2]Department of Epidemiology, University of North Carolina Chapel Hill, Chapel Hill, USA

BACKGROUND AND AIM: Researchers need to estimate sample size and statistical power as part of good study planning. Closed-form power equations exist for simple hypothesis tests but not for more complex settings. Estimating power with Monte Carlo simulations is flexible and applicable to a large class of models. Out of a sufficiently large number of simulations, the proportion of times in which a hypothesis test is rejected can be used to estimate power. However, it is not straightforward to code a simulation for non-experienced programmers. To simplify this process, we present an R package for power analysis of studies involving mixtures, which can be easily modified for other complex data settings.

METHODS: This package runs power analysis given a data generative model and an inference model. It can estimate a data generative model that preserves dependence structures between variables given existing data (continuous, binary, or ordinal). If no data are available, it provides a framework for users to specify a valid sampling distribution. It interfaces with several existing and newly developed analysis strategies for assessing associations between exposures to mixtures and health outcomes. Users can generate power curves to assess the trade-offs between sample size, effect size, and power of a design. Advanced users can easily integrate customized data generative and inference models. It also implements parallelism.

RESULTS: We demonstrate the utility of the package through several examples using synthetic data and mixtures data from NHANES. Users with basic knowledge of R can conduct power analysis using Monte Carlo simulation in only a few lines of code.

CONCLUSIONS: We provide an R package that can simulate mixed-typed data with realistic dependence structures and allows researchers to easily conduct power analysis for a large class of models.

KEYWORDS: power analysis, R package, mixtures

O-OP-090 Mixtures, linear index models and log-transformation of exposure data

Thomas Webster[1], Marc Weisskopf[2]
[1]*Boston University School of Public Health, Boston, USA,* [2]*Harvard T.H. Chan School of Public Health, Boston, USA*

BACKGROUND AND AIM: Chemical exposure data are often right-skewed. Many investigators log-transform exposure data, but the rationale is often unstated. Here we investigate the potential impact for mixtures epidemiology, focusing on models that create linear indices such as wqs, qgcomp and BMIM (Bayesian Multiple Index Model). Such models have a long history in toxicology/pharmacology, providing an important intersection with mixtures epidemiology. Does log-transformation of exposure affect fits of linear index models and judgments about additivity and interaction?

METHODS: We use simulated data and concepts from toxicology/pharmacology. Linear index models of the form f[index], where f[.] is the exposure-response function and index is a weighted sum of exposures with non-negative weights, are essentially equivalent to the relative potency model of toxicology/pharmacology (where dose-response curves differ only in potency), a classic additive model.

RESULTS: Log-transformation of right-skewed exposure data is not required for regression modeling of outcome data. While it may help with potential influential points, there are other methods for examining this problem. It does change the shape of the assumed dose-response curve, although this may not matter much for single exposures. But log-transformation of exposure data alters the shape of isoboles, the level sets (contours) of response functions. for f[.] modeled as a Hill function, it changes the shape of isoboles describing the linear index model (parallel, negatively sloped straight lines) to curved, indicating interaction and implying that a linear index model would no longer properly fit the data.

CONCLUSIONS: Log-transformation of exposure data may cause artifacts in the modeling of mixtures data using index models.

O-OP-091 Integrating biological knowledge in Kernel-based analyses of environmental mixtures and health

Glen McGee, Ander Wilson, Brent Coull, Thomas Webster
[1]*University of Waterloo, Waterloo, Canada*

A key goal of environmental health research is to assess the risk posed by mixtures of pollutants. As epidemiologic studies of mixtures can be expensive to conduct, it behooves researchers to incorporate prior knowledge about mixtures into their analyses. This work extends the Bayesian multiple index model (BMIM), which assumes the exposure-response function is a non-parametric function of a set of linear combinations of pollutants formed with a set of exposure-specific weights. The framework is attractive because it combines the flexibility of response-surface methods with the interpretability of linear index models. We propose three strategies to incorporate prior toxicological knowledge into construction of indices in a BMIM: (a) constraining index weights, (b) structuring index weights by exposure transformations, and (c) placing informative priors on the index weights. We propose a novel prior specification that combines spike-and-slab variable selection with informative Dirichlet distribution based on relative potency factors often derived from previous toxicological studies. In simulations we show that the proposed priors improve inferences when prior information is correct and can protect against misspecification suffered by naive toxicological models when prior information is incorrect. Moreover, different strategies may be mixed-and-matched for different indices to suit available information (or lack thereof). We demonstrate the proposed methods on an analysis of data from the National Health and Nutrition Examination Survey and incorporate prior information on relative chemical potencies obtained from toxic equivalency factors available in the literature.

O-OP-092 Identifying drivers of vulnerability to heat and cold in European cities: an inverse probability weighting approach

Pierre Masselot[1], Jacopo Vanoli, Malcolm Mistry, Francesco Sera, Antonio Gasparrini, MCC Collaborative Research Network, EXHAUSTION Project
[1]*London School of Hygiene & Tropical Medicine, London, UK*

BACKGROUND AND AIM: Vulnerability to non-optimal temperature widely varies geographically, depending on local climatic, environmental, topologic and socio-economic characteristics. All these characteristics are highly interdependent and disentangling each one's individual contribution to modify the risk is a complex task. We aim to assess individual effect modification of multiple characteristics on temperature-mortality associations using a novel inverse probability weighting (IPW) approach.

METHODS: Using city-level exposure-response functions from 191 cities in Europe, we estimated effect modification from 22 city-level characteristic using a mixed-effects meta-regression model. for each characteristic, we first estimated generalized propensity scores using a gradient boosting algorithm, and then performed the meta-regression with IPW to reduce confounding by other correlated factors. for both heat and cold, we quantified the effect modification as the relative risk (RR) ratio for an interquartile increase in the vulnerability factor.

RESULTS: for cold, significant RR increases were found associated with the distance to the coast, with a ratio of 1.131 (95%CI: 1.024-1.248) for coastal versus inland cities. Higher vulnerability to cold was also found in hotter cities, with a RR ratio of 1.054 (95%CI: 1.025-1.084) associated with average annual temperature. for heat, significant increases in vulnerability were found associated with total population (RR ratio of 1.023, 95%CI: 1.010-1.035) and population density (1.040, 95%CI: 1.027-1.052), as well as the average NO2 level (1.105, 95%CI: 1.066-1.146).

CONCLUSIONS: The application of a novel IPW methodology embedded in a two-stage design can contribute to identify independent roles of local characteristics in modifying mortality risks associated with non-optimal temperature. Results show that vulnerability to heat and cold varies depending on different factors, for instance climatological and geographical features, versus population density and pollution, respectively. These findings can contribute to a better understanding of temperature-related risks and in the design of adaptation policies.

O-OP-093 Comparing effects of air pollution on mortality within the ELAPSE project under standard and causal approaches

Massimo Stafoggia[1,2], Antonis Analitis[3], Jie Chen[4], Sophia Rodopoulou[3], Kathrin Wolf[5], Xiao Wu[6], Francesca Dominici[6], Gerard Hoek[4], Bert Brunekreef[4], Evangelia Samoli[3]

[1]Lazio Region Health Service - Asl Roma 1, Rome, Italy, [2]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Athens, Greece, [4]Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, The Netherlands, [5]Institute of Epidemiology, Helmholtz Zentrum München GmbH - German Research Center for Environmental Health, Neuherberg, Germany, [6]Harvard T.H Chan School of Public Health, Cambridge, USA

BACKGROUND AND AIM: The association between long-term exposure to air pollution and mortality is well established using regression-based statistical approaches for covariate adjustment, however there is a limited number of observational studies using causal models.

METHODS: We analyzed data from the ELAPSE pooled cohort, consisting of eight adult cohorts from six European countries (enrolled 1985–2005; follow-up 2011–15), and one administrative cohort of adults in Rome (Italy) (enrolled 2001; follow-up 2015). Annual mean exposures to particulate matter < 2.5 µm (PM2.5) and nitrogen dioxide (NO2) were assigned to baseline residential addresses from Europe-wide land-use regression models. for each pollutant per cohort, we estimated generalized propensity scores (GPS), i.e., the conditional density of air pollution mean exposures given pre-exposure individual and area-level covariates. We subsequently fit Cox proportional hazard regression either by standard covariate adjustment or GPS adjustment via inverse-probability weighting (IPW), regression or matching.

RESULTS: of 325,367 and 1,263,712 participants in the pooled and Rome cohorts, 47,131 and 235,543 deceased from natural causes. When using standard regression-based Cox models, 5 and 10 µg/m3 increments in PM2.5 and NO2 were associated with hazard ratios (HRs) of 1.131 (95%CI: 1.107, 1.156) and 1.085 (95%CI: 1.069, 1.101) in the pooled cohort, and 1.066 (95%CI: 1.037-1.095) and 1.028 (95%CI: 1.019-1.036) in the Rome cohort, respectively. When we accounted for GPS via IPW or adjustment for GPS ventiles, results were comparable: for example, PM2.5 and NO2 HRs in the Rome cohort were 1.052 (95%CI: 1.017, 1.087) and 1.023 (95%CI: 1.012, 1.034) in models accounting for GPS via IPW. When we adjusted for GPS by matching, results were sensitive to hyper-parameter specifying pseudo-populations.

CONCLUSIONS: Long-term exposure to air pollution was associated with natural-cause mortality in both standard and causal models. Heterogeneous estimates across methods require further investigation.

KEYWORDS: Causal models, particulate matter, nitrogen dioxide, generalized propensity score.

O-OP-094 Nationwide geospatial analysis of county-level racial/ethnic composition and public drinking water arsenic and uranium

Irene Martinez-Morata[1], Benjamin C Bostick, Otakuye Conroy-Ben, Dustin T Duncan, Miranda R Jones, Maya Spaur, Kevin P Patterson, Seth J Prins, Ana Navas-Acien, Anne E. Nigra
[1]*Columbia University Mailman School of Public Health, New York, USA*

BACKGROUND AND AIM: There is no safe level of exposure to inorganic arsenic or uranium. Both metals are frequently detected in community water systems (CWSs), which serve 90% of the US population. Sociodemographic and regional inequalities in CWS arsenic and uranium have been identified at the CWS level, but nationwide studies of disparities by racial/ethnic composition are critically needed. We conducted the first nationwide geospatial assessment of the county-level association between racial/ethnic composition and CWS arsenic and uranium concentrations(2000-2011) for 2,631 conterminous counties.

METHODS: First, we assessed spatial autocorrelation via Moran's I and identified Local Indicators of Spatial Association(LISA) clusters. Then, we estimated the geometric mean ratio(GMR) of county-level CWS metal concentrations per 10% higher proportion of each racial/ethnic group via spatial lag regression, adjusting for population density, percentage of public water sourced from groundwater, household income, and education. We evaluated spatial non-stationarity in the strength and direction of the association via geographically weighted regression.

RESULTS: In fully adjusted nationwide models, for a 10% higher county proportion of Hispanic/Latino and American Indian/Alaskan Native residents, the geometric mean (95% CI) of CWSs metal concentration was higher by 6% (4, 8) and 7% (3, 11) respectively for arsenic, and by 17% (13, 22) and 2% (-4, 8), respectively, for uranium. Nationwide associations were inverse for non-Hispanic White and non-Hispanic Black residents, although geographically weighted regression identified a positive relationship between a higher proportion of non-Hispanic Black residents and CWS metals in the Midwestern and Southwestern US.

CONCLUSIONS: Racial/ethnic composition is associated with public drinking water metal concentrations, adding to a growing body of literature characterizing nationwide environmental and racial injustices in US public drinking water contaminants. Findings from this study can advance environmental justice initiatives by informing infrastructure investment and regulatory action to protect communities disproportionately exposed to major environmental contaminants.

KEYWORDS: arsenic, uranium, drinking water, racism, environmental justice.

O-OP-095 Addressing U.S. racial-ethnic inequality in air pollution exposure

Yuzhou Wang[1], Joshua Apte[2,3], Jason Hill[4], Cesunica Ivey[2], Regan Patterson[5], Allen Robinson[6], Christopher Tessum[7], Julian Marshall[1]

[1]Department of Civil and Environmental Engineering, University of Washington, Seattle, USA, [2]Department of Civil and Environmental Engineering, University of California, Berkeley, USA, [3]School of Public Health, University of California, Berkeley, USA, [4]Department of Bioproducts and Biosystems Engineering, University of Minnesota, St. Paul, USA, [5]Congressional Black Caucus Foundation, Washington, USA, [6]Department of Mechanical Engineering, Carnegie Mellon University, Pittsburgh, USA, [7]Department of Civil and Environmental Engineering, University of Illinois, Urbana, USA

BACKGROUND AND AIM: Air pollution levels in the US have decreased dramatically over the past decades, yet national racial-ethnic exposure disparities persist. It is unknown, however, how to systematically eliminate these disparities and even whether that outcome is possible.
AIM: To investigate three potential approaches to reducing or eliminating national exposure inequalities: (1) location-specific emission reductions (hereafter, "location"), (2) sector-specific emission reductions ("sector"; analogous to BACT-type approaches), and (3) requiring regions to meet a concentration standard ("NAAQS-like"). "Sector" and "NAAQS-like" approaches mirror aspects of current regulations; "location" would be a new regulatory approach.

METHODS: We use the InMAP (Intervention Model for Air Pollution) source-receptor matrix (ISRM) to estimate long-term average fine particulate matter (PM2.5) concentrations across the contiguous US caused by anthropogenic emissions. We employ the 2014 US EPA National Emission Inventory, grouped into 14 source sector and spatially allocated to 52,411 ISRM grid-cells. Emissions reductions for "location" and "sector" are an optimization to maximally reduce racial-ethnic disparities; "NAAQS-like" simulates successive, proportional emission-reductions in each region violating the hypothetical NAAQS.

RESULTS: The base level (no emission reduction) PM2.5 concentration disparity is 1.4 μg/m³ (20%) greater-than-average exposure for non-Hispanic Black people. Our results show that national inequalities in exposure can be eliminated with minor emission-reductions (optimal: ~1% of total emissions) if they target specific locations. In contrast, eliminating exposure inequality using existing regulatory strategies would require eliminating essentially all emissions (if targeting specific economic sectors) or is not possible (if requiring urban regions to meet concentration standards).

CONCLUSIONS: Our findings suggest that incorporating location-specific emissions reductions into the US air quality regulatory framework is crucial to eliminating long-standing national exposure disparities by race-ethnicity.

KEYWORDS: air pollution, environmental justice, fine particulate matter, air quality regulatory

O-OP-096 Socioeconomic disparities in aerosol pollutant exposure may be amplified by ultrafine particles despite declining PM2.5

Arshad Arjunan Nair[1], Gan Luo[1], Ian Ryan[1], Xinlei Deng[1], Shao Lin[1], Fangqun Yu[1]
[1]*State University of New York at Albany, Albany, USA*

BACKGROUND AND AIM: No study has investigated the spatiotemporal race-ethnicity and income disparities in ultrafine particles (UFP; ≤0.1μm) exposure, which is increasingly identified as a key subcomponent of $PM_{2.5}$-related health effects. This study aims to establish the importance of distinguishing UFP from $PM_{2.5}$ and quantify their race-ethnicity and income disparities in New York State (NYS).

METHODS: Exposure disparities among seven race-ethnicity groups (Hispanics of any race, non-Hispanic Asian, Black, Native, Pacific& White alone, and Other/Mixed) and by household income across spatial scales (state, county, county subdivision, NCHS urban levels) during the period 2013–2020 for UFP and $PM_{2.5}$, were quantified using Census data. A global three-dimensional chemical transport model with state-of-the-science aerosol microphysical processes were used to estimate UFP/$PM_{2.5}$ that have been validated extensively with observations.

RESULTS: The average New Yorker was exposed to 5171#·cm^{-3} UFP and 8.2μg·m^{-3} $PM_{2.5}$ in 2013–2020. Minority race-ethnicity groups were invariably exposed to greater daily aerosol pollution in NYS (+51–104% UFP & +1.9–32% $PM_{2.5}$). Race-ethnicity exposure disparities for $PM_{2.5}$ exposure have declined over time; by −6% from 2013–2017 and plateauing thereafter despite increasing $PM_{2.5}$. Crucially and in contrast, these disparities have persisted (+10%) for UFP exposure and even widened in periods of declining UFP. Economic status (median household income) by itself does not reveal significant exposure disparities. However, in tandem with race-ethnicity it uncovers these disparities as disproportionately magnified for socioeconomically disadvantaged subgroups.

CONCLUSIONS: $PM_{2.5}$ decline was associated with decline in race-ethnicity exposure disparities. which continued despite a post-2018 reversal in $PM_{2.5}$ trends. However, race-ethnicity UFP exposure disparities were much larger, more disproportionate, and increased or remained constant across various income strata and levels of urbanicity. The need to distinguish ultrafine (UFP) from fine ($PM_{2.5}$) aerosols is established through microphysical, geostatistical, and exposure assessment perspectives.

KEYWORDS: air pollution, ultrafine particles, particulate matter, environmental justice, socioeconomic status

O-OP-097 The Role of Exposure to Per- and Polyfluoroalkyl Substances in Racial/Ethnic Disparities in Hypertension: Results from the Study of Women's Health Across the Nation

Ning Ding[1], Carrie Karvonen-Gutierrez[1], Bhramar Mukherjee[2], Siobán Harlow[1], Sung Kyun Park[1,3]
[1]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, USA, [2]Department of Biostatistics, School of Public Health, University of Michigan, Ann Arbor, USA, [3]Department of Environmental Health Sciences, School of Public Health, University of Michigan, Ann Arbor, USA

BACKGROUND AND AIM: Racial/ethnic disparities in hypertension are a pressing public health problem. Most studies have focused on the role of socio-demographic and lifestyle factors. Little is known about the potential mediating role of per- and polyfluoroalkyl substances (PFAS), a pervasive environmental contaminant. We examined the extent to which racial/ethnic disparities in incident hypertension are explained by racial/ethnic differences in serum PFAS concentrations.

METHODS: We included 1,058 hypertension-free midlife women with serum PFAS concentrations in 1999-2000 from the multi-racial/ethnic Study of Women's Health Across the Nation with approximately annual follow-up visits through 2017. Causal mediation analysis was conducted using accelerated failure time models. Quantile-based g-computation was used to evaluate the joint effects of PFAS mixtures.

RESULTS: Black participants had higher risks of developing hypertension (relative survival: 0.58, 95% CI: 0.45-0.76) compared with White participants, which suggests racial/ethnic disparities in the timing of hypertension onset. The percent of this difference in timing that was mediated by PFAS was 8.2% (95% CI: 0.7-15.3) for perfluorooctane sulfonate (PFOS), 6.9% (95% CI: 0.2-13.8) for 2-(N-ethyl-perfluorooctane sulfonamido) acetate (EtFOSAA), 12.7% (95% CI: 1.4-22.6) for 2-(N-methyl-perfluorooctane sulfonamido) acetate (MeFOSAA), and 19.1% (95% CI: 4.2, 29.0 for PFAS mixtures). Significant differences in time to hypertension were not observed when comparing Japanese or Chinese to White participants. The percentage of the disparities in hypertension between Black versus White women that could have been eliminated if everyone's PFAS concentrations were dropped to the 10th percentile observed in this population was 10.2% (95% CI: 0.9-18.6) for PFOS, 7.5% (95% CI: 0.2-14.9) for EtFOSAA, and 17.5% (95% CI: 2.1-29.8) for MeFOSAA).

CONCLUSIONS: These findings suggest differences in PFAS exposure may be an unrecognized modifiable risk factor that partially accounts for racial/ethnic disparities in the timing of hypertension onset among midlife women.

KEYWORDS: Racial/ethnic disparities, hypertension, midlife women, mediation analysis, environmental justice

O-OP-098 Racial/ethnic disparities in phthalate metabolite mixtures and risk of preterm birth: A pooled study of 16 US cohorts

Barrett Welch[1,2], Alex P. Keil[3], Jessie P. Buckley[4], Stephanie M. Engel[3], Tamarra James-Todd[5], Ami R. Zota[6], Kelly K. Ferguson[1], and the Phthalates and Preterm Birth Pooled Study Team

[1]Epidemiology Branch, NIEHS, [2]School of Public Health, University of Nevada, Reno, [3]University of North Carolina at Chapel Hill, [4]Johns Hopkins Bloomberg School of Public Health, [5]Department of Environmental Health, Harvard T.H. Chan School of Public Health, [6]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University,

BACKGROUND AND AIM: Environmental phthalate exposure is ubiquitous in pregnancy and may be a risk factor for preterm delivery. In the United States (US), large racial/ethnic disparities in phthalate exposure may be an important contributor to the racial/ethnic disparities in preterm birth. Utilizing the largest study of phthalates and preterm birth to date, we 1) investigated racial/ethnic disparities in phthalate exposure and 2) estimated how racial/ethnic disparities in preterm birth might improve by equitably reducing phthalate exposure.

METHODS: We pooled individual-level data from 16 US cohorts (N=6,045) on 9 prenatal urinary phthalate metabolites. We categorized participant race/ethnicity as non-Hispanic white (43%), non-Hispanic Black (13%), Hispanic/Latina (38%), or Other (5%; based on sparsity of sub-categories). We investigated confounder-adjusted differences in urinary phthalate metabolite concentrations by maternal race/ethnicity. We used g-computation to estimate changes in preterm birth by race/ethnicity after simultaneous, racial/ethnic-specific reductions in the concentration of all 9 phthalate metabolites. Our hypothetical intervention eliminated racial/ethnic disparities in the distributions of metabolite concentrations.

RESULTS: for 8 of the 9 phthalate metabolites, concentrations were highest among non-Hispanic Black participants and lowest among non-Hispanic whites. Covariate-adjusted differences in metabolite concentrations were most pronounced for monoethyl phthalate and mono-isobutyl phthalate, which were 143% (95% confidence interval [95CI]: 114%, 175%) and 80% (95CI: 66%, 95%) higher among non-Hispanic Black compared to non-Hispanic white participants, respectively. The hypothetical intervention to simultaneously reduce concentrations of metabolites by race/ethnicity, principally among non-white racial/ethnic groups, showed significant reductions in preterm birth. for non-Hispanic Black participants, the pre- and post-intervention probability of preterm birth was 117 (95CI: 94, 141) and 88 (95CI: 61, 118) preterm per 1,000 live births, respectively, representing a relative reduction of 25% (95CI: 16%, 35%).

CONCLUSIONS: Considerable differences in exposure to phthalates could play an important role in the racial/ethnic disparities in preterm birth within the US.

O-OP-099 Exposure to lead, cadmium, mercury and arsenic among Asian children and adolescents in the United States: NHANES 2015-2018

Lanxin Song[1], Ondine von Ehrenstein[1]
[1]*University of California Los Angeles, Los Angeles, USA*

BACKGROUND AND AIM: Toxic metals adversely influence child development at low concentrations. Higher concentrations of heavy metals were reported among Asians compared to other racial/ethnic groups in earlier NHANES cycles (2011–2014). We examined whether Asian children/adolescents had higher concentrations of several metals compared to other racial/ethnic groups in recent NHANES cycles, as well as potential mediation by fish/shellfish consumption.

METHODS: Data from 5,293 participants (1-19 years) of NHANES cycles 2015–2018 were included with blood measurement of lead (Pb), cadmium (Cd), mercury (Hg) and methylmercury (MeHg), and urinary arsenic (As), monomethylarsonic acid (MMA) and dimethylarsinic acid (DMA). Survey-weighted linear models were assessed for differences in log-transformed metals concentrations between Asians and non-Asians and potential effect measure modification by SES factors. A model-based mediation analysis was conducted to assess the average causal mediation effect of recent fish/shellfish consumption.

RESULTS: Asian children/adolescents had higher blood/urine concentrations of Pb, Cd, Hg, MeHg, As, MMA and DMA, respectively, compared to non-Asians or whites, adjusting for age, sex, BMI-Z score, birthplace, parental education level, family income level and survey cycle. Interactions were estimated between being Asian with parental education with more pronounced associations between lower parental education and higher concentrations of blood Pb, Cd, Hg and MeHg. We estimated mediating effects of recent fish and shellfish consumption for Hg and MeHg exposure in Asians relative to non-Asians; proportions of the total differences mediated were 11% by fish and 7% by shellfish and more pronounced comparing Asians to whites only.

CONCLUSIONS: Asian children and adolescents have higher exposure to several heavy metals and their parent's education may play a more critical role than among non-Asians. Dietary consumption of fish and shellfish may explain some of the elevated exposure. Preventions efforts should be targeted to these potentially higher risk families.

KEYWORDS: NHANES, heavy metals, Asian, children, adolescents, SES, seafood, mediation

ORAL PRESENTATIONS SESSION 20: Exposure assessment, measurement error, uncertainty and correction methods

O-OP-100 Exposure assessment of acetaminophen use in pregnancy: a study comparing self-reported intake with maternal and newborn biomarker measures

Zeyan Liew[1], Pengfei Guo[1], Jingyuan Xiao[1], Clary Clish[2], Amy Deik[2], Hong Yan[1], Andrew DeWan[1], Caroline Johnson[1]
[1]Yale School of Public Health, New Haven, USA, [2]The Broad Institute, Cambridge, USA

BACKGROUND AND AIM: Acetaminophen (APAP) is the most commonly used medication during pregnancy. Increasingly, studies have reported potential adverse associations between maternal prenatal use of APAP and offspring asthma, adverse reproductive outcomes, and neurodevelopmental disorders. However, most studies have relied on self-reported maternal exposure which has the potential for exposure misclassifications. We conducted this study to compare maternal self-reported APAP intake and three acetaminophen metabolites measured in urine collected during pregnancy and umbilical cord serum samples.

METHODS: We used maternal interview data and biospecimens from the Nutrition in Pregnancy cohort of 2291 pregnant women recruited from Connecticut and Western Massachusetts during 1996-2000. We selected three exposure groups including 10 mothers who reported frequent intake (14 days+) of APAP in the first 3 months of pregnancy, 10 who reported frequent intake in the last 3 months of pregnancy, and 10 who reported never using APAP in these two periods from the cohort. We analyzed three APAP metabolites (parent compound, acetaminophen glucuronide, and 3-(N-acetyl-l-cystein-S-yl)-acetaminophen) levels in the maternal urine (avg. 24 gestational weeks) and the umbilical cord serum samples.

RESULTS: The parent APAP compound and 3-(N-acetyl-l-cystein-S-yl)-acetaminophen) were detected in all urine and serum samples analyzed (100%), while acetaminophen glucuronide was less detectable in the cord serum (40% vs. 100% in urine). APAP metabolites in maternal urine and cord serum were correlated (r=0.43-0.70) within mother-child pairs. All three urinary and cord serum APAP metabolite levels were more strongly correlated with the reported number of days of APAP intake in late pregnancy (r=0.57-0.73; p-values <0.03, rank tests), and less with early pregnancy intake (r=0.18-0.34; p-values 0.21-0.60, rank tests).

CONCLUSIONS: Our findings suggest detailed intake data collected in maternal interviews is an efficient and valid measure to indicate exposure to APAP in pregnancy, while biomarker measures can be used to represent a specific exposure period of interest.

O-OP-101 Development of spatiotemporal high-resolution temperature data for São Paulo, Brazil; a valuable resource for epidemiologists

Aina Roca-Barcelo[1], Monica Pirani[1], Frédéric B. Piel[1,2], Adelaide C. Nardocci[3], Paolo Vineis[1], Daniela Fecht[1,4]
[1]MRC Centre for Environment and Health, Department of Epidemiology and Biostatistic, Imperial College London, London, UK, [2]National Institute for Health Research Health Protection Research Unit in Environmental Exposures and Health, Imperial College London, London, UK, [3]Department of Environmental Health, School of Public Health, University of São Paulo, São Paulo, Brazil, [4]National Institute for Health Research Health Protection Research Unit on Chemical and Radiation Threats and Hazards, Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, London, UK

BACKGROUND AND AIM: Most studies investigating the temperature-mortality association in cities rely on temperature recordings from few meteorological stations or models at coarse spatial resolution, implicitly assuming an homogenous spatial distribution across. Evidence from urban heat island studies, remote sensing data, and atmospheric and physical sciences suggest this assumption does not hold. Overlooking the spatial variability of temperature exposure in cities may lead to biased epidemiological findings and limit our ability to identify areas of high risk. Herein, we aim to develop an open-access dataset of daily ambient temperature at 500 meters resolution for the municipality of São Paulo (2015-2020).

METHODS: We obtained daily mean temperature data from 60 ground stations within the city and used spatiotemporal regression kriging to predict temperature at unmeasured locations. This technique uses multiple linear regression to model the spatiotemporal trend in temperature, and spatiotemporal kriging to model the regression residuals spatiotemporal autocorrelation. for the multilinear regression, we used several earth observation products including data relating to topography, the built environment and atmospheric processes, as explanatory covariates. The regression residuals were modelled by fitting a sum-metric spatiotemporal variogram model. We validated the model using a leave-one-out and 5-fold cross-validation.

RESULTS: of the 60 monitoring stations, 36 had data >75% valid data. Temperature records showed some spatial heterogeneity (interstation standard deviation: 1.4° C), supporting the need for spatially resolved temperature data. of all covariates used in the multilinear regression model, remotely sensed land surface temperature was the best predictor. Any residual variability was modelled through spatiotemporal kriging. Validation using R2 and root-mean-square-error indicators is ongoing.

CONCLUSIONS: This dataset provides epidemiologists with a unique opportunity to investigate exposure to daily mean temperature in São Paulo at high spatio-temporal resolution, and to identify areas of high risk for certain health outcomes, e.g., mortality, over time and space.

O-OP-102 Comparison of weather station and climate reanalysis data for modelling temperature-related mortality

Malcolm Mistry[1], Rochelle Schneider[1,2], Antonio Gasparrini[1], Pierre Masselot[1], Ana M. Vicedo-Cabrera[3], Group JRC[4], Group MCC[5]

[1]Department of Public Health, Environments and Society, London School of Hygiene & Tropical Medicine (LSHTM), London, UK, [2]Forecast Department, European Centre for Medium-Range Weather Forecast (ECMWF), Reading, UK, [3]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, [4]The Joint Research Center (JRC), European Commission, Ispra, Italy, [5]Multi-Country Multi-City (MCC) Collaborative Research Network, London, UK

BACKGROUND AND AIM: Epidemiological analyses of health risks associated with non-optimal temperature are traditionally based on ground observations from weather stations. Though generally considered representative of the actual ambient conditions and individual's exposure, their broader application in environmental epidemiology is often constrained by inhomogeneous records and the sparse density of meteorological stations. Climate reanalysis represents an alternative option that provide complete spatio-temporal exposure coverage, and yet are to be systematically explored for their suitability in assessing temperature-related health risks at a global scale.
AIM: The aim of the study is to provide the first comprehensive analysis over multiple regions to assess the suitability of the most recent generation of reanalysis datasets for health impact assessments and evaluate their comparative performance against traditional station-based data.

METHODS: We applied the well-established time-series analyses with quasi-Poisson regression (with distributed lag non-linear models and multivariate meta-regression) to model the location specific temperature-mortality associations, across 612 cities within 39 countries over the period 1985–2019, covering a wide range of climates and including low- and middle-income countries. Briefly, we first systematically compared the correlation between daily temperature series derived from ground station observations and ERA5-Land/ERA5 reanalysis, then we evaluated differences in estimated exposure-response functions of temperature-mortality relationships, and finally we compared their performance using fit statistics.

RESULTS: Our findings show that reanalysis temperature from the last ERA5 products generally compare well to station observations, with similar non-optimal temperature-related risk estimates. However, the analysis offers some indication of lower performance in tropical regions, with a likely underestimation of heat-related excess mortality.

CONCLUSIONS: Reanalysis data represent a valid alternative source of exposure variables in epidemiological analyses of temperature-related risk. The consistent spatio-temporal coverage also makes it attractive for quantifying population attributable fractions, an indicator important for health planners and policy makers.

KEYWORDS: mortality, temperature, reanalysis, ERA5-Land, distributed lag models.

O-OP-103 Measurement Error Correction for Ambient PM2.5 Exposure Using Stratified Regression Calibration: Effects on All-Cause Mortality

Yijing Feng[1], Yaguang Wei[1], Xinye Qiu[1], Brent Coull[1], Joel Schwartz[1]
[1]*Harvard T.H. Chan School of Public Health, Boston, USA*

BACKGROUND AND AIM: We define measurement error as the difference between actual and predicted PM2.5 concentrations near subjects' home. Previous studies on the impact of measurement error for PM2.5 were mostly simulation studies or used single regression calibration model to correct for measurement error. However, the relationship between actual and error-prone
PM2.5 concentration may vary by time and region. Here we aim to correct the measurement error of PM2.5 predictions using stratified regression calibration and investigate how the measurement error biases the association between PM2.5 and mortality.

METHODS: The "gold-standard" measurements of PM2.5 were daily monitoring data from 2,156 sites across the United States between 2000-2016. The error-prone measure was PM2.5 estimated by ensemble machine learning models. PM2.5 data was stratified by seasons, elevation and census divisions. We regressed daily monitoring PM2.5 on modeled PM2.5 from the same location and time using model below by strata.
E(PM2.5monitoring)= β0j+ β1j PM2.5modeled+εj
Calibrated PM2.5 was calculated with stratum-specific calibration parameters β0j and β1j for each ZIP code and season and aggregated to annual level. Association between calibrated and error-prone annual PM2.5 and all-cause mortality were estimated using mortality data from Medicare beneficiaries with Quasi-Poisson regression models adjusting for demographics, socioeconomic status, access to healthcare, population density and meteorologic factors.

RESULTS: Across 72 strata, the median of β0 and β1 were 0.40 (25% 0.06, 75% 0.95) and 0.93 (25% 0.83, 75% 0.98). From calibrated and error-prone PM2.5 data, we estimated that each 10μg/m3 increase in PM2.5 was associated with 12.2% (95%CI 11.9-12.4) and 11.6% (95%CI 11.4-11.9) increase in the probability of death among Medicare beneficiaries, conditional on confounders.

CONCLUSIONS: Regression calibration parameters of PM2.5 varied by season and region. Using error-prone measure of PM2.5 underestimated the association between PM2.5 and all-cause mortality. Modern exposure models produce relatively small bias.

KEYWORDS: PM2.5; measurement error

O-OP-104 Addressing Geographic Uncertainty: Greenness and Depression Incidence in a Prospective Cohort Study of US Women

Charlotte Roscoe[1,2], Li Xu[3,4], Jooyoung Lee[3,4], Donna Spiegelman[3,4,5], Jaime E. Hart[1,2], Francine Laden[1,2], Molin Wang[3,4], Peter James[6]

[1]Department of Environmental Health and Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, USA, [4]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [5]Department of Biostatistics, Center on Methods in Implementation and Prevention Science, Yale School of Public Health, New Haven, USA, [6]Division of Chronic Disease Research Across the Lifecourse (CoRAL), Department of Population Medicine Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA

BACKGROUND AND AIM: Geographic uncertainty, including uncertainty in the selection of a spatial scale for exposure, may bias health effect estimates. for example, studies showed protective associations of residential greenspace exposure with depression, but there is no standardized approach for selecting the appropriate buffer sizes to examine this association. By applying a novel statistical approach, we aimed to empirically identify buffer sizes and simultaneously report effect estimates in a longitudinal analysis of greenness and depression.

METHODS: We followed Nurses' Health Study cohort participants who were free of depressive symptoms at baseline (2000) and who reported doctor-diagnosed depression, antidepressant use, and important depression risk factors on biennial questionnaires from 2000 to 2016 (n = 41,945). We used high-resolution (30m x 30m) Landsat data to assess annual average greenness in multiple buffer sizes around participants' residential addresses: 90m, 150m, 270m, 510m, 750m, 990m, 1230m, 1500m, and 2100m. We used penalized Cox regression to estimate regression coefficients to identify buffers within which greenness was associated with risk of depression. Specifically, we modeled NVDI effects as a function of buffer size using B-splines, while adopting a group bridge penalty to identify relevant buffers, with an additional penalty to smooth the effect estimate curves.

RESULTS: Over 449,139 person-years follow-up, 5,454 incident cases occurred. Greenness was protectively associated with incident depression after adjusting for confounders. Our penalized approach identified greenness within the buffer distance of 150m around the residential address as the most relevant for depression incidence, with a 2% decrease in depression risk for each 0.1 increase in NDVI (95% CI 0.3%, 3.6%) within the 150m empirically identified buffer area.

CONCLUSIONS: To account for geographic uncertainty in assessing the impact of greenness on incident depression, we applied a novel statistical approach to identify that NDVI exposure within 150m was associated with lower risk of depression.

O-OP-105 Geomagnetic Disturbances Reduce Heart Rate Variability in the Normative Aging Study

Carolina Zilli Vieira[1], Eric Garshick[2], Kelly Chen[1], Joel Schwartz[1], Man Liu[1], Pantel Vokonas[2], Petros Koutrakis[1]
[1]Harvard University, Boston, USA, [2]VA Normative Aging Study, Veterans Affairs Boston Healthcare System and the Department of Medicine, Boston University School of Medicine, Boston, MA, USA, Boston, USA

Solar and geomagnetic activity have been linked to increased cardiovascular (CVD) events. We hypothesize that heart rate variability (HRV) may be the biological mechanism between increased CVD risk and intense geomagnetic disturbances (GMD). To evaluate the impact of intense GMD on HRV in 618 male participants enrolled in the Normative Aging Study (Greater Boston Area), we performed repeated-measures using mixed-effects regression models. We evaluated two HRV outcomes: the square root of the mean squared differences of successive normal-to-normal intervals (r-MSSD) and the standard deviation of normal-to-normal heartbeat intervals (SDNN). We used data on global planetary K-Index (Kp) from middle latitudes as a GMD parameter from the NOAA. We found a near immediate effect of higher Kp on reduced HRV for exposures from 6 to 24 hours prior to electrocardiogram recording. A 75th percentile increase in 15-hour Kp prior the examination was associated with a -1.5% change in r-MSSD (95% CI: -2.3%, -0.6%, p-value = 0.0008) and a -0.8% change in SDNN (95% CI: -1.3%, -0.2%, p-value = 0.007). The associations remained similar after adjusting the models for air pollution, over the exposure window prior to the event. This is the first study to demonstrate the potential adverse effects of intense GMD on reduced heart rate variability in a large epidemiologic cohort over an extended period, which may have important clinical implications.

ORAL PRESENTATIONS SESSION 21: Air pollution and cancer

O-OP-106 Long term exposure to air pollution and kidney parenchyma cancer – Effects of Low-level Air Pollution: a Study in Europe (ELAPSE)

BACKGROUND AND AIM: Particulate matter (PM) is classified as a group 1 human carcinogen. Previous experimental studies suggest that particles in diesel exhaust induce oxidative stress, inflammation and DNA damage in kidney cells, but the evidence from population studies linking air pollution to kidney cancer is limited.

METHODS: We included six cohorts from the "Effects of low level air pollution: A study in Europe" (ELAPSE) collaboration. We developed hybrid models combining monitoring and land use data, satellite observations, and dispersion model estimates for nitrogen dioxide (NO2), fine PM (PM2.5), black carbon (BC), warm season ozone (O3), and eight elemental components of PM2.5 (copper, iron, potassium, nickel, sulfur, silicon, vanadium, and zinc) to assign exposure to participants' residential addresses. We defined kidney parenchyma cancer according to the International Classification of Diseases 10th and 9th Revision codes C64 and 189.0. We applied Cox proportional hazard models adjusting for potential confounders at the individual and area-level.

RESULTS: A total of 302,493 persons were included in the analyses. During a total of 5,497,514 person-years of follow-up (mean 18.2 years), 847 incident cases of kidney parenchyma cancer occurred. Median (5–95%) exposure levels of NO2, PM2.5, BC and O3 were 24.1 µg/m3 (12.8–39.2), 15.3 µg/m3 (8.6–19.2), 1.6 10-5/m (0.7–2.1), and 87.0 µg/m3 (70.3–97.4), respectively. The results of the fully adjusted linear analyses showed a hazard ratio (95% confidence interval) of 1.03 (0.92, 1.15) per 10 µg/m³ NO2, 1.04 (0.88, 1.21) per 5 µg/m³ PM2.5, 0.99 (0.89, 1.11) per 0.5 10−5m−1 BC, and 0.88 (0.76, 1.02) per 10 µg/m³ O3. The analyses did not show associations between any of the elemental components of PM2.5 and cancer of the kidney parenchyma.

CONCLUSIONS: We did not observe evidence of an association between long-term ambient air pollution exposure and incidence of kidney parenchyma cancer.

O-OP-108 Impacts of long-term PM2.5 exposure on Endocrine related cancer patients in South Korea

Ejin Kim[1], Insung Song[2], Young Joo Park[3], Kyungho Choi[1], Minjoo Kim[4], Shinje Moon[5], Whanhee Lee[6], Student Dohoon Kwon[2], Student Jeongmin Moon[2], Student Jinah Park[2], Student Cinoo Kang[2], Jieun Min[2], Jieun Oh[2], Ho Kim[1,7]

[1]Institute of Health and Environment and Graduate School of Public Health, Seoul National University, Seoul, Republic of Korea, [2]Department of Public Health Science, School of Public Health, Seoul National University, Seoul, Republic of Korea, [3]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea, [4]Department of Internal Medicine, Healthcare Research Institute, Seoul National University Hospital Healthcare System Gangnam Center, Seoul, Republic of Korea, [5]Division of Endocrinology and Metabolism, Department of Internal Medicine, Hallym University Kangnam Sacred Heart Hospital, Hallym University College of Medicine, Republic of Korea, [6]Departmemt of Environmental Medicine, College of Medicine, Ewha Womans University, Republic of Korea, [7]Institute of Sustainable Development & Department of Public Health Science, School of Public Health, Seoul National University, Republic of Korea

BACKGROUND AND AIM: In previous studies, endocrine tumors reported to be associated with endocrine disrupting chemicals (hereafter, EDCs). Among EDCs, air pollution is a carcinogen classified as an environmental factor. We investigated the relationship between air pollution and endocrine tumors.

METHODS: National health insurance recipients are subject to regular national health checkups. We linked this information with the data of the occurrence of the first cancer from the national cancer registration project. Those who were diagnosed with cancer (breast cancer (C50), prostate cancer (C61), and thyroid cancer (C73)) were selected from the health checkup subjects between 2007 and 2010.
The Extreme Boosting model was trained on a dataset gained from both satellite and observational data collected from 2015 to 2020 in South Korea. The model was used to predict monthly average PM2.5 values for each 1km grid nationwide for the period from 2007 to 2020. Grid values within a city district were averaged to obtain a monthly average PM2.5 value for all nationwide 229 city districts. We employed Cox's proportional hazards models with age, sex (only thyroid cancer patients), Body Mass Index (BMI), smoking status, blood pressure, waist circumference and total cholesterol as covariates. Follow-up started at 2007 following entry into the cohort, and the end date of the study was 31th Oct. 2021. Annual mean ambient PM2.5 of the patients' residential address was used as time-varying exposures.

RESULTS: In the time-varying cox model, the hazard ratio (HR) of mortality was 1.042 (95%CI: 1.031-1.052), 1.031 (95%CI: 1.022-1.039) and 1.029 (95%CI: 1.016-1.042) for breast cancer, prostate cancer patients and thyroid cancer patients, respectively.

CONCLUSIONS: We observed that an increase in PM2.5 concentrations increased the risk of mortality in patients diagnosed with breast cancer, prostate cancer, and thyroid cancer, respectively.

KEYWORDS: Endocrine-related cancer, cohort study, fine particle matter, Extreme Boosting model

O-OP-109 Exposure to Wildfires and Cancer Incidence in Canada: A Population-Based Cohort Study

Jill Korsiak[1], Lauren Pinault[2], Tanya Christidis[2], Richard T. Burnett[3], Michal Abrahamowicz[1], Scott Weichenthal[1]
[1]Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, Canada, [2]Health Analysis Division, Statistics Canada, Ottawa, Canada, [3]Environmental Health Science and Research Bureau, Health Canada, Ottawa, Canada

BACKGROUND AND AIM: Wildfires emit many carcinogenic pollutants that contaminate air, water, terrestrial and indoor environments. However, little is currently known about the relationship between exposure to wildfires and cancer risk. The aim of this study was to investigate the associations between residential exposure to wildfires and the incidence of several cancer outcomes in a national, population-based cohort in Canada

METHODS: We conducted a cohort study of over two million Canadians followed for cancer incidence over 20 years (approximately 34 million person-years). Exposures to wildfires were assigned based on area burned within a 20 or 50 km radius of residential locations and updated for annual residential mobility. Multivariable Cox proportional hazards models were used to estimate associations between exposure to wildfires and specific cancers associated with carcinogenic compounds released by wildfires including lung and brain cancer, non-Hodgkin lymphoma, multiple myeloma, and leukemia, adjusted for many personal and neighbourhood-level covariates.

RESULTS: Wildfire exposure was consistently associated with slightly increased incidence of lung cancer and brain tumors. for example, cohort members experiencing a wildfire within 50 km of residential locations in the past ten years had a 4.9% (adjusted HR= 1.049, 95% CI: 1.028-1.071) relatively higher incidence of lung cancer than unexposed populations, and a 10% (adjusted HR= 1.100, 95% CI: 1.026-1.179) relatively higher incidence of brain tumors. Similar associations were observed for the 20 km buffer size. Wildfires were not associated with hematologic cancers in this study, and concentration-response trends were not readily apparent when area burned was modelled as a continuous variable.

CONCLUSIONS: Long-term exposure to wildfires may increase the risk of lung cancer and brain tumors. Further work is needed to develop long-term estimates of wildfire exposures that capture the complex mixture of environmental pollutants released during these events.

KEYWORDS: wildfires, cancer

O-OP-110 Exposure to indoor wood-burning stoves and fireplaces and risk of lung cancer among Sister Study participants

Suril Mehta[1], M. Elizabeth Hodgson[2], Ruth M. Lunn[1], Claire E. Ashley[3], Whitney D. Arroyave[2], Dale P. Sandler[4], Alexandra J. White[4]

[1]Integrative Health Assessments Branch, Division of the National Toxicology Program, National Institute of Environmental Health Sciences, Research Triangle Park, USA, [2]Integrated Laboratory Systems, LLC an Inotiv Company, Morrisville, USA, [3]Gillings School of Global Public Health, University of North Carolina-Chapel Hill, Chapel Hill, USA, [4]Epidemiology Branch, Division of Intramural Research, National Institute of Environmental Health Sciences, Research Triangle Park, USA

BACKGROUND AND AIM: Epidemiological evidence from case-control studies has identified exposure to household combustion of biomass fuel (primarily wood) as a probable lung carcinogen. However, few studies have been conducted in the United States, where indoor wood-burning and usage patterns differ. We examined the association of exposure to indoor wood smoke from fireplaces and stoves with incident lung cancer in U.S. women.

METHODS: 50,399 women were studied in the U.S.-based prospective Sister Study cohort (recruited 2003-2009) who answered baseline exposure information and did not have lung cancer before enrollment. at baseline, women reported their frequency of use of wood-burning stoves and/or fireplaces in their longest-lived adult residence. Cox regression was used to estimate adjusted hazard ratios (HRadj) and 95% confidence intervals (CI) for the association between indoor wood-burning fireplace/stove use and incident lung cancer.

RESULTS: During an average of 11.3 years of follow-up, 520 lung cancer cases were diagnosed. Overall, 62.2% of the study population reported the presence of an indoor wood-burning fireplace/stove at their longest-lived adult residence. Compared to those without a wood-burning fireplace/stove, an elevated risk of lung cancer was observed in women who used their wood-burning fireplace/stove ≥30 days/year (HRadj = 1.20; 95% CI = 0.94, 1.52; p-for-trend=0.09). Associations were more pronounced in never smokers, with elevated HRs observed in women reporting use both 1-29 days/year (HRadj = 1.87; 95% CI = 1.07, 3.28) and ≥30 days/year (HRadj = 1.69; 95% CI = 0.92, 3.11). Findings were stronger among women who were younger, had less educational attainment and lived in urban settings.

CONCLUSIONS: Our prospective analysis of a cohort of U.S. women found that frequent use of wood-burning indoor fireplaces/stoves was associated with incident lung cancer, consistent with earlier findings.

O-OP-111 Influence of neighborhood social and natural environment on prostatic tumor histology in a US-based cohort of male health professionals

Hari Iyer[1], J. Bailey Vaselkiv[2], Konrad Stopsack[2], Yiwen Zhang[2], Kathryn L. Penney[3], Steven Balk[5], Michelangelo Fiorentino[6], Jaime E. Hart[3], Peter James[4], Immaculata De Vivo[3], Lorelei Mucci[3], Francine Laden[3], Timothy R. Rebbeck[1]

[1]Dana-farber Cancer Institute, Boston, USA, [2]Harvard T. H. Chan School of Public Health, Boston, USA, [3]Channing Division of Network Medicine, Brigham & Women's Hospital, Boston, USA, [4]Harvard Pilgrim Health Care Institute & Harvard Medical School, Boston, USA, [5]Beth Israel Deaconess Medical Center, Boston, USA, [6]University of Bologna, Bologna, Italy

BACKGROUND AND AIM: Neighborhood social and physical environments may contribute to prostate cancer (CaP), but biological mechanisms remain unclear. We examined associations between neighborhood factors and inflammation-related prostatic histology.

METHODS: Men diagnosed with CaP from 1986-2009 in the Health Professionals Follow-up Study were included. Addresses, demographic, clinical, and lifestyle data were provided through biennial questionnaires. Decennial census data were used to estimate neighborhood socioeconomic status (nSES) based on a summary z-scaled measure of nine census tract-level measures of income, wealth, education, and racial composition. Segregation was estimated using census tract-level Index of Concentration at Extremes (ICE). Neighborhood greenness within 270 meters of the participants' address was estimated using seasonal averaged Landsat Normalized Difference Vegetation Index (NDVI). Slides containing surgical tissue underwent a standardized histopathologic review. Chronic inflammation was assessed based on increasing presence of mononuclear cells. Focal atrophy was assessed through Simple Atrophy (SA), Simple Atrophy with Cyst Formation (SACF), and Postatrophic Hyperplasia (PAH). Exposures were assessed at baseline and using updated cumulative averages. Adjusted odds ratios (aOR) for inflammation (nominal) and focal atrophy (binary) measures were estimated from covariate-adjusted logistic regression models, per interquartile range (IQR) increase in each exposure.

RESULTS: Among 967 CaP cases with ≥1 lesion, each IQR increase in baseline NDVI (aOR: 0.76, 95% CI: 0.59, 0.98), Income-ICE (aOR: 0.79, 95% CI: 0.61, 1.04) and Race/Income ICE (aOR: 0.79, 95% CI: 0.63, 0.99) was associated with lower PAH. An IQR increase in nSES was associated with lower SACF (aOR: 0.77, 95% CI: 0.60, 0.99). No associations were observed for chronic inflammation. Associations using cumulative updated average exposures were weaker for NDVI but similar for nSES and ICE.

CONCLUSIONS: Favorable neighborhood socioeconomic and natural environments were associated with lower PAH but not other prostatic lesions. Prostatic inflammation arising from environmental sources may result in distinct pathological signatures.

Tuesday, September 20

ORAL PRESENTATIONS SESSION 22: Health effects of short-term air pollution exposure

O-OP-112 Acute effects of ambient air pollution on asthma emergency department visits in 10 US states

Jianzhao Bi[1], Rohan D'Souza[2], Shannon Moss[2], Noah Scovronick[2], Howard Chang[2], Stefanie Ebelt[2]
[1]University of Washington, Seattle, USA, [2]Emory University, Atlanta, USA

BACKGROUND AND AIM: Ambient air pollution is a major risk factor for increased asthma morbidity. However, previous short-term health effect studies in the US have been limited to a small number of cities or pollutants.
OBJECTIVES: This study examined acute age-specific effects of exposure to particulate matter (PM2.5, PM10), major PM2.5 components (elemental carbon [EC], organic carbon [OC], nitrate, sulfate), and gaseous pollutants (O3, NOx/NO2, SO2, CO) on emergency department (ED) visits for asthma during 2005-2014 in 10 US states (Arizona, California, Georgia, Maryland, Missouri, Nevada, New Jersey, New York, North Carolina, and Utah).

METHODS: We used quasi-Poisson log-linear time-series models with unconstrained distributed lags to estimate acute (8-day) effects of air pollution exposure on asthma ED visits at agency monitoring sites, controlling for meteorology, time, and influenza ED visits. We used a Bayesian hierarchical model to combine site-specific associations. We also conducted age-stratified analyses (aged 1-4, 5-17, 18-49, 50-64, and 65+).

RESULTS: We observed positive associations between 8-day exposure to particulate matter (e.g., PM2.5: rate ratio [RR] = 1.016, 95% confidence internal [CI] = [1.008, 1.025] per 6.21 μg/m³ increase), major PM2.5 components (e.g., EC: RR of 1.010 [1.002, 1.018] per 0.52 μg/m³), and gaseous pollutants (e.g., O3: RR of 1.048 [1.026, 1.070] per 0.02 ppm). Associations of traffic-related pollutants (NOx, CO, EC, and OC) were generally weaker for same day (lag 0) exposures than for exposures at longer lags before the ED visit; in contrast, PM and O3 showed strongest effects at lag day 0. Total and carbonaceous PM had more pronounced associations within younger age groups (aged 17 and below) than older age groups.

CONCLUSIONS: This study reports associations between short-term air pollution exposure and increased risks of asthma ED visits. We found that short-term particular matter exposure posed a higher risk on children and adolescents than on adults.

O-OP-113 Short-term ambient air pollution exposure and risk of atrial fibrillation in patients with intracardiac devices

Marcus Dahlquist[1,2], Viveka Frykman[2,3], Massimo Stafoggia[1,4], Eva Qvarnström[2], Gregory A. Wellenius[5], Petter Ljungman[1,2]

[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Department of Cardiology, Danderyd University Hospital, Danderyd, Sweden, [3]Department of Clinical Sciences, Danderyd University Hospital, Karolinska Institutet, Danderyd, Sweden, [4]Department of Epidemiology, Lazio Region Health Service, Rome, Italy, [5]Department of Environmental Health, Boston University School of Public Health, Boston, USA

INTRODUCTION: Atrial fibrillation (AF) is the most common cardiac arrhythmia and is associated with substantial morbidity and mortality. Short term exposure to fine particulate matter (PM2.5) air pollution has been causally linked to higher risk of cardiovascular disease, but the association with atrial fibrillation (AF) is less clear.

METHODS: We conducted a time-stratified case-crossover study to estimate the association between short-term air pollution levels and risk of AF episodes. The episodes were identified among patients with paroxysmal AF and an intracardiac devices able to register and store AF episodes. We obtained air pollution and temperature data from fixed monitoring stations and used conditional logistic regression to quantify the association of fine particulate matter (PM2.5) and ozone (O3) with onset of AF episodes, adjusting for temperature and public holidays.

RESULTS: We analyzed 584 episodes of AF from 91 participants and observed increased risk of AF episodes with PM2.5 levels for the 48-72 hours lag (OR 1.05 CI [1.01,1.09] per IQR)] and 72-96 hour (OR 1.05 CI [1.00,1.10] per IQR). Our results were suggestive of an association between O3 levels and AF episodes during the warm season. We did not observe any statistically significant associations for PM10 nor NO2.

CONCLUSIONS: Short-term increases in PM2.5 in a low-pollution level environment were associated with increased risk of AF episodes in a population with intracardiac devices. Our findings add to the evidence of a potential triggering of AF by short term increases in air pollution levels, well below the new WHO air quality guidelines.

O-OP-114 Longitudinal assessment of the association between short-term air pollution exposure and symptoms of generalized anxiety disorder in Nurses' Health Study II

Unnati Mehta[1], Melissa Fiffer[1], Olivia Okereke[2,3], Brent Coull[4], Jeffrey Yanosky[5], Joel Kaufman[6,7], Francine Laden[1,2,8], Nicole Deville[2,8], Jaime Hart[1,2]

Chan School of Public Health, Boston, USA, [2]Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Harvard Medical School, Boston, USA, [4]Department of Biostatistics, Harvard University T. H. Chan School of Public Health, Boston, USA, [5]Department of Public Health Sciences, The Pennsylvania State University College of Medicine, Hershey, USA, [6]Department of Environmental and Occupational Health Sciences, University of Washington Seattle School of Public Health, Seattle, USA, [7]Departments of Medicine and Epidemiology, University of Washington Seattle School of Public Health, Seattle, USA, [8]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Emerging evidence has linked air pollution exposure to mental health outcomes, such as anxiety. However, most previous studies are cross-sectional and specific methods of defining anxiety have varied. We used a longitudinal framework to investigate the association between one-, three-, and 12-month average $PM_{2.5}$ and NO_2 exposure and clinically-relevant generalized anxiety disorder (GAD) in a prospective, U.S.-based cohort study.

METHODS: We included 79,838 participants who had outcome and exposure data. Anxiety was measured in 2013 and 2017 using Generalized Anxiety Disorder Assessment (GAD-7). GAD-7 scores for both time points were dichotomized at a clinically-relevant cutoff (GAD-7 ≥ 5), indicating at least mild symptoms. Time-varying $PM_{2.5}$ ($\mu g/m^3$) and NO_2 (ppb) at each residential address were assigned using spatiotemporal prediction models for one, three, and 12 months prior to questionnaire return. We used generalized estimating equations (GEE) to estimate odds ratios (OR) and 95% confidence intervals (95% CI), adjusting for known risk factors of anxiety and potential confounders. We assessed effect modification by neighborhood socioeconomic status (nSES) using stratified models.

RESULTS: In multivariable models, interquartile range increases in exposure to average one-month $PM_{2.5}$ (OR: 1.02, 95% CI: 1.00, 1.04), one-month NO_2 (OR: 1.02, 95% CI: 1.01, 1.04), three-month NO_2 (OR: 1.03, 95% CI: 1.01, 1.04), and 12-month NO_2 (OR: 1.03, 95% CI: 1.01, 1.05) were associated with small elevated risks of GAD. There was evidence of effect modification by nSES, with those living in lower nSES areas being more susceptible to effects of short-term air pollution. for example, the OR for one-month average NO_2 in the lowest quintile of nSES was 1.06, 95% CI: 1.02, 1.11.

CONCLUSIONS: In this cohort of women, we found that higher exposure to short-term air pollution was associated with increased risk of clinically-relevant anxiety symptoms, and that nSES could be an important effect modifier.

O-OP-115 Heterogeneity in acute $PM_{2.5}$ mortality: big data strategies in the Mexico City Metropolitan Area

Ivan Gutierrez-Avila[1], Elena Colicino[1], Arfer K. B.[1], Just A. C.[1]
[1]*Icahn School of Medicine at Mount Sinai, New York City, USA*

BACKGROUND AND AIM: Identification of subgroups at greater risk of mortality from $PM_{2.5}$ may inform targeted public health interventions. The case-crossover design is a powerful tool for studying acute $PM_{2.5}$ mortality associations in large registries where statistical interaction indicates differentially susceptible subgroups. We explore shrinkage with resampling to identify these groups in a big data context.

METHODS: We used a time-stratified case-crossover design to investigate the association between $PM_{2.5}$ with 1.5 million ICD-10 coded non-external 18+ years-old death records from the Mexico City Metropolitan Area, 2004–2019. Daily municipal-level exposures for $PM_{2.5}$ and temperature came from population-weighting 1km satellite-based model predictions, and were scaled to z-scores. We assessed whether the subgroup-specific association of $PM_{2.5}$ exposure (lag_{01}) with daily mortality varied from the overall association for $PM_{2.5}$ by including weighted effect coded interaction terms of lag_{01} $PM_{2.5}$ by cause-of-death:age-group:sex groupings (56 interaction terms), adjusting for temperature. We fit conditional logistic regression with shrinkage for regularization (ridge regression), and cross-validation to select the value of λ with the minimum mean square error. Finally, bootstrap resampling was used for coefficient confidence intervals (95%CI).

RESULTS: Overall, a 10μg/m³ higher lag_{01} $PM_{2.5}$ was associated with 1.46% higher mortality (95%CI: 1.30-1.77). Subgroups exhibited substantial variation (point estimates from 1.1% to 1.91%) with the strongest associations seen for: circulatory system in females ≥80 years-old (1.91%, 95%CI: 1.51%-2.92%); respiratory system in females ≥80 years-old (1.86%, 95%CI: 1.44%-3.30%); and respiratory system in females 65-79 years-old (1.83%, 95%CI: 1.56%-3.61%).
CONCLUSION: Regularization techniques and inclusion of multi-way interactions in big data analyses aid in systematically identifying specific subpopulations with enhanced response to $PM_{2.5}$ relative to the population-average association.

O-OP-116 The effect of ambient air pollution and wildfire smoke on emergency department visits for persons experiencing homelessness in San Diego, California

Lara Schwarz[1,2], Andrew Nguyen[3], Edward M Castillo[4], Jesse J Brennan[4], Theodore Chan[4], Rosana Aguilera[3], Alexander Gershunov[3], Tarik Benmarhnia[3]

[1]Herbert Wertheim School of Public Health and Longevity Science, University of California, San Diego, La Jolla, USA, [2]San Diego State University, San Diego, USA, [3]Scripps Institution of Oceanography, University of California San Diego, La Jolla, USA, [4]Department of Emergency Medicine, University of California San Diego, San Diego, USA

BACKGROUND AND AIM: Homelessness may increase vulnerability to the adverse health effects of air pollution. San Diego (SD) was the urban center with the fifth largest number of people experiencing homelessness in the United States. This study aims to determine the effect of wildfire-specific PM2.5 and PM2.5 from other sources on emergency department (ED) visits for individuals experiencing homelessness in SD.

METHODS: A unique dataset with granularity on socio-demographics of ED visits from 2012 to 2020 was utilized. A validated ensemble model combining machine learning algorithms and spatio-temporal imputation technique was applied to isolate daily wildfire-specific PM2.5. A weighted daily exposure was estimated based on point-in-time counts of people experiencing homelessness in SD. A time stratified case-crossover design was applied to study the association between wildfire-specific PM2.5 and PM2.5 from other sources and ED visits for respiratory diagnoses, adjusting for specific humidity, wind speed and maximum temperature.

RESULTS: While representing less than 0.3% of SD County, over 10% of the 33,446 ED patients admitted for respiratory disease to a single health system were experiencing homelessness at the time of admission. for housed patients, an effect was observed for every 10□g/m3 increase in non-wildfire PM2.5 [OR:1.14, 95%CI: 1.03,1.27] with weaker imprecise estimates for wildfire-PM2.5 [OR:1.02, 95%CI: 0.9,1.17]. In contrast, no strong evidence was found for non-wildfire PM2.5 on ED visits of people experiencing homelessness [OR:0.94, 95%CI: 0.69,1.29], while wildfire-specific PM2.5 had stronger albeit imprecise impacts [OR:1.22, 95%CI: 0.92,1.61].

CONCLUSIONS: As the intensity of wildfires rises, understanding risks for vulnerable populations such as those experiencing homelessness is critical in developing effective mitigation strategies. As the first epidemiological study to quantify effects of PM2.5 on this population, we hope to pave the way for future research to understand their risks in the context of climate and social change.

BACKGROUND AND AIM: Despite serious biomass burning in the Southeast Asian region, there is a lack of epidemiological studies that directly evaluate the health effects of particulate matter attributed to biomass burning. This study aims to estimate the short-term effects of particulate matter ≤10μm (PM_{10}) on hospital admissions in Peninsular Malaysia, distinguishing between PM_{10} originating from biomass burning and other sources.

METHODS: We identified biomass burning by evaluating daily hotspot information from MODIS satellite sensor and the HYSPLIT backward wind trajectories at five districts during 2005 – 2015. Days with wind trajectories passing through biomass burning were known as "haze days". We estimated PM_{10} concentrations attributed to biomass burning by decomposing total concentrations using the moving mean of PM_{10} on non-haze days. We fitted district-specific quasi-Poisson regression models to estimate associations of PM_{10} attributable to biomass burning and non-biomass burning with daily hospitalizations due to respiratory and cardiovascular diseases (ICD-10: J00-J99 and I00-I99, respectively). To obtain a regional average, we pooled district-specific results using random-effects meta-analysis.

RESULTS: We analyzed respiratory (210,960 cases) and cardiovascular (178,952 cases) hospitalizations. On average, 50% of study period was identified as haze days (PM_{10} due to biomass burning >0μg/m³). Average PM_{10} levels attributed to biomass burning and non-biomass burning were 6.6μg/m³ (SD: 51.7) and 41.6μg/m³ (SD: 20.6) respectively. Increases of 10μg/m³ biomass burning PM_{10} and non-biomass burning PM_{10} during non-haze day (lag 0–1 days) were associated with increases in respiratory hospital admissions of 0.44% (95% CI: 0.06, 0.82%) and 0.86% (95% CI: 0.31, 1.41%), respectively. We could not see any significant associations for cardiovascular hospital admissions. District-specific estimates of the associations appeared to be homogeneous.

CONCLUSIONS: PM_{10} from both biomass burning and other emission sources were positively associated with respiratory hospitalizations in Peninsular Malaysia.

ORAL PRESENTATIONS SESSION 23: Child health and exposure to pesticides and other chemicals

O-OP-118 Associations between urinary paraben concentrations and measures of cardiometabolic risk in pre-school children of the ENVIRONAGE birth cohort

Brigitte Reimann[1], Hanne Sleurs[1], Yinthe Dockx[1], Leen Rasking[1], Catherine Pirard[2,3], Corinne Charlier[2,3], Tim S Nawrot[1,4], Michelle Plusquin[1]

[1]Centre for Environmental Sciences, Hasselt University, 3590 Diepenbeek, Belgium, [2]Laboratory of Clinical, Forensic and Environmental Toxicology, CHU of Liege, B35, 4000 Liege, Belgium, [3]Center for Interdisciplinary Research on Medicines (CIRM), University of Liege (ULg), CHU (B35), 4000 Liege, Belgium, [4]Department of Public Health, Environment & Health Unit, Leuven University (KU Leuven), 3000 Leuven, Belgium

BACKGROUND AND AIM: Parabens are widely used as antimicrobial preservatives in personal care products. Endocrine-disrupting effects have been described previously, but studies investigating obesogenic or cardiovascular effects have shown discordant results. Cardiometabolic changes associated with paraben exposure and predictive for later life health conditions may already be visible in early life.

METHODS: Paraben concentrations [methyl (MeP), ethyl (EtP), propyl (PrP), and butyl (BuP)] were measured by ultra-performance liquid chromatography/tandem mass spectrometry in 300 urinary samples from 4-6-year-old children of the ENVIRONAGE birth cohort. Values below the limit of quantification (LOQ) were imputed by censored likelihood multiple imputation. The association with anthropometric and cardiovascular measurements (BMI z-scores, waist circumference, blood pressure and retinal microvasculature) was analyzed in multiple linear regression models with a priori selected covariates. Effect modification by sex was investigated by including interaction terms.

RESULTS: The geometric means (geometric SD) of urinary MeP, EtP, and PrP levels above the LOQ were 32.60 (6.64), 1.26 (3.50), and 4.82 (4.11) µg/L respectively. for BuP 97% of all measurements were below the LOQ. In adjusted models with log-transformed paraben values MeP was associated with central retinal venular equivalent (β = 1.33, p = 0.029) and inversely associated with BMI z-scores (β = -0.065, p = 0.019). PrP was associated with the retinal tortuosity index (β = 0.0018, p = 0.0034). Additionally, EtP was significantly associated with BMI z-scores in boys (β = 0.12, p = 0.012).

CONCLUSIONS: The inverse association between MeP and BMI z-scores could illustrate underlying biological mechanisms related to endocrine-disrupting properties of parabens.
Associations between parabens and retinal microvasculature in pre-school children may indicate adverse effects on cardiometabolic health even at a young age and provide a starting point for further research on paraben-related modes of action.

KEYWORDS: Parabens, BMI z-scores, blood pressure, retinal microvasculature, ENVIRONAGE birth cohort

O-OP-119 Persistent organic pollutant exposure and thyroid function among 12-year-old children

BACKGROUND AND AIM: Polychlorinated biphenyls (PCBs), organochlorine pesticides (OCPs) and per- and polyfluoroalkyl substances (PFASs) are persistent organic pollutants (POPs) globally spread in environment with numerous toxicological properties, including thyroid endocrine disruption. We aimed to assess the associations between various POPs and thyroid hormones among boys and girls aged 12 years, accounting for puberty stages.

METHODS: Exposure to 4 PCBs, 3 OCPs and 6 PFASs was assessed through blood-serum measurements at age 12 in 476 children of the PELAGIE mother-child cohort (France). Thyroid function was assessed in blood-serum by measuring free triiodothyronine (fT3), free thyroxine (fT4) and thyroid-stimulating hormones (TSH). Puberty status was assessed by clinical examination according to the Tanner stages. Associations were estimated with linear regression for each POPs and each hormone (both log-transformed), and adjusted for potential confounders. Exposure levels were categorized when a non-linear dose-response relation was suggested. Analyses were performed for girls (n=227) and boys (n=249) separately.

RESULTS: Among boys, hexachlorobenzene and Perfluorodecanoic acid were associated with decreased fT3 (β=-0.07 95%CI=[-0.12,-0.02] and β=-0.03 95%CI=[-0.06,-0.00] respectively). Perfluorohexanesulfonic acid (PFHxS) was associated with increased fT4, with higher beta coefficients for the 2nd tercile (compared to 1st tercile reference). After stratification on pubertal Tanner stages, PCBs and OCPs seemed associated with increased TSH in the early puberty group (stages 1 and 2); but, decreased TSH in the stage 3 and late puberty group (stages 4 and 5).
Among girls, PFHxS was associated with decreased TSH (β=-0.15 95%CI=[-0.29,-0.00]) and Perfluorooctanoic acid was associated with decreased fT3 (β=-0.06 95%CI=[-0.12,-0.01]). After stratification on pubertal status, no evidence of heterogeneity has been observed.

CONCLUSIONS: Consistently with literature, this study showed associations between some POPs and thyroid hormone levels. Furthermore, some of these associations seemed heterogenous among boys according to pubertal status.

KEYWORDS: persistent organic pollutant, thyroid hormones, adolescence

O-OP-120 Association of Prenatal Exposure to Persistent Organic Pollutants and Childhood Lipid Levels: The Rhea Birth Cohort (Greece)

Marina Vafeiadi[1], Theano Roumeliotaki[1], Katerina Margetaki[1], Vicky Bembi[1], Christos Lionis[1], Manolis Kogevinas[2], Leda Chatzi[3]

[1]Department of Social Medicine, School of Medicine, University of Crete, Heraklion, Greece, Heraklion, Greece, [2]ISGlobal, Barcelona, Spain, [3]Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Lipid disorders in childhood are associated with an earlier onset and greater risk of cardiovascular disease in adulthood. Prenatal exposure to persistent organic pollutants (POPs) has been linked to cardiometabolic risk factors in childhood, but there are limited studies evaluating the persistence of these associations into early adolescence. We assessed the impact of in-utero exposure to POPs on lipid profiles during childhood in the RHEA birth cohort in Greece.

METHODS: Maternal serum concentrations of several polychlorinated biphenyls (PCBs), dichlorodiphenyldichloroethene (DDE), and hexachlorobenzene (HCB) were measured in first trimester. We measured triglycerides (TG), total cholesterol (TC), HDL- and LDL-cholesterol at 4, 6, and 11 years. Generalized estimating equations and multivariate regression models assessed the associations with repeated and single time-point measures, respectively. We also tested effect modification by sex.

RESULTS: We did not find any strong evidence of lipid levels at age-four being associated to prenatal POPs exposure. DDE exposure in the third tertile (>2846 ng/mL) was associated with higher TC (β= 8.01 mg/dL, 95% CI:1.66, 14.36), HDL (β= 3.25 mg/dL, 95% CI: 0.04, 6.46) and LDL (β= 6.29 mg/dL, 95% CI: 0.78, 11.79). HCB in the second tertile (69 – 102.5 ng/mL) was associated with lower TC (β= -7.27mg/dL, 95% CI: -13.36, -1.19) and HDL (β= -3.34 mg/dL, 95% CI: -6.40, -0.27). We observed strong negative associations between all POPs and age-six TG levels. Similarly, HCB and PCB118 were associated with lower TC and LDL levels at 11 years. In GEE models of repeated outcome measures DDE was associated with higher TC and HDL levels. No clear differences by sex were observed.

CONCLUSIONS: Our data indicate that in utero exposures to POPs may be associated with changes in child circulating lipids. These findings require further exploration in other settings and larger cohorts.

KEYWORDS: prenatal, POPs, lipids, children

O-OP-121 Association of prenatal exposure to heavy metal mixtures and anogenital distance in newborns

Tal Michael[1], Amalia Levy[1], Ariela Hazan[2], Elkana Kohn[2], Matitiahu Berkovitch[2], Anna Brik[2], Moshe Betser[3], Miki Moskovich[3], Ayelet Livne[4], Rimona Keidar[4], Malka Britzi[5], Frida Schwartsburd[5], Ori Hochwald[6], Liron Borenstein-Levin[6], Ido Solt[7]

[1]Department of Public Health, faculty of health sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, [2]Clinical Pharmacology and Toxicology Unit, Pediatric Division, Shamir (Assaf Harofeh) Medical Center Affiliated to Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, Israel, [3]Delivery Rooms and Maternity Ward, Shamir (Assaf Harofeh) Medical Center Affiliated to Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, Israel, [4]Neonatal Intensive Care Unit, Shamir (Assaf Harofeh) Medical Center Affiliated to Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, Israel, [5]National Residue Control Laboratory, Kimron Veterinary Institute, Veterinary Services, Ministry of Agriculture and Rural Development, Beit-Dagan, Israel, [6]Department of Neonatology, Rambam medical center and Technion Israel Institute of Technology, Haifa, Israel, [7]Division of Maternal-Fetal Medicine, Rambam Health Care campus, The Rappaport Faculty of Medicine, Technion, Haifa, Israel

BACKGROUND AND AIM: Although the association between prenatal exposure to multiple metals and newborns' anthropometrics has been extensively studied, little is known about the reproductive toxicity and the endocrine disturbance characteristics of these metals. Hence, this study aimed to investigate the associations between prenatal exposures to a wide scope of metals to newborn's anogenital distance, as a marker of endocrine disruptions.

METHODS: We used data of 889 mother-infant pairs, from two major hospitals in Israel. Associations between eight metals (arsenic, cadmium, chromium, mercury, lead, nickel, selenium and thallium) detected in maternal urine samples from day of delivery to anogenital distance index (AGI) at birth were examined. Adjusted estimates were calculated separately for males and females, using single-exposure models, and weights-quantile sums (WQS) models accounting for metals mixtures.

RESULTS: Females found more susceptible to prenatal metals exposure as their z-scaled anoclitoris distance index (AGIac) was positively associated to chromium (β = .158 [95%CI:.061–.256]), nickel (β = .083 [95%CI:.005–.161]) and thalium (β = .140 [95%CI:.022–.258]). Their Z-scaled anofourchette distance index was positively associated to nickel (β = .079 [95%CI:.001–.158]). Z-scaled anoscrotal distance index (AGIas) was the only measure found associated to exposure in the WQS models (β = -.329 [95%CI:-.629– -.030]) and was associated to nickel and selenium. In the single-exposure models, chromium found positively associated (β = .111 [95%CI:.017–.206]) to the Z-scored anoscrotal distance index (AGIas) among males.

CONCLUSIONS: The results suggest prenatal exposure to chromium, nickel and thallium may be associated to alterations of females AGD, while chromium, nickel and selenium to changes in males AGD. Since AGD alterations could represent wider endocrine interruptions, the effects of these metals on biological and chemical mechanisms during the vulnerable period of pregnancy should be further investigated.

O-OP-122 Mixture exposure to plastic-related short half-life chemicals and associations with childhood asthma and allergies: The Hokkaido Study

Yu Ait Bamai[1], Celine Gys[2], Michiel Bastiaensen[2], Atsuko Ikada-Araki[1,3], Rahel Mesfin Ketema[1,3], Houman Goudarzi[4], Chihiro Miyashita[1], Satoshi Konno[4], Adrian Covaci[2], Reiko Kishi[1]

[1]Center for Environmental and Health Sciences, Hokkaido University, Japan, [2]Toxicological Center, University of Antwerp, Belgium, [3]Faculty of Health Sciences, Hokkaido University, Japan, [4]Department of Respiratory Medicine, Graduate School of Medicine, Hokkaido University, Japan

In recent years, exposure to environmental chemicals is thought to be one of the factors contributing to allergies. However, studies examining the effects of mixture chemical exposures on allergies are limited. The aim of this study is to examine the associations between exposure to mixtures of phthalates, phosphorous flame retardants (PFRs), bisphenols (BPs) and childhood allergies.

This study is a part of an on-going birth cohort, the Hokkaido Study. Wheeze, rhino-conjunctivitis, and eczema were defined by the ISAAC questionnaire at age 7. Morning void urine of children was also collected at age 7 for exposure measurements. We included 346 children who were selected based on a case-cohort design (n=400) and we completed exposure measurements of all three classes of chemicals. We measured 10 and 13 urinary metabolites of phthalates and PFRs respectively using LC-MS/MS, and 7 BPs using GC-MS/MS. Associations between the chemical mixtures and allergies were examined by Weighted Quantile Sum (WQS) analyses adjusted for sex, BMI, and environmental tobacco smoke. The exposure levels were corrected by individual urinary creatinine and ln-transformed.

The most dominant urinary markers of phthalates, PFRs and BPs were 5cx-MEPP (median 38.5 ng/mL), BCIPHIPP (0.38 ng/mL), and BPA (0.89 ng/mL), respectively. In WQS analyses, exposure to mixtures of chemicals was associated with increasing risks of wheeze (OR, 95%CI: 2.0, 1.3-3.1), rhino-conjunctivitis (1.8, 1.1-3.1), and eczema (1.8, 1.2-2.8). The contributions of each chemical were BDCIPP (33%) and cx-MiNP (13%) for wheeze, BPF (13%) and BPA (10%) for rhino-conjunctivitis, and BBOEHEP (23%) and 5oxo-MEHP (18%) for eczema, respectively. Compounds showing high contributions to rhino-conjunctivitis and eczema were consistent with previous reports examining single exposures. However, the interpretation should be considered with caution, as urinary concentrations were measured only once, and the study was cross-sectional with a modest sample size.

KEYWORDS: Mixture exposure, childhood allergies, cross-sectional study

O-OP-123 Oxidative stress of glyphosate, AMPA and metabolites of pyrethroids and chlorpyrifos pesticides among primary school children in Cyprus

Konstantinos Makris[1], Nikolaos Efthymiou[1], Corina Konstantinou[1], Elena Anastasi[2], Greet Schoeters[3], Marike Kolossa-Gehring[4], Andromachi Katsonouri[2]

[1]Cyprus University of Technology/Cyprus International Institute for Environmental and Public Health, Limassol, Cyprus, [2]Cyprus State General Laboratory, Ministry of Health, Nicosia, Cyprus, [3]The Flemish Institute for Technological Research (VITO) and the University of Antwerp, Belgium, [4]German Environment Agency (Umweltbundesamt), Berlin, Germany

BACKGROUND AND AIM: Exposure to pyrethroids and chlorpyrifos has been previously associated with adverse effects on children's health. Evidence on the human toxicity of glyphosate (GLY) and its primary metabolite, aminomethylphosphonic acid (AMPA) is limited, particularly for children. This study aimed to i) assess the exposure determinants of the pesticides measured in children in Cyprus, and ii) determine the association between urinary pesticides and biomarkers of DNA and lipid oxidative damage.

METHODS: A children's study was set up in Cyprus (ORGANIKO study) being aligned with the methodology of the European Human Biomonitoring Initiative (HBM4EU). Urinary GLY and AMPA, pyrethroid metabolites and the chlorpyrifos metabolite TCPy were measured in 177 children aged 10-11 years old, using mass spectrometry. Oxidative stress was assessed with 8-iso-prostaglandin F2a (8-iso-PGF2α) and 8-hydroxy-2'-deoxyguanosine (8-OHdG), both measured with immunoassays. Questionnaires about demographics, pesticide usage, and dietary habits were completed by parents. Multivariable regression models examined associations between pesticides and biomarkers of effect using two creatinine adjustments (cr1: adding it as covariate and cr2: biomarkers of exposure and effect were creatinine-adjusted).

RESULTS: Parental educational level was a significant predictor of urinary pyrethroids but not for GLY/AMPA. Median[interquartile range, IQR] for GLY and AMPA were <LOQ[<LOQ, 0.19] µg/L and 0.18[0.10, 0.29] µg/L, respectively, while a moderate correlation was shown between GLY and AMPA (r=0.45). The 8-OHdG was positively associated with AMPA (beta=0.17; 95% CI: 0.02, 0.31, p=0.03 cr2, and beta = 0.12; 95% CI: -0.0,0.24, p=0.06, cr1), albeit not with GLY (p>0.05). Similar significant associations with 8-OHdG were shown for 3-PBA and the chlorpyrifos metabolite (TCPy). No associations were observed between the aforementioned pesticides and 8-iso-PGF2α (p>0.05).

CONCLUSIONS: This is the first children's health dataset demonstrating the association between AMPA and DNA oxidative damage, globally. More data is needed to replicate the observed trends in other children's populations around the globe.

ORAL PRESENTATIONS SESSION 24:
Light at night, sleep and impacts of urbanicity on health

O-OP-124 Artificial light at night exposure and sleep behaviors in adults of Shahedieh Cohort Study

Mohammad Javad Zare Sakhvidi[1], Amirhoushang Mehrparvar[2], Jun Yang[3]
[1]Occupational Health Department, School of Public Health, Shahid Sadoughi University of Medical Sciences, Yazd, Islamic Republic of Iran, [2]Industrial diseases research center, Shahid Sadoughi University of Medical Sciences, Yazd, Iran, [3]School of Public Health, Guangzhou Medical University, Guangzhou, China

BACKGROUND AND AIM: More than 60% of the world's population lives under light-polluted skies which are growing exponentially. Artificial light at night (ALAN) exposure has been suggested to be associated with different health outcomes such as sleep problems which could be the precursor of other disorders. In this study, we evaluated the association between ALAN exposure and sleep behaviors in a cohort of adults in Iran.

METHODS: We used the data from the Shahedieh cohort study (a branch of the PERSIAN Cohort), with 10,000 participants aged 35-70 years. Outcomes were sleep duration (in hours), sleep latency (in minutes), daytime dysfunction (yes/no), habitual sleep deficiency (in minutes), and using sleep medication. We used satellite remote sensing data maintained by the National Oceanic and Atmospheric Administration's Earth Observation Group to estimate ALAN exposure (nanoWatts/cm2/sr) at participant's residential addresses. Multiple linear (for sleep behaviors) and logistic regression (for medication use) models were adjusted for various personal and contextual covariates (all associations are for an IQR increase in ALAN).

RESULTS: The mean age of participants was 48.2 (SD=9.53), and 50.9% were women. ALAN intensity was in the range of 9.35 to 64.1 nanoWatts/cm2/sr [IQR:7.27]. A significant association was observed between ALAN exposure and habitual sleep deficiency (β=0.364; 95% CI: 0.046, 0.682). An increase in ALAN exposure was associated with an increase in time to fall asleep at night (β=1.541; 95% CI: 0.066, 3.017). Increased odds of using sleep medication was associated with an increase in ALAN exposure (odds ratio: 1.191; 95% CI: 1.018, 1.393). The findings were not significant for sleep duration (β=-0.016; 95%CI: -0.073, 0.041), and daytime nap duration (β=1.257; 95% CI: -0.772, 3.285).

CONCLUSIONS: ALAN can be regarded as a threat to healthy sleep behaviors and in larger scope general health.

KEYWORDS: Artificial light at night; Sleep; Urbanization; Environmental epidemiology

O-OP-125 Light at night exposure and risk of depression and other mental disorders: a systematic review

Stefano Tancredi[1,2], Teresa Urbano[1], Marco Vinceti[1,3], Tommaso Filippini[1,4]
[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, [2]Population Health Laboratory (#PopHealthLab), University of Fribourg, Fribourg, Switzerland, [3]Department of Epidemiology, Boston University School of Public Health, Boston, US, [4]School of Public Health, University of California Berkeley, Berkeley, US

BACKGROUND AND AIM: In modern society, individuals are increasingly exposed to artificial light at night (LAN) i.e., different sources of light altering the natural day-night cycle. Emerging evidence suggests a possible association between LAN exposure and physiological and behavioral changes, with implications on mood and mental health at the population level. We performed a systematic review of observational studies to investigate if LAN exposure, may be associated with an increased risk of mental diseases in humans.

METHODS: We reviewed the epidemiological evidence about the association between LAN exposure as assessed either via satellite photometry (outdoor LAN) or via measurements of bedroom brightness (indoor LAN), and risk of mental disorders. We systematically searched the PubMed, Embase and Web of Science databases up to April 1, 2022. Studies were included if they assessed the link between exposure to indoor or outdoor LAN and one or more mental disorders.

RESULTS: Nine eligible studies were included in this review: six studies had a cross-sectional design, two had a longitudinal design with a median follow-up of 24 months, and one was a case-cohort study. Studies were published between 2002 and 2022. Seven studies were conducted in adult populations, one in adolescents, and one in children. Mental disorders investigated include anxiety and mood disorders, depression, bipolar disorder and autism.
Overall, we found moderate evidence of a positive association between LAN exposure and depressive symptoms and to a lesser extent other mental disorders, though the number of studies was limited and potential residual confounding such as socioeconomic factors, noise, or air pollution may have influenced the results.

CONCLUSIONS: Although more robust evidence is needed, the epidemiological evidence produced so far seems to support an association between LAN and risk of depressive disorders.

KEYWORDS: mental disorders; light at night; depression; systematic review, environmental risk factors

O-OP-126 External exposome and sleep outcomes in the Nurses' Health Study

Cindy Hu[1], Matthew Bozigar[2], Charlie Roscoe[1,3], Susan Redline[4], Tianyi Huang[3,4], Grete Wilt[1], Peter James[1,5], Francine Laden[1,3], Jaime Hart[1,3]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [2]Department of Environmental Health, Boston University of Public Health, Boston, USA, [3]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [4]Division of Sleep of Sleep and Circadian Disorders, Departments of Medicine and Neurology, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [5]Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Care Institute, Boston, USA

BACKGROUND AND AIM: Multiple environmental exposures, including greenness, light-at-night, and air pollution, have been associated with sleep. However, these associations have not been investigated using large longitudinal cohorts with repeated measures. We examined the association between multiple environmental exposures and sleep duration and quality in the Nurses' Health Study (NHS).

METHODS: Between 2000 and 2014, 81,202 NHS participants self-reported sleep duration on biennial questionnaires, and in 2000, 81,294 NHS participants self-reported sleep quality. We estimated annual average greenness using Landsat Normalized Difference Vegetation Index (NDVI) in 270m buffers, annual average light-at-night (LAN) from the U.S. Defense Meteorological Satellite Program's Operational Linescan System, and predicted PM2.5 from validated nationwide spatiotemporal models at each residential address. Due to evidence of non-linearity, we modeled exposures in quintiles. Sleep duration was dichotomized (≥7 hours; <7 hours) and modeled with generalized estimating equations. Sleep quality was dichotomized (difficulty sleeping none/a little/some of the time; difficulty sleeping a good bit of/all the time) and modeled using logistic regression. We estimated odds ratios (OR) of adverse sleep outcomes comparing the highest and lowest quintile and 95% confidence intervals (CI) for each exposure. We adjusted for individual-level risk factors and included all exposures simultaneously for mutual adjustment.

RESULTS: In mutually-adjusted models, higher annual average residential greenness exposure was associated with suggestive lower odds of short sleep duration (OR: 0.97 95% CI: 0.94, 1.00) with similar associations for poor sleep quality (OR: 0.97; 95% CI: 0.90, 1.00). Higher exposure to LAN was associated higher odds of with short sleep duration (OR: 1.18 95% CI: 1.14, 1.23) and poorer sleep quality (OR: 1.12; 95% CI: 1.03, 1.22). Higher exposure to PM2.5 was not associated with sleep outcomes.

CONCLUSIONS: In the NHS cohort, lower residential greenness and higher LAN exposures were associated with lower self-reported sleep duration and quality.

O-OP-127 Association between outdoor light at night, sleep duration, and sleep quality in the US based-Health Professionals Follow-Up Study

Ilkania Chowdhury-Paulino[1], Jaime Hart[2,5], Hari Iyer[3], Grete Wilt[2], Cindy Hu[2], Sarah Markt[6], Rachel Nethery[4], Francine Laden[1,2,5], Lorelei Mucci[1]

[1]Department of Epidemiology, Harvard TH Chan School of Public Health, Boston, USA, [2]Department of Environmental Health, Harvard TH Chan School of Public Health, Boston, USA, [3]Division of Population Sciences, Dana-Farber Cancer Institute, Boston, USA, [4]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, USA, [5]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [6]Department of Population and Quantitative Health Sciences, Case Western Reserve University, Cleveland, USA

BACKGROUND AND AIM: Artificial illumination on the Earth's surface has increased over time. Light plays a central role in regulating circadian rhythm, the body's internal clock, mainly by inhibiting the production of the sleep promoting hormone melatonin. The increase in artificial light at night (LAN) has negative consequences for human health, as circadian disruption is a risk factor for weight gain, cardiovascular disease, and cancer. We evaluated whether exposure to outdoor LAN is associated with sleep duration and sleep quality in the US based-Health Professionals Follow-up Study (HPFS).

METHODS: HPFS consists of 51,529 men enrolled in 1986 aged 40-75, our study is limited to men who reported a home address at baseline. We estimated participants' LAN with 1 km2 resolution using data from the US Defense Meteorological Satellite Program's Operational Linescan System to geocoded address histories. Participants self-reported their sleep duration in 1987, 2000, and 2008 and answered 5 questions regarding their sleep quality in 2004. We used multinomial logistic regression to estimate odds ratios and 95% confidence intervals adjusting for participants' age, population density, and neighborhood SES (nSES).

RESULTS: The mean level of LAN at baseline was 30.8 nW/cm2/sr. The distribution of age was similar, but population density and nSES differed across levels of LAN. An interquartile increase in LAN was associated with increased odds of sleeping ≤6 hours compared to 7-8 hours (OR: 1.20, 95%CI: 1.12,1.29), never feeling rested compared to most of the time (OR: 1.18, 95%CI: 1.05,1.34), and difficulty falling asleep (OR: 1.18, 95%CI: 1.02,1.36).

CONCLUSIONS: We found positive associations between LAN and measures of sleep duration and sleep quality in a large cohort of older adult men. This aligns with findings from other studies that living in areas of greater LAN has a negative impact on sleep health.

O-OP-128 Physical Environmental Hazards and Major Depression in Older U.S. Adults: The Health and Retirement Study

Jennifer D'Souza[1], Rachel Bergmans[1], Alan Fossa[1], Adam A. Szpiro[2], Carlos Mendes de Leon[1], Joel Kaufman[2], Richard Hirth[1], Jessica Faul[1], Sara Adar[1]
[1]University of Michigan, Ann Arbor, USA, [2]University of Washington, Seattle, USA

BACKGROUND AND AIM: Major depression is a leading cause of disability. Although much research focuses on individual risk factors and interventions, environmental risk factors may also play an important role in major depression. We quantified associations of road noise and light at night with prevalent major depression.

METHODS: We used data from the 2008-2016 biennial interviews of the Health and Retirement Study, a nationally-representative cohort of older adults in the United States. Major depression status was determined using the Composite International Diagnostic Interview Short Form, with a cutoff of ≥5. We estimated average road noise and light at night for the year prior to each interview at participant residences using the Department of Transportation Road Noise Model and satellite imagery from the Defense Meteorological Satellite Program, respectively. To estimate prevalence ratios, we used a modified Poisson regression model that accounted for sampling weights and design effects, adjusted for demographic characteristics, individual and neighborhood SES, time, co-exposures, and geographic area.

RESULTS: There were 23,874 participants with complete data. The mean baseline age was 63 years, 53% were female, 74% were Non-Hispanic White, and 15% ever reported major depression. Compared to the lowest exposure quartiles, those in the highest quartiles of noise and light exposure were more likely to be Black, have less than a high school education and reside in an urban area. In fully adjusted models, interquartile differences in both noise and light were suggestively associated with an approximately 10% greater prevalence of major depression (PR per IQR of noise: 1.08, 95% CI: 0.98, 1.20; and light: 1.12, 95%CI: 0.96, 1.31).

CONCLUSIONS: Exposure to noise and light at night may increase depression in older adults, possibly by disrupting health sleep. Modifying physical hazards in the environment may be a way to reduce the burden of depression.

KEYWORDS: Noise, Light, Depression

ORAL PRESENTATIONS SESSION 25: Environment and cardiovascular disease

O-OP-129 Long-term exposure to transportation noise and incidence of ischemic heart disease: A pooled analysis of nine Scandinavian cohorts

Andrei Pyko[1,2], Nina Roswall[3], Mette Sørensen[3,4], Göran Pershagen[1,2]
[1]CAMM, Region Stockholm, Stockholm, Sweden, [2]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Danish Cancer Society Research Centre, Copenhagen, Denmark, [4]Department of Natural Science and Environment, Roskilde University, Roskilde, Denmark

BACKGROUND AND AIM: Transportation noise may induce cardiovascular disease, but the public health implications are unclear. This study aimed to assess exposure-response relationships for ischemic heart disease (IHD) associated with road, railway and aircraft noise exposure.

METHODS: We performed pooled analyses for nine cohorts from Denmark and Sweden, including 132,801 subjects. Time-weighted long-term exposure to road, railway, and aircraft noise, as well as air pollution, was estimated based on residential history. Hazard ratios (HR) were calculated using Cox proportional hazards models, following adjustment for lifestyle and socioeconomic risk factors, and exposure-response relationships were evaluated using cubic splines.

RESULTS: A total of 22,459 incident cases of IHD, including 7,682 cases of myocardial infarction, were identified from national registers over an average of 20 years of follow-up. The adjusted HR for IHD was 1.03 (95% confidence interval 1.00, 1.05) per 10 dB Lden for both road and railway 5-year mean noise exposure. Moreover, for road traffic noise, a deviation from linearity in the exposure-response function was indicated, with a threshold around 55 dB Lden. Higher risks appeared for IHD excluding angina pectoris (12,399 cases), with HRs of 1.06 (1.03, 1.08) and 1.05 (1.01, 1.08) per 10 dB Lden for road and railway noise, respectively. Corresponding HRs for myocardial infarction were 1.02 (0.99, 1.05) and 1.04 (0.99, 1.08). Increased risks were also observed for aircraft noise but without clear exposure-response relations.

CONCLUSIONS: Long-term exposure to road, railway and aircraft noise was associated with an increased risk of IHD, particularly after the exclusion of angina pectoris cases, which are less well-identified in the registries. A threshold of around 55 dB Lden was suggested in the exposure-response relation for road traffic noise and IHD.

KEYWORDS: road traffic noise, railway noise, aircraft noise, ischemic heart disease, myocardial infarction, exposure-response function

O-OP-130 Association between long-term exposure to air pollution and cardio-metabolic phenotypes – A MRI-data based analysis

Margarethe Woeckel[1], Susanne Rospleszcz[1], Michael Ingrisch[2], Kathrin Wolf[1], Susanne Breitner-Busch[1], Fabian Bamberg[3], Christopher Schlett[3], Corinna Storz[4], Alexandra Schneider[1], Sophia Stöcklein[2], Annette Peters[1]
[1]Institute of Epidemiology, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany, [2]Department of Radiology, University Hospital of Munich, LMU Munich, Munich, Germany, [3]Department of Diagnostic and Interventional Radiology, Faculty of Medicine, Medical Center - University of Freiburg, Freiburg, Germany, [4]Department of Neuroradiology, Faculty of Medicine, Medical Center - University of Freiburg, Freiburg, Germany

BACKGROUND AND AIM: Long-term exposure to ambient air pollution is supposed to affect both the cardiovascular system and adipose tissue (AT) metabolism. However, its role in the early subclinical stages of development before manifestation of cardiometabolic disease is unclear. Thus, we aimed to investigate the impact of long-term exposure to air pollution on cardiometabolic phenotypes derived from magnetic resonance imaging (MRI).

METHODS: Phenotypes of left (LV) and right cardiac ventricle, whole body AT, and organ AT were obtained by whole-body MRI in 400 participants of the population-based KORA cohort. Land-use regression models were used to estimate residential long-term exposures to several air pollutants, including particulate matter (PM) with different diameters and nitrogen oxides (e.g. NO_2). Associations between exposures and MRI phenotypes were modeled using confounder-adjusted linear regression. Additionally, we performed several stratified analyses, e.g. for diabetes status, hypertension, or age group.

RESULTS: Participants' mean age was 56±9 years, 42% were female. Increasing levels of several air pollutants were associated with decreased LV wall thickness; a 6.0µg/m³ IQR (interquartile range) increase in NO_2 was significantly associated with a -1.89% decrease (95% confidence interval [95%-CI]: -3.70;-0.09) in mean global LV wall thickness. We also found significant associations between various air pollutants and increased cardiac AT. A 2.1µg/m³ IQR increase in PM_{10} was associated with an 8.83% [95%-CI: 1.19;16.49] increase in mean total epi- and pericardial AT. Similar effects were seen for mean diastolic (8.53% [95%-CI: 0.84;16.23]) and systolic (8.57% [95% CI: 0.10;16.17]) pericardial AT, respectively. We saw a similar trend for liver and renal AT. Associations with whole-body AT were only detected in participants with diabetes in the stratified analysis.

CONCLUSIONS: Our results indicate that long-term exposure to air pollution is associated with subclinical cardiometabolic disease states, particularly in metabolically vulnerable subgroups.

KEYWORDS: cardiometabolic phenotypes, ambient air pollution, magnetic resonance imaging.

O-OP-131 Association of short-term exposure to ambient PM1 with total and cause-specific cardiovascular disease mortality

Ruijun Xu[1], Jing Wei[2], Tingting Liu[1], Yingxin Li[1], Chunyu Yang[1], Chunxiang Shi[3], Gongbo Chen[4], Yun Zhou[5,6], Hong Sun[7], Yuewei Liu[1]

[1]Department of Epidemiology, School of Public Health, Sun Yat-sen University, Guangzhou, China, [2]Department of Atmospheric and Oceanic Science, Earth System Science Interdisciplinary Center, University of Maryland, College Park, USA, [3]Meteorological Data Laboratory, National Meteorological Information Center, Beijing, China, [4]Department of Occupational and Environmental Health, School of Public Health, Sun Yat-sen University, Guangzhou, China, [5]State Key Laboratory of Respiratory Disease, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China, [6]Department of Preventive Medicine, School of Public Health, Guangzhou Medical University, Guangzhou, China, [7]Department of Environment and Health, Jiangsu Provincial Center for Disease Control and Prevention, Nanjing, China

BACKGROUND AND AIM: The acute effects of exposure to ambient particulate matter with an aerodynamic diameter ≤1 μm (PM1) on cardiovascular disease (CVD) mortality remain poorly understood. We aimed to investigate the association of short-term exposure to ambient PM1 with total and cause-specific CVD mortality, and estimate the corresponding excess mortality.

METHODS: Using the Jiangsu provincial mortality surveillance system, we conducted a time-stratified case-crossover study among 988 446 CVD deaths in Jiangsu province, China during 2015-2019. Daily residential PM1 exposures for each subject was assessed using a validated grid data. Conditional logistic regression models integrated with distributed lag linear or nonlinear models were performed to conduct exposure-response analyses.

RESULTS: Each 10 μg/m3 increase of PM1 exposure during the same day of CVD death and 1 day prior was significantly associated with a 1.46% (95% confidence interval [CI]: 1.27%, 1.66%), 1.46% (0.15%, 2.78%), 1.93% (1.24%, 2.64%), 1.25% (0.93%, 1.57%), 1.37% (1.07%, 1.66%), and 1.71% (1.22%, 2.21%) increase in odds of mortality from total CVDs, chronic rheumatic heart diseases (CRHD), hypertensive diseases, ischemic heart diseases (IHD), stroke, and sequelae of stroke, respectively. The excess fraction of total CVD mortality attributable to PM1 exposure was 5.72%, while the cause-specific excess fractions ranged from 5.34% for IHD to 8.25% for CRHD. Significantly higher associations and excess fractions were identified for mortality from total and/or certain cause-specific CVDs in adults 80 years or older.

CONCLUSIONS: Short-term exposure to ambient PM1 was associated with increased risk of total and cause-specific CVD mortality, which may lead to a considerable excess mortality especially among older adults. Our findings highlight a potential approach to prevent premature deaths from CVDs by reducing ambient PM1 exposures and provide essential quantitative data for the formulation of future air quality standards for ambient PM1.

KEYWORDS: Cardiovascular diseases; PM1; Mortality; DLM; DLNM; Case-crossover study.

O-OP-132 Association of Volatile Organic Compound Exposure with Blood Pressure in the National Health and Nutrition Examination Survey (2011-2016)

Katlyn McGraw[1], Daniel Riggs[2], Aruni Bhatnagar[2], Ana Navas-Acien Ana Navas-Acien[2], Diachi Shimbo[1], Tiffany Sanchez[1]

[1]Columbia University, New York, USA, [2]University of Louisville, Louisville, 40202

BACKGROUND AND AIM Volatile organic compounds (VOCs) are environmental pollutants generated from a variety of different combustion sources, consumer and household products, and tobacco smoke. Exposure to VOCs has been associated with cardiovascular disease (CVD) risk factors, such as increased blood pressure (BP); however, limited research has been conducted in the general population. We hypothesized that higher levels of VOC exposure are associated with higher BP.

METHODS: To examine the relationship between VOC exposure and BP, we acquired and combined three cycles of data from the National Health and Nutrition Examination Survey (NHANES) over the years 2011-2016 for a final sample size of n=5,616 participants. Ultra-performance liquid chromatography/mass-spectrometry was used to measure the levels of 27 urinary VOC metabolites. Metabolites were adjusted for urinary creatinine and multiple measures of systolic and diastolic BP were averaged. Linear regression models adjusted for age, sex, race, education, BMI, smoking status, HDL, cholesterol, triglycerides, diabetes, blood pressure medications, eGFR, and NHANES cycle year were used to estimate associations between VOC metabolites and BP.

RESULTS: Participants were 52% female, median age of 47, 32% had hypertension, and 7.4% had diabetes. Urinary VOC metabolites were higher among tobacco users than non-users, except for metabolites of benzene, cyanide, and toluene. We found a 0.6 (95% CI: 0.2, 1.0) mmHg higher systolic BP per interquartile range of 1,3-butadiene metabolite, DHBMA. In subgroup analysis, this association was independent of age and persisted in women, non-tobacco users, Mexican Americans, and individuals not diagnosed with CVD or hypertension. Urinary metabolites of acrolein were associated with systolic BP in non-tobacco users, Non-Hispanic Blacks, women, and individuals not diagnosed with CVD or hypertension.

CONCLUSIONS:These results suggest exposures to VOCs, particularly acrolein and 1,3-butadiene, may be relevant, yet understudied contributors to CVD risk in the general population.

KEYWORDS: blood pressure, vocs, cvd, chemicals

O-OP-133 Residential exposure to petroleum refining and stroke in the southern United States

Honghyok Kim[1], Natalia Festa[2], Kate Burrows[3], Dae Cheol Kim[4], Thomas Gill[2], Michelle Bell[1]
[1]Yale University School of The Environment, New Haven, USA, [2]Yale University School of Medicine, New Haven, USA, [3]The Institute at Brown University for Environment and Society, Providence, USA, [4]Seoul National University Graduate School of Public Health, Seoul, South Korea

BACKGROUND AND AIM: The southern United States (U.S.) sustains a disproportionate burden of incident stroke and associated mortality, compared to other parts of the U.S. A large proportion of this risk remains unexplained. Petroleum production and refining (PPR) is concentrated within this region and emits multiple pollutants implicated in stroke pathogenesis. The relationship between residential PPR exposure and stroke has not been studied. We aimed to investigate the census tract-level association between residential PPR exposure and stroke prevalence for adults (≥18 years) in seven southern U.S. states in 2018.

METHODS: We conducted spatial distance- and generalized propensity score-matched analysis that adjusts for sociodemographic factors, smoking, and unmeasured spatial confounding. PPR was measured as inverse-distance weighted averages of petroleum production within 2.5km or 5km from refineries, which was strongly correlated with measured levels of sulfur dioxide, a byproduct of PPR.

RESULTS: The prevalence of self-reported stroke ranged from 0.4% to 12.7% for all the census tracts of the seven states. Hispanic population and people with low socioeconomic status resided closer to petroleum refineries. The non-Hispanic Black population was exposed to higher PPR, while non-Hispanic White population was exposed to lower PPR. Residential PPR exposure was significantly associated with stroke prevalence. One standard deviation increase in PPR within 5km from refineries was associated with 0.20 (95% confidence interval: 0.08, 0.33) percentage point increase in stroke prevalence. PPR explained 5.5% (2.1, 9.0) of stroke prevalence in the exposed areas. These values differed by states: 1.0% (0.4, 1.7) in Alabama to 11.1% (4.2, 17.9) in Mississippi, and by census tract-level: 0.08% (0.02, 0.12) to 23.8% (9.0, 38.6).

CONCLUSIONS: PPR is associated with self-reported stroke prevalence, suggesting possible links between pollutants emitted from refineries and stroke. The increased prevalence due to PPR may differ by sociodemographic factors.

O-OP-134 Phthalates and Incident Diabetes in Midlife Women: The Study of Women's Health Across the Nation (SWAN)

Mia Peng[1], Carrie Karvonen-Gutierrez[1], William Herman[1,2], Bhramar Mukherjee[1,3], Sung Kyun Park[1,4]
[1]Department of Epidemiology, University of Michigan School of Public Health, Ann Arbor, USA, [2]Department of Internal Medicine, School of Medicine, University of Michigan, Ann Arbor, USA, [3]Department of Biostatistics, University of Michigan School of Public Health, Ann Arbor, USA, [4]Department of Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, USA

BACKGROUND AND AIM: Phthalates are hypothesized to contribute to diabetes, but longitudinal evidence in humans is limited. We examined whether phthalate exposure was associated with a higher incidence of diabetes in a racially/ethnically diverse cohort of midlife women.

METHODS: In the Study of Women's Health Across the Nation-Multipollutant Study, we followed 1308 women without diabetes in 1999/2000 for six years. Eleven phthalate metabolites were measured in spot urine samples in 1999/2000 and 2002/2003. Incident diabetes was ascertained between 1999/2000 and 2005/2006. Cox proportional hazards models with time-varying exposure were used to estimate the hazard ratio (HR) of diabetes associated with each phthalate metabolite, adjusting for demographic, lifestyle, and health-related factors. Effect modification by race/ethnicity was examined with interaction terms.

RESULTS: Sixty-one women developed diabetes over six years (cumulative incidence = 4.7%). Among all women, several high-molecular-weight (HMW) phthalate metabolites were associated with a higher incidence of diabetes, but none were statistically significant. There was effect modification by race/ethnicity. Among White women, each doubling of phthalate metabolite concentrations was associated with 22-77% higher incidence of diabetes (HR = 1.22, 95% confidence interval (CI): 0.87, 1.72 for mono-n-butyl phthalate; HR = 1.77, 95% CI: 1.27, 2.46 for ∑HMW phthalate metabolites). In contrast, phthalate metabolites were not associated with diabetes incidence in Black or Asian women. Post-hoc analyses showed positive associations between phthalates and insulin resistance in non-White women, suggesting non-White women were not immune to phthalates.

CONCLUSIONS: Some phthalate metabolites were associated with a higher incidence of diabetes over six years of follow-up, but the associations were inconsistent across racial/ethnic groups. Different susceptibility to phthalates is unlikely to explain racial/ethnic differences. Whether phthalates cause diabetes requires further investigation.

KEYWORDS: phthalates, diabetes, women

ORAL PRESENTATIONS SESSION 26: Environmental equity: environmental inequalities and health implications (2)

O-OP-135 Interrogating the use of "maternal" in environmental epidemiology: opportunities for increasing linguistic and substantive precision

Corinna Keeler[1], Radhika Dhingra[2], Hanna Jardel[1], Brooke Staley[1], Adrien Wilkie[1]
[1]Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, USA, [2]Department of Environmental Science and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, USA

BACKGROUND AND AIM: The term "maternal" is used ubiquitously, yet often imprecisely, in environmental epidemiologic research of parental exposures occurring during pre-conception and gestation that influence fetal, infant, and childhood outcomes. Without a clear definition, the term "maternal" can be non-specific, since co-parenting arrangements such as those involving queer women may involve more than one mother; similarly, the term may inaccurately conflate the individual who experiences pregnancy with the person/people who perform the labor of post-birth parenting, as with cases of surrogacy and adoption. Additionally, the term may be non-inclusive, for example, of many trans men and gender-nonconforming people who have uteruses and experience pregnancy but may not be appropriately described using a "maternal" classification.

METHODS: We (1) present a conceptual model of unacknowledged familial relationships relevant to exposure measurement in pre-conception, gestational, and post-natal windows, (2) address methodological shortcomings that follow from the unconsidered use of "maternal" (e.g. exposure misclassification, population selection) and how these challenges may be addressed in common administrative datasets, and (3) discuss the opportunities presented by more specific language use, including explicit inclusion of LGBTQ+ and other family structures within environmental health literature.

RESULTS: We find that the term "maternal" is both non-specific and non-inclusive, which has methodological and ethical implications that are especially relevant in environmental epidemiologic studies of perinatal exposures. Terms that are more substantively precise for the exposures and covariates being measured, such as "gestational" or "caregiver," may more accurately capture the relevant exposures and covariates for a given analysis. We provide guidance on determining how characteristics of study design and cohort construction may inform the specification of parental variables.

CONCLUSIONS: Linguistic specificity and inclusivity in environmental epidemiology is important both methodologically and ethically, and will promote clearer science communication about exposure measurement and variable operationalization.

KEYWORDS: gestational parent, maternal, exposure misclassification, LGBTQ+

O-OP-136 Sociodemographic disparities and metal concentrations in US drinking water supplies

Mona Dai[1], Xindi Hu[2], Brent Coull[3], Chris Campbell[4], David Andrews[4], Olga Naidenko[4], Elsie Sunderland[1]
[1]Harvard John A. Paulson School of Engineering and Applied Sciences, Cambridge, USA, [2]Mathematica, Inc., Oakland, USA, [3]Harvard T.H. Chan School of Public Health, Boston, USA, [4]Environmental Working Group (EWG), Washington DC, USA

BACKGROUND AND AIM: Few drinking water studies have examined metal contamination in the context of environmental justice and fewer have investigated drivers. This study explores associations between sociodemographic disparities and metal concentrations in US public water systems (PWS) and whether these associations are mediated by the availability of best available technologies (BAT).

METHODS: We assessed arsenic, total chromium, manganese, and selenium concentrations for over 380,000 water samples collected between 1975-2017 from 13,000+ PWS in 15 states from a national drinking water database curated by the Environmental Working Group. We queried PWS characteristics, including BAT use, from the US EPA and averaged sociodemographic data from the 2017 US Census and environmental factors from the USGS and PRISM Climate Group within PWS service area boundaries. We developed a two-step Hurdle model to first predict the probability of metal detection and secondly, among detections, predict chemical concentrations.

RESULTS: We found significant relationships between sociodemographic variables and metal concentrations, although directionality varied by metal. Higher percentages of non-English speakers were associated with increasing detection probability for arsenic (0.17, 95% confidence interval [0.06, 0.28]), but decreasing detection probabilities for chromium (-0.18 [-0.28, -0.07]) and manganese (-0.43 [-0.55, -0.32]). Arsenic (binomial: 0.18 [0.08, 0.28]; regression: 0.07 [0.02, 0.12]) and manganese (binomial: 0.33 [0.02, 0.33]; regression: 0.10 [0.04, 0.16]) indicated uniform positive associations with respect to increases in Black population percentages. We did not find evidence that these associations were mediated through BATs.

CONCLUSIONS: We found some evidence that linguistically isolated communities and communities of color are associated with higher metal concentrations in drinking water. Since we did not find BAT to be a mediator, other local policies, such as historic zoning, may explain these associations. Future work may explore disparities at other spatial levels and consider how financial and operational procedures affect drinking water metal pollution.

O-OP-137 Environmental health impacts and inequalities in green space and air pollution exposures in six European cities

Evelise Pereira Barboza[1,2,3], Kiran Apsunde[4], Marta Cirach[1,2,3], John Gallagher[4], Julia Gäeckle[5], Tamara Iungman[1,2,3], Hans Keune[6], Sasha Khomenko[1,2,3], Tadhg Macintyre[7], Natalie Mueller[1,2,3], Mark Nieuwenhuijsen[1,2,3]
[1]Barcelona Institute for Global Health ISGlobal, Barcelona, Spain, [2]Department of Experimental and Health Sciences, Universitat Pompeu Fabra, Barcelona, Spain, [3]CIBER Epidemiología y Salud Pública, Madrid, Spain, [4]Trinity College Dublin, Dublin, Ireland, [5]RWTH Aachen University, Aachen, Germany, [6]Universiteit Antwerpen, Antwerpen, Belgium, [7]Maynooth University, Maynooth, Ireland

BACKGROUND AND AIM: The GoGreenRoutes project (Horizon 2020/869764) aims to introduce co-created nature-based solutions (NBS) as interventions to enhance access to green space in six medium-sized European cities (Burgas, Lahti, Limerick, Tallinn, Umea, and Versailles). We analyzed the spatial distribution and health impacts associated with unequal exposure to air pollution and green space prior to the implementation of these NBS interventions in each city.

METHODS: We retrieved air pollution (NO_2 and $PM_{2.5}$) and green space (NDVI and % Green Area proxies) data at a 250m x 250m grid-cell level for each city, in addition to population and mortality data for 2015. We compared baseline exposures to WHO guidelines and calculated the exposure differences at the grid-cell level. We applied a comparative risk assessment methodology to estimate the mortality burden attributable to not achieving the WHO guidelines. We evaluated exposures and attributable mortality distributions and their associations to understand current urban environmental inequalities.

RESULTS: We found high variability in air pollution and green spaces levels between and within all six cities. Around 60% of the population lacked green space and 90% of the population were exposed to air pollution above WHO guidelines. Overall, we estimated a city range between 3-37 and 2-71 deaths/100,000 persons were attributable to exceedances in WHO NO_2 and $PM_{2.5}$ limit values, respectively; 4-13 deaths/100,000 persons were associated with lack of Green Area; and 18-35 deaths/100,000 persons were linked to NDVI levels below the city target. Green space and air pollution were highly spatially correlated, likewise their attributable burdens.

CONCLUSIONS: Our results suggest that urban populations in the analyzed cities are affected simultaneously by lack of green space and increased air pollution. We expect NBS interventions will contribute to reducing the environmental health burden and inequalities in the GoGreenRoutes cities.

KEYWORDS: Health impact assessment; urban health; health equity; nature-based solutions.

O-OP-138 DDT for malaria elimination: an ethical dillema

Nosiku Munyinda[1]
[1]*University of Zambia, Lusaka, Zambia*

From the year 2000, an estimated 500,000 kg of DDT has been imported for Indoor Residual Spraying (IRS) and applied in Zambian homes without any studies conducted to ascertain its fate in the environment and resultant effects on humans. This study aimed to quantify DDT exposure, identify community exposure pathways and establish neurodevelopmental outcomes in children of selected communities in Zambia.
Samples of top layer soils and water from drinking sources were collected from communities in Zambia. The DDT and its metabolites were extracted by QuECHERS method and Solid Phase Extraction for soils and water respectively. Analyses were by Gas Chromatography tandem Mass Spectrometry. A questionnaire was used in the community survey and Neurodevelopment assessments were conducted on Mother and child pairs with the use of the Ages and Stages Questionnaire.
Median levels of of DDT and its metabolites were found at 100.4 ng/g (IQR 90.9-110) and 725.4 ng/l (IQR 540-774.5) for Soils and Water respectively. Both were above reference values of World Health Organization (WHO) and Food and Agriculture Organization (FAO). The study revealed multiple community exposure pathways through water, crops and edible livestock implying significant Human Health Risks particularly among poorer populations. Highly negative significant associations were found between DDT soil levels and Gross Motor, Problem Solving and Personal Social domains. Variables including mother's age, educational level, income, child's age and complications during pregnancy were associated with neurodevelopment in children.
The presence of DDT in these media suggests possible limitations in environmental safeguards put in place during Indoor Residual Spraying. These health risks fall disproportionately among poorer communities with poor housing and socio-economic status. There is need for a holistic malaria elimination approach which should place more emphasis on preventive measures such as improvement of housing structures to reduce reliance on toxic substances.

DDT Exposure Children Ethical

O-OP-139 Work environment characteristics of environmental epidemiologists and mental health conditions – A cross sectional survey among ISEE members

Jutta Lindert[1], Felix Sisenop[1], Associate Atanu Sarkar[2], Ruth A. Etzel[3]
[1]University of Applied Sciences Emden / Leer, Hamburg, Germany, [2]Memorial University of Newfoundland, Canada, [3]Milken Institute School of Public Health George Washington University, Washington, D.C., USA

BACKGROUND AND AIM: Working environment (verbal/physical abuse, threats, difficulties of publishing due to other than scientific interests, political interests) of environmental epidemiologists (EEs) is largely unknown. The aim of this study was to assess; a) working environment factors b) health situation of EEs and 3) associations between working environment and health situation of EEs.

METHODS: A cross-sectional survey among the ISEE members was conducted in February 2022. We assessed socio-demographics (age, gender, education), employment status, working environment and stress, depression, and anxiety. Descriptive statistics were conducted with the full sample at baseline to characterize employment status and employment related events (past and current). In addition to descriptive statistics, we explored the associations between working conditions and mental health conditions by calculating multiple linear regression analyses.

RESULTS: Majority of the participants (N=442) were females and from North America (316, 47% followed by Europe (139, 21%). As regards to work most were faculty members (298, 50%) and assistant or associate professors (270, 47%) with main areas of research of air pollution (187, 37%), chemicals (151, 30%) and climate change (75, 15%). Almost half of participants reported verbal abuse (246, 46%) and one-fifth threats of physical abuse at the workplace. Research was reported to be forbidden to get published by 11%. Increasing age was inversely associated with depression, anxiety and stress symptoms. Verbal and threats of physical abuse and difficulties to disseminate results were related to increased levels of depression, anxiety and stress symptoms. Political pressure was not related to increased levels of mental health conditions.

CONCLUSIONS: Study findings suggest that a comprehensive workplace prevention program accompanied by research identifying scientists job stress in different workplaces is critical. To prevent exposures and improve the mental health conditions of EEs, workplace violence prevention procedures at the organizational and at the societal level are needed.

ORAL PRESENTATIONS SESSION 27: In search of epigenetic signatures of environmental exposures

O-OP-140 HDMAX2: A framework for High Dimensional Mediation Analysis with application to maternal smoking, placental DNA methylation and birth outcomes

Basile Jumentier[5], Claire Cécile Barrot[1,5], Maxime Estavoyer[4], Jorg Tost[2], Barbara Heude[3], Olivier François[5], Johanna Lepeule[1]

[1]Inserm U1209, Grenoble, France, [2]Laboratory for Epigenetics and Environment, Centre National de Recherche en Genomique Humaine, CEA – Institut de Biologie François Jacob, University Paris Saclay, Evry, France, [3]Université de Paris, CRESS, Inserm, INRAE, Paris, France, [4]Inria Grenoble - Rhône-Alpes Inovallée 655 Avenue de l'Europe - CS 90051 38334 Montbonnot, France, Montbonnot, France, [5]Université Grenoble-Alpes, Centre National de la Recherche Scientifique, Grenoble INP, TIMC CNRS UMR 5525, Grenoble, France

BACKGROUND AND AIM: High-dimensional mediation analysis is an extension of unidimensional mediation analysis that includes multiple mediators, and is increasingly used in environmental epidemiology to evaluate the indirect epigenetic effects of environmental exposures on health outcomes. However, analyses involving high-dimensional mediators raise several statistical issues. While many methods have recently been developed to tackle those issues, no consensus has been reached about the optimal combination of approaches.

METHODS: We developed HDMAX2, a new multi-step approach to mediation that combines latent factor regression models for epigenome-wide association studies with max-squared tests for mediation, and considers CpGs and aggregated mediator regions (AMR). HDMAX2 was carefully evaluated on simulated data, and compared to state-of-the- art multi-dimensional epigenetic mediation

METHODS: Then it was applied to assess the indirect effects of exposure to maternal smoking (MS) on term birth weight (BW) and gestational age (GA) at delivery in a study of 470 women from the EDEN cohort.

RESULTS: HDMAX2 resulted in increased power compared to state-of-the-art multi-dimensional mediation methods, and identified several AMRs not identified in previous mediation analyses of exposure to MS on BW and GA. The results provided evidence for a polygenic architecture of the causal pathway with an overall indirect effect of CpGs and AMRs of 44.5g lower BW (32.1% of the total effect size). HDMAX2 also identified AMRs having simultaneous effects both on GA and BW. Among the top hits of both GA and BW analyses, regions located in COASY, BLCAP and ESRP2 also mediated the relationship between GA on BW, suggesting a reverse causality in the relationship between GA and the methylome.
DISCUSSION: This study brought up several statistical improvements of high-dimensional mediation analyses, which revealed an unsuspected complexity of the causal relationships between exposure to MS and BW at the epigenome-wide level.

KEYWORDS: Mediation; high dimension; causal inference; epigenetics; DNA methylation; pregnancy

O-OP-141 Arsenic Exposure, Blood DNA Methylation and Cardiovascular Disease

Arce Domingo[1,2,3], Kiran Makhani[4], Angela Riffo-Campos[5,6], Maria Tellez-Plaza[1], Kathleen Oros Klein[4], Pooja Subedi[7], Jinying Zhao[7], Katherine Moon[8], Anne Bozack[9], Karin Haack[10], Walter Goessler[11], Jason Umans[12], Lyle Best[13], Ying Zhang[14], Miguel Herreros[15], Ronald Glabonjat[2], Kathrin Schilling[2], Marta Galvez-Fernandez[1,2], Kent Taylor[16], Craig Johnson[17], Peter Durda[18], Russell Tracy[18], Jerome Rotter[16], Stephen Rich[19], David Van den Berg[20], Silva Kasela[21,22], Jack Kent[10], Tiffany Sanchez[2], Tuuli Lappalainen[21,22], Kurt Lohman[23], Yongmei Liu[23], Daniele Fallin[24], Shelley Cole[10], Koren Mann[4,25], Ana Navas-Acien[2]

BACKGROUND AND AIM: Epigenetic dysregulation has been proposed as a key mechanism for arsenic-related cardiovascular disease (CVD). We evaluated differentially methylated positions (DMPs) as potential mediators on the association between arsenic and CVD.

METHODS: Blood DNA methylation was measured in 2321 participants of the Strong Heart Study (SHS), a prospective cohort of American Indians. We identified DMPs that are potential mediators between arsenic and CVD. In a cross-species analysis, we compared those DMPs with differential liver DNA methylation following early life arsenic exposure in the apolipoprotein E knock-out (apoE-/-) mouse model of atherosclerosis. We conducted replication in three independent cohorts: the Framingham Heart Study, Women's Health Initiative and the Multi-Ethnic Study of Atherosclerosis.

RESULTS: A total of 20 and 13 DMPs were potential mediators in the SHS for the association between arsenic and CVD incidence and mortality, respectively, several of them annotated to genes related to diabetes. Eleven of these DMPs were similarly associated with incident CVD in the three replication cohorts. In the mouse model, differentially methylated regions (DMRs) in 20 of those genes and DMPs in 10 genes were associated with arsenic.

CONCLUSIONS: Differential DNA methylation might be part of the biological link between arsenic and CVD. The gene functions suggest that diabetes might be an important mechanism for arsenic induced cardiovascular risk in populations with a high burden of diabetes.

KEYWORDS: Arsenic, DNA methylation, cardiovascular disease, epigenetics, American Indians

O-OP-142 Epigenetic Mediation of Prenatal Tobacco and Alcohol Exposure and Infant Neurodevelopment in a South African Birth Cohort: A High-Dimensional Mediation Analysis

Sarina Abrishamcar[1], Junyu Chen[1], Dakotah Feil[1], Anna Kilanowski[6,7,8], Nastassja Koen[3,4,5], Aneesa Vanker[2], Kirsten A. Donald[2,3], Heather J. Zar[2,4], Dan J. Stein[3,4,5], Anke Huels[1,9]

[1]Department of Epidemiology, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Department of Paediatrics and Child Health, Red Cross War Memorial Children's Hospital, University of Cape Town, Cape Town, South Africa, [3]Neuroscience Institute, University of Cape Town, Cape Town, South Africa, [4]South African Medical Research Council (SAMRC) Unit on Risk and Resilience in Mental Disorders, University of Cape Town, Cape Town, South Africa, [5]Department of Psychiatry and Mental Health, University of Cape Town, Cape Town, South Africa, [6]Institute of Epidemiology, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany, [7]Institute for Medical Information Processing, Biometry, and Epidemiology, Pettenkofer School of Public Health, LMU Munich, Munich, Germany, [8]Division of Metabolic and Nutritional Medicine, von Hauner Children's Hospital, University of Munich Medical Center, Munich, Germany, [9]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA

BACKGROUND AND AIM: Prenatal tobacco exposure (PTE) and prenatal alcohol exposure (PAE) have been associated with an increased risk of delayed neurodevelopment in children as well as differential newborn DNA methylation (DNAm). However, the biological mechanisms connecting PTE and PAE, DNAm, and neurodevelopment are largely unknown. Here we aim to determine whether differential DNAm in cord blood mediates the association between PTE and PAE and neurodevelopment in 113 children of 6 months of age from the South African Drakenstein Child Health Study.

METHODS: PTE and PAE were assessed antenatally using urine cotinine measurements and the ASSIST questionnaire, respectively. DNAm was measured from cord blood using the EPIC and 450K BeadChips. Neurodevelopment was measured at 6 months across five domains (cognitive, language, motor, adaptive behavior, socioemotional) using the Bayley Scale of Infant and Toddler Development, Third Edition. We conducted a high-dimensional mediation analysis using a novel approach called the divide-aggregate composite null test (DACT), followed by causal mediation analysis to estimate the average causal mediation effects (ACME) and total effect (TE).

RESULTS: In this population, 35% of mothers actively smoked and 23% of mothers consumed alcohol during pregnancy. We identified 31 CpG sites and 8 CpG sites to have a significant mediating effect (ACME and TE P <0.05) between PTE and cognitive and motor development, respectively. for PAE, 16 CpG sites and 1 CpG site had a significant mediating effect on motor and adaptive behavior development, respectively.

CONCLUSIONS: These findings suggest that changes in the methylome may in part explain the biological mechanisms underlying the relationship between PTE and PAE and infant neurodevelopment. The identification of significant CpG sites could provide novel insights for early detection of disease and potential prevention targets in translational research and community interventions in at-risk populations.

KEYWORDS: epigenomics; mediation analysis; neurodevelopment; prenatal smoking; prenatal alcohol exposure

O-OP-143 Prenatal wildfire exposure associates with differential placental DNA methylation and pregnancy traits

Logan Williams[1,2,3], Julia Mouat[1,2,3], Amanda Goodrich[4], Elizabeth Angel[4], Sean Raffuse[5], Janine LaSalle[1,2,3], Rebecca Schmidt[2,3,4]

[1]Department of Medical Microbiology and Immunology, University of California Davis, Davis, USA, [2]Perinatal Origins of Disparities Center, University of California Davis, Davis, USA, [3]MIND Institute, University of California Davis, Davis, USA, [4]Department of Public Health Sciences, University of California Davis, Davis, USA, [5]Air Quality Research Center, Davis, USA

BACKGROUND AND AIM: As the effects of anthropogenic climate change increase the frequency and severity of wildfires in arid regions, the impacts of prenatal wildfire smoke exposure (WFE) on prenatal health will become relevant to an increasing number of pregnant women. Prior investigations have found associations between WFE and pregnancy complications, and postulated DNA methylation as a potential contributing mechanism for this effect. This preliminary study will investigate the placental DNA methylation changes associated with prenatal WFE, and search for differential methylation patterns that could inform the relationship between prenatal WFE and adverse pregnancy outcomes.

METHODS: DNA was extracted from 136 unique placental samples (124 not exposed to 2008 CA wildfires during pregnancy, 12 exposed) associated with metadata on wildfire exposure as well as other traits of interest. DNA underwent bisulfite conversion and subsequent whole genome bisulfite sequencing to reveal placental methylome. Placental methylomes were used to perform comethylation network analysis via the Comethyl package, generating modules of correlated methylation patterns across samples. Comethylation modules were then tested for association with sample metadata, including wildfire exposure.

RESULTS: Four comethylation modules (darkorange, darkred, saddlebrown, and plum2) were associated ($p<0.05$) with prenatal WFE. Two of these modules (darkorange and plum2) were also associated with maternal weight gain or gestational diabetes, with these modules being enriched for genes implicated in endothelial, vascular, neuronal, and DNA repair pathways. The darkred comethylation module was also associated with child and paternal Hispanic ethnicity characteristics, with the module itself being enriched for genes involved in mitochondrial chain respiratory pathways.

CONCLUSIONS: A significant association exists between prenatal WFE, placental DNA methylation, and maternal weight gain. Larger cohorts of WFE samples are required to bolster the associations identified in this discovery analysis.

KEYWORDS: wildfires, prenatal, methylation

O-OP-144 Exposure to Ambient Gaseous Pollutants, Serum miRNA Networks, Lipid Metabolism, and Non-Alcoholic Fatty Liver Disease in Young Adults

William Patterson[1], Jesse Goodrich[3], Elizabeth Costello[3], Frederick Lurmann[2], Zhanghua Chen[3], Lida Chatzi[3], Frank Gilliland[3], Tanya Alderete[1]

[1]Department of Integrative Physiology, University of Colorado Boulder, Boulder, USA, [2]Sonoma Technology, Inc., Petaluma, USA, [3]Department of Population and Public Health Sciences, Keck School of Medicine, USC, Los Angeles, United State of America

BACKGROUND AND AIM: Exposure to gaseous ambient air pollutants (GP) has been associated with altered lipid metabolism in young adults. MicroRNA (miRNA) networks regulate gene expression and may mediate this relationship. This work aimed to investigate associations of serum miRNA networks with GP, lipid metabolism, and non-alcoholic fatty liver disease (NAFLD) in young adults.

METHODS: Participants were 124 young adults (17-22 years) from the Metabolic and Asthma Incidence Research (Meta-AIR) cohort. Residential GP exposure (nitrogen dioxide [NO_2]; 24-hour and 8-hour maximum ozone [O_3]; redox-weighted oxidative capacity [Ox]) was spatially interpolated from monitoring stations via inverse-distance-squared weighting. Liver fat was imaged by MRI and NAFLD was defined by ≥5.5% hepatic fat fraction. Serum miRNAs were assayed via NanoString and networks were constructed by weighted gene correlation network analysis (WGCNA). The first eigenvector (z-score) of each network represents the similarity of an individual's miRNA profile to a given network. Multivariable linear and logistic regression models adjusted for age, sex, ethnicity, and body mass index. Effect estimates are scaled to one standard deviation of exposure. Pre-specified metabolic pathways pertinent to lipid metabolism were examined for enrichment with DIANA-mirPath which extracts experimentally-validated mRNA targets from TarBase and facilitates KEGG pathway analysis.

RESULTS: Prior-month 24-hr O_3 and Ox and prior-year NO_2 were inversely associated with the miRNA eigenvector (β=-0.018, p=0.046; β=-0.016, p=0.026; β=-0.019, p=0.022, respectively) of the network comprised of miR-130a-3p, miR-148b-3p, miR-191-5p, miR-199-3p, miR-223-3p, miR-23a-3p, and miR-320e. This miRNA eigenvector was also inversely associated with LDL-cholesterol (β=-6.26, p=0.028) and associated with lower odds of NAFLD (OR=0.37, p=0.007). The mRNA targets of these miRNAs were enriched in the fatty acid biosynthesis pathway ($p<0.001$).

CONCLUSIONS: Exposure to GP may contribute to dysregulated lipid metabolism and NAFLD risk among young adults by perturbation of miRNA networks governing fat metabolism.

KEYWORDS: microRNA, biomarker, NAFLD, ozone, NO_2, air pollution

O-OP-145 Mitochondrial DNA Copy Number Dynamics from Birth through Adolescence in a Population of Dominican and African American Children

Allison Kupsco[1], Tessa Bloomquist[1], Heng Hu[1], Deliang Tang[1], Jeff Goldsmith[1], Andrew G Rundle[1], Julie B Herbstman[1], Andrea A Baccarelli[1]
[1]*Columbia University Mailman School of Public Health, New York, USA*

BACKGROUND AND AIM: Mitochondria are vital for cellular energy production, metabolism, and signaling; however, they are uniquely susceptible to damage from environmental toxicants. Mitochondrial DNA copy number (mtDNAcn) is a widely used biomarker in human population studies and is associated with several exposures, including air pollution and metals. Yet, little is known about the dynamics of mtDNAcn throughout childhood and its longitudinal associations with key population characteristics. Our objective was to profile mtDNAcn from birth through adolescence to better inform future environmental health research.

METHODS: Data were collected from a cohort of mother-child pairs from New York City recruited 1998-2006 and followed through 18 years. Using duplexed qRT-PCR we quantified mtDNAcn relative to nuclear DNA from 662 participants using blood collected from the umbilical cord (n=450), children aged 5-7 (n=510), and adolescents aged 15-18 (n=278). We examined mtDNAcn across childhood with linear mixed-effects models (LMM) and latent class growth models (LGCM). We then examined associations with key population characteristics (maternal lifestyle during pregnancy and birth outcomes).

RESULTS: Relative mtDNAcn was lowest at birth (mean ± SD: 0.67 ± 0.35) and increased in childhood (1.24 ± 0.50) then slightly declined in adolescence (1.13 ± 0.44). MtDNAcn values across visits were moderately correlated (r=0.32-0.44). LGCM identified two trajectories of mtDNAcn: a high group (n=615) and a smaller low group (n=47). We observed no differences in mtDNAcn by sex or by race/ethnicity. In LMMs, longitudinal mtDNAcn was positively associated with prenatal environmental tobacco smoke exposure but negatively associated with maternal education and maternal receipt of public assistance at birth. No associations were observed with child birth outcomes.

CONCLUSIONS: MtDNAcn levels were dynamic through childhood and are associated with prenatal factors. These results underscore the need for the investigation of mtDNAcn dynamics and predictors for environmental health research.

KEYWORDS: Biomarkers, mitochondria, mtDNA, children's environmental health

ORAL PRESENTATIONS SESSION 28: The exposome and health

O-OP-146 Metabolomics links lifestyle variables to breast cancer in the Long Island Breast Cancer Study Project

Miao Yu[1], Qian Li[1], Georgia Dolios[1], Peijun Tu[1], Susan Teitelbaum[1,2], Jia Chen[1,2], Lauren Petrick[1,2,3]
[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, USA, [2]The Institute for Exposomics Research, Icahn School of Medicine at Mount Sinai, USA, [3]The Bert Strassburger Metabolic Center, Sheba Medical Center, Israel

BACKGROUND AND AIM: Healthy lifestyle has been associated with decreased risk of developing breast cancer. Using untargeted metabolomics profiling, we aim to identify the molecular mechanisms connecting lifestyle and breast cancer through network analysis.

METHODS: A total of 50 post-menopausal women with breast cancer and 50 cancer-free controls were selected from the Long Island Breast Cancer Study Project (LIBCSP). We measured untargeted plasma metabolomics using liquid chromatography- high resolution mass spectrometry (LC-HRMS). Using 'enet', we retained metabolites found in active molecular network (AMN) clusters for analysis. LASSO was used to explore associations between cancer status and metabolites; 14 lifestyle related variables including smoking, physical activity, alcohol consumption, meat consumption, fruit and vegetables consumption, supplemental vitamin use; and 20 covariates including various reproductive factors. LASSO was repeated to explore associations between selected lifestyle factors and metabolites. Results were displayed as a network to uncover biological pathways linking lifestyle factors to breast cancer.

RESULTS: After filtering, 1797 metabolomics peaks in the plasma samples remained. of these, 851 "active" metabolites were retained in 197 correlation AMN clusters. Through LASSO, breast cancer status was associated with 66 "active" metabolites. Several of these metabolites were also associated with lifestyle variables including meat consumption, alcohol consumption, and supplemental β-carotene, B12 and folate use. No individual lifestyle factors were directly associated with breast cancer status through LASSO, suggesting that metabolites may act as biological intermediaries between healthy lifestyle factors and breast cancer. In particular, 13-HPODE, a metabolite linked with inflammation, was associated with breast cancer status and connected to β-carotene supplement usage through an AMN.

CONCLUSIONS: We found several plasma metabolites associated with both lifestyle factors and breast cancer status. These results suggest that inflammation may play a mechanistic role linking supplement usage to breast cancer status.

KEYWORDS: breast cancer, lifestyle factors, metabolomics, network analysis

O-OP-147 External exposome and all-cause mortality in two large administrative cohorts: Rome (Italy) and Greece

Federica Nobile[1], Konstantina Dimakopoulou[2], Roel C H Vermeulen[3], Jelle J Vlaanderen[3], Evangelia Samoli[2], Massimo Stafoggia[1], on behalf of the EXPANSE Project Team

[1]Department of Epidemiology, Lazio Region Health Service / ASL Roma 1, Rome, Italy, [2]Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Athens, Greece, [3]Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, Netherlands

BACKGROUND AND AIM: Many studies reported associations between long-term exposure to several environmental stressors and mortality, however little is known on the complex interplay between the urban exposome and health. We characterized the external exposome through a limited number of exposure domains and investigated their association with mortality in two large cohorts (Rome and Greece).

METHODS: Within the EXPANSE project, we analyzed two population-based cohorts: Rome (Italy) (30+ years; 2011-2019) and Greece (37+; 2014-2019). Multiple exposures were assigned at the residential addresses, and were divided into three a-priori defined domains: 1) land-built environment (NDVI, imperviousness surfaces, distance to water); 2) air pollution (fine particulate matter ($PM_{2.5}$), nitrogen dioxide (NO_2), black carbon (BC) and warm-season ozone (warm-O_3)); 4) temperature (annual, cold-season and warm-season mean and standard deviation (SD)). Each domain was synthesized through Principal Component Analysis (PCA). We applied Cox proportional hazards regression models using the obtained principal components as exposures.

RESULTS: In each cohort and for each domain, we selected the first principal component. It explained more than 55% of variance, ranging from 57.4% (land-built environment for Rome) to 83.3% (air pollution for Rome). We estimated a protective effect between the land-built environment domain and all-cause mortality, with hazard ratios (HR) of 0.984 (95%CI: 0.977-0.991) in Rome and 0.980 (0.976-0.984) in Greece, per interquartile range increments. Associations with the air pollution component were positive and statistically significant, with HR of 1.011 (1.005-1.018) and 1.060 (1.051-1.068), respectively. The air temperature domain was associated with mortality only in the Greek cohort. Results were similar in multi-component analyses.

CONCLUSIONS: We found associations between different components of the external exposome and mortality in two large administrative cohorts. The same approach will be applied in the other administrative cohorts of EXPANSE: Switzerland, Sweden, Netherlands and Catalunya (Spain).

KEYWORDS: exposome, population-based cohort, principal component analysis.

O-OP-148 The urban exposome and type 2 diabetes: A deep learning approach

Haykanush Ohanyan[1,2,3,4], Lützen Portengen[1], Oriana Kaplani[1,5], Gerard Hoek[1], Joline WJ Beulens[2,3,4,6], Jeroen Lakerveld[2,3,4], Roel Vermeulen[1]

[1]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, [2]Department of Epidemiology and Data Science, Amsterdam Public Health research institute, Amsterdam UMC, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, [3]Amsterdam Public Health, Health Behaviours and Chronic Diseases, Amsterdam, Netherlands, [4]Upstream Team, www.upstreamteam.nl. Amsterdam UMC, VU University Amsterdam, Amsterdam, Netherlands, [5]Leiden University, Leiden, Netherlands, [6]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherland

BACKGROUND AND AIM: Type 2 diabetes (T2D) is a chronic disease with high individual and societal burden. Risk of T2D is partly influenced by urban characteristics, such as air pollution, or indirectly through their relation with lifestyle behaviours (e.g. walkability, food environment). Environmental characteristics are generally studied individually in their association with T2D, but occur simultaneously in real life, and may associate with T2D in nonlinear and non-additive ways. We aimed to identify which factors of the urban exposome are associated with T2D by applying artificial neural networks (ANN). In addition, we compared results of ANN model with penalized regression LASSO, as a more conventional method.

METHODS: We analyzed baseline data from 14,829 participants of the Occupational and Environmental Health Cohort study living across the Netherlands. Self-reported questionnaire data were used to identify participants diagnosed with T2D (n=676(4.6%)). Exposome variables (n=86) were linked to individual home addresses, including air pollution, traffic noise, green-space, chemicals in drinking water, built environmental and neighborhood socio-demographic characteristics. Models were adjusted for individual socio-demographic variables. Nested cross-validation was used to determine the optimal model parameters of both approaches (ANN and LASSO), and the cross-validated predictive accuracies were compared.

RESULTS: One exposure was selected by each approach. Living in neighborhoods with a higher share of non-Western immigrants (selected by ANN) was associated with a higher risk of T2D. Higher average home value in residential neighborhood (selected by LASSO) was associated with a lower risk of T2D. Cross-validated prediction error logLoss (sd) was 0.177 (0.0060) for ANN and 0.167 (0.0022) for LASSO.

CONCLUSIONS: Neighborhood socio-demographic characteristics are associated with the risk of T2D. Accuracy of the ANN model was lower than LASSO, which might be due to the low prevalence of diabetes and relatively weak signal in the data.

KEYWORDS: Multiple exposures, Machine learning, Neighborhood socio-demographic characteristics

O-OP-149 Exploring early life exposome related to low birth weight through machine learning methods

Mei Huei Chen[1,2], Chi Jen Chen[3], Tsung Ta Wu[1], Ching Chun Lin[4], Yung Chun Chang[5], Pau Chung Chen[4,6,7]
[1]Institute of Population Health Sciences, National Health Research Institutes, Miaoli County, Taiwan, [2]Department of Pediatrics, National Taiwan University College of Medicine and Hospital, Taipei City, Taiwan, [3]Institute of Epidemiology and Preventive Medicine, National Taiwan University College of Public Health, Taipei City, Taiwan, [4]Institute of Environmental and Occupational Health Sciences, National Taiwan University College of Public Health, Taipei City, Taiwan, [5]Graduate Institute of Data Science, Taipei Medical University Hospital, Taipei City, Taiwan, [6]Department of Environmental and Occupational Medicine, National Taiwan University College of Medicine and Hospital, Taipei City, Taiwan, [7]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli County, Taiwan

BACKGROUND AND AIM: Regarding the multifactorial etiology of low birth weight (LBW), the contribution of environmental hazards is increasing. Exposome refer to totality of a life's exposure including multiple pollutants, lifestyle and sociodemographic factors should provide a holistic view on LBW. This study aims to explore early life exposome related to LBW and identify important factors through machine learning

METHODS: We recruited 486 mother-infant pairs from Taiwan Birth Panel Study, with LBW defined as birth body weight below 2500 gm. Early life factors included 27 environmental pollutants measured in cord blood or maternal urine, estimated outdoor air pollutants (particulate matter 2.5 (PM2.5), nitrogen dioxide (NO2) and greenness (Normalized Difference Vegetation Index (NDVI)) and questionnaires on socioeconomic levels, health behaviors and diet during pregnancy. The association between exposome and LBW were examined by five machine learning methods including Naïve bayes, Support vector machine (SVM), Random forest, XGBoost (eXtreme gradient boosting) and Ensemble learning. Model performance was evaluated by area under Receiver operator characteristic (ROC) curve. And, features selection was used to identify important features.

RESULTS: SVM method and Random forest provided the best prediction based on AUC= 0.73 and 0.74, respectively. The top five important features selected from best model prediction of Random forest include: perfluorooctyl sulfonate (PFOS) in cord blood, uranium and zinc in maternal urine, maternal pre-pregnancy body mass index, maternal gestational weight gain.

CONCLUSIONS: Machine learning approaches could be useful tools for modeling early life exposome associated with LBW. Environmental pollutants and maternal weight status are critical for LBW risk.

KEYWORDS: exposome, machine learning, environmental pollutants, low birth weight

O-OP-150 Impact of residential relocation on environmental exposures in European cohorts: an exposome-wide approach

Apolline Saucy[1], Ulrike Gehring[2], Erik Melén[3], Petter Ljungman[3], Åsa Persson[3], Anke Huss[2], Sergio Olmos[1], Cyrille Delpierre[4], Jeroen de Bont[3], Kees de Hoogh[5], Jelle Vlaanderen[2], Roel Vermeulen[2], Cathryn Tonne[1]
[1]ISGlobal, Barcelona, Spain, [2]Utrecht University, Utrecht, The Netherlands, [3]Karolinska Institutet, Stockholm, Sweden, [4]Inserm / University Toulouse, Toulouse, France, [5]Swiss TPH / University of Basel, Basel, Switzerland

BACKGROUND AND AIM: Residential relocation can cause simultaneous changes in multiple environmental exposures and provides a unique opportunity to examine the health impacts of interventions on the external exposome. However, the likelihood of relocation can be influenced by various individual, household, and neighbourhood characteristics that can also influence health. Including Swedish and Dutch adults (SDPP, AMIGO, mean age 49 years) and children (PIAMA, BAMSE, 0-20 years) cohorts, we investigated the factors associated with relocation and changes in multiple environmental exposures across life stages.

METHODS: We used uni- and multivariable logistic regression to identify predictors of moving (yes/no) including age, sex, ethnicity, education and chronic cardio-respiratory diseases (asthma, hypertension) at baseline. We then conducted multivariable linear regression to identify predictors of changes in individual exposures (air pollution, green space, blue space, impervious surfaces) among participants who relocated during the first four years of follow-up.

RESULTS: On average, 7% of the participants relocated each year. Before relocation, movers consistently presented higher levels of air pollution than non-movers. Predictors of moving in adults cohorts included younger age, past and current smoking, lower levels of education, but not sex or pre-existing asthma or hypertension. In children cohorts, moving was associated with higher levels of socioeconomic status and parental education. These characteristics were also associated with moving to greener, less polluted areas. Among movers in adults cohorts, older individuals moved to areas with increased pollution and grey space. However, relocating to areas with higher levels of pollution and less green space was associated with higher education levels in SDPP, and lower education levels in AMIGO.

CONCLUSIONS: Several individual characteristics including age, smoking and education were associated with residential relocation. Among movers, the predictors of exposure change due to relocation varied across cohorts and life stages.

KEYWORDS: external exposome; air pollution; built environment, residential relocation

O-OP-151 Metabolic Pathways Altered by Air Pollution Exposure in Association with Lipid Profiles in Young Adults

Jiawen Liao[1], Jesse Goodrich[1], Chenyu Qiu[1], Douglas I. Walker[2], Fred Lurmann[3], Dean P. Jones[4], Frank FIlliland[1], Lida Chazi[1], Zhanghua Chen[1]

[1]University of Southern California, Los Angeles, USA, [2]Icahn School of Medicine at Mount Sinai, New York, USA, [3]Sonoma Technology Inc, Petaluma, USA, [4]Emory University, Atlanta, USA

BACKGROUND AND AIM: Air Pollution is a risk factor for obesity and cardiometabolic diseases in children and adults. We aim to examine the metabolic perturbations associated with air pollution and cardiometabolic health.

METHODS: In year 2014 – 2018, we conducted a cross-sectional study assessing lipid profiles (triglycerides, total cholesterol, high-density lipoprotein (HDL) cholesterol, low-density lipoprotein (LDL) cholesterol, very-low-density lipoprotein (VLDL) cholesterol), untargeted serum metabolomics using liquid chromatography-high-resolution mass spectrometry, and one-month and one-year averaged air pollution exposures to NO2, O3, PM2.5 and PM10 at residential addresses among 132 young adults in southern California. A Metabolome-wide association study was conducted to identify metabolomic signatures associated with air pollution exposure. Mummichog pathway enrichment analysis was used to assess altered metabolic pathways, followed by annotations of metabolomic features. Principal component analysis (PCA) of 36 metabolites with confirmed identity was performed to reduce dimensionality and identify clusters. Lastly, regression models were used to analyze the associations of metabolomic PC scores with air pollution and lipid profiles.

RESULTS: In total, 4937 and 4372 metabolomic features were detected using HILIC positive and C18 negative modes, with 2047 and 1228 features significantly associated with at least one air pollutant in positive and negative ion mode, respectively ($p < 0.05$). Metabolic pathways associated with air pollution exposure included fatty acid, glycerophospholid, tryptophan, and tyrosine metabolism. PCA of 48 metabolites involved in the identified pathways indicated that one-month O3, PM10, PM2.5 and one-year NO2 air pollution exposure was positively associated with free fatty acids and oxidative byproducts-related PC score ($p < 0.05$). This PC score shown to be negatively associated with total cholesterol and LDL cholesterol ($p < 0.05$).

CONCLUSIONS: This study indicated that air pollution exposure is associated with dysregulated fatty acid and lipid metabolism.

ORAL PRESENTATIONS SESSION 29: Impacts of environmental exposures on COVID-related outcomes

O-OP-152 A Spatial and Contextual Exposome-Wide Association Study of COVID-19 Hospitalizations in Florida, USA

Hui Hu[1], Jiang Bian[2], Yi Zheng[1], Jaime Hart[1,3], Francine Laden[1,3,4], Peter James[3,5], Jennifer Fishe[6], Jingchuan Guo[7], William Hogan[2], Elizabeth Shenkman[2]

[1]Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [2]Department of Health Outcomes and Biomedical Informatics, College of Medicine, University of Florida, Gainesville, USA, [3]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [4]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [5]Department of Populatin Medicine, Harvard Pilgrim Healthcare, Boston, USA, [6]Department of Emergency Medicine, University of Florida College of Medicine - Jacksonville, Jacksonville, USA, [7]Department of Pharmaceutical Outcomes & Policy, College of Pharmacy, University of Florida, Gainesville, USA

BACKGROUND AND AIM: Recent studies suggested that long-term environmental exposures may be important determinants of COVID-19 severity. However, very few environmental factors have been studied, and often separately without considering the totality of the environment (i.e., the exposome). To address this gap, we conducted a spatial and contextual exposome-wide association study (ExWAS) of COVID-19 hospitalizations in Florida, USA (US).

METHODS: We obtained electronic health records data of 50,368 patients 18 years and older with a positive SARS-CoV-2 PCR/Antigen lab test or a COVID-19 diagnosis between March 2020 and October 2021 from the OneFlorida+ Data Trust. Patients' exposures to 211 spatial and contextual exposome factors during 2015-2019 were integrated and spatiotemporally linked to their residential addresses. A two-phase analytical procedure was used. (1) A random 50:50 split divided the data into discovery and replication sets. Associations between COVID-19 hospitalizations and individual exposome factors were examined using mixed-effect logistic regression models, with multiple comparisons addressed. (2) A multivariable regression model including all variables that were statistically significant from both the discovery and replication sets was fitted. Odds ratio for each standard deviation increase (ORSD) and 95% confidence interval (95% CI) were reported.

RESULTS: A total of 12 and 21 variables were statistically significant in the discovery and replication sets, respectively. Among the 7 variables included in Phase 2, 3 variables remained statistically significant, including (1) hydrochloric acid (ORSD: 1.93, 95% CI: 1.11, 3.38), obtained from the US Environmental Protection Agency's National Air Toxics Assessment, (2) density of fitness and recreational sports centers (ORSD: 0.94, 95% CI: 0.92, 0.97), assessed using the US Census Business Pattern, and (3) neighborhood deprivation index (ORSD: 1.09, 95% CI: 1.06, 1.12), derived using the American Community Survey.

CONCLUSIONS: Long-term exposures to three spatial and contextual exposome factors were associated with COVID-19 hospitalizations in Florida, USA.

O-OP-153 Spatial Analysis of Ambient Air Pollution and COVID-19 Death in a Hospitalized Cohort of Confirmed Cases in Southern California

Michael Jerrett[1], Claudia Nau, Deborah R. Young, Rebecca K. Butler, Christina Batteate, Jason Su, Richard T. Burnett, Michael Kleeman
[1]*University of California Los Angeles, Los Angeles, USA*

BACKGROUND AND AIM: Recent evidence links ambient air pollution to COVID-19 incidence, severity, and death, but few studies have analyzed individual-level health data with high quality exposure models.
OBJECTIVE: We sought to assess whether air pollution exposures led to greater risk of death during or after hospitalization in confirmed COVID-19 cases among patients who were members of the Kaiser Permanente Southern California (KPSC) healthcare system.

METHODS: We used 1 km resolution chemical transport models (CTMs) to estimate ambient concentrations of several common air pollutants, including ozone, nitrogen dioxide, and fine particle matter (PM2.5). We also derived estimates of pollutant exposures less-commonly available in epidemiological studies, including ultra-fine particulate matter (PM0.1), PM chemical species, and PM sources. We used Cox proportional hazards models to assess associations between air pollution exposures and death from COVID-19, while controlling for potential individual and contextual confounders.

RESULTS: We found significant associations between COVID-19 death and several air pollution exposures, including: PM2.5 mass, PM0.1 mass, PM2.5 nitrates, PM2.5 elemental carbon, PM2.5 on-road diesel, and PM2.5 on-road gasoline. Based on the interquartile (IQR) exposure increment, effect sizes ranged from hazard ratios (HR) = 1.12 for PM2.5 mass and PM2.5 nitrate to HR ~ 1.06-1.07 for other species or source markers. Humidity and temperature in the month of diagnosis were also significant predictors of COVID-19 death and inverse modifiers of the air pollution effects.
CONCLUSION: Higher air pollution exposures were associated with a greater risks of COVID-19 death in a cohort of patients hospitalized for COVID-19 in Southern California.

O-OP-154 COVID-19 disease severity in hospitalized patients is associated with short- and long-term exposure to air pollutants

Stijn Vos[1], Elien De Waele[2], Pieter Goeminne[2], Esmée Bijnens[1], Eva Bongaerts[1], Annick De Weerdt[3], Philippe Jorens[3], Tim Nawrot[1,4]

[1]Centre for Environmental Sciences, Hasselt University, Diepenbeek, Belgium, [2]AZ Nikolaas, Sint-Niklaas, Belgium, [3]Antwerp University Hospital, Antwerp, Belgium, [4]Department of Public Health & Primary Care, Occupational & Environmental Medicine, KU Leuven, Leuven, Belgium

BACKGROUND AND AIM: Existing evidence suggests that exposure to air pollutants (AP) such as particulate matter (PM2.5 and PM10), nitrogen dioxide (NO2) and black carbon (BC) is associated with COVID-19 infection rates and mortality. We investigated whether exposure to AP was associated with COVID-19 disease severity in a cohort of hospitalised COVID-19 patients.

METHODS: 329 COVID-19 patients were recruited at the time of admission to hospital. Clinical parameters and outcomes were collected from medical records, including the duration of stay, the early-warning score (EWS), oxygen saturation, and PaO2/FiO2 ratios. Daily exposure levels for PM2.5, PM10, NO2 and BC were modelled using a high-resolution spatiotemporal model. Black carbon particles in blood were quantified using femtosecond pulsed laser illumination. Associations between exposure to air pollutants and clinical outcomes were modelled using multiple regression models while adjusting for potential confounders.

RESULTS: The duration of stay increased by 1 to 6 days for an interquartile range (IQR) increase in average exposure to AP in the week before admission (PM2.5: +5.2 days, NO2: +5.8 days). Similarly, an IQR increase in long-term exposure (to AP was associated with increased duration of stay (PM2.5: +2.8 days, NO2: +3.2 days, BC: +2.8 days). Furthermore, an increase in PM2.5 exposure 1 week before admission was associated with higher EWS (+0.40). Finally, IQR increases in long-term exposure to PM10, BC and NO2 as well as blood black carbon load were associated with odds of admission to the intensive care unit (OR: +1.32, +2.12, +2.46 and +1.19 respectively).
CONCLUSION: Exposure to AP was associated with duration of stay and EWS scores at the time of admission, which implies a potential link between AP exposure and COVID-19 disease severity, and a significant influence of AP exposure on the pressure on medical care systems during the COVID-19 pandemic.

O-OP-156 Antibody Response after COVID-19 Vaccination in Healthy Adults Exposed to Perfluoroalkyl Substances in Ronneby, Sweden

Axel Andersson[1], Ph.D. Anna Lundgren[2,3], Ph.D. Ying Li[1], M.D. Julia Cederlund[4], M.D. Elisavet Pataridou[4], Ph.D. Christel Nielsen[5], Ph.D. Christian Lindh[5], Ph.D. Sandra Søgaard Tøttenborg[6,7], Ph.D. Kajsa Ugelvig Petersen[7], Ph.D. Tony Fletcher[8], Ph.D. Mats Bemark[2,3], Ph.D. M.D. Kristina Jakobsson[1,9]

[1]School of Public Health and Community Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [2]Department of Microbiology and Immunology, Institute of Biomedicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [3]Department of Clinical Immunology and Transfusion Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden., Gothenburg, Sweden, [4]Kallinge Primary Health Care Unit, Region Blekinge, Kallinge, Sweden, [5]Division of Occupational and Environmental Medicine, Department of Laboratory Medicine, Lund University, Lund, Sweden, [6]Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [7]Department of Occupational and Environmental Medicine, Bispebjerg and Frederiksberg Hospital, University of Copenhagen, Copenhagen, Denmark, [8]London School of Hygiene and Tropical Medicine, London, UK, [9]Occupational and Environmental Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden

BACKGROUND AND AIMS: Per- and polyfluoroalkyl substances (PFAS) are widely used, environmentally ubiquitous chemicals. Inhabitants in Ronneby, Sweden, have had long-term, moderate to high PFAS-exposure through drinking water contaminated by firefighting foams.
PFAS has been associated with decreased vaccine-induced antibody responses in children. Effects in adults have been poorly investigated, in part owing to lack of well-designed trials of primary immunizations in PFAS exposed populations.
The novelty of vaccination against COVID-19 and the associated clinical trials, offers a unique opportunity to investigate if PFAS decrease vaccine-induced antibody response in adults.

METHODS: Healthy, COVID-19 unvaccinated adults, 20-60 years old, from Ronneby (n=319; Perfluorooctanesulfonic acid (PFOS) median 46 ng/mL, range 1-543) and referents from neighboring Karlshamn (n=41; PFOS median 4 mg/mL, range 1-36), were vaccinated with two doses of the mRNA vaccine Spikevax® (Moderna). Seven PFAS were measured in serum before vaccination. Serum IgG antibodies against the spike antigen were measured before vaccination, and at five weeks (n=350) and six months (n=329) after the second vaccination.
Regression analyses of antibodies were fitted against serum PFAS levels, quartile groups, smooth splines and between exposed and reference areas, adjusting for sex, age, smoking and previous SARS-CoV-2-infection.

RESULTS: Participants from Ronneby and referents had similar, high antibody levels (100% positive) five weeks and six months post vaccination, with waning levels over time.
Regression models showed no clear pattern between antibody levels at five weeks or six months after vaccination and PFAS exposure. Results were replicated using different exposure indices, covariate adjustments and sensitivity analyses, and consistent for seven different PFAS compounds.

CONCLUSIONS: In this clinical trial, with a wide PFAS exposure range and a low dropout rate, we assessed no indication that moderate to high PFAS exposure adversely affected antibody production in adults after COVID-19 mRNA vaccination.

KEYWORDS: PFAS, Immunotoxicity, Antibody, COVID-19 Vaccination

O-OP-157 The association of COVID-19 incidence with temperature, humidity, and UV radiation – A Global multi-city analysis

BACKGROUND AND AIM: The possible associations of COVID 19 transmission and meteorological factors is a topic of scientific debate. A multitude of studies have been conducted worldwide, with inconsistent findings. However, often these had methodological issues, e.g. did not exclude important confounding factors, or had limited geographic or temporal resolution.

METHODS: We analysed data from 455 cities across 20 countries around the globe over an observation period before the vaccine roll out began, ranging from 3 February to 31 October 2020. We used a time-series analysis that assumes a quasi-Poisson distribution of the cases and incorporates distributed lag non-linear modelling for the exposure association at city-levels while considering effects of autocorrelation, long-term trends and day of the week. The confounding by governmental measures was accounted by incorporating the Oxford Governmental Stringency Index. The effects of daily mean air temperature, relative and absolute humidity, and UV radiation were estimated by applying a meta-regression of local estimates with multi-level random effects for location, country, and climatic zone.

RESULTS: We found that air temperature and absolute humidity influenced the spread of COVID-19 over a lag period of 15 days. Pooling the evidence globally showed that overall low temperatures (7.5°C compared to 17.0°C) and low absolute humidity (6.0 g/m³ compared to 11.0 g/m³) were associated with higher COVID 19 incidences (RRtemp=1.33 with 95%CI: 1.08; 1.64 and RRAH=1.33 with 95%CI: 1.12; 1.57). for RH and UV no evidence of an association was found. These results were robust to sensitivity analysis. However, the study results also emphasised the heterogeneity of these associations in different countries.

CONCLUSIONS: Globally, our results suggest that comparatively low temperatures and low absolute humidity were associated with increased risks of COVID 19 incidence. However, this study underlines regional heterogeneity of weather-related effects on COVID-19 transmission.

KEYWORDS: Temperature, Humidity, UV Radiation, COVID-19

ORAL PRESENTATIONS SESSION 30: Child health, air pollution exposure and greenspace

O-OP-158 Air quality and children allergic diseases and neurodevelopmental disorders - A nationwide birth cohort follow-up approach

Shu-Li (Julie) Wang[1], Chong-Shiow Wang[1], Tsung Lin Tsai[1], Chih-Da Wu[2]
[1]National Health Research Institutes, Zhunan Town, Miaoli County, Taiwan, [2]National Cheng Kung University, Tainan City, Taiwan

BACKGROUND AND AIM: Air pollution was associated with decreased lung function and intelligence. However, sizeable prospective follow-up studies with pre-and postnatal exposure considerations are scarce. The research is urgent due to the potential life-long lung and brain functional effects and the new WHO air quality guideline. In addition, extensive data-based investigations of two distinguished disorders might help examine potential confounders. The goal is to investigate prenatal exposure to nitrogen dioxide (NO2) and postnatal allergic diseases and neurodevelopmental disorders in a national-wide birth cohort.

METHODS: We used the National Health Insurance Research Database (NHIRD) and the Taiwan Maternal and Child Health Database (TMCHD) to establish a national birth cohort born from 2007-to 2011 to follow the cumulative incidence of children's allergic diseases neurodevelopmental disorders till 2017. As a result, there were 759,142 infant-mother pairs finally included in the cohort without significant abnormalities. In addition, we utilized hybrid land-use regression models and machine learning methods to assess daily exposure to nitrogen dioxide (NO2) air pollutants, adopting the data of 76 national air-monitoring stations.

RESULTS: The children experienced significantly increased allergic diseases [Hazard Ratio (HR), atopic dermatitis: 1.42 (Confidence Interval 1.38~1.45); asthma 1.21 (CI 1.19~1.23); allergic rhinitis: 1.22 (1.20~1.24)] and neurodevelopmental disorders [HR, autism: 1.52 (1.41~1.63); attention deficit hyperactivity disorder: 1.41 (1.36~1.46)] but not for epilepsy [HR, 1.04 (0.97~1.12)] with the 3rd tertile exposure to NO2 concentration (≥ 20.0 ppb) as compared to the lower (≤ 15.1 ppb) prenatally, adjusted for paid insurance amount, maternal smoking status, and parental history of the individual examined diseases in the Cox's model.
CONCLUSION: The incidence of children's allergic diseases and neurodevelopmental disorders increased significantly at the 3rd tertile of NO2 concentration before birth. Therefore, our result also corresponded to the new WHO guideline of optimized 20 ppb for NO2.

O-OP-159 In-utero exposure to air pollution and blood pressure in children from the Rhea birth cohort study, Greece

Theano Roumeliotaki[1], Katerina Margetaki[1], Minas Iakovides[2], Euripides Stephanou[2], Manolis Kogevinas[3], Leda Chatzi[4], Marina Vafeiadi[1]

[1]Department of Social Medicine, School of Medicine, University of Crete, Heraklion, Greece, [2]Environmental Chemical Processes Laboratory (ECPL), Department of Chemistry, University of Crete, Heraklion, Greece, [3]ISGlobal, Barcelona, Spain, [4]Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: High blood pressure (BP) in childhood has been linked with hypertension and impaired cardiovascular health within adulthood. Exposure to air pollution has been associated with elevated BP in children but only a few studies evaluated the persistence of these associations into early adolescence. We investigated the association between pregnancy exposure to air pollution and BP through childhood in the Rhea birth cohort in Greece.

METHODS: Residential exposure to particulate matter <10 μm (PM10) and <2.5 μm (PM2.5) during pregnancy was estimated with temporally adjusted land-use regression models. We measured systolic (SBP) and diastolic (DBP) blood pressure at 4, 6, and 11 years. Hypertension was defined as DBP or SBP ≥95th sex-, age- and height-percentiles. Generalized estimating equation and multivariate regression models assessed the associations (per 5 μg/m³) with repeated and single time-point measures, respectively. We also tested effect modification by sex and maternal smoking.

RESULTS: Median (IQR) levels of PM2.5 and PM10 during pregnancy were 14.4 (2.4) μg/m3 and 35.6 (2.3) μg/m3, respectively. PM10 was associated with higher SBP and DBP in boys but lower in girls (p-interaction= 0.025 and 0.036) at 4 years. We also observed higher risk for hypertension overall (1.62; 95% CI: 1.04, 2.53) and in boys (2.01; 95% CI: 1.07, 3.79), and in children born to non-smoking mothers during pregnancy (2.14; 95% CI: 1.25, 3.66). Higher PM2.5 was associated with lower SBP in boys at 6 (β= -3.75 mmHg; 95% CI: -7.14, -0.36) and 11 years (β= -4.49 mmHg; 95% CI: -9.09, 0.11; p-interaction= 0.068 and 0.072). Sex differences in BP trajectories were also observed.

CONCLUSIONS: This study suggests that prenatal air pollution exposure may affect blood pressure during childhood. Further research is needed to understand sex differences and the role of co-exposure to maternal smoking.

KEYWORDS: Blood pressure, childhood, air pollution, prenatal

O-OP-160 Short-term air pollution exposure and anxiety symptoms in children from Mexico City

Laura McGuinn[1], Allan Just[1], Ivan Gutierrez[1], Itai Kloog[1], Lourdes Schnaas[2], Sandra Martinez[2], Brent Coull[3], Daniel Klein[4], Martha Maria Tellez-Rojo[5], Rosalind Wright[1], Robert Wright[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]National Institute of Perinatology, Mexico City, Mexico, [3]Department of Biostatistics, Harvard T. H. Chan School of Public Health, Boston, USA, [4]Department of Psychology, Stony Brook University, Stony Brook, USA, [5]Center for Nutrition and Health Research, National Institute of Public Health, Cuernavaca, Mexico

BACKGROUND AND AIM: Short-term air pollution exposure has been linked to mental health conditions in adults; however, there is limited research in the younger populations in which symptoms often first arise. In this study, we examined the association between recent fine particulate matter (PM2.5) exposure and symptoms of anxiety in a cohort of 8–9-year-olds in Mexico City.

METHODS: Participants included 455 mother-child pairs from a longitudinal birth cohort study in Mexico City. Anxiety symptoms were assessed at the 8–9-year study visit by trained psychologists using the Spanish version of the Revised Children's Manifest Anxiety Scale. Daily PM2.5 predictions were estimated using a 1km satellite-based exposure model and averaged over several recent exposure windows including 1-12 months and 1-4 weeks prior to anxiety assessment. We additionally used recent weekly exposure averages in distributed lag models. Linear regression models were used to estimate the change in continuous anxiety symptoms with each 5-µg/m3 increase in PM2.5. Models were adjusted for maternal education, maternal age, child's age at study visit, child sex, and season of study visit. We additionally assessed sex-specific effects by including an interaction term between PM2.5 and sex.

RESULTS: A 5-unit increase in PM2.5 exposure averaged over the 1 month prior to study visit was associated with higher anxiety symptoms in the child (β= 0.65, 95% CI: 0.01, 1.30). These associations were primarily seen in females (β= 1.05, 95% CI: 0.10, 1.95, p-int: 0.10). Using DLM approaches, we identified a critical window for exposures 0-2 weeks prior to anxiety assessment.

CONCLUSIONS: Fine particulate matter exposure was associated with elevated levels of child anxiety symptoms, particularly for more recent exposures.

O-OP-161 Prenatal exposure to residential green space and cord blood DNA methylation: epigenome wide association studies in the ENVIRONAGE cohort

Rossella Alfano[1], Esmee Bijnens[1], Tim Nawrot[1], Michelle Plusquin[1]
[1]*Hasselt University, Diepenbeek, Belgium*

BACKGROUND AND AIM: DNA methylation may be an underlying mechanism between green space and health. Although newborn DNA methylation is sensitive to environmental influences during prenatal life, the impact of green space has not been studied yet. This study evaluated whether prenatal exposure to residential green space is associated with cord blood DNA methylation.

METHODS: We conducted epigenome-wide association studies using data from two subpopulations (N=198 and 349) of the ENVIRONAGE cohort. Cord blood DNA methylation was measured by Illumina HumanMethylation 450K and EPIC BeadChip arrays, respectively in the two subpopulations. High (vegetation >3m), low (vegetation <3m) and total (including both) green space exposure was estimated within 100 and 1000 m distance around the maternal residence using high-resolution data. We used linear mixed models to identify differentially methylated sites, and two different approaches (ENmix-combp and DMRcate) to identify differentially methylated regions. Functional analysis was performed by associating green space with cord expression of the genes mapped to the identified signals.

RESULTS: Prenatal exposure to total, low and high residential green space within 100 and 1000 m was associated with six differentially methylated regions (annotated to COL9A3, GPR27, LINC00612, LINC01973, PARD6G-AS1, ZNF274 genes), in common to the two subsets. Methylation at 7 CpGs was associated with prenatal exposure to total and high green space at 100 and 1000 m distance, with no overlap between the two subsets. Expression level of the FSTL3 gene decreased with prenatal exposure to total green space at 1000 m buffer.

CONCLUSIONS: Our results demonstrate that prenatal residential exposure to green space is associated with cord blood DNA methylation, mainly at loci organized in regions, and that these signals may have functional relevance.

O-OP-163 Assessment of the joint effects of PM2.5 and pollen on childhood asthma exacerbation in the Philadelphia metropolitan region, 2011-2016

Wanyu Huang[1], Leah Schinasi[1], Chén Kenyon[2], Lucy Robinson[1], Anneclaire De Roos[1]
[1]Dornsife School of Public Health, Drexel University, Phiadelphia, USA, [2]Policy Lab, Children's Hospital of Philadelphia, Philadelphia, USA

BACKGROUND AND AIM: Mechanistic evidence suggests synergism of PM2.5 and pollen in their effects with asthma exacerbation (AE). Nevertheless, few epidemiologic studies have investigated health impacts of their joint exposures. We conducted a time-series study for the interactions between both triggers during the pollen season (Mar 18 – Oct 30) within the Philadelphia region.

METHODS: PM2.5 levels were averaged from the nearest monitor values for asthmatic individuals identified through electronic health records from the Children's Hospital of Philadelphia, and pollen concentrations from a National Allergy Bureau-certified monitor in Center City, Philadelphia. We applied quasi-Poisson regression in distributed lag non-linear model (DLNM), with both PM2.5 (natural spline, 3df) and pollen (total/oak tree, grass, total/ragweed and other) (piecewise linear terms) in addition to interaction terms, and adjusted for temperature, relative humidity, long-term/seasonal trends, day-of-week, and holidays. for each PM2.5/pollen combination, one was treated as the main exposure, the other, the effect modifier in categorical terms for strata-specific estimates.

RESULTS: We observed increased RRs for the association between same-day total tree pollen and daily AE rates (90th vs. 0) at higher PM2.5 levels, 7-day preceding the exacerbation event (low: 0.95, 95% CI: 0.79 – 1.16; medium: 1.10, 95% CI: 0.93 – 1.31; 1.05, 95% CI: 0.86-1.28). Same-day association for late-season grass pollen was stronger, when followed a high PM2.5 concentration 5-day before the event (1.05, 95% CI: 0.97-1.14), than when following low PM2.5 (1.02, 95% CI: 0.95-1.09). However, we also observed decreased RRs for association between PM2.5 and AE, at increased tree/late-season grass pollen concentrations.

CONCLUSIONS: Our study provides evidence suggesting interactions for several exposure combinations; however, many had no association with AE, and others suggested antagonistic effects. With mixed evidence, continued epidemiologic studies are called in the total impact of concurrent environmental asthma triggers.

KEYWORDS: PM2.5, pollen, interaction, children, asthma exacerbation (AE)

O-OP-277 Characterization of shed baby tooth metal concentrations in Project Viva

Pi-i Debby Lin[1], Christine Austin[2], Sheryl Rifas-Shiman[1], Manish Arora[2], Emily Oken[1]
[1]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA, [2]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York City, USA

BACKGROUND AND AIM: Shed baby teeth can provide retrospective information on early life metal exposure. We described the associations of baby tooth metal levels with maternal blood metal levels during pregnancy and other characteristics.

METHODS: Project Viva participants (recruited in early pregnancy 1999–2002 in eastern Massachusetts) provided shed baby teeth for metal analysis (As, Ba, Bi, Cd, Co, Cr, Cu, Li, Mg, Mn, Mo, Ni, Pb, Sn, Sr, Zn) using laser ablation-inductively coupled plasma mass spectrometry (LA-ICP-MS, measurement range: 21 weeks before birth to 55 weeks after birth). We measured maternal erythrocyte metals in the first trimester (As, Ba, Cd, Cr, Cu, Mg, Mn, Pb, Sn, Zn) and the second trimester (Pb and Mn) using ICP-MS. We calculated Spearman correlations between erythrocyte metals and dentine metals and used multivariable linear regression to evaluate associations of participants' characteristics, including mother's age at enrollment, race/ethnicity, highest educational attainment, household income, smoking during pregnancy, parity, and child's sex with dentine metal levels.

RESULTS: Participants (N=144) were mostly white (72%) and 81% were college graduates, 67% had household incomes >$70,000/year, and 13% smoked during pregnancy. We observed significant positive correlations between erythrocyte and dentine Pb, with the strongest correlation observed between 2nd-trimester erythrocyte Pb and mean of pre-birth dentine Pb ($r=0.78$, $p<0.001$, $N=86$). Smoking during pregnancy, mother's age, and race/ethnicity were associated with metal levels in the baby tooth. for example, after adjusting for all characteristics mentioned in the methods, smoking during pregnancy was associated with higher dentine Sr (both pre and post-birth) and higher dentine Li post-birth.

CONCLUSIONS: Maternal blood Pb strongly correlated with prenatal and postnatal dentine Pb. Dentine metal levels varied by some maternal characteristics, which may be useful for understanding the relationship of dentine metal levels with health outcomes in future work.

ORAL PRESENTATIONS SESSION 31: Air pollution, cognitive function and dementia-related health outcomes

O-OP-164 The 2018 Japan Floods increased prescriptions of anti-dementia drugs among disaster victims: a retrospective cohort study based on a national health insurance database

Saori Kashima[1,2,3], Shuhei Yoshida[3], Oakazaki Yuji Okazaki[3,4], Shinya Ishii[5], Soichi Koike[6], Masatoshi Matsumoto[3]
[1]Environmental Health Sciences Laboratory, Graduate School of Advanced Science and Engineering, Hiroshima University, Higashi-Hiroshima, Japan, [2]Center for the Planetary Health and Innovation Science, IDEC Institute, Hiroshima University, Hiroshima University, Higashi-Hiroshima, Japan, [3]Department of Community-Based Medical Systems, Graduate School of Biomedical and Health Sciences, Hiroshima, Japan, [4]Department of Emergency Medicine, Hiroshima City Hiroshima Citizens Hospital, Hiroshima, Japan, [5]Department of Medicine for Integrated Approach to Social Inclusion, Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan, [6]Division of Health Policy and Management, Center for Community Medicine, Jichi Medical University, Yakushiji, Japan

BACKGROUND AND AIM: The occurrence of weather-related disasters is increasing with the progression of global climate change. Natural disasters increase the risk of impaired cognitive function of elderly victims. It is not clear what effects such natural disasters have on the prescriptions of drug treatment for dementia. Thus, we evaluated the effect of the 2018 Japan Floods, the second-largest water-related disaster in Japan, on the prescriptions of anti-dementia drugs (ADD) for elderly people.

METHODS: From the National Database of Health Insurance Claims, we extracted prescription data in Hiroshima, Okayama and Ehime prefectures for one year before and after the disaster. From the database, 1,710,119 people aged 65 years or over were selected as the study participants. Sex- and age-adjusted odds ratios (ORs) of victims for new ADD prescriptions were calculated using logistic regression models. A difference-in-difference analysis was conducted to take into account the trends for the ORs before the disaster. Furthermore, among continuous ADD users, the effects of disaster on the increasing trend for ADD prescriptions (daily dose or number of drug types) was also evaluated.

RESULTS: of 1,710,119 people enrolled, 15,994 (0.9%) were recorded as a disaster-victims, and 112,289 (6.6%) were prescribed ADD. Among original non-users, victims were more likely to start using ADD after the disaster than non-victims [adjusted OR=1.33 (95% CI:1.16–1.52)]. Among continuous users, an increasing trend for ADD prescriptions was more often observed for victims than non-victims [1.61 (1.13–2.31)]. These associations were maintained even after considering the pre-disaster trend of ADD use.

CONCLUSIONS: The natural disaster results in an increased number of users of anti-dementia medications. Special attention to such neurological shifts and welfare support is needed for elderly victims of a large-scale natural disaster.

O-OP-165 The challenge of pre-enrollment selection bias in estimating the effects of air pollution on cognitive decline and other dementia-related outcomes

Ryan Andrews[1], Sara D. Adar[2], Joel D. Kaufman[3], Cami Christopher[1], Todd Beck[4], Kumar B. Rajan[4], Klodian Dhana[4], Denis Evans[4], Jennifer Weuve[1]

[1]Boston University, Boston, USA, [2]University of Michigan, Ann Arbor, USA, [3]University of Washington, Seattle, USA, [4]Rush University Medical Center, Chicago, USA

BACKGROUND AND AIM: Research on air pollution's (AP) association with dementia-related outcomes has proliferated; however, selection bias is a concern. Past research has addressed selection bias from differential post-enrollment attrition, but differential pre-enrollment selection may also be influential depending on who survives to the eligible age of enrollment and enrolls. In this project, we quantify potential biases arising from differential selection into studies of older adults through simulations based on real-world studies of AP and cognitive decline.

METHODS: We simulated 1,000 cohorts of 100,000 hypothetical participants. Participants were assigned a realistic AP exposure based on prior studies, plus an unmeasured binary covariate value (U). Our simulation models specified that AP had no effect on cognitive decline, whereas U had a small positive effect. We selected 10,000 participants from each cohort to form 1,000 analytic samples, where the probability of selection depended on both AP and U. We quantified the magnitude of the resulting "collider-stratification" selection bias by comparing the average estimated effect of AP on cognitive decline across our analytic samples with the true (unbiased) value of zero. We also explored whether these biases were sensitive to AP-U interactions.

RESULTS: The association between AP and cognitive decline was upwardly biased when lower AP exposure and the presence of U increased the probability of selection. The bias magnitude was particularly sensitive to multiplicative AP-U interactions. Importantly, we could replicate prior observational study findings without resorting to extreme parameter values.

CONCLUSIONS: Pre-enrollment selection bias can lead to qualitatively inaccurate effect estimates in studies of older adults. These cohorts are often highly selected by virtue of their survival to eligible study age and willingness to enroll. Bias analyses (e.g., our simulation-based approach) can help identify key assumption violations that could nullify or reverse environmental effect estimates.

KEYWORDS: Air pollution; Cognitive decline; Selection bias

O-OP-166 The impact of long-term exposure to fine particulate matter on incident dementia among U.S. older adults

Tszshan Ma[1], Haisu Zhang[1], Kyle Steenland[1], Joel Schwartz[2], Maayan Yitshak-Sade[3], Xiao Wu[4], Liuhua Shi[1]
[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [3]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [4]Stanford Data Science and Department of Statistics, Stanford University, Stanford, USA

BACKGROUND AND AIM: Growing studies link long-term fine particle (PM2.5) exposures to increased risk of Alzheimer's disease and other dementias, but there is a lack of comprehensive evaluation of these findings using causal inference modeling approaches.

METHODS: Based on the Medicare Chronic Conditions Warehouse (2000-2018), we constructed two nationwide U.S. population-based cohorts of enrollees aged ≥65 for dementia and Alzheimer's disease (AD), respectively. Coupled with high-resolution population-weighted air pollution exposure data, we estimated the effect of long-term exposure to PM2.5 on dementia and AD incidence using five distinct statistical approaches. Two traditional regression approaches for confounding adjustment: 1) Cox proportional hazards model, and 2) Poisson regression; two causal inference modeling approaches rely on the potential outcomes framework and generalized propensity scores (GPS). These approaches adjust for measured confounders (demographic characteristics, Medicaid eligibility, and ZIP-level covariates) using 1) matching by GPS, and 2) weighting by GPS. We further applied the difference-in-differences approach that controls for unmeasured confounders by design.

RESULTS: We identified ~5.0 million incident dementia cases (N=18,442,459; dementia cohort) and ~2.4 million incident AD cases (N=19,092,115; AD cohort). Using the five distinct approaches, we found that an increase in annual PM2.5 by 5 μg/m³ leads to a statistically significant 6-10% and 10-16% increase in dementia and AD risk, respectively.

CONCLUSIONS: Our study provides comprehensive evidence of the link between long-term PM2.5 exposure and increased incidence of dementia and AD, raising awareness of the continued importance of assessing the impact of air pollution exposure on neurological disorders among older adults.

KEYWORDS: fine particulate matter, Alzheimer's disease and dementias, causal inference modeling

O-OP-167 PM2.5 and dementia – APOE-ε4 and odor identification ability as moderators

John Andersson[1], Anna Sundström[1], Maria Nordin[1], David Segersson[2], Bertil Forsberg[3], Rolf Adolfsson[4], Anna Oudin[3]

[1]Umeå University, Dept. of Psychology, Umeå, Sweden, [2]Swedish Meteorological and Hydrological Institute, dept. of Air Quality Research, Norrköping, Sweden, [3]Umeå University, dept. of Public Health and Clinical Medicine, Umeå, Sweden, [4]Umeå University, dept. of Clinical Sciences, Umeå, Sweden

BACKGROUND AND AIM: There is growing evidence that long term exposure to air pollution increases the risk of dementia. However, more research regarding possible moderators and mediators are needed in order to identify vulnerable populations, and to better understand the complicated pathways between air pollution and dementia. The aim of this study was to investigate 1) the associations between PM2.5 exposure and dementia incidence, and 2) the possible mediating or moderating role of APOE-ε4 and odor identification ability, two known risk factors of dementia.

METHODS: Data was drawn from the Betula project, a longitudinal study on aging, memory, and dementia in Sweden. DNA was extracted via blood samples to allow for genotyping of the APOE gene. Odor identification ability was assessed using the Scandinavian Odor Identification Test (SOIT). Variation in within-city annual mean PM2.5 concentrations were obtained from a dispersion-model and matched at the participants' residential address. Proportional hazard regression was used to calculate hazard ratios.

RESULTS: of 1846 participants, 348 developed dementia during the follow up period. Each 1 µg/m3 increase in annual mean PM2.5-concentration was associated with a hazard ratio of 1,24 for dementia (95% CI: 1,02–1,51). Both APOE status and odor identification ability acted as moderators, as in subsequent analyses, significant associations persisted only for APOE-ε4 carriers, and low performers on the SOIT.

CONCLUSIONS: Locally emitted PM2.5 was associated with an increased risk of dementia in this moderately polluted setting. APOE-ε4 carriers, and those with below average odor identification ability were particularly vulnerable.

O-OP-168 Association between ambient air pollution exposure and plasma β-amyloid levels in the French Three-City study : preliminary results

Jeanne Duchesne[1], Laure-Anne Gutierrez[1], Jie Chen[2], Danielle Vienneau[3,4], Kees de Hoogh[3,4], Bénédicte Jacquemin[5], Karen Ritchie[1], Claudine Berr[1], Marion Mortamais[1]

[1]Institute for Neurosciences of Montpellier, Univ Montpellier, Inserm, Montpellier, France, [2]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]University of Basel, Basel, Switzerland, [5]INSERM, Univ Rennes, EHESP, Irset Institut de Recherche en Santé, Environnement et Travail, UMR-S 1085, Rennes, France

BACKGROUND AND AIM: Existing research suggests an association between air pollution exposure and Alzheimer's Disease (AD). However, underlying biological mechanisms are still unknown. We aimed to evaluate if air pollution exposure was associated with plasma β-amyloid (Aβ) levels.

METHODS: We selected 287 participants of the Three-City study who were cognitively unimpaired at 12-year follow-up. Aβ levels were measured on plasma samples stored at baseline and at 10 years (INNO-BIA plasma Aβ forms kits (Innogenetics)). Land-use regression models were used to estimate fine particulate matter (PM2.5), nitrogen dioxide (NO2) and black carbon (BC) exposure at participants' residential address over the 5-year preceding the baseline visit. Linear regression was performed to assess the association of each pollutant with plasma Aβ levels at baseline and with their evolution over time.

RESULTS: Participants' median age at baseline was 68.8 (IQR: 5.1), and 56.1% were women. Median levels (IQR) of plasma Aβ at baseline were 158.8 (37.5) pg/mL for Aβ1-40 and 41.4 (11.9) pg/mL for Aβ1-42. Median Aβ1-42/Aβ1-40 ratio was 0.255 (IQR: 0.065). We found that exposure to the three air pollutants was associated with decreased Aβ1-42/Aβ1-40 ratio at baseline. for instance, an IQR increase in PM2.5 (1.8 µg/m3) was associated with a 0.0119 decrease in the Aβ ratio (95% CI: -0.0209; -0.0029). There were no significant associations between air pollutants and Aβ evolution over time.

CONCLUSIONS: In our cognitively unimpaired population, exposure to air pollution was associated with decreased plasma Aβ ratio at baseline. These results seem to corroborate previous ones on air pollution detrimental effect on cognition, as a decreased plasma Aβ ratio may predict AD. Further longitudinal studies using cutting edge methods to quantify plasmatic Aβ levels and brain Aβ deposits are still needed to better understand the influence of air pollution on the neuropathological process in AD.

KEYWORDS: Air pollution, Alzheimer's Disease, Biomarkers

O-OP-169 Associations of particulate matter exposures with brain cortical thickness and white matter hyperintensities: effect modification by c-reactive protein

Jaelim Cho[1], Heeseon Jang[1], Seung-Koo Lee[1], Young Noh[2], Sang-Baek Koh[3], Sun-Young Kim[4], Changsoo Kim[1]
[1]Yonsei University College of Medicine, Seoul, Republic of Korea, [2]Gachon University Gil Medical Center, Incheon, Republic of Korea, [3]Wonju College of Medicine, Yonsei University, Wonju, Republic of Korea, [4]Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Republic of Korea

BACKGROUND AND AIM: Numerous studies have shown the effect of particulate matter exposure on brain imaging markers. However, little evidence exists about whether the effect differs by the level of systemic inflammation, a mechanism of neurotoxicity of particulate matter. We investigated whether the level of c-reactive protein (CRP; a marker of systemic inflammation) modifies the associations of particulate matter exposures with brain cortical thickness and white matter hyperintensities (WMH).

METHODS: Adults with no dementia or stroke were recruited. Concentrations of particulate matter ≤10 μm in diameter (PM10) and ≤2.5 μm (PM2.5) at each participant's home address were estimated. Mean cortical thickness (n=874) and WMH volumes (n=397) were estimated from brain magnetic resonance images. We built generalized linear and logistic regression models for mean cortical thickness and WMH volumes (higher versus lower than median), respectively. Significance of the CRP group (higher versus lower than median) difference in the association was expressed as p for interaction.

RESULTS: Particulate matter exposures were significantly associated with a reduced mean cortical thickness only in the higher CRP group among men (p for interaction=0.012 for PM10 and 0.006 for PM2.5). A 10 μg/m3 increase in PM10 was associated with having higher volumes of total WMH (odds ratio, 1.67; 95% confidence interval, 1.01–2.76) and periventricular WMH (1.81; 1.10–2.98). A 1 μg/m3 increase in PM2.5 was associated with having a higher volume of periventricular WMH (odds ratio, 1.53; 95% confidence interval, 1.01–2.33). These associations did not significantly differ by the level of CRP.

CONCLUSIONS: Particulate matter exposures were associated with a reduced mean cortical thickness in men with a high level of systemic inflammation. Particulate matter exposures were associated with having a high volume of WMH, with no evidence of effect modification by the level of systemic inflammation.

KEYWORDS: air pollution; neuroimaging; inflammation

ORAL PRESENTATIONS SESSION 32: Health consequences of meteorological events and precipitation

O-OP-170 The influence of rainfall measurement on the associations between rainfall and acute gastro-intestinal illness in North Carolina

Kristen Downs[1], Charles Konrad[2]
[1]Department of Environmental Sciences and Engineering, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, USA, [2]Department of Geography, University of North Carolina at Chapel Hill, Chapel Hill, USA

BACKGROUND AND AIM: Climate change and extreme weather are predicted to have a significant impact on diarrheal diseases. However, rainfall depends on local conditions and studies use varied measurements (e.g., absolute rainfall, heavy rainfall, or antecedent conditions) to define exposures. We systematically explored the influence of different rainfall measures on the association between acute gastrointestinal illness (AGI) and rainfall in North Carolina.

METHODS: Common measures of rainfall were derived from recent studies (e.g., absolute rainfall (mm); heavy rainfall (90th, 95th, 99th percentile) and constructed from PRISM gridded daily weather data spatially aggregated to the ZIP code level. Rate ratios between rainfall (lagged 0-7 days) and AGI were estimated using quasi-Poisson time series models. All-cause AGI was defined by the daily emergency department (ED) visits per ZIP code using ICD-9 diagnosis codes from North Carolina's syndromic surveillance system (2008-2015). Unadjusted and adjusted (for mean temperature and relative humidity) model estimates and goodness-of-fit measures were compared across rainfall measures.

RESULTS: Between 2008-2015, there were 1.07M ZIP code-days with at least one ED visits for all-cause AGI per ZIP code per day in North Carolina. Adjusting for lagged mean temperature and relative humidity, we observed a 4.2% increase (RR=1.035; 95% CI: 1.029-1.040) and 5.1% (1.051; 1.035-1.067) in AGI ED visits respectively following lagged 90th and 99th percentile rainfall (1 day lag), with similar patterns for lags 2-7. By contrast, a 0.1% change in AGI ED visits was associated with a 1 mm increase in rainfall depending on the lag (e.g., lag 1: 1.001-1.001, 1.002 vs. lag 7: 0.999; 0.999-1.000).

CONCLUSIONS: Heavy rainfall was associated with an increase in AGI rates, but absolute rainfall had a much smaller and ambiguous effect. These results suggest the importance of rainfall measurement and adjustment for other weather variables.

KEYWORDS: diarrhea, rainfall, weather, climate, time series, exposure measurement

O-OP-171 Exploring the association between precipitation and mental health hospitalizations in Switzerland

Sujung Lee[1,2], Coral Salvador[1,2,3], Alexandre Tuel[2,4], Olivia Romppainen-Martius[2,4], Ana Maria Vicedo-Cabrera[1,2]
[1]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, [2]Oeschger Center for Climate Change Research, University of Bern, Bern, Switzerland, [3]Centro de Investigación Mariña, Universidade de Vigo, Environmental Physics Laboratory (EPhysLab), Ourense, Spain, [4]Institute of Geography, University of Bern, Bern, Switzerland

BACKGROUND AND AIM: While several studies proved the relationship between temperature and mental health, limited evidence exists on the effect of other weather factors, such as precipitation. The aim of this study was to assess the impact of precipitation on mental disorders in Switzerland between 2009–2019.

METHODS: Daily hospitalizations between 2009–2019 were obtained from Switzerland's Federal Office of Statistics. Daily precipitation was taken from 2km gridded maps developed by MeteoSwiss. We conducted aggregated case-crossover analysis with a conditional quasi-Poisson regression to assess the association up to 7 days after the exposure. We considered daily precipitation in millimeters (mm), and persistent extreme precipitation events (PEP90.2) when daily precipitation exceeded the 90th percentile for more than 2 days. The analysis was conducted separately in eight Swiss main cities (Basel, Bern, Geneva, Lausanne, Lugano, Luzern, St. Gallen, and Zurich) and stratified by sex, age (<65years, ≥65years), and group of diagnosis (ICD-10). Models were adjusted by daily mean temperature.

RESULTS: The total number of hospital admissions included in the study was 147,768. On average, the risk of hospitalization increased by 38% (95%CI:1.30-1.46) for every 10mm increase in daily precipitation and by 52% (95%CI:1.33-1.74) for PEP90.2 events. Larger risks were found in males (1.67;95%CI:1.42-1.96, vs 1.38; 95%CI:1.17-1.63 in females) and under 65 years old (1.53;95CI:1.33-1.77 vs 1.45;95%CI:1.17-1.80 in ≥65years) for PEP90.2 events. By sub-diagnosis categories, larger risks were found for adult personality disorders (F60-F69) in daily precipitation (1.61;95%CI:1.42-1.83) and PEP90.2 (1.94;95%CI:1.34-2.80), while no evidence was found for developmental disorders (F80-F98) and similar risks to the average in the remaining groups. We observed a positive association in all cities with higher risks in Luzern for daily precipitation (1.68; 95%CI:1.43-1.97) and PEP90.2 (2.22; 95%CI:1.33-3.69).

CONCLUSIONS: Our findings suggest that extreme precipitation events could have adverse impacts on mental health in Switzerland.

KEYWORDS: Precipitation; Climate change; Mental health

O-OP-172 Sex and Age Characteristics of Thunderstorm Asthma Emergency Department Visits in a Midwest Metropolitan Environment (2007-2018)

Luke Smith[1], Richard MacLehose[1], Christine Wendt[2], Jesse Berman[1]
[1]University of Minnesota School of Public Health, Minneapolis, USA, [2]University of Minnesota Medical School, Minneapolis, USA

BACKGROUND AND AIM: Severe asthma has been shown to occur in the combined presence of high pollen and thunderstorm conditions, also known as 'thunderstorm asthma.' Studied as severe epidemic events, recent work has explored less dramatic, but more persistent chronic occurrences. We explore thunderstorm asthma-related emergency department (ED) visits in the Minneapolis-St. Paul region and evaluate unknown risk differences by sex and age groups.

METHODS: We define a thunderstorm asthma exposure event as daily occurrence of 2 or more lightning strikes during high pollen periods. We use daily counts of asthma-related ED visits from the Minnesota Hospital Association (2007-2018). We estimate relative and absolute risk of severe asthma during thunderstorm asthma events for the full population and sex and age subgroups.

RESULTS: The overall population had a 1.055 (95% CI: 1.019, 1.093) relative risk of asthma-related ED visits during thunderstorm asthma conditions. We observe a greater relative risk on the day of the exposure for males (RR 1.07; 95% CI: 1.02, 1.12) compared to females (RR 1.04; 95% CI: 1.00, 1.09), and observed age 18-44 years and 45 and up to be most vulnerable. Children have no significant increase in ED visits during thunderstorm asthma events. Absolute risk counts show similar patterns to these age and sex results, but age-sex subgroups show more variation in absolute vs relative risk for males compared to females.

CONCLUSIONS: Our results support an association between ED visits and thunderstorm asthma, and provide evidence of varying risk by sex across the life course. Thunderstorm asthma shows a unique pattern where middle-aged males and older females show the greatest risk, unlike baseline asthma incidence that is greatest in male children and middle-aged females. These patterns have implications for unrecognized at-risk groups and provide clinical information for this unique asthma exposure.

KEYWORDS: Climate change, thunderstorm asthma, pollen, ED visits

O-OP-173 Dust Storms and Respiratory Emergency Department Visits in the Southwestern United States

Claire Rowan[1], Rohan D'Souza[1], James Crooks[2], Kirk Hohsfield[2], Daniel Tong[3], Howard Chang[1], Stefanie Ebelt[1]
[1]Emory University, Atlanta, USA, [2]National Jewish Health, Denver, USA, [3]George Mason University, Fairfax, USA

BACKGROUND AND AIM: Climate change is projected to increase the risk of dust storms, particularly in the southwestern US. Research on dust storm impacts is hindered by challenges in dust storm identification. This study assesses the potential link between dust storms and respiratory-related emergency department (ED) visits in the southwestern US.

METHODS: We acquired data for 2005-2016 from IMPROVE (Interagency Monitoring of PROtected Environments) monitoring sites in California (n=2), Arizona (n=5), Nevada (n=2), and Utah (n=1). Applying a validated algorithm that identifies dust events of natural origin, dust storm days at each IMPROVE site were identified. We acquired patient-level ED visit data from state agencies and selected visits for respiratory diseases, asthma, and chronic obstructive pulmonary disease (COPD) among patients residing within 50 km of a monitoring site. Using a case-crossover design, we estimated associations of ED visits and dust storms, controlling for meteorology, ozone, and holidays.

RESULTS: During 2005-2016, 37 dust storm days occurred at the 10 IMPROVE sites. Mean PM10 and PM2.5 levels were 3-6 times greater on dust compared to non-dust storm days. We observed associations of respiratory ED visits and dust storms, with strongest associations at lag 3 [odds ratio of 1.049 (95% confidence interval: 1.002-1.098)]. Results were driven by Arizona, with an odds ratio for respiratory ED visits of 1.068 (95% confidence interval: 1.008-1.133). Associations for asthma were similar, although with larger uncertainty given fewer ED visits. Associations for COPD were consistent with the null.

CONCLUSIONS: Using a monitoring-based exposure metric, we observed associations among respiratory ED visits and dust storms. The results add to growing evidence of the health threat posed by dust storms. The dust storm metric was limited by lack of daily monitoring data; future research will incorporate satellite and models for enhanced dust storm characterization.

BACKGROUND AND AIM: Recent studies have suggested that heat may trigger preterm birth (PTB), which is assumed a risk for infant mortality and childhood and adult health. However, evidence is still limited. Our objective was to investigate the short-term association between the exposure to heat during the last days of pregnancy and the risk of PTB in multiple locations from different geoclimatic zones.

METHODS: The analysis was restricted to all singleton births born in the warm season (5 hottest months) in 106 locations across 7 countries included in the MCC network, Canada(19 cities), Ecuador(2), Estonian(4), Japan(47), Paraguay(1), Switzerland(16) and Spain(51), between 1979-2015. A two-stage design was applied with first conditional quasi-Poisson regression with distributed lag nonlinear models to estimate the association between daily mean temperature (lags 0-4) and PTB in each location. A multivariate meta-analytic model was then fitted to pool individual estimates at the country level.

RESULTS: Daily mean temperature ranged from 6ºC (Estonian) to 26ºC (Ecuador). The PTB percentage ranged from 3.8% (Thurgau, Switzerland) to 11.2% (Asunción, Paraguay). Overall, the PTB risk increased by 10% (95% CI: 6.6-13.5) for moderate heat (95th centile of temperature), and by 11.3% (8-14.7) for extreme heat (99th centile) compared to the minimum risk temperature (1th centile). Robust increases were found in all countries except Ecuador. The lowest heat-related PTB risk was found in Switzerland (6% (1.5-10.6) and 5.5% (0.4-10.8) for moderate and extreme heat, respectively), whereas the highest risk was found in Estonian (18% (8.3-28.5) and 23.3% (12.2-35.4)).

CONCLUSIONS: Our preliminary findings support previous findings suggesting that hot temperatures may be a serious threat for perinatal health. This is the first study of its kind at a word-wide scale. Ongoing analyses on a broader set of locations within the MCC network will contribute to complete the picture.

ORAL PRESENTATIONS SESSION 33: Air pollution and emerging health outcomes

O-OP-175 A cohort study of the multi-pollutant effects of PM2.5, NO2, and O3 on C-reactive protein levels during pregnancy

Priyanka Gogna[1], Michael M Borghese[2], Paul J Villeneuve[3], Premkumari Kumarathasan[2], Markey Johnson[4], Robin H Shutt[2], Jillian Ashley-Martin[2], Maryse F Bouchard[5,6], Will D King[1]

[1]Queen's University, Kingston, Canada, [2]Environmental Health Science and Research Bureau, Health Canada, Ottawa, Canada, [3]School of Mathematics and Statistics, Carleton University, Ottawa, Canada, [4]Water and Air Quality Bureau, Health Canada, Ottawa, Canada, [5]Department of Environmental and Occupational Health, Montreal, Canada, [6]CHU Sainte-Justine Research Center, Montreal, Canada

BACKGROUND AND AIM: Individual air pollutants and green space are associated with inflammation in pregnancy, but their combined effects are not well understood. Our objective was to study the multipollutant effects of PM2.5, NO2, and O3 on C-reactive protein (CRP) levels in maternal blood (a marker of inflammation implicated in adverse pregnancy outcomes).

METHODS: We analyzed data collected from 1,170 pregnant Canadian women enrolled in the MIREC Study. Maternal blood concentrations of CRP were measured in the third trimester. Residentially-based ambient concentrations of PM2.5, NO2, and O3 during the 14 days prior to blood draw were estimated using satellite-derived concentrations and land use regression models. Green space was measured using the Normalized Difference Vegetative Index (NDVI). We fit multipollutant linear regression models using 14-day average estimates of PM2.5, NO2, and O3. We also evaluated the effects of pollutant mixtures using Weighted Quantile Sum Regression (WQSR), and by calculating the Air Quality Health Index (AQHI), a Canadian risk communication tool that derives a weighted average of the pollutants.

RESULTS: In multipollutant models that included NO2 and O3, each interquartile range (IQR) increase in 14-day average PM2.5 (IQR: 6.9 µg/m3) was associated with 27.1% (95% CI: 6.2, 50.7) higher CRP concentrations. In air pollution mixture models, each IQR increase in AQHI was associated with 37.7% (95% CI: 13.9, 66.5) higher CRP levels; and an IQR increase in the WQSR was associated with 78.6% (95% CI: 29.7, 146.0) higher CRP levels. Associations between air pollution and CRP were not confounded or modified by NDVI.

CONCLUSIONS: We provide evidence for stronger effects of the combined mixture of PM2.5, NO2, and O3 on inflammation levels during pregnancy compared with individual pollutants. This research emphasizes the importance of examining multipollutant analyses in future investigations.

O-OP-176 Association between environmental air pollution and olfactory functioning among Italian adolescents and young adults in Northern Italy

Stefano Renzetti[1], Christoph van Thriel[2], Stefano Calza[1], Elena De Angelis[1], Demetrios M Papazaharias[3], Elza Rechtman[3], Azzurra Invernizzi[3], Roberto G Lucchini[1,4], Elena Colicino[3], Alessandra Patrono[1], Matteo Rota[1], Donald R Smith[5], Marialuisa Volta[1], Robert O Wright[3], Donatella Placidi[1], Megan K Horton[3]

[1]Università degli Studi di Brescia, Brescia, Italy, [2]Leibniz Research Centre for Working Environment and Human Factors (IfADo), Dortmund, Germany, [3]Icahn School of Medicine at Mount Sinai, New York, USA, [4]Florida International University, Miami, USA, [5]University of California Santa Cruz, Santa Cruz, USA

BACKGROUND AND AIM: Olfaction is a critical physiological process with various functions in humans and olfactory impairments are associated with neurodegenerative disease and decreased quality of life. Olfactory receptors are in direct contact to ambient air, and thus, olfactory function is uniquely vulnerable to airborne pollutants. Here, we investigate associations between ambient air pollutant exposure and olfactory function in adolescents and young adults in the province of Brescia, Italy.

METHODS: This study included 207 subjects (52.7% female, 15-25 years) enrolled in the ongoing longitudinal Public Health Impact of Metals Exposure (PHIME) study. All participants completed a baseline (2008-2014) and follow-up (2017-2021) olfactory performance assessment using the "Sniffin' Sticks", a psychophysical test to assess odor threshold, discrimination and identification. Spatial annual average concentrations of particulate matter (PM) PM10, PM2.5 and nitrogen dioxide (NO2) were estimated for the target area between 2016-2019 on a 4 x 4 km2 spatial resolution grid by means of the Chemical Transport Model ARIA Regional. We applied multivariable beta regression models to test for associations between each pollutant and olfactory functions.

RESULTS: All air pollution annual average values were below European air quality standards (mean +/- SD □g/m3 PM2.5 = 18.4 +/- 5.1; PM10 = 21.0 +/- 5.3; NO2 = 32.1 +/- 9.8). We observed a significant negative association between NO2 and olfactory threshold score; a 14% decrement (approximately 2 score points) for each 10 unit increase in NO2 (p = 0.042), adjusting for age, sex, Sniffin' identification baseline score, having a cold and/or allergic rhinitis, IQ and passive smoking exposure.

CONCLUSIONS: These results suggest increased NO2 exposure is associated with reduced olfactory function in these Italian adolescents and young adults. The identification of risk factors for olfactory functions can help prevent reduced quality of life and improve recovery.

KEYWORDS: Olfactory functions; air pollution; NO2; PM2.5; PM10

O-OP-177 Air pollution, telomere length, and related health outcomes in the UK Biobank Cohort

Chia-Ling Kuo[1], Douglas Brugge[1]
[1]*University of Connecticut Health, Farmington, USA*

BACKGROUND AND AIM: Ambient air pollution (AP) has been associated with shorter telomere length (TL), which is a hallmark of biological aging and may lead to respiratory and cardiovascular disease, and lung cancer. We investigated the association between AP and TL and associated health outcomes.

METHODS: Data was from the UK Biobank (n=412,575). Participants aged 40 to 70 were recruited from 2006-2010. Baseline leukocyte TL was measured as T/S ratio. Residential AP estimates from 2010 included annual means of NO2, PM10, and PM2.5 in µg/m3. AP levels were associated with TL using linear regression models. Logistic regression models were used to link AP or TL to incident coronary artery disease (CAD) (n=26,345 cases) and lung cancer (n=4,079 cases) through 2021. Covariates included age, sex, ethnicity, education, Townsend deprivation index, BMI, smoking status, alcohol intake, physical activity, and greenspace (1000m buffer).

RESULTS: We confirmed that longer TL was associated with reduced risk of incident CAD (OR=0.95 per SD increase in TL, p=1.51×10-15) but increased risk of incident lung cancer (OR=1.05 per SD increase in TL, p=0.003). Higher NO2 or PM2.5 was significantly associated with shorter TL (β=-0.021, -0.020, 0.002 SD comparing NO2 in (20, 30], (30, 40], >40 to NO2≤20, overall p=4×10-6; β=-0.010 SD comparing PM2.5>10 to PM2.5≤10, p=0.012). Both also were associated with increased risk of CAD (OR=1.11, 1.11, 1.09 comparing NO2 in (20, 30], (30, 40], >40 to NO2≤20, overall p=1.3×10-5; OR=1.04 comparing PM2.5 >10 to PM2.5≤10, p=0.027) but not risk of lung cancer. In contrast, PM10 was not associated with TL, incident CAD or lung cancer.

CONCLUSIONS: NO2 or PM2.5 concentrations were associated with shorter TL and risk of CAD. TL may play a mediation role in the relationship between AP and CAD.

KEYWORDS: coronary artery disease, lung cancer, NO2, PM10, PM2.5

O-OP-178 Association of air pollution with incidence of end stage renal disease in two European cohorts and effect modification by chronic conditions

Giulia Cesaroni[1], Matteo Renzi[1], Andrea Jaensch[2], Claudia Marino[1], Pietro Manuel Ferraro[3], Emmanuel Zitt[4,5], Kees de Hoogh[6,7], Massimo Stafoggia[1], Bert Brunekreef[8], Gabriele Nagel[2,4], Gudrun Weinmayr[2]

[1]Department of Epidemiology, Lazio Region Health Service / ASL Roma 1, Rome, Italy, [2]Institute of Epidemiology and Medical Biometry, Ulm University, Ulm, Germany, [3]Università Cattolica del Sacro Cuore, Rome, Italy, [4]Agency for Social and Preventive Medicine (aks), Bregenz, Austria, [5]Department of Internal Medicine 3, LKH Feldkirch, Feldkirch, Austria, [6]Swiss Tropical and Public Health Institute, Basel, Switzerland, [7]University of Basel, Basel, Switzerland, [8]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, the Netherlands

BACKGROUND AND AIM: End-stage kidney disease (ESKD) poses a high burden on patients and the health system. While studies indicating associations of air pollution with chronic kidney disease are accumulating, studies on ESKD are still scant. We investigate the association of long-term exposure to nitrogen dioxide (NO_2), fine particulate matter ($PM_{2.5}$) and black carbon (BC) with ESKD in two large population-based European cohorts.

METHODS: Individuals in the Rome Longitudinal Study (RoLS) and the Vorarlberg Health Monitoring and Prevention Program (VHM&PP) were followed up with Dialysis and Transplant Registries from 1985 to 2019 and 2011 to 2019, respectively.
Long-term exposures to NO_2, $PM_{2.5}$ and BC were approximated by concentration at residence determined with Europe-wide hybrid land use regression models at 100x100m scale.
Hazard ratios (HR) were determined from Cox-proportional hazard models with age as time axis and adjusted for individual and neighbourhood confounders; effect modification by various factors was tested.

RESULTS: RoLS contributed 3,231 cases from 1,939,461 individuals (mean age 52.4 years; crude incidence rate (CIR) 0.22 per 1,000 person years) and VHM&PP 501 cases from 136,823 individuals (mean age 42.1 years; CIR 0.14).
In RoLS, ESKD was significantly associated with $PM_{2.5}$ In RoLS (HR 1.37 [1.06, 1.76] for an increase of 5 $\mu g/m^3$) whereas in VHM&PP, ESKD was associated with BC (HR 1.17 [0.98,1.39] for 0.5*10-5m-1), and NO_2 (HR 1.14 [0.96,1.35] for 10 $\mu g/m^3$).
Statistically significant effect modification was found in RoLS for all pollutants with higher HRs in diabetic and hypertensive subjects. for example, comparing non-diabetics and diabetics, respectively, the HRs for $PM_{2.5}$ was 1.24 (0.96,1.60) vs 1.86 (1.44,2.40) in RoLS.

CONCLUSIONS: Air pollution was associated with ESKD in both cohorts and in Rome may possibly be a potent trigger for ESKD in persons with chronic conditions.

O-OP-179 Medium- and Long-Term PM2.5 Exposures and Sudden Cardiac Death in a Prospective Cohort of US Women

William Borchert[1], Rachel Nethery[2], Jaime Hart[1,4,5], Francine Laden[1,3,4,5], Christine Albert[6]
[1]Harvard TH Chan School of Public Health, Department of Environmental Health, Boston, USA, [2]Harvard TH Chan School of Public Health, Department of Biostatistics, Boston, USA, [3]Harvard TH Chan School of Public Health, Department of Epidemiology, Boston, USA, [4]Harvard Medical School, Boston, USA, [5]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, USA, [6]Cedars Sinai, Los Angeles, USA

BACKGROUND AND AIM: Previous studies have reported associations between short-term exposure to fine particulate matter (PM2.5) and acute cardiac events. However, the effect of long-term exposure to PM2.5 on the risk of sudden cardiac death (SCD) is unknown. We prospectively examined associations between medium- and long-term exposures to PM2.5 and incidence of SCD in the Nurses' Health Study (NHS) cohort, a nationwide prospective cohort of female nurses in the US.

METHODS: Women in NHS (N=117,358) were followed via biennial questionnaires. Spatiotemportal prediction models were used to estimate monthly time-varying, residential exposure to PM2.5. To enable examination of different time windows of exposure simultaneously, given the high correlation between time windows, we calculated cumulative average PM2.5, the difference between the cumulative average and 12-month moving average, the difference between the 12- and 3-month moving averages, and the difference between the 3- and 1-month moving averages. Confirmed SCD cases 1988-2013 were identified by medical records and next-of-kin reports. We used time-varying Cox proportional hazards models adjusted for preexisting conditions, demographics, socioeconomic status, region, and season to calculate hazard ratios (HR) and 95% confidence intervals (CI) for each exposure time window (in separate and co-adjusted models). We explored deviations from linearity with cubic splines.

RESULTS: During 2,070,412 person-years of the study, there were 320 confirmed SCDs. There was no evidence of deviations from linearity, therefore we present HRs from continuous models per 10μg/m3 increase in each of the time windows of PM2.5. In multivariable adjusted models, only the difference in exposures between the 12- and 3- month moving averages was associated with risk of SCD (HR=1.06; 95%CI: 1.00, 1.12).

CONCLUSIONS: The results of the study suggest an association between medium-term PM2.5 exposure and SCD, suggesting that seasonal exposures may be an important time window of susceptibility.

KEYWORDS: Particulate matter, air pollution, sudden death

O-OP-180 Metal Constituents of Fine Particulate Matter Mass and Incident Depression: A Community-based Cohort Study in China

Xinhan Zhang[1], Miss. Fanjia Guo[1], Zhebin Yu[1], Miss. Fang Wei[1], Xiaofeng Wang[2], Jianbing Wang[3], Mingjuan Jin[1], Dandan Xu[2], Zhijian Chen[2], Mengling Tang[4], Kun Chen[1]

[1]Department of Epidemiology and Biostatistics at School of Public Health and the Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, Hangzhou, China, [2]Zhejiang Provincial Center for Disease Prevention and Control, Hangzhou 310051, China., Hangzhou, China, [3]Department of Epidemiology and Biostatistics at School of Public Health and National Clinical Research Center for Child Health of the Children's Hospital, Zhejiang University School of Medicine, Hangzhou, China, Hangzhou, China, [4]Department of Epidemiology and Biostatistics at School Public Health and the Fourth Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, Hangzhou, China

BACKGROUND AND AIM: Little is known about the effects of chemical constituents of fine particulate matter (particles with aerodynamic diameter ≤ 2.5 μm, PM2.5). This study aims to estimate the associations between constituents of PM2.5 and incident depression.

METHODS: This large cohort study recruited the local adults in Ningbo, a southeastern coastal city in China. Depression cases were ascertained from local Health Information System. Daily PM2.5 samples were collected at seven monitoring sites for the 10th-16th seven consecutive days and further measured for ten PM2.5-bound metals. Land-use regression models were conducted to predict the residential PM2.5-bound metals exposure. We conducted three cox proportional hazards models which respectively employed single constituent, constituent adjusting for PM2.5 and constituent residual calculated by PM2.5 as exposures to estimate the effect of constituents on incident depression. Environmental Risk Score (ERS) and Weighted Quintile Score (WQS) were utilized to estimate the overall effect of all metals.

RESULTS: In fully adjusted constituent models, the higher concentrations of ambient Lead(Pb), Nickel(Ni), Mercury(Hg), Chromium(Cd) and Beryllium(Be) were significantly associated with higher risk of incident depression. In ERS analyses, one main effect (Tl), three squared terms (Hg, Cd and Al) and twelve pairwise interactions (Tl & Pb, Tl & Be, et al) were selected by adaptive elastic-net (AENET) for construction of ERS of incident depression-related ambient metal mixtures. The ERS index was positively and significantly associated with depression incidence. and similar results were found for WQS index which suggesting that Al, Sb, Hg, Tl, Mn and Be contributed the most to the association.

CONCLUISIONS: These findings highlighted the associations of exposure to PM2.5-bound metals with incident depression. Further studies are needed to confirm the findings and examine the underlying mechanisms.

KEYWORDS: PM2.5-bound Metal, depression, Cox Proportional Hazardous Regression, ERS, WQS.

ORAL PRESENTATIONS SESSION 34: Exposure to chemicals and adverse health outcomes

O-OP-181 Exposure To Perfluoroalkyl Substances and Risk of Hepatocellular Carcinoma In The Multiethnic Cohort

Jesse Goodrich[1], Douglas Walker[2], Xiangping Lin[2], Hongxu Wang[1], Rob McConnell[1], David Conti[1,3], Lida Chatzi*[1], Veronica Wendy Setiawan*[1,3]

*[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA; *These authors contributed equally, [2]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Norris Comprehensive Cancer Center, Los Angeles, USA*

BACKGROUND AND AIM: Exposure to per- and polyfluoroalkyl substances (PFAS), a class of persistent organic pollutants, is ubiquitous. Animal studies suggest that PFAS may increase risk of fatty liver and hepatocellular carcinoma (HCC) via impacts on hepatic lipid, amino acid, and glucose metabolism, but human data are lacking. We examined associations of PFAS exposure, altered metabolic pathways, and risk of non-viral HCC.

METHODS: In this nested case-control study, prediagnostic plasma PFAS and metabolomics were measured in 50 incident HCC cases and 50 individually matched controls from the Multiethnic Cohort Study (MEC). Cases and controls were matched by age, sex, race, and study area. PFAS exposure and risk of HCC were examined using conditional logistic regression. A metabolome wide association study and pathway enrichment analysis was performed for PFAS exposure and HCC risk, and key metabolites/metabolic pathways were identified using a meet in the middle approach.

RESULTS: High perfluorooctane sulfonic acid (PFOS) levels (90th percentile from NHANES>55 µg/L) were associated with more than 4 fold increased risk of HCC (OR=4.5; 95% CI: 1.2-16.0). The pathway enrichment analysis showed that PFOS exposure was associated with alterations in amino acid and glycan biosynthesis pathways, which were in turn associated with HCC risk. We identified four metabolites linking PFOS exposure with HCC, including glucose, butyric acid (a short chain fatty acid), α-Ketoisovaleric acid (a branched-chain α-keto acid), and 7alpha-Hydroxy-3-oxo-4-cholestenoate (a bile acid), each of which was positively associated with PFOS exposure and risk of HCC.

CONCLUSIONS: Exposure to high levels of PFOS was associated with increased risk of HCC, and the likely mechanisms were via alterations in glucose, amino acid, and bile acid metabolism. Larger studies are warranted to confirm these findings.

KEYWORDS: Chemical exposure, exposome, perfluorinated alkyl substance, hepatocellular carcinoma, metabolome, bile acid, metabolic pathway

O-OP-182 Metabolic changes associated with polybrominated biphenyls and polychlorinated biphenyls in the Michigan PBB registry

Susan Hoffman[1], Donghai Liang[2,1], Youran Tan[2], Metrecia Terrell[1], M. Elizabeth Marder[3], Hillary Barton[1], Melanie Pearson[2], Dean Jones[4], Dana Barr[2], Michele Marcus[1,2]

[1]Department of Epidemiology, Emory University, Atlanta, USA, [2]Gangarosa Department of Environmental Health, Emory University, Atlanta, USA, [3]Department of Environmental Toxicology, University of California Davis, Davis, USA, [4]School of Medicine, Emory University, Atlanta, USA

BACKGROUND AND AIM: Polybrominated Biphenyls (PBBs) and Polychlorinated Biphenyls (PCBs) are endocrine-disrupting chemicals (EDCs). In Michigan, people were exposed to PBBs during a time-limited contamination event in the 1970s and are continuously exposed to PCBs. Using high-resolution metabolomics (HRM), this study aimed to identify biological mechanisms underlying human health effects of PBB and PCB exposure.

METHODS: HRM profiling was conducted on serum samples from the Michigan PBB Registry collected from a subset of 500 individuals representing both F0 (directly exposed to PBB) and F1 (exposed through parents) generations from 2011 to 2014. This study measured PBB-153 stratified by generation and ΣPCB (PCB-118, PCB-138, PCB-153, and PCB-180) in the total combined subset (as all experienced direct PCB exposure). Metabolite and metabolic pathway perturbation were evaluated using an untargeted HRM workflow.

RESULTS: Both exposure measures had high detection levels. Mean levels were 1.75-ng/mL (SD: 13.9) for PBB-153 and 1.04-ng/mL (SD: 0.788) for ΣPCBs. 124 and 86 metabolomic features were significantly associated with PBB-153 in F0 and F1 ($p<0.005$), respectively. There were 2,861 features associated with ΣPCB (FDR corrected $p<0.2$). Pathway enrichment analysis revealed perturbations associated with ΣPCB in numerous oxidative stress and inflammation pathways (e.g., carnitine shuttle, glycosphingolipid, and vitamin B9 metabolism). Perturbations associated with PBB-153 in F0 were related to oxidative stress pathways (e.g., pentose phosphate and vitamin C metabolism) and in F1 were related to energy production (e.g., pyrimidine, aminosugars, and lysine metabolism). Authentic chemical standards were used to confirm the chemical identity of 29 metabolites associated with ΣPCB levels and 10 metabolites associated with PBB-153 levels.

CONCLUSIONS: Our results demonstrated that serum PBB-153 and ΣPCB levels were associated with perturbations in inflammation and oxidative stress-related pathways, which differed when stratified by generation. These findings support future investigations of molecular mechanisms underlying PBB and PCB exposure on health, emphasizing exposure timing.

O-OP-183 Relations between concentrations of perfluoroalkyl substances (PFAS) in drinking water and serum in adults living near PFAS hotspots

BACKGROUND & AIM: Contaminated drinking water (DW) is a major source of exposure to per- and polyfluoroalkyl substances (PFAS) at locations around PFAS production facilities, airports and air force bases with extensive use of firefighting foam. We investigated quantitative relations between concentrations in DW and serum of nine perfluorinated alkyl acids (PFAAs), a very persistent PFAS subgroup, in Swedish adult populations living near PFAS hotspots.

METHODS: We established a data set that consisted of paired concentration measurements in DW and serum from 261 subjects in four areas receiving PFAA-contaminated DW and from 137 subjects living in an area with non-contaminated DW. The relations between PFAAs in DW and serum were examined using linear regression analysis. The regression equations enabled us to derive (i) PFAA serum concentrations due to background exposure from sources other than the local DW (e.g. food, dust and textiles), (ii) population-mean PFAA serum-water ratios (SWR) and (iii) PFAA concentrations in DW causing serum PFAA concentrations significantly elevated above background (DWES).

RESULTS: PFAA concentrations in DW varied widely (2.5-1790 ng/L for ΣPFAA). The estimated mean background serum concentrations ranged from below 0.1 ng/mL (PFPeA, PFHpA, PFBS) to 5.2 ng/mL (PFOS). The increases in serum PFAA with increasing concentration in DW were statistically significant for all PFAAs except PFPeA and PFDA. SWR estimates were <10 for short-chained PFAAs and >30 for long-chained PFAAs. Calculated DWES ranged between 18 ng/L (PFOA) and 178 ng/L (PFHxA).

CONCLUSIONS: Health risks from PFAAs are related to the body burden, reflected by their concentration in serum. for population exposure assessment, it is easier and less expensive to measure PFAA concentrations in drinking water and the relationships derived herein should be helpful in the risk assessment and risk management of PFAA in drinking water.

KEYWORDS: drinking water, perfluoroalkyl substances, human biomonitoring

O-OP-184 Exposure of the Portuguese population to metals and metalloids: results from a national study

Sónia Namorado[1,2,3], Inês Delgado[4], Inês Coelho[4], Sandra Gueifão[4], Marta Ventura[4], Joana Ogura[1], Susana Silva[1]
[1]Department of Epidemiology, National Institute of Health Doutor Ricardo Jorge, Lisbon, Portugal, [2]NOVA National School of Public Health, Public Health Research Centre, Universidade NOVA de Lisboa, Lisbon, Portugal, [3]Comprehensive Health Research Center, Universidade NOVA de Lisboa, Lisbon, Portugal, [4]Department of Food and Nutrition, National Institute of Health Doutor Ricardo Jorge, Lisbon, Portugal

Metals and metalloids are elements present in the environment that can originate from natural and anthropogenic sources. However, exposure to some of these elements can cause adverse health effects due to their toxicological potential. As such, it is important to assess their levels in the human body, which can be done through human biomonitoring. Several studies assessed these elements' levels in the Portuguese population, but were mainly focused on hotspots or specific groups. As such, the aim of this work was to assess the exposure to metals and metalloids in the Portuguese population using samples collected in the study "Exposure of the Portuguese Population to Environmental Chemicals: a study nested in INSEF 2015" (INSEF-ExpoQuim).
INSEF-ExpoQuim was an epidemiologic study including 297 participants aged 28-39 years, living in Portugal for ≥ 12 months and able to follow an interview in Portuguese. Fieldwork was developed between June 2019 and February 2020 following the guidelines of the HBM4EU project. First morning urine samples were collected along with data on sociodemographic characteristics, living conditions and residential history, habits/lifestyle, nutrition, health, occupation and substance specific information. Total concentrations of arsenic (As), lead (Pb), cobalt (Co), copper (Cu), manganese (Mn), molybdenum (Mo), nickel (Ni), selenium (Se) and zinc (Zn) were determined by inductively coupled plasma mass spectrometry.
As, Cu, Mo, Se and Zn were detected in the majority of the samples analysed, while Mn was detected in around half and Pb, Co and Ni were detected in less than half. Results will be presented, including a description of the biomarkers' levels in the Portuguese population.
This study is the first developed in Portugal to provide an assessment of the exposure at a national level and its results may support the development and implementation of policy measures aimed at minimizing exposure and improving the population's health.

O-OP-185 Occupational exposure and asbestos related disease in Brazil, 2007 to 2021

Me. Klauss KS Garcia[1], Cristiano B Miranda[1], Rafael Buralli[1]
[1]*General Coordination of Occupational Health, Ministry of Health of Brazil, Brasília, Brazil*

Occupational asbestos exposure is a major public health problem, resulting in more than 222.000 deaths per year globally and several socioeconomic impacts. Brazil is historically one of the world's largest producer and consumer of asbestos, which is mainly used in cement and mining activities. This work describes the notifications of work-related diseases of individuals exposed to asbestos in Brazil.

METHODS: We gathered data on work-related asbestos' disease from the Notifiable Diseases Information System (Sinan) from 2007 to 2021, considering Pneumoconiosis and Cancer. Absolute and relative frequencies of sociodemographic and epidemiological characteristics were described.

RESULTS: From 2007 to 2021, 2,246 cases of work-related Pneumoconiosis and Cancer with asbestos exposure were registered. 2008 was the year with most records (n=625), followed by 2017 (n=511), with an annual average of 149 cases. Most cases occurred among male workers (96.0%), aged between 50-69y (64.5%), white (12.8%) or black (8.5%), with low educational level – up to 4 years (10.0%). Top five occupations were: workers from construction material facilities, (32,7%), urban construction (13,4%), metal handling facilities (4,3%), potters (4,2%) e masonry (3,2%). The State of São Paulo, where is located most of the companies that used asbestos in Brazil, and has relatively good surveillance of asbestos disease, concentrated 84.2% of all notified cases.

CONCLUSIONS: Despite the important underreporting of chronic diseases, there is a high burden of asbestos diseases in Brazil, mainly affecting elderly men (due to the disease's long latency) and less-skilled occupations. Thus, it is essential to strengthening public policies, health surveillance, and care, considering the particularities of asbestos-related diseases and territories.

O-OP-186 Addressing Commercial Determinants of Health in African Pesticide Research

Hanna-Andrea Rother[1]
[1]*Division of Environmental Health, University of Cape Town, Mowbray (7700), South Africa*

Pesticide research, particularly in low- and middle-income countries (LMICs) continues to identify exposure risks and why pesticide poisonings continue (e.g., poor surveillance, weak legislation, use of highly hazardous pesticides, high-risk use and application practices). Focus often is on highlighting specific pesticide products, exposure risk contexts and vulnerable populations, as well as behaviours of farmers, workers and consumers. What is, however, less often assessed in pesticide research is the impact of commercial determinants on health (CDoH), which is referred to as "strategies and approaches used by the private sector to promote products and choices that are detrimental to health", and the role of corporate capture. In this review, the aim was to identify the key components of CDoH impacting on health outcomes for populations, particularly in Southern Africa, exposed to pesticides. Five strategies of the pesticide industry were identified that result in exposure risks and negative health outcomes. These strategies and concepts include: the social responsibility approach (e.g., responsible and safe use), mis- and lack of information (e.g., confidential business information), corporate capture (e.g., revolving staff door with regulators), apportioning blame (e.g., "misuse"), and uncertainty science (e.g., products are innocent until proven guilty, corporate research funding). The findings and complexity of each of these strategies will be presented. The impact of epidemiological research for evidence policy making will continue to be undermined as long as the CDoH are not addressed along side research. It is recommended that researchers include an analysis of pesticide commercial determinants as part of epidemiological research and that environmental health curricula include training on commercial determinants of environmental health. Young pesticide researchers need guidance on navigating corporate research funding, conflicts of interest and the long-term impact on their careers. To reduce pesticide poisonings in LMICs, CDoH need to be identified and addressed by researchers.

ORAL PRESENTATIONS SESSION 35: Occupational exposures and respiratory outcomes

O-OP-187 Exposure Trends and Half-lives of Per- and Polyfluoroalkyl Substances (PFAS) in Australian Firefighters

Sandra Nilsson[1], Kayla Smurthwaite[2], Lesa L Aylward[3], Margaret Kay[1], Leisa-Maree Toms[4], Leisa King[1], Shelby Marrington[1], Craig Barnes[5], Martyn D Kirk[2], Jochen F Mueller[1], Jennifer Braeunig[1]

[1]The University of Queensland, Woolloongabba, Australia, [2]The Australian National University, Canberra, Australia, [3]Summit Toxicology, LLP, La Quinta, USA, [4]Queensland University of Technology, Kelvin Grove, Australia, [5]Airservices Australia, Canberra, Australia

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFASs) are persistent manmade compounds used in aqueous film forming foam (AFFF). The extensive use of AFFF has led to widespread environmental PFAS contamination and exposures to firefighters. The aim of this study is to determine PFAS blood serum concentration trends and apparent serum elimination half-lives in firefighters after the replacement of AFFF.

METHODS: Current and former employees of an Australian corporation providing aviation firefighting services, where AFFF had been used in the past, were recruited to participate in this study. Special focus was placed on re-recruiting participants who had provided blood samples five years prior. Participants were asked to provide a blood sample and complete a questionnaire. Serum samples were analysed for 40 different PFASs using HP LC-MS/MS.

RESULTS: A total of 799 participants provided blood samples. of these, 130 previously provided blood serum five years prior. Mean serum concentrations of perfluorooctane sulfonate (PFOS, 27 ng/mL), perfluoroheptane sulfonate (PFHpS, 1.7 ng/mL) and perfluorohexane sulfonate (PFHxS, 14 ng/mL) were significantly higher than the levels in the general Australian population. Serum concentrations were associated with the use of PFOS/PFHxS based AFFF. Participants who commenced service after the replacement of this foam had serum concentrations similar to those in the general Australian population. Average individual apparent half-lives were estimated to be 5.0 years (perfluorooctanoic acid (PFOA)), 7.8 years (PFHxS), 7.4 years (PFHpS) and 6.5 years (PFOS).

CONCLUSIONS: This study shows how workplace interventions such as replacement of AFFF, can benefit employees at risk of occupational exposure.

O-OP-188 Atrazine use and cancer risk within the Agricultural Health Study (AHS) cohort: An update

Richard Remigio[1], Gabriella Andreotti[1], Jonathan Hofmann[1], Patricia Erickson[1], Christine Parks[2], Jay Lubin[1], Paul Albert[1], Dale Sandler[2], Laura Beane Freeman[1]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, USA, [2]Epidemiology Branch, National Institute of Environmental Health Sciences, Research Triangle, USA

In the United States, atrazine is a common agricultural herbicide. Few epidemiologic studies have evaluated cancer risks associated with this ubiquitous chemical. A previous analysis within the Agricultural Health Study (AHS) in 2011 found limited evidence of cancer risk based on 3,146 exposed cases. Here, we updated that analysis with additional follow-up time and exposure information.

Information about lifetime pesticide use was reported on questionnaires at enrollment (1993-1997) and follow-up (1999-2005). Among 53,508 pesticide applicators in Iowa (IA) and North Carolina (NC), there were 6,401 incident exposed cancer cases identified through linkage to state cancer registries through 2017 (IA) and 2014 (NC). We evaluated cumulative intensity-weighted lifetime days of atrazine use. Atrazine exposures were categorized into quartiles among users and compared to a non-exposed referent group. Poisson regression was applied to estimate rate ratios (RR) and 95% confidence intervals (CI) adjusting for age, smoking status and pack-years, alcohol use, family cancer history, and correlated pesticides. We also stratified by age at cancer diagnosis.

Approximately 71% of applicators reported ever using atrazine. Greater use of atrazine was associated with increased risk of cancers of the lung (RRQ4=1.21, CI=0.95-1.55, p-trend=0.19, n=551 cases), and prostate (RRQ4=1.12, CI=0.98-1.28, p-trend=0.10, n=2,521); the association was stronger for aggressive prostate cancer (RRQ4=1.37, CI=1.02-1.84, p-trend=0.07, n=553). The association with prostate cancer was most pronounced among those diagnosed <50 years of age (RRQ4=3.53, CI=1.34-9.29, p-interaction=0.012). Associations with lung cancer did not vary by age.

Our findings with an average of 8.5 years of additional follow-up and twice as many cases compared to a previous analysis, suggest increased risk of prostate and lung cancers is associated with atrazine use. The associations with prostate cancer were most notable among those diagnosed at younger ages and those with aggressive disease. Further work is needed to investigate the reasons for these observations.

O-OP-189 Pesticide exposure, genetic susceptibility, and prostate cancer risk in the Agricultural Health Study

Lauren Hurwitz[1], Laura Beane Freeman[1], Gabriella Andreotti[1], Jonathan Hofmann[1], Jia Liu[1], Kristine Jones[1], Christine Parks[2], Dale Sandler[2], Jay Lubin[1], Sonja Berndt[1], Stella Koutros[1]
[1]U.S. National Cancer Institute, Bethesda, USA, [2]U.S. National Institute of Environmental Health Sciences, USA

BACKGROUND AND AIM: Specific pesticides have been associated with risk of prostate cancer, but interactions with genetic susceptibility loci have rarely been studied. We examined the joint associations of pesticides and genetic variants with prostate cancer risk.

METHODS: We studied 1,162 cases (588 aggressive) and 2,206 frequency-matched controls nested in the Agricultural Health Study cohort. History of pesticide use was self-reported at enrollment. Genotyping was conducted using the OncoArray-500K BeadChip (Illumina Inc). Logistic regression models estimated the joint associations of pesticides previously linked to prostate cancer (fonofos, terbufos, malathion, aldrin, linuron, and dimethoate) and 256 individual genetic variants and an aggregated polygenic risk score (PRS) with risk of total and aggressive prostate cancer. Likelihood ratio tests assessed multiplicative interaction.

RESULTS: We observed multiplicative interaction between fonofos and the PRS in relation to risk of total and aggressive prostate cancer. Compared to the reference group (non-exposed, PRS scores <median), those with fonofos exposure and PRS scores >median had elevated risks of total (OR 1.35, 95% CI 1.06-1.73, p-int=0.03) and aggressive (OR 1.49, 95% CI 1.09-2.04, p-int=0.19) prostate cancer. There was also evidence of interaction between the six pesticides and individual genetic variants occurring in genomic regions associated with 1) cancer signaling pathways, 2) hormonal perturbations relevant for prostate cancer, 3) DNA damage response and 4) neurological traits; many of the examined pesticides have known neurologic mechanisms.

CONCLUSIONS: Joint exposure to the organophosphate insecticide fonofos and genetic susceptibility may further elevate the risk for total and aggressive prostate cancer, above the independent effects of each. These results, as well as those observed for individual genetic markers, suggest potential mechanisms by which these pesticides may increase prostate cancer risk.

KEYWORDS: Prostate Cancer, Pesticides, Occupational exposure, Genetic susceptibility

O-OP-190 Exploration of occupations as risk factors for lung cancer in hierarchical and penalization penalized regression models accounting for multiple known exposures

Calvin Ge[1], Lützen Portengen[2], Susan Peters[2], Ann Olsson[3], Joachim Schüz[3], Thomas Brüning[4], Hans Kromhout[2], Kurt Straif[5], Roel Vermeulen[2]

[1]TNO, Utrecht, Netherlands, [2]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, [3]International Agency for Research on Cancer, Lyon, France, [4]Institute for Prevention and Occupational Medicine of the German Social Accident Insurance-Institute of the Ruhr University, Bochum, Germany, [5]ISGlobal, Barcelona, Spain

BACKGROUND AND AIM: Traditional occupational epidemiological analysis typically emphasize on disease risks associated with specific single exposures or single occupations. We used hierarchical and regularization models to explore occupational risks at the job-title level associated with lung cancer while accounting for exposures to multiple known lung carcinogens.

METHODS: We pooled lung cancer case-control study subjects from 14 European and Canadian studies. Associations between ever employment in 1,288 five-digit ISCO-68 occupations and lung cancer were screened using two approaches: Bayesian hierarchical and LASSO penalized regressions. Both modeling approaches account for age, smoking, sex, study, and fully quantitative exposures to six known occupational lung carcinogens: asbestos, chromium, diesel engine exhaust, nickel, PAHs, and silica. False positive findings in the Bayesian hierarchical and LASSO models were controlled using horseshoe priors and stability selection, respectively. Lung cancer odds ratios for selected occupations were estimated using unconditional logistic regression model with identical covariates.

RESULTS: Our final analyses included 16,901 lung cancer cases and 20,965 controls. There were notable overlaps in jobs selected by the hierarchical and penalization modeling approaches. Occupations selected by both modeling approaches with positive associations with lung cancer after controlling for known exposures include carpenters (OR: 1.77; 95CI: 1.36, 2.33) and construction bricklayers (OR: 1.40; 95CI: 1.17, 1.67). Similarly selected occupations but with negative associations with lung cancer include secondary school teachers (OR: 0.36; 95CI: 0.23, 0.55), production managers (OR: 0.65; 95CI: 0.53, 0.79), and government executive officials (OR: 0.7; 95% CI: 0.61, 0.79).

CONCLUSIONS: We demonstrated viable agnostic approaches in identifying employment risk factors for lung cancer. Future work involves investigations of factors that contribute to the observed elevated or lower cancer risks, which may involve gaps in current exposure assessment and modeling framework, and/or exposures to other lung carcinogens yet to be elucidated.

O-OP-191 Lung Cancer Risk in Relation to Jobs Held in a Nationwide Case-Control Study in Iran

Bayan Hosseini[1]

[1]International Agency for Research on Cancer, Lyon, France, [2]Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Iran

BACKGROUND AND AIM: Globally, lung cancer is the most frequent occupational cancer, but the risk of lung cancer related to the occupations in Iran is not clear. We aimed to assess whether workers in various occupational groups would experience an increased lung cancer risk.

METHODS: We used the IROPICAN nationwide hospital-based case-control study including 658 incident lung cancer cases and 3477 controls. We assessed the risk of cancer in relation to ever working in major International Standard Classification of Occupations (ISCO-68) groups and specific jobs, while controlling for individual potential confounders including cigarette smoking and opium consumption.

RESULTS: We observed elevated odds ratio (OR) for lung cancer in male construction workers (OR=1.4; 95% confidence interval (CI), 1.0- 1.8), and petroleum industry workers (3.2; CI, 1.1- 9.8), and in female farmers (2.6; CI, 1.3- 5.3), and female bakers (5.5; CI, 1.0, 29.8). The positive trend has been observed for the duration of employment as a construction worker in men (p trend < 0.004), and farming in women (p trend < 0.5). Increase risk of squamous cell carcinoma (SCC) was associated with ever construction industry workers for males (1.9; CI, 1.2- 3.0), whilst both SCC and adenocarcinoma subtypes were associated with working as farmers for females (3.8; CI, 1.4- 9.9), even more pronounced for adenocarcinoma (4.3; CI, 1.1- 17.2).

CONCLUSIONS: Although we did observe association between some occupations and lung cancer, we recommend developing an occupational exposure assessment tool specific for working conditions in Iran to allow the study of specific occupational agents.

KEYWORDS: Occupational cancer, Lung cancer, Exposure, Carcinogen, Iran

O-OP-192 Study of Parental Occupational Exposures to Solvents and Risk of Autism Spectrum Disorder in Offspring

Aisha Dickerson[1], Johnni Hansen[2], Marc Weisskopf[3], Diana Schendel[4,5], M. Daniele Fallin[1]
[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, USA, [2]Danish Cancer Society Research Center, Copenhagen, Denmark, [3]Harvard T.H. Chan School of Public Health, Boston, USA, [4]Aarhus University, Aarhus, Denmark, [5]Drexel University, Philadelphia, USA

BACKGROUND AND AIM: Solvents can accumulate in fat and later metabolize during pregnancy. Additionally, these toxicants could lead to germline mutations. We investigated associations between multiple parental occupational solvent exposures and odds of autism spectrum disorder (ASD) diagnosis in offspring.

METHODS: Using population-based data from the Danish National Patient Registry, we identified a subset of ASD cases from 1982 to 2016 and 1:100 sex and birth-year matched controls obtained from the Central Population Register. We determined parental occupation history from age 16 years through 6 months post-childbirth from the Danish Pension Fund and estimated cumulative benzene, methylcyclohexane, toluene, trichloroethylene, perchloroethylene, and 1,1,1-trichloroethane exposure for mothers and fathers based on job exposure matrices (JEMs). Conditional logistic regression was used to estimate adjusted odds ratios (aOR) and 95% confidence intervals (CI) for exposures one year prior to conception and during pregnancy.

RESULTS: In analysis of data from 1898 people with ASD and 141,702 without ASD, there were no observed associations between maternal solvent exposures during pregnancy and risk of ASD in offspring. However, analysis for maternal benzene exposure one year prior to conception revealed higher adjusted odds for those with any exposure (aOR=1.55; 95% CI 1.02, 2.37). Additionally, although there were no significant associations between paternal solvent exposures during pregnancy and ASD risk, there were significantly increased odds of ASD in offspring whose fathers were exposed to benzene (aOR=3.07; 95% CI 1.72, 5.46) and toluene (aOR=1.66; 95% CI 1.05, 2.62) one year before conception.

CONCLUSIONS: Although previous studies have suggested parental solvent exposure during pregnancy can contribute to pathogenesis of ASD, our findings suggest that risk may be increased through exposures prior to conception. However, unavoidable non-differential misclassification from the use of JEMs may have masked truly increased risk during pregnancy.

ORAL PRESENTATIONS SESSION 36: Air pollution: maternal and neonatal health

O-OP-193 Exposure to ambient fine particulate matter (PM2.5) from local sources during pregnancy may reduce birth weight: An administrative cohort study from southern Sweden

Festina Balidemaj[1], Erin Flanagan[1], Ebba Malmqvist[1], Ralf Rittner[1], Karin Källén[1], Daniel Oudin Åström[1], Anna Oudin[1]
[1]*Lund University, Lund, Sweden*

INTRODUCTION: While prenatal exposure to air pollution has been shown to reduce birth weight, epidemiological studies where source-specific exposure data is available are still very few. The aim of the present study was to investigate the associations between source-specific exposure to ambient fine particulate matter (PM2.5) from different local sources during pregnancy and birth weight of the child.
MATERIALS AND

METHODS: We defined an administrative cohort using data on 40,245 singleton births in southern Sweden. Exposure to ambient PM2.5 at the residential address during pregnancy was modelled with 100 x 100 m spatial resolution. Concentrations of PM2.5 from all local sources (all-source PM2.5), tailpipe exhaust, vehicle wear-and-tear, and small-scale residential heating were investigated separately. The relationship between birth weight (continuous) and low birth weight (<2,500 grams) were analysed using linear and logistic regression, respectively, in crude and adjusted models.

RESULTS: There were associations between each local source of PM2.5 and birth weight as a continuous variable in the adjusted models. Birth weight decreased by an average of 34 grams (95% confidence interval, CI: 26–43) in association with a 1 μg/m3 increase in all-source PM2.5 in the adjusted models. Tailpipe exhaust seemed to have the greatest effect per 1 μg/m3 increase, with a mean reduction of 278 grams (95% CI: 207–349), followed by vehicle wear-and-tear: mean decrease of 106 grams (95% CI: 81–132). for small-scale residential heating, the corresponding decline was 36 grams on average (95% CI: 14–57). The only local source of PM2.5 associated with low birth weight (<2500 g) was small-scale residential heating, with an adjusted odds ratio (OR) of 1.50 (95% CI: 1.12–2.03).

CONCLUSIONS: Locally produced prenatal exposure to all-source PM2.5, tailpipe exhaust, vehicle wear-and-tear, as well as small-scale residential heating may all reduce newborns' birth weight.

O-OP-194 Air Pollution Exposure during Pregnancy and Childhood, APOE ε4 Status and Polygenic Risk Score for Alzheimer's Disease, and Brain Structural Morphology in Preadolescents

Esmée Essers[1,2], Anne-Claire Binter[1], Alexander Neumann[2], Tonya White[2], Silvia Alemany[3], Mònica Guxens[1,2]
[1]ISGlobal, Barcelona, Spain, [2]Department of Child and Adolescent Psychiatry/Psychology, Erasmus MC, Rotterdam, Netherlands, [3]Vall d'Hebron Research Institute, Barcelona, Spain

BACKGROUND AND AIM: Air pollution exposure is associated with impaired neurodevelopment, altered structural brain morphology in children and neurodegenerative disorders. Differential susceptibility to air pollution may be influenced by genetic features. We aimed to evaluate whether the apolipoprotein E (APOE) genotype or the polygenic risk score (PRS) for Alzheimer's Disease (AD), modify the association between air pollution exposure during pregnancy and childhood and structural brain morphology in preadolescents.

METHODS: We included 1186 children from the Generation R Study. Concentrations of 14 air pollutants were calculated at the participants' home address during pregnancy and childhood using land-use-regression models. Structural brain images were collected at age 9–12 years to assess (sub)cortical brain volumes. APOE status and PRS for AD were examined as effect modifiers. We conducted single-pollutant analyses with a two-way interaction between air pollution and APOE status or PRS for AD and multi-pollutant analyses with the two-way interaction.

RESULTS: Higher pregnancy PMcoarse and childhood PAHs exposure was differentially associated with larger cerebral white matter volume in APOE ε4 carriers compared to non-carriers (29485 mm3 [95% CI 6189, 52781] and 18663 mm3 [469, 36856], respectively). Higher pregnancy PMcoarse exposure was differentially associated with larger cortical grey matter volume in children with higher compared to lower PRS for AD (19436 mm3 [825, 38046]).

CONCLUSIONS: APOE status and PRS for AD have a possible modifying effect on the association between air pollution exposure and brain structural morphology in preadolescents. Both seem to modify the association towards the typical development of the brain, with increasing cortical volumes, highlighting the possibility of the antagonistic pleiotropic effect (i.e., protective effect in early life but altered neurodegenerative processes in adulthood). Future studies should research this antagonistic pleiotropic effect and study trajectorial brain development using a longitudinal design.

KEYWORDS: environmental pollution, neurodevelopment, neuroimaging, genetic modifiers

O-OP-195 A population-based cohort study of traffic congestion and term birth weight using vehicle telematics data

Mary Willis[1,2], David Schrank[3], Chunzue Xu[1], Lena Harris[4], Beate Ritz[5], Elaine Hill[4], Perry Hystad[1]
[1]Oregon State University, Corvallis, USA, [2]Boston University, Boston, USA, [3]Texas Transportation Institute, Bryan, USA, [4]University of Rochester, Rochester, USA, [5]University of California, Los Angeles, Los Angeles, USA

BACKGROUND AND AIM: Over 11 million Americans reside within 150 m of a major highway, an area of high air pollution exposure. Traffic congestion further contributes to this problem but has not been evaluated in epidemiological studies to-date. We hypothesize that degraded air quality due to traffic congestion will have an adverse impact on infant birth weight.

METHODS: Using a population-based birth cohort in 2015-2016 for the State of Texas, we limited our study population to addresses within 1,000 m of a road in this database. We calculated traffic congestion around each geocoded maternal address at delivery for 100 m, 300 m, and 500 m buffer distances. We leveraged novel congestion and vehicle volume measurement data from the Texas Most Congested Roads database, which contains measurements of traffic volume, delay, and emissions from connected vehicle and device data. We used linear regressions to evaluate the association between traffic congestion and term birth weight, adjusting for sociodemographic characteristics and vehicle volume.

RESULTS: Among 580,992 births, we find consistent negative associations between traffic congestion and term birth weight. We observed a 15.8 g reduction in term birth weight (95% CI: -20.5, -11.1) among the highest quintile of delay exposure at 500 m compared to births with no delay exposure in this buffer distance. Results are similar, though attenuated, for truck-specific congestion. When we calculate excess vehicle emissions from congestion, we observe a -17.6 g reduction in term birth weight (95% CI: -21.4, -13.9) when comparing the highest and lowest quintiles.

CONCLUSIONS: Our study provides important new evidence that traffic congestion is associated with adverse infant health outcomes, in addition to total traffic volumes on nearby roads. Therefore, programs to reduce traffic congestion may have positive co-benefits for infant health with respect to birth weight.

KEYWORDS: traffic-related air pollution, infant health, birth weight

O-OP-196 Geospatial determinants of maternal and child exposure to fine particulate matter in Kintampo, Ghana: Levels within the household and community, by building density and nearby roadways

Danielle Medgyesi[1], Mohammed Nuhu Mujtaba[2], Qiang Yang[3,4], Sulemana Abubakari[2], Alison G Lee[5], Jeremy R Porter[1,6], Steven N Chillrud[3], Kaali Seyram[2], Darby W Jack[1], Kwaku Poku Asante[2]

[1]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA, [2]Kintampo Health Research Centre, Research and Development Division, Ghana Health Service, Kintampo North Municipality, Ghana, [3]Lamont-Doherty Earth Observatory, Columbia University, Palisades, USA, [4]Elsevier Global STM Journals, New York, USA, [5]Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai, New York, USA, [6]Department of Sociology, School of Humanities and Social Sciences, Brooklyn College, Brooklyn, USA

BACKGROUND AND AIM: Personal exposure to fine particulate matter ($PM_{2.5}$) from household air pollution is well-documented in Sub-Saharan Africa, but spatial patterns of exposure are poorly characterized. Our study aimed to evaluate personal exposure to $PM_{2.5}$ when within the household and community, and during typical hours of cooking, among mothers and children in rural communities near Kintampo, Ghana. We also explored other geographic determinants of exposure.

METHODS: Our study included 259 sessions of geolocated, gravimetrically-calibrated one-minute $PM_{2.5}$ measurements from participants in the GRAPHS Child Lung Function Study. Household boundaries were defined using a 50-meter buffer around participants' homes. Community boundaries were developed by applying a spatial clustering algorithm to an open-source dataset of building footprints in Africa. for each GPS location, we estimated building density (500m buffer) and proximity to roadways (100m buffer). We estimated the percentage change in logarithm $PM_{2.5}$ by location (household, community), time of day (morning/evening cooking hours versus nighttime), building density and proximity to roadways using linear mixed effect models.

RESULTS: Relative to nighttime household exposures, $PM_{2.5}$ exposure during evening cooking hours increased by 175% (95CI=162-188%) and 75% (95CI=50-105%) in the household and community, respectively. Exposures were elevated in areas with the highest versus lowest quartile of building density (Q1vsQ4=28%, 95CI=14-45%). The effect of building density was strongest when modeled jointly with evening cooking hours, and influenced levels in both the household and community (64% and 82% increase from Q1 to Q4, respectively). Being proximal to a tertiary or trunk roadway increased $PM_{2.5}$ exposure by 44% (95CI=24-67%) and 13% (95CI=4-22%), respectively.

CONCLUSIONS: Our findings suggest that neighbors' cooking and other community $PM_{2.5}$ sources contribute substantially to personal $PM_{2.5}$ exposure. Building density may exacerbate community exposures when multiple households are cooking simultaneously. Proximity to tertiary or trunk roadways increase personal $PM_{2.5}$ exposure.

O-OP-197 Effects of a liquefied petroleum gas cookstove and fuel intervention on fetal and neonatal outcomes: a multi-country randomized controlled trial conducted by the Household Air Pollution Intervention Network (HAPIN) trial

Ashley Younger[1], Abbey Alkon[1], Kristen Harknett[1], Miles A Kirby[2], Amy E. Lovvorn[3], Jiantong Wang[3], Anaité Diaz-Artiga[4], John P. McCracken[5], Ghislaine Rosa[6], Kalpana Balakrishnan[7], Adly Castañaza-Gonzalez[4], Libny Monroy-Alarcon[4], Alexie Mukeshimana[8], Sarada S. Garg[7], Lindsay Underhill[9], Howard H. Chang[3], Joshua Rosenthal[10], Aris Papageorghiou[11], William Checkley[12], Jennifer L. Peel[13], Thomas F. Clasen[3], Lisa Thompson[3,14]

[1]University of California, San Francisco, San Francisco, USA, [2]Harvard T.H. Chan School of Public Health, Harvard University, Cambridge, USA, [3]Rollins School of Public Health, Emory University, Atlanta, USA, [4]Center for Health Studies, Universidad del Valle de Guatemala, Guatemala City, Guatemala, [5]College of Public Health, University of Georgia, Athens, USA, [6]London School of Hygiene and Tropical Medicine, London, UK, [7]Sri Ramachandra Institute of Higher Education and Research, Chennai, India, [8]Eagle Research Center, Kigali, Rwanda, [9]Washington University in St. Louis, St. Louis, USA, [10]Fogarty International Center, National Institutes of Health, Bethesda, USA, [11]University of Oxford, Oxford, UK, [12]School of Medicine, Johns Hopkins University, Baltimore, USA, [13]Colorado State University, Fort Collins, USA, [14]Nell Hodgson Woodruff School of Nursing, Atlanta, USA

BACKGROUND AND AIM: Household air pollution (HAP) from cooking with solid fuels used during pregnancy has been associated with adverse pregnancy outcomes. The HAPIN trial is a randomized controlled trial of liquefied petroleum gas (LPG) stoves and fuel distribution in 3200 households conducted across Guatemala, India, Peru, and Rwanda. We describe the effects of the LPG intervention on fetal/infant stillbirth, neonatal mortality and congenital anomalies.

METHODS: Pregnant women (18-35 years of age; gestation confirmed by ultrasound at 9-20 weeks) were randomly assigned to an intervention arm (n=1593) or control arm (n=1607). Participants were monitored for stillbirth (fetal death ≥ 20 weeks gestation), neonatal mortality (death of any live-born infant in first 28 completed days of life), and congenital anomalies (any structural/functional anomalies that occur during intrauterine life). Analyses were performed according to intention-to-treat (ITT) analysis, and binary outcomes were compared between the two arms using log binomial models.

RESULTS: Pregnant women were enrolled in the study and received their LPG stoves at 15.4 (SD 3.1) weeks gestation. We recorded 47 congenital anomalies (23 intervention, 24 control), 56 stillbirths (28 intervention, 28 control), and 41 neonatal deaths (20 intervention, 21 control) between enrollment and 28 days of live of the infant. Compared to the control arm, the relative risk among women randomized to the intervention was 0.96 (95% CI: 0.55, 1.70) for congenital anomaly, 1.01 (95% CI: 0.60, 1.70) for stillbirth and 0.97 (95% CI: 0.53, 1.77) for neonatal mortality.

CONCLUSIONS: We did not find a significant reduction in incidence of stillbirth, neonatal mortality and congenital anomalies. The small number of cases may have contributed to the lack of power and the intervention was introduced after the first trimester, which may be too late to find a protective effect.

KEYWORDS: household air pollution; congenital anomalies, stillbirth, neonatal mortality.
intention-to-treat, HAPIN trial

O-OP-198 Effect of Ramadan fasting during pregnancy on birth weight of term newborns: Modification by biomass fuel use in Kaduna, Nigeria

Musa Kana[1]
[1]*Kaduna State University, Kaduna, Kaduna, Nigeria*

BACKGROUND AND AIM: Ramadan fasting during pregnancy linked with low dietary intake could adversely affect fetal growth. However, previous studies report mixed findings on the effect of fasting on infant birth weight. Therefore, this study of term newborns aims to estimate the association between Ramadan fasting during pregnancy and birth weight and evaluate the effect modification by maternal biomass fuel exposure.

METHODS: Our study included 1,514 mother-child pairs recruited from Kaduna in northwestern Nigeria. The outcome variable was birth weight. The exposure was Ramadan fasting based on the overlap between Ramadan and index pregnancy, cooking fuel type, categorized as biomass fuel or liquefied petroleum gas and kerosene (reference). We estimated the covariate-adjusted association between Ramadan fasting and birth weight. In addition, we performed stratified analysis and estimated interaction to compare the association between biomass fuel and birth weight for various trimesters of Ramadan fasting exposure.

RESULTS: 639 (42%) mothers were exposed to Ramadan fasting during pregnancy; first (338, 53%), second (187, 29%), and third trimester (114, 18%). Adjusting for maternal age, education, parity, BMI at birth, and child sex, mothers exposed to Ramadan fasting delivered infants weighing an average of 31g lighter (95%CI −80 to 18) than the unexposed. The association between biomass fuel and birth weight was not significantly different for women exposed and unexposed to fasting (Pinteraction=0.77). But we observed a disparity by trimester of fasting exposure in the association of biomass fuel with birth weight; first (-146g 95%CI -294 to 1), second (-58g 95%CI -240 to 125), and third trimester (-57g 95%CI -396 to 282).

CONCLUSIONS: Ramadan fasting during pregnancy is not associated with birth weight. Furthermore, maternal biomass fuel use is significantly related to reduced birth weight only among mothers exposed to Ramadan fasting during the first trimester.

KEYWORDS: Ramadan fasting; biomass fuel; birth weight; Nigeria

ORAL PRESENTATIONS SESSION 37: Using metabolomics to understand mechanisms of environmental exposures

O-OP-199 Agricultural pesticide exposure related to metabolic changes in Parkinson's disease patients

Kimberly Paul[1], Myles Cockburn[2], Jeff Bronstein[1], Douglas I Walker[3], Dean Jones[4], Beate Ritz[1]
[1]UCLA, Los Angeles, USA, [2]USC, Los Angeles, USA, [3]Mount Sinai, New York City, USA, [4]Emory University, Atlanta, USA

BACKGROUND AND AIM: There are currently 13,543 pesticide products with 1059 active ingredients registered in California, potentially exposing residents of agricultural regions through drift and contamination. In order to comprehensively study agricultural pesticide exposure in a population-based study of Parkinson's (PD), we determined networks of pesticide co-exposures due to living near agricultural applications (Central Valley, California). We estimated the risk of PD with patterns of co-exposure and assessed how PD-implicated co-exposures were related to the metabolome of patients in order to help understand biologic mechanisms and responses to exposure.

METHODS: We used lifetime participant address histories (n=1653), land-use maps, and the pesticide use reports database to estimate residential proximity-based exposure to 722 pesticides over a 40-year period. We applied an unsupervised, weighted pesticide co-exposure model based on WGCNA and exposure correlations to determine co-exposure modules, assessed influence on PD risk, and performed an exposure-related untargeted metabolome wide association study using LCMS data (5072 metabolites).

RESULTS: Our co-exposure model identified seven co-exposure modules based on 288 pesticides applied near the home of >25 participants. of these, two were related to an increased risk of PD. Most strongly, one module representing co-exposures to 35 pesticides (OR=1.21 per SD, 95% CI=1.09, 1.38). Among the PD patients, this pesticide co-exposure module was related to differential intensity of 442 metabolites at $p<0.05$ (73 FDR<0.10, 10 FDR<0.05). This metabolite set was most strongly enriched for glycosphingolipid (p=0.002) and glycerophospholipid (p=0.003) metabolism pathways.

CONCLUSIONS: Agriculturally, pesticides are rarely applied in isolation. We identified co-exposure modules related to PD risk. Among patients, the exposure mixture was strongly related to disturbances in biologic pathways relevant to PD pathogenesis (e.g., glycosphingolipids linked to inflammation and mitochondrial function in PD) and also known to be targeted by a number of pesticides (e.g., glycerophospholipids and choline/cholinergic pathways).

O-OP-200 Air pollution, proteomics, metabolomics, and cardiometabolic health in the Framingham Heart Study

Laura Corlin[1,2], Ki-Do Eum[2], Trenton J Honda[3], Helen Suh[2]
[1]Tufts University School of Medicine, Boston, USA, [2]Tufts University School of Engineering, Medford, USA, [3]Bouve College of Health Sciences, Northeastern University, Boston, USA

BACKGROUND AND AIM: We examined whether proteomic and metabolomic correlates of air pollution exposure were associated with prevalent and incident cardiometabolic health outcomes (CVD, defined as cardiovascular disease or cardiometabolic multi-morbidity).

METHODS: We linked annual average black carbon (BC) and particulate matter (PM2.5) with metabolomic and/or proteomic data (quantified using liquid chromatography/tandem mass spectrometry and SomaScan platform, respectively), and with CVD status among Framingham Offspring Study participants at examination cycle five [1991-1995; n=2409]). Adjusting for age, sex, smoking, body mass index, physical activity, and batch (for proteins), we used linear models to examine associations between each -omic biomarker and each air pollutant, and logistic models to examine the likelihood of 1) having CVD at examination cycle five and 2) developing CVD or CVD-related mortality through 2018. We used Reactome to conduct an overrepresentation analysis for pathways enriched among the significantly ($p<0.05$) associated -omics biomarkers. Pathways were considered enriched if the false discovery rate (using the Benjamani-Hochberg method) was <0.05.

RESULTS: of 220 metabolites, eight were associated with PM2.5 (e.g., citrate, a cholesterol ester, a phosphatidylcholine), four were associated with BC (creatinine, phenylalanine, symmetric dimethylarginine, and triiodothyronine), 73 were cross-sectionally associated with CVD, and 94 were longitudinally associated with CVD/CVD-related mortality. A diacylglycerol was associated with PM2.5 and both CVD variables. Phenylalanine was associated with BC and incident CVD/CVD-related mortality. of 1373 proteins, we found associations for 160 with PM2.5, 66 with BC, 138 with cross-sectional CVD, and 137 with incident CVD/CVD-related mortality. Proteins associated with one or both air pollutants and both health outcomes were overrepresented in 21 pathways (e.g., mitogen-activated protein kinase signaling and cascade, platelet degranulation and platelet activation, formation and dissolution of fibrin clots, and extracellular matrix organization).

CONCLUSIONS: Proteomic and metabolomic markers associated with air pollution exposure may provide insight into how air pollution relates to cardiometabolic health.

O-OP-201 Salivary metabolomic signatures and body mass index (BMI) in Italian adolescents: a pilot study

Sandra India-Aldana[1], Anu Joshi[1], Damaskini Valvi[1], Roberto Lucchini[1,2], Donatella Placidi[2], Lauren Petrick[1], Megan Horton[1], Megan Niedzwiecki[1], Elena Colicino[1]
[1]Icahn School of Medicine at Mount Sinai, New York, USA, [2]University of Brescia (UNIBS), Brescia, Italy

BACKGROUND AND AIM: The prevalence of childhood obesity remains high in several Southern Mediterranean countries, reaching approximately 20%. In adolescents, obesity surveillance is scarce and little is known about the metabolomic profiles underlying obesity. Metabolomics can enable a better understanding of the mechanisms involved in environmentally-associated obesity. We characterized the molecular signatures of Italian adolescents associated with body mass index (BMI).

METHODS: We collected saliva samples and assessed BMI in a subset of n=93 adolescents enrolled in the Public Health Impact of Metal Exposure (PHIME) study during 2007-2014. A total of 217 untargeted metabolites were identified using LC-HRMS. Robust linear regression analyses (univariate, adjusted for socio-demographic factors and location, and sex-stratified) were used to cross-sectionally assess the associations between metabolomic signatures and age- and sex-specific BMI z-scores (z-BMI).

RESULTS: This subset of PHIME adolescents (median age 12 years; 52% female) were of medium socioeconomic status and had normal z-BMIs (median, IQR: 20.1, 17.8-22.1 kg/m2). A higher z-BMI was observed in boys compared to girls. In adjusted analyses, deoxyadenosine and uridine metabolites were inversely related to z-BMI ($p<0.02$). In females, one bile acid (hyocholic acid), one benzenoid (2,3-dihydroxybenzoic acid), and two aspartic acids were associated with higher z-BMI ($p<0.05$). In males, four metabolites (deoxycarnitine, deoxyadeno sine, hyodeoxycholic acid, and trigonelline) were downregulated and three metabolites (allantoin, D-alanine, theobromine/theophylline/paraxanthine) were upregulated in relation to z-BMI ($p<0.05$). In univariate analyses, several benzenoids were additionally identified to be upregulated in relation to z-BMI.

CONCLUSIONS: Metabolites related to purine and nucleotide metabolism, as well as benzenoids, amino acids, and bile acids were altered in relation to BMI in adolescents, particularly in males. Given that obesity rates are higher among males than females, future metabolomic studies with larger sample size may help understand the mechanisms underlying sex-dimorphic obesity and improve prevention strategies.

KEYWORDS: BMI, obesity, metabolomics, adolescents

O-OP-202 Using High-Resolution Metabolomics for Identifying Metabolic Profiles Associated with Ambient Air Pollution in the Cancer Prevention Study-II Nutrition Cohort

Donghai Liang[1], Ziyin Tang[1], W. Ryan Diver[2], Jeremy Sarnat[1], Sabrina Chow[1], Haoran Cheng[1], Michele Turner[3], Ying Wang[2]

[1]Emory University, Atlanta, USA, [2]American Cancer Society, Atlanta, USA, [3]Barcelona Institute for Global Health, Barcelona, Spain

BACKGROUND AND AIM: Mechanisms underlying ambient air pollution toxicity remains largely unknown despite the established links between air pollution and numerous adverse health effects. There is growing interest in applying high-resolution metabolomics (HRM) to study air pollution and health. Broad application of HRM is limited, however, due to concerns over statistical power and study generalizability.

METHODS: Using previously collected data, we conducted a cross-sectional metabolomics wide association study among 1,263 postmenopausal women within the American Cancer Society Cancer Prevention Study-II Nutrition Cohort. Modeled estimates of PM2.5 (1999-2004), NO2 (2006), and O3 (2002-2004) concentrations were linked to the participant residence at enrollment. Metabolic profiling on serum samples collected between 1998-2001 was measured by mass spectrometry-based platforms. We followed an untargeted metabolome-wide association study framework to evaluate metabolite and metabolic pathway perturbations associated with chronic exposures to air pollution.

RESULTS: We detected and analyzed 1,186 metabolites in serum samples, with an average technical intraclass correlation coefficient of 87% and coefficient of variance of 23%. Sixty-five unique metabolites were significantly associated with at least one air pollutant (false positive discovery rate <0.05), after controlling for covariates, including sociodemographic, smoking status, and year of blood draw. We observed perturbations in several inflammatory and oxidative stress related metabolic pathways associated with lipid, xenobiotic, amino acid, and vitamin metabolism. We subsequently confirmed the chemical identity of 43 unique metabolites with level 1 evidence, including diacylglycerol, taurine, docosapentaenoate, alpha- carboxyethylhydroxychroman, and palmitoyl ethanolamide.

CONCLUSIONS: In this large cross-sectional analysis of air pollution and serum metabolites in postmenopausal women, we identified several novel metabolic markers and pathways associated with long-term exposures to air pollution and replicated others. These results support future development of sensitive metabolic markers of air exposures, as well as corresponding investigation into the specific molecular mechanisms and disease etiologies indicated by these markers.

KEYWORDS: Air Pollution, Metabolomics

O-OP-203 Mapping the mechanistic evidence of wood smoke and wildfire studies in humans

Whitney Arroyave[2], Mona Sethi[2], Courtney Lemeris[3], M. Elizabeth Hodgson[2], Suril Mehta[1], Ruth Lunn[1]
[1]NIEHS, Research Triangle Park, USA, [2]Integrated Laboratory Systems LLC, an Inotiv Company, Morrisville, USA, [3]ICF, Durham, USA

BACKGROUND AND AIM: Wood smoke is a complex mixture of gases, chemicals, and fine particles generated by wood-burning and wildfires. We are conducting a cancer hazard evaluation of wood smoke for possible listing in the U.S. Report on Carcinogens. The database of cancer epidemiology studies for exposure to wood smoke, but not wildfire, is adequate to conduct an evaluation. As mechanistic evidence may inform the overall hazard evaluation, especially for wildfires, we mapped the published evidence by biomarkers for the key characteristic of carcinogens (KCC), focusing here on studies in exposed humans.

METHODS: We systematically searched three bibliographic databases for relevant biomarker studies on wildfire and wood smoke exposure. for selected studies reporting on the three most common KCCs (genotoxicity, oxidative stress, immune biomarkers), we extracted information including specific KCC biomarkers (e.g., mutations), results, study design, and population, and presented the data in an interactive evidence map.
RESULTS: Wood smoke: Most human studies (26) found positive associations with KCCs, consistent with the >70 non-human studies (in vitro and in vivo). Inflammation, inflammatory cytokines, and lipid peroxidation were the most common KCCs in humans. The studies were primarily intervention or cross-sectional in populations cooking or heating with wood or randomized studies of controlled exposure.
Wildfires: Human studies (15) were largely positive for immune biomarkers but inconsistent for genotoxicity and oxidative stress, whereas non-human studies (17) were generally positive for all endpoints. Most studies measured KCCs in firefighters (13) before or after exposure (e.g., work shift or natural wildfire event).

CONCLUSIONS: Wildfires are increasing in frequency and intensity due to climate change, and exposure to wood smoke remains a worldwide concern. This mechanistic evidence will help inform the cancer hazard evaluations of these exposures. Ongoing risk-of-bias evaluations may explain heterogeneity in human wildfire studies.

KEYWORDS: Wood smoke, wildfires, biomarkers, exposed humans

O-OP-204 Air pollution exposure during pregnancy and placental metabolomics

Lina Mu[1], Kexin Zhu[1], Rujie Liu[2], Tiange Shi[3], Rachael Hageman Blair[3], Li Chu[4], Jun Zhang[5], Jun Zhang[4], Yanjun Guo[6], Lihua Qiao[5], Zhongzheng Niu[1], Meng Wang[1], Zeinab Farhat[1], Alexandra Grippo[1], Changxing Ma[3], Lijian Lei[2]
[1]Department of Epidemiology and Environmental Health, School of Public Health and Health Professions, University at Buffalo, The State University of New York, Buffalo, USA, [2]Department of Epidemiology, School of Public Health, Shanxi Medical University, Taiyuan, China, [3]Department of Biostatistics, School of Public Health and Health Professions, The State University of New York at Buffalo, Buffalo, USA, [4]Department of Obstetrics and Gynecology, Beijing Anzhen Hospital, Capital Medical University, Beijing, China, [5]Research Center for Public Health, Tsinghua University, Beijing, China, [6]Department of Obstetrics and Gynecology, Aerospace Center Hospital, China

BACKGROUND AND AIM: Prenatal exposure to air pollution has been shown to adversely affect birth outcomes and child health. But few studies have applied metabolomics approach to understand the relevant biological mechanisms. We aim to investigate the metabolomic profiling in the placenta associated with prenatal air pollution exposure.

METHODS: This pilot analysis included twenty healthy, non-smoking pregnant women delivered at Anzhen Hospital in Beijing, China in 2017. Untargeted metabolomic profiling was performed on maternal placental tissues using UPLC-MS/MS. Maternal exposure to PM2.5 throughout pregnancy at residential and working addresses was estimated by a high-resolution hybrid spatiotemporal model. Linear regression and pathway enrichment analysis were performed to identify metabolites and metabolic pathways associated with trimester-specific and whole-pregnancy air pollution exposure, adjusting for maternal age, gestational age, pre-pregnancy BMI, and diet.

RESULTS: The means (SDs) of PM2.5 levels in the first, second, and third trimester, and the whole pregnancy were 107.6 (28.7), 64.3 (11.3), 53.3 (5.8), and 73.5 (12.1) μg/m3, respectively. A total of 897 known compounds were identified from the placental tissues. PM2.5 exposure during the first trimester was associated with changes in 65 metabolites in placental samples, but none remained significant after multiple comparisons (the false discover rate [FDR] at 0.05). We identified three placental metabolic pathways significantly associated with PM2.5 exposure in the first trimester, including valine, leucine and isoleucine biosynthesis (FDR <0.001), aminoacyl-tRNA biosynthesis (FDR =0.003), and arginine biosynthesis (FDR =0.006). We did not observe significant changes in individual metabolites or metabolic pathways in response to PM2.5 exposure in other two trimesters or during the whole pregnancy.

CONCLUSIONS: Prenatal exposure to air pollution might affect amino acids metabolism in the placenta and more studies are needed to further elucidate underlying mechanisms.

KEYWORDS: Air pollution, Pregnancy, Metabolomics

ORAL PRESENTATIONS SESSION 38: Greenspace, built environment, and health

O-OP-205 Neighborhood built environment, psychosocial stressors, and telomere length of birth parents and infants from San Francisco, California

Lara Cushing[1], Rachel Morello-Frosch, Ana Pelegrini Guimaraes[2], Nicholas Depsky[3], Hasibe Caballero-Gomez[1], Stephanie Eick[4], Erin DeMicco[5], Jue Lin[5], Tracey Woodruff[5]

[1]University of California Los Angeles, Los Angeles, USA, [2]San Francisco State University, San Francisco, USA, [3]University of California Berkeley, Berkeley, USA, [4]Emory University, Atlanta, USA, [5]University of California, San Francisco, San Francisco, USA

BACKGROUND AND AIM: Shorter telomere length is a biomarker of cellular aging previously associated with chronic stress and exposure to air pollution. Aspects of the neighborhood built environment can contribute to stress and air pollution exposures. We examine joint associations between residential greenspace, traffic, noise, and individual-level measures of psychosocial stressors on telomere length in birth parents and their newborns.

METHODS: Telomere length (T/S ratio) was measured in delivery cord blood of 490 newborns and 288 second trimester parental whole blood samples from the Chemicals in Our Bodies cohort from San Francisco, California. Three measures of neighborhood built environment were constructed from secondary data based on residential address: greenspace (normalized difference vegetation index [NDVI]), traffic volume, and noise. Perceptions of neighborhood quality, stress, and depression were collected via second trimester questionnaire. Measures hypothesized to be beneficial (NDVI, neighborhood quality) were reverse coded for ease of interpretation. We used quantile g-computation to assess joint associations between these exposures and newborn and parental T/S in separate models that controlled for age, race/ethnicity, education, parity, pre-pregnancy BMI, and gestational age (cord T/S only).

RESULTS: Parental and cord T/S were weakly correlated (Spearman rho = 0.21) but not strongly correlated with built environment or stress measures (rho from -0.12 to 0.13). A simultaneous one quartile increase in all exposures was associated with a mean change of -0.02, 95% confidence interval [-0.08, 0.04] in newborn T/S and -0.04 [-0.10, 0.01] in parental T/S. Effect estimates were stronger but less precise in paired samples (-0.06, [-0.16, 0.04] for newborn and -0.05 [-0.12, 0.03] for parental T/S), with depression assigned the largest negative weight.

CONCLUSIONS: Results from this cross-sectional study suggest prenatal exposure to adverse built environments and psychosocial stressors are associated with small reductions in telomere length of newborns and their birth parents.

KEYWORDS: urban, perinatal

O-OP-206 Residential Greenness and Depression in Older U.S. Adults: Evidence from The Health and Retirement Study

Alan Fossa[1], Rachel Bergmans[2], Jennifer D'Souza[1], Carlos Mendes de Leon[1], Adam Szpiro[3], Jon Zelner[1], Kara Zivin[4,5,6], Sara Adar[1]

[1]University of Michigan School of Public Health - Department of Epidemiology, Ann Arbor, USA, [2]Michigan Medicine - Department of Anesthesiology, Chronic Pain & Fatigue Research Center, Ann Arbor, USA, [3]University of Washington School of Public Health - Department of Biostatistics, Seattle, United Stated of America, [4]Michigan Medicine - Department of Obstetrics and Gynecology, Ann Arbor, USA, [5]Michigan Medicine - Department of Psychiatry, Ann Arbor, USA, [6]University of Michigan School of Public Health - Department of Health Management and Policy, Ann Arbor, USA

BACKGROUND AND AIM: The physical environment influences mental health. In this study, we investigated residential greenness in relation to major depressive disorder (MDD), a leading cause of disability. We also tested effect modification by climate and urbanicity given that vegetation types and human interaction with vegetation differs across these settings.

METHODS: We used biennial survey data from 2008 through 2016 from a cohort of older U.S. adults. We calculated greenness at participant home addresses as the maximum normalized difference vegetation index (NDVI) for the year preceding each survey, averaged within 250m and 1km buffers. A score of ≥5 on the Composite International Diagnostic Interview Short Form indicated MDD. We used Köppen-Geiger classifications, which identify vegetation biomes, to characterize climate, and Beale codes for urbanicity. To estimate prevalence ratios, we used Poisson regression accounting for repeated measures and incorporated survey weights. Our models adjusted for individual and neighborhood socio-demographics, geography, sunshine, and bluespace.

RESULTS: We included 27,829 participants who contributed 91,479 observations to our analysis. Participants were 66 (±11) years old on average, 83% White, and 28% completed college, with a 12-month prevalence of MDD of 8%. In fully adjusted models, an interquartile range higher NDVI within 250m was associated with a 12% lower prevalence of MDD (PR:0.88, 95% CI:0.81-0.96). This association was stronger in cold (PR:0.82, 95% CI:0.73-0.92) climates (p-interaction: 0.091), and urban (PR:0.84, 95% CI:0.76-0.93) areas (p-interaction: 0.222). We found similar results for 1km NDVI.

CONCLUSIONS: More residential greenness was associated with less MDD, suggesting greening interventions could improve mental health. Since we found evidence of effect modification by climate and urbanicity, those planning interventions should consider vegetation types and prioritize areas where they may be particularly beneficial. Future studies could better identify vegetation types and communities most in need of greening interventions.

KEYWORDS: Mental health, greenspace, built environment

O-OP-207 Early Life Exposure to Greenspace and Autism Spectrum Disorder and the Mediating Effects of Air Pollution in Ontario, Canada

Eric Lavigne[1], Hwashin Shin[1], Malia Murphy[2], Kasim Abdulaziz[3], Shi-Wu Wen[4]
[1]Health Canada, Ottawa, Canada, [2]OMNI Research Group, Clinical Epidemiology Program, Ottawa Hospital Research Institute, Ottawa, Canada, [3]BORN Ontario, Children's Hospital of Eastern Ontario, Ottawa, Canada, [4]Department of Obstetrics and Gynecology, University of Ottawa, Ottawa, Canada

BACKGROUND AND AIM: Early life exposure to greenspace is associated with health benefits on childhood development, but the pathways of this relationship are not completely understood. This study aimed to evaluate early life exposure to different greenspace metrics on the development on autism spectrum disorder (ASD) and whether these associations are mediated by reductions in ambient air pollution.

METHODS: This case-control study included 1,801 ASD cases and 9002 controls less than 5 years of age identified from 2012 to 2017 using health administrative databases in the province of Ontario, Canada. Greenspace metrics were estimated using the Normalized Difference Vegetation Index (NDVI), Green View Index (GVI) and percent tree canopy coverage using values within 250 m of participants' residential postal codes at birth. Conditional logistic regression was used to investigate associations between greenspace exposure and ASD while adjusting for maternal age, parity, maternal comorbidities, substance use (i.e. smoking and alcohol), socioeconomic status and urbanicity. We estimated the mediation effects of nitrogen dioxide (NO2), fine particulate matter (PM2.5), and ozone (O3) using causal mediation analyses.

RESULTS: In the adjusted model, we found that one interquartile range (IQR) increase in percentage tree canopy was associated with a 6% reduction in the odds of ASD (Odds ratio = 0.94; 95% CI: 0.90, 0.98). No associations were found for NDVI and GVI in relation to ASD. We found that 81.8% (77.6 – 85.9), 20.1% (16.6 – 23.6) and 13.6% (11.1 – 16.0) of the association between tree canopy exposure and ASD was mediated through reductions in NO2, PM2.5, and O3, respectively.

CONCLUSIONS: Early life exposure to greenspace might reduce the risk of ASD through reductions in ambient air pollution, in particular traffic pollution from NO2. Our findings may provide support to communities on the potential health benefits of greenspaces.

O-OP-208 Association of Greenspace Exposure at Midlife with Cognitive Decline Later in Life in a Study of US Women

Marcia P Jimenez[1], Maude Wagner[2], Francine Laden[3], Jaime E Hart[4], Francine Grodstein[2], Peter James[5]
[1]Boston University School of Public Health, Boston, USA, [2]Rush Medical College and Rush Alzheimer's Disease Center, Chicago, USA, [3]Harvard T.H. Chan School of Public Health and Brigham and Women's Hospital, Boston, USA, [4]Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [5]Harvard Medical School and Harvard Pilgrim Health Care Institute; Harvard TH Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Greenspace may slow cognitive decline by increasing opportunities for physical activity and social connection or reducing stress or air pollution. However, studies on the association between greenspace and cognitive decline are sparse. We investigated the prospective association between greenspace at midlife and cognitive decline later in life.

METHODS: Using data from the US-based Nurses' Health Study (mean age=61y), we assessed residential greenspace in a 270m buffer as the cumulative average from 1986 to 1994 using Landsat Normalized Difference Vegetation Index data. We examined 16,352 women who were enrolled in a substudy starting in 1995-2001 (74y) through 2008. Participants underwent up to four repeated measures of five cognitive tests. A global composite score was calculated as the average of all z-scores for each task to evaluate overall cognitive functioning. We evaluated the association between greenspace and subsequent cognitive decline using linear mixed models adjusted for age, education, neighborhood socioeconomic status, and depression.

RESULTS: In fully adjusted models, those living in the highest quintile of greenspace had an annual slope of decline that was slower by 0.01 units of the global composite score (95%CI 0.00001, 0.012) compared to those in the lowest quintile. To help interpret this estimate, we find that one year of age is related to a -0.01 unit mean annual difference for global cognition; thus, more greenspace appeared equivalent to slowing cognitive aging by one year. We found similar associations for the Telephone Interview for Cognitive Status (TICS); participants living in the highest greenspace quintile had an annual rate of decline that was slower by 0.04 units in the TICS score (95%CI 0.01, 0.07) compared to those in the lowest quintile.

CONCLUSIONS: Higher greenspace exposure in early adulthood is associated with a slower rate of cognitive decline later in life in this cohort of US women.

O-OP-209 Residential proximity to greenspace and human birth defects

Kari Weber[1], Wei Yang[2], Suzan Carmichael[2,3], Thomas Luben[4], Tania Desrosiers[5], Cory Keeler[5], Tabassum Insaf[6], Mimi Le[7], Shannon Pruitt Evans[8,9], Paul Romitti[10], Mahsa Yazdy[11], Wendy Nembhard[1], Gary Shaw[2], National Birth Defects Prevention Study

[1]Department of Epidemiology and Arkansas Center for Birth Defects Research and Prevention, Fay W. Boozman College of Public Health, University of Arkansas for Medical Sciences, Little Rock, USA, [2]Department of Pediatrics, Stanford University School of Medicine, Stanford, USA, [3]Department of Obstetrics and Gynecology, Stanford University School of Medicine, Stanford, USA, [4]Center for Public Health and Environmental Assessment, Office of Research and Development, U.S. Environmental Protection Agency, Research Triangle Park, USA, [5]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA, [6]Bureau of Environmental and Occupational Epidemiology, New York State Department of Health and Department of Epidemiology and Biostatistics, University at Albany, Albany, USA, [7]Birth Defects Epidemiology and Surveillance Branch, Texas Department of State Health Services, Austin, USA, [8]Eagle Global Scientific LLC, San Antonio, USA, [9]Division of Birth Defects and Infant Disorders, National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, USA, [10]Department of Epidemiology, College of Public Health, The University of Iowa, Iowa City, USA, [11]Center for Birth Defects Research and Prevention, Massachusetts Department of Public Health, Boston, USA

BACKGROUND AND AIM: Residential proximity to greenspace is associated with various health outcomes. We estimated associations between maternal residential proximity to greenspace and selected structural birth defects, including effect modification by neighborhood-level factors.

METHODS: Data were from the National Birth Defects Prevention Study (1997-2011) and included 19,065 infants with at least one eligible birth defect (cases) and 8,925 without birth defects (controls) from eight Centers throughout the United States. Participants provided their addresses throughout pregnancy, which were systematically geocoded and linked to greenspace, US Census and Department of Agriculture data. Greenspace was estimated using normalized difference vegetation index (NDVI); average maximum NDVI was calculated within 100m and 500m concentric buffers surrounding each geocoded address at conception to estimate residential NDVI. We used logistic regression to estimate odds ratios (ORs) and 95% confidence intervals comparing those in the highest and lowest quartiles of residential NDVI, and subsequently stratifying by rural/urban and neighborhood median income.

RESULTS: After multivariable adjustment, for the 500m buffer, inverse associations were observed for tetralogy of Fallot, secundum atrial septal defects, anencephaly, anotia/microtia, cleft lip ± cleft palate, transverse limb deficiency, omphalocele, and gastroschisis (aORs: 0.54-0.86). Significant heterogeneity was observed after stratification by rural/urban for hypoplastic left heart, coarctation of the aorta, and cleft palate with inverse associations only among those in rural areas. Stratification by neighborhood median income showed significant heterogeneity for secundum atrial septal defects, anencephaly, anotia/microtia, and anorectal atresia with inverse associations only among those in a high-income neighborhood (aORs: 0.45-0.81). Results were similar for 100m buffer analyses and similar patterns were observed for other defects, though results were less precise.

CONCLUSIONS: Our results suggest that perinatal residential proximity to more greenspace may contribute to a reduced risk of certain birth defects, especially among those living in rural or high-income neighborhoods.

O-OP-210 Air pollution, greenspace and active travel infrastructure impacts on stress while walking, cycling, or in motorized transport

Miss Xiuleng Yang[1], Emma McCoy[1], Guillem Vich[2], Esther Anaya-Boig[1], Ione Avila-Palencia[3], Christian Brand[4], Gloria Carrasco-Turigas[2], Evi Dons[5], Regine Gerike[6], Thomas Göetschi[7], Mark Nieuwenhuijsen[2], Juan Pablo Orjuela[4], Luc Int Panis[8], Arnout Standaert[8], Audrey de Nazelle[1]

[1]Imperial College London, London, UK, [2]Barcelona Institute for Global Health, Barcelona, Spain, [3]Queen's University Belfast, Belfast, UK, [4]University of Oxford, Oxford, UK, [5]Hasselt University, Belgium, [6]Dresden University of Technology, Dresden, Germany, [7]University of Oregon, Eugene, USA, [8]Flemish Institute for Technological Research, Mol, Belgium

BACKGROUND AND AIM: Recent studies have shown that active travel is generally associated with lower levels of both perceived and measured stress. Specific microenvironmental conditions encountered during daily journeys, however, may lead to varying degrees of stress experienced at that moment. Our aim is to evaluate how travel mode-specific stress, as measured by Galvanic Skin Response (GSR), varies given different levels of Black Carbon (BC) and greenspace exposure, and by road type.

METHODS: BC and GSR were collected alongside confounders and travel information from 122 participants across 3 European cities for 3 weeks as part of the Physical Activity through Sustainable Transport Approaches (PASTA) study. Greenspace and road type were identified from the geo-locations recorded by a GPS device also worn by participants. A Bayesian Doubly Robust (BDR) estimation method via bootstrapping (which allows us to incorporate randomness originating from the random nature of the unobserved observations of GSR and to simulate the posterior distribution of GSR given the measured covariates) was employed to estimate the effect of BC, green space and road type on cycling-/walking-/motoring-specific GSR, while accounting for confounders such as physical activity, gender, and age.

RESULTS: BC significantly increases GSR when people are cycling or walking, but has no statistically significant effect on people in motorized transport. In reverse, greenspace and traveling on roads with active travel infrastructures (i.e. cycleways and/or pedestrian paths) both lead to lower GSR while walking and cycling, with again no effect on people in motorised transport.

CONCLUSIONS: Decreasing air pollution, improving active travel infrastructure and increasing greenspace along travel routes can reduce stress experienced during active travel. Reducing traffic and improving active travel microenvironments may thus further enhance benefits of walking and cycling in reducing stress in urban populations.

KEYWORDS: Built environment, urban planning, stress, air pollution, active travel, causal inference.

ORAL PRESENTATIONS SESSION 39: Reproductive outcomes and exposure to air pollution

O-OP-211 Ambient Black Carbon Particles Travel From Mother Into the Fetal Circulation and Organs During Gestation

Eva Bongaerts[1], Laetitia L Lecante[2], Hannelore Bové[1], Maarten BJ Roeffaers[3], Marcel Ameloot[4], Paul A Fowler[2], Tim S Nawrot[1,5]

[1]Centre for Environmental Sciences, Hasselt University, Diepenbeek, Belgium, [2]Intstitute of Medical Sciences, University of Aberdeen, Aberdeen, UK, [3]Department of Microbial and Molecular Systems, KU Leuven, Leuven, Belgium, [4]Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium, [5]Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium

BACKGROUND AND AIM: Prenatal exposure to particulate air pollution has been linked to multiple adverse birth outcomes causing burden of disease later in life. To date, evidence is lacking whether ambient particulates can both reach and cross the human placenta to exert direct effects on fetal organ systems during gestation.

METHODS: We used white light generation under femtosecond pulsed illumination to detect black carbon particles in samples collected at the maternal-fetal interface. Maternal-perinatal and fetal samples were collected within the framework of two independent studies, including the mother-newborn ENVIRONAGE (ENVIRonmental influence ON AGEing in early life) Belgian birth cohort and the SAFeR (Scottish Advanced Fetal Research) Scottish cohort of electively terminated normally progressing pregnancies. Appropriate validation experiments were performed to confirm the carbonaceous nature of the identified particles.

RESULTS: Here, we provide evidence of (i) the presence of black carbon particles in cord blood, confirming their ability to cross the placenta and enter the fetal circulation, (ii) a strong correlation ($r \geq 0.50$; $p<0.0001$) between the maternal-perinatal particle load (in maternal blood (n=60), term placenta (n=60), and cord blood (n=60)) and residential ambient black carbon exposure during pregnancy, and (iii) the presence of black carbon particles in first and second trimester tissues (fetal liver (n=36), lung (n=36), and brain (n=14)) of electively terminated normally progressing pregnancies from an independent study.

CONCLUSIONS: This study provides, to the best of our knowledge, the first conclusive evidence that maternally inhaled carbonaceous air pollution particles can cross the placenta and then translocate into human fetal organs during gestation. Further research is now needed to assess their direct effects on fetal organ development and unravel the complexity of particulate air pollution-related health effects in early life.

O-OP-212 Traffic-Related Air Pollution and DNA Methylation of the Follicular Fluid

Audrey Gaskins[1], Robert Hood[1], Jennifer Ford[2], Russ Hauser[2], Alicia Smith[3], Todd Everson[1]
[1]Emory University Rollins School of Public Health, Atlanta, USA, [2]Harvard T.H. Chan School of Public Health, Boston, USA, [3]Emory University School of Medicine, Atlanta, USA

BACKGROUND AND AIM: Higher exposure to traffic-related air pollution (TRAP) is related to lower fertility, with specific adverse effects on the ovary. Epigenetics, specifically DNA methylation (DNAm), may underlie this association but given its tissue specificity, exploring potential mechanisms in toxicological-relevant target tissues is essential. Our objective was to explore the relation between TRAP exposure and follicular fluid (FF) DNAm.

METHODS: Our study included 62 women undergoing in vitro fertilization at a fertility center in Boston, Massachusetts (2005-2015). TRAP exposure was defined using a spatiotemporal model to estimate residence-based daily nitrogen dioxide (NO2) concentrations in the 3 months prior. FF was collected during oocyte retrieval and DNAm levels were profiled using the Infinium MethylationEPIC BeadChip. We estimated epigenetic age via an existing granulosa cell clock and other common epigenetic clocks. We used linear regression to test whether accelerated epigenetic age, or differential DNAm across the genome, was associated with NO2 exposure while adjusting for surrogate variables and other confounders.

RESULTS: Epigenetic age as measured using the granulosa cell clock was moderately correlated with reported age ($r=0.48, p<0.001$). Other epigenetic age estimators performed poorly in the FF. There was no association between NO2 exposure and accelerated epigenetic aging ($\beta=-0.05$ 95%CI -1.20,1.10). NO2 exposure was associated with 8 differentially methylated regions and 22 differentially methylated positions, after adjusting the significance threshold for 704,169 tests. The genes annotated were enriched for GATA1 transcription factor binding and for DNA-methyltransferase activity (q-val<0.05). Some of the differentially methylated genes, including KCNQ1, VRK1, GPER, MLH1, and PLET1, have been linked to reproductive and fertility outcomes.

CONCLUSIONS: Our study suggests that differences in FF DNAm could be a plausible mechanism potentially linking TRAP exposure to ovarian dysfunction. Future work to improve assessment of epigenetic age in reproductive tissues, such as FF, is warranted.

O-OP-213 Prenatal depression increases susceptibility to periconceptional ambient air pollution exposure in relation to risk of gestational hypertension

Zhongzheng Niu[1], Rima Habre[1], Tingyu Yang[1], Brendan H. Grubbs[2], Claudia Toledo-Corral[1], Genevieve F. Dunton[1], Deborah Lerner[3], Laila Al-Marayati[2], Fred Lurmann[4], Nathan Pavlovic[4], Theresa M. Bastain[1], Carrie V. Breton[1], Shohreh F. Farzan[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [2]Department of Obstetrics and Gynecology, University of Southern California, Los Angeles, USA, [3]Eisner Health, Eisner Health, USA, [4]Sonoma Technology, Inc, Petaluma, USA

BACKGROUND AND AIM: Exposure to air pollutants has been associated with elevated blood pressure during pregnancy. However, the influences of preconception and prenatal exposures to ambient air pollution on gestational hypertension (GH) remain unclear. Even less is known about the potential effect modification by individual risk factors, including depression.

METHODS: In 559 pregnant participants enrolled the Maternal and Developmental Risks from Environmental and Social Stressors (MADRES) study, we estimated daily levels of ambient particulate matter (PM_{10}; $PM_{2.5}$), nitrogen dioxide (NO_2), and ozone (O_3) using spatial interpolation. Gestational hypertension without proteinuria was ascertained from medical records by physician diagnosis or defined as two abnormally high blood pressure measurements after 20 gestational weeks (GW). We used distributed lag models with Poisson regression to identify sensitive exposure windows by estimating weekly associations of exposures from pre-conception week 12 to GW 24 with GH risk, adjusting for maternal and meteorological factors. Analyses were additionally stratified by the Center for Epidemiologic Studies Depression Scale score (CES-D, <16 vs. ≥16), median pre-pregnancy body mass index (BMI, <27.5 vs. ≥27.5 kg/m²), median age (<28 vs. ≥28 years), and newborn sex to explore differential susceptibilities.

RESULTS: Forty-two (7.5%) participants were diagnosed with GH. An IQR increase in $PM_{2.5}$ exposure in the window from GW6 to GW17 and PM_{10} from GW7 to GW14 was associated with 10.1% (95% CI: 9.5-10.8%) and 10.9% (9.7-12.2%) increased risk of GH, respectively. Among 163 participants with probable depression (CES-D≥16), per IQR increase in $PM_{2.5}$ exposure from GW6 to GW24 was associated with 26.8% (25.7-27.9%) increased GH risk.

CONCLUSIONS: Early-to-mid pregnancy exposures to ambient air pollution were associated with increased risk of GH. A wider sensitive window of $PM_{2.5}$ exposure and stronger effects were seen in participants with probable depression compared to those without.

KEYWORDS: air pollution, gestational hypertension, sensitive window, susceptibility, prenatal depression, preconception

O-OP-214 Upstream oil and gas production and risk of spontaneous preterm birth in California: A matched sibling study

David Gonzalez[1,2], Wei Yang[2], Michael Baiocchi[2], Marshall Burke[2], Joan Casey[3], Mark Cullen[4], Rachel Morello-Frosch[1], Gary Shaw[2]

[1]University of California, Berkeley, Berkeley, USA, [2]Stanford University, Stanford, USA, [3]Columbia University, New York, USA, [4]Independent Consultant,

BACKGROUND AND AIM: Recent studies have reported associations between exposure to upstream oil and gas production and adverse birth outcomes, including preterm birth. Uncertainties remain about the potential for bias from unobserved confounders. Our aim was to determine whether exposure to oil and gas wells in the preproduction and production stages increased risk of preterm birth by leveraging variation in exposure among parents who gave birth two or more times during the study period.

METHODS: We examined the association between exposure to oil and gas wells and preterm birth risk using birth outcomes data linked to parental covariates from the California Office of Statewide Health Planning and Development and oil and gas production data from the California Geologic Energy Management Division. We undertook a matched sibling study with approximately 1.5 million births delivered to 660,000 multiparous gestational parents in California between 1998 and 2011, each geocoded to the parental residence at time of delivery. Our primary analyses focused on parents who moved 10 km or less between births. for each birth and trimester of pregnancy, we assessed exposure to the count of wells in preproduction and total sum of oil and gas production volume within 1 km. We estimated exposure-response curves using adjusted linear regression models with a fixed effect for the parent, which controls for potential unobserved, time-invariant parental confounders.

RESULTS: In within-parent (i.e., longitudinal matched-sibling) models, high exposure to preproduction wells was associated with 5% higher preterm birth risk and exposure to increased production volume was associated with 2% higher risk, both for delivery at 28-31 weeks. The results were not consistent across model specifications.

CONCLUSIONS: We did not observe consistent evidence of an association between upstream oil and gas production activities and preterm birth risk among parents with varying exposure between pregnancies, except under certain modeling specifications.

O-OP-215 Ambient air pollution concentrations and incidence of spontaneous abortion

Amelia Wesselink[1], Kipruto Kirwa[2], Perry Hystad[3], Joel Kaufman[2], Adam Szpiro[2], Mary Willis[1,3], David Savitz[4], Jonathan Levy[1], Kenneth Rothman[1], Ellen Mikkelsen[5], Elizabeth Hatch[1], Lauren Wise[1]

[1]Boston University School of Public Health, Boston, USA, [2]University of Washington School of Public Health, Seattle, USA, [3]Oregon State University, Corvalis, USA, [4]Brown University School of Public Health, Providence, USA, [5]Aarhus University Hospital, Aarhus, Denmark

BACKGROUND AND AIM: Previous epidemiologic studies suggest that air pollution exposure may be a risk factor for spontaneous abortion (SAB), i.e., pregnancy loss before 20 weeks' gestation. However, most studies identified SABs from administrative records, which likely under-ascertain losses early in pregnancy. In a prospective preconception cohort study of couples trying to conceive, we examined the association between residential ambient air pollution concentrations and SAB incidence.

METHODS: Eligible female participants enrolled during 2013-2019. They were aged 21-45 years, residents of the United States or Canada, and trying to conceive without fertility treatments. Participants completed online questionnaires at enrollment, every 8 weeks during preconception, and about 8 weeks and 32 weeks of pregnancy. We restricted our analysis to the 5,513 participants who conceived within 12 cycles of follow-up. We estimated two-week average residential ambient concentrations of particulate matter <2.5 μm (PM2.5), nitrogen dioxide (NO2), and ozone (O3) using country-specific spatiotemporal models. We used Cox proportional hazards regression with gestational weeks as the time scale to estimate incidence rate ratios (IRRs) and 95% confidence intervals (CI) for an interquartile range (IQR) increase in exposure, adjusting for individual- and neighborhood-level confounders.

RESULTS: 19% of participants reported a SAB during follow-up; of these, 72% were early losses (<8 weeks of gestation, median=6 weeks). Air pollution concentrations were not appreciably associated with SAB incidence. Among US participants, IRRs for a one-IQR increase in concentrations during the two weeks before conception were 1.08 (95% CI: 0.93-1.24) for PM2.5 (IQR=3.0 μg/m3), 1.02 (95% CI: 0.90-1.15) for NO2 (IQR=5.4 μg/m3), and 1.00 (95% CI: 0.86-1.17) for O3 (IQR=10.7 μg/m3). Associations were similar among Canadian participants, and among those reporting early losses.

CONCLUSIONS: Air pollution concentrations showed little association with SAB incidence in this cohort of pregnancy planners.

KEYWORDS: air pollution, preconception cohort, pregnancy loss, spontaneous abortion

O-OP-216 Prenatal cadmium exposure in relation to placental and birth size: effect modification by fetal sex and genetic variation in the placental barrier transporter ABCG2

Emily Barrett[1,2,3], Zorimar Rivera-Núñez[1,2], Kylie Getz[1], Pamela Ohman-Strickland[1,2], Ranran Zhang[1,2], Danielle Kozlosky[2,4], Cathleen Doherty[2], Brian Buckley[2], Jessica Brunner[3], Carolyn Salafia[5], Richard Miller[3], Thomas O'Connor[3], Lauren Aleksunes[2,4]

[1]Rutgers School of Public Health, Piscataway, USA, [2]Environmental and Occupational Health Sciences Institute, Rutgers University, Piscataway, USA, [3]University of Rochester School of Medicine and Dentistry, Rochester, USA, [4]Ernest Mario School of Pharmacy, Rutgers University, Piscataway, USA, [5]Placental Analytics, Larchmont, USA

BACKGROUND AND AIM: Cadmium accumulates in the placenta and may adversely impact fetal growth, however results have varied across epidemiological studies. Largely ignored in these studies are polymorphisms in genes encoding placental barrier transporters such as ABCG2, which reduces placental accumulation and fetal chemical exposures. We examined maternal cadmium concentrations in relation to placental and infant size at birth, evaluating effect modification by fetal sex and ABCG2 genotype.

METHODS: We measured urinary cadmium in each trimester and in term placenta from mothers participating in the UPSIDE-ECHO cohort (NY,USA; n=254). Birthweight, birth length, and placental weight were obtained from medical records and direct measurement; fetoplacental weight ratio(FPR) was calculated and ABCG2 C421A/Q141K(rs2231142) genotype was assessed. We fit multivariable linear regression models examining log-transformed urinary and placental cadmium concentrations in relation to birthweight, birth length, placental weight, and FPR, adjusting for covariates.

RESULTS: Cadmium was measurable in 85-91% of urine samples (by trimester; medians 0.18-0.30 μg/L) and 99% of placentas (median 4.4 μg/g). 17% of placentas had a reduced-function ABCG2 polymorphism (AA or AC genotype). A ln-unit increase in placental cadmium was associated with lower placental weight (β=-19.15g, 95%CI: -36.36,-1.93) and higher FPR (β=0.25, 95%CI: -0.02,0.51); associations with birthweight were inverse, but non-significant. Notably, cadmium was associated with reduced placental weight (β=-48.08g, 95%CI: -96.05,-0.12) and higher FPR (β=0.80, 95%CI: 0.15,1.46) in AA/AC participants, with null associations in wild-type CC participants. Associations with reduced placental weight were stronger in females (β=-24.93g, 95%CI: -49.38,-0.48) compared to males (β=-13.94g, 95%CI: -37.94,11.05). Few associations were observed between specific gravity-adjusted urinary cadmium and newborn/placental size.

CONCLUSIONS: Cadmium was associated with reduced placental growth and efficiency in female infants as well as participants with the reduced-function ABCG2 transporter variant, confirming prior in vitro studies. Individuals with ABCG2 polymorphisms may be particularly vulnerable to cadmium's developmental toxicity.

ORAL PRESENTATIONS SESSION 40: Child health and exposure to air pollution

O-OP-217 Accumulation of Black Carbon Particles in Placenta, Cord Blood and Childhood Urine on the Intestinal Microbiome Diversity and Composition in Four-to-Six-Year-Old Children

Thessa Van Pee[1], Janneke Hogervorst[1], Yinthe Dockx[1], Katrien Witters[1], Sofie Thijs[1], Congrong Wang[1], Eva Bongaerts[1], Jonathan, D. Van Damme[2], Jaco Vangronsveld[1,3], Marcel Ameloot[4], Jeroen Raes[5,6], Tim Nawrot[1,7]
[1]Centre for Environmental Sciences, Hasselt University, Diepenbeek, Belgium, [2]Department of Biological Sciences, Thompson Rivers University, Kamloops, Canada, [3]Department of Plant Physiology and Biophysics, Faculty of Biology and Biotechnology, Maria Curie-Skłodowska University, Lublin, Poland, [4]Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium, [5]Department of Microbiology and Immunology, Rega Instituut, KU Leuven–University of Leuven, Leuven, Belgium, [6]Center for Microbiology, VIB, Leuven, Belgium, [7]Department of Public Health and Primary Care, Leuven University, Leuven, Belgium

The gut microbiome plays an essential role in human health. Despite the link between air pollution exposure and various diseases, its association with the gut microbiome during susceptible life periods remains scarce. In this study, we examined the association between black carbon (BC) particles quantified in pre- and post-natal biological matrices and bacterial richness and diversity measures, and bacterial families. 85 stool samples were collected from four-to-six-year-old children enrolled in the ENVIRONAGE cohort. We performed 16S rRNA gene sequencing to calculate bacterial richness and diversity indices (Chao1 richness, Shannon and Simpson diversity) and the relative abundance of bacterial families. BC particles were quantified via white light generation under femtosecond pulsed laser illumination in placental tissue and cord blood (pre-natal exposure biomarkers), and urine (post-natal exposure biomarker). We used robust multivariable-adjusted linear models to examine the associations between quantified BC loads and richness and diversity measures. Additionally, we performed differential relative abundance analyses of bacterial families while correcting for sampling fraction bias. Results are expressed as percentage change per BC doubling. Two diversity indices were negatively associated with placental BC (Shannon: -4.38%, p=0.04; Simpson: -0.90%, p=0.04), cord blood BC (Shannon: -3.28%, p=0.05; Simpson: -0.91, p=0.02), and urinary BC (Shannon: -3.39%, p=0.0007; Simpson: -0.89%, p<0.0001). The explained variance of BC on the above indices varied from 5.90 to 16.81%. Multi-exposure models showed stronger relationships with urinary BC loads for both indices. Placental BC was negatively associated with the bacterial families Defluviitaleaceae and Marinifilaceae, and urinary BC with Christensenellaceae and Coriobacteriaceae. These results show that BC particles quantified in pre- and post-natal biological matrices may influence the composition and diversity of the childhood intestinal microbiome, addressing the influential role of air pollution exposure during pregnancy and early life on human health.

O-OP-218 Coal ash and depression in children aged 6-14 years old

Kristina M Zierold[1], Clara G Sears[2], John V Myers[3], Guy N Brock[3], Charlie H Zhang[4], Lonnie Sears[5]
[1]University of Alabama at Birmingham - Dept of Environmental Health Sciences, Birmingham, USA, [2]University of Louisville - Dept of Environmental Medicine, Louisville, USA, [3]The Ohio State University - Center for Biostatistics, Columbus, USA, [4]University of Louisville - Dept of Geographic and Environmental Sciences, Louisville, USA, [5]University of Louisville - Dept of Pediatrics, Louisville, USA

BACKGROUND AND AIM: When coal is burned for energy, coal ash, a hazardous waste product, is generated. Throughout the world, over 1 billion tons of coal ash is produced yearly. In the United States, over 78 million tons of coal ash was produced in 2019. Fly ash, the main component of coal ash contains neurotoxic metal(loid)s that may affect children's neurodevelopment and mental health. The objective of this study was to investigate the association between fly ash and depressive problems in children aged 6-14 years old.

METHODS: Children and their parents/guardians were recruited from 2015-2020. Tobit regression and Poisson regression were used to assess the association between coal fly ash and depressive problems. To determine fly ash presence, Scanning Electron Microscopy was conducted on polycarbonate filters containing PM10 from the homes of the study participants. Depressive problems in children were measured using the Depressive Problems DSM and withdrawn/depressed syndromic problem scales of the Child Behavior Checklist.

RESULTS: In covariate-adjusted Tobit regression models, children with fly ash on the filter had higher scores on the DSM Depressive Problems (3.14 points; 95% CI=0.40, 5.89) and the syndromic withdrawn depression (2.63 points; 95% CI = -0.20, 5.46) scales compared with children who did not have fly ash on the filter. Poisson regression supported these findings.

CONCLUSIONS: Coal ash is one of the largest waste streams in the U.S., but it is not classified as a hazardous waste by the Environmental Protection Agency. To our knowledge, no studies have assessed the impact of coal ash on children's mental health. This study highlights the need for further research into the effects of coal ash exposure on children's mental health, and improved regulations on release and storage of coal ash.

KEYWORDS: coal ash; fly ash; children's mental health; depression; children's environmental health

O-OP-219 Association of improved air quality with lung development from childhood until young adulthood: The BAMSE study

Zhebin Yu[1], Simon Kebede Merid[1,2], Tom Bellander[1,3], Anna Bergström[1,3], Antonios Georgelis[1,3], Jenny Hallberg[1,2,4], Inger Kull[2,4], Petter Ljungman[1,5], Susanna Klevebro[2,4], Gang Wang[1,2], Göran Pershagen[1,3], Olena Gruzieva[1,3], Erik Melén[2,4]

[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Department of Clinical Sciences and Education, Södersjukhuset,Karolinska Institutet, Stockholm, Sweden, [3]Centre for Occupational and Environmental Medicine, Region Stockholm, Stockholm, Sweden, [4]Sachs Children's Hospital, Sweden, [5]Department of Cardiology, Danderyd Hospital, Sweden

BACKGROUND AND AIM: The beneficial effect of improving air quality on lung function development in children remains understudied. We assessed associations of changes in ambient air pollution levels with lung function growth from childhood until young adulthood in a Swedish cohort study.

METHODS: In the prospective birth cohort BAMSE (Children, Allergy, Milieu, Stockholm Epidemiology), spirometry was conducted at the 8-year (2002-2004), 16-year (2011-2013) and 24-year follow-ups (2016-2019). Participants with one spirometry measurement at 8 years and at least one another measurement in subsequent follow-ups were included (1509 participants with 3837 spirometry measurements). Ambient air pollution levels (particulate matter≤2.5 µm [PM2.5], particulate matter≤10 µm [PM10], black carbon [BC] and nitrogen oxides [NOx]) at residential addresses during the lifetime were estimated using dispersion modelling. Linear mixed-effect models were used to estimate the association between air pollution level change and lung function development.

RESULTS: Overall, individual air pollution levels decreased progressively during the study period. for example, median (interquartile range, IQR) of PM2.5 decreased from 8.2 (0.92) µg/m3 during 2002-2004 to 5.22 (0.67) µg/m3 during 2016-2019. Reduction of air pollution exposure was associated with higher rate of growth for both FEV1 and FVC. for each IQR decrease in PM2.5, the growth rate increased by 3.7 ml/year (95%CI: 1.3-6.0, P<0.001) for FEV1 and 7.9 ml/year (95%CI:4.3-11.4, P<0.001) for FVC. Significant associations with lung function growth were also observed for reduction of PM10, BC and NOx. These associations persisted after adjustment for potential confounders. The beneficial effect from improved air quality was not statistically modified by asthma, allergic sensitization, early-life air pollution exposure or dietary intake of antioxidants.

CONCLUSIONS: Long-term reduction of air pollution is associated with positive lung function development from childhood to young adulthood.

KEYWORDS: air pollution, lung function, spirometry, improved air quality, cohort

O-OP-220 Air Pollution Exposure during Pregnancy and Childhood, Cognitive Function, and Emotional and Behavioral Problems in Adolescents

Michelle Kusters[1,2], Esmée Essers[1,2], Ryan Muetzel[2], Albert Ambrós[1], Henning Tiemeier[2,3], Mònica Guxens[1,2]
[1]ISGlobal, Barcelona, Spain, [2]Department of Child and Adolescent Psychiatry/Psychology, Erasmus MC, University Medical Centre, Rotterdam, The Netherlands, [3]Department of Social and Behavioral Science, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Exposure to air pollution may impact neurodevelopment during childhood, but current evidence on the association with cognitive function and mental health is inconclusive and primarily focusses on young children. Therefore, we aim to study the association of exposure to air pollution during pregnancy and childhood, with cognitive function and emotional and behavioral problems in adolescents.

METHODS: We used data from 5,170 participants of a birth cohort in Rotterdam, the Netherlands. Concentrations of fourteen air pollutants at participant's home addresses were estimated during pregnancy and childhood, using land use regression models. We included four cognitive domains and an estimated full-scale IQ. Internalizing, externalizing, and attention problems were self- and parent-reported. We used linear regression models to assess the association of each air pollutant, with cognitive function and emotional and behavioral problems, adjusting for socioeconomic status and lifestyle characteristics. Then, we performed multipollutant analyses using the Deletion/Substitution/Addition (DSA) algorithm

RESULTS: Air pollution exposure was not associated with full-scale IQ, working memory, or processing speed. Higher exposure to few air pollutants was associated with higher fluid reasoning and verbal IQ scores (e.g. 0.22 points of fluid reasoning (95%CI 0.00; 0.44) per 1 µg/m3 increase in organic carbon during pregnancy). Higher exposure to some air pollutants was also associated with less internalizing, externalizing, and attention problems (e.g. -0.27 internalizing problems (95% CI -0.52; -0.02) per each 5 ng/m3 increase in copper during pregnancy).

CONCLUSIONS: Higher exposure to air pollution during pregnancy and childhood was not associated with lower cognitive function or more emotional and behavioral problems in adolescents. Based on previous literature and biological plausibility, the observed protective associations are probably explained by negative residual confounding, selection bias, or chance and do not represent a causal relationship.

KEYWORDS: air pollution; cognitive function; mental health; adolescents; traffic

O-OP-221 Agricultural burning in Imperial Valley, California and respiratory symptoms in children: a cross-sectional, repeated measures analysis

Elizabeth Kamai[1], Brandyn C. Ruiz[1], Yoshira Ornelas Van Horne[1], Jill E. Johnston[1], Shohreh F. Farzan[1]
[1]*Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA*

BACKGROUND AND AIM: The open burning of agricultural fields after harvesting is an under-recognized and understudied source of air pollution in rural communities. Smoke from agricultural burning contains air toxics that may adversely impact respiratory health. Imperial County in southeastern California is a highly productive agricultural valley that heavily employs agricultural burning. We investigated associations between individual-level exposure to agricultural burning and parent-reported respiratory symptoms in children.

METHODS: We leveraged the Children's Assessing Imperial Valley Respiratory Health and the Environment cohort of 744 elementary school students in five predominantly Hispanic low-income communities in Imperial County. Parents reported children's respiratory health symptoms and family demographic characteristics in questionnaires collected at enrollment and in annual follow-up assessments from 2017-2021. Permitted agricultural burns in Imperial County from 2016-2021 were spatially linked to children's geocoded residential addresses. We used generalized estimating equations to evaluate associations between repeated measures of respiratory symptoms and exposure to agricultural burning within 5 km in the 12 months prior to each assessment.

RESULTS: Two-thirds (495, 68%) of children lived within 5 km of at least one agricultural burn during the study period. Children exposed to agricultural burns were generally similar to unexposed children. After adjustment for language of parent questionnaire, health insurance, child sex, grade, school, and asthma diagnosis at baseline, children living within 5 km of agricultural burning had greater odds of reported bronchitis (OR 4.30, 95% CI 1.74-10.7), bronchitic symptoms (OR 1.98, 95% CI 1.16-3.40), and asthma medication use (OR 1.90, 95% CI 0.96-3.76), compared to unexposed children.

CONCLUSIONS: To our knowledge, this is the first U.S. study of agricultural burning and children's respiratory health. This work suggests that reducing agricultural burning could improve children's respiratory health. Further research quantifying how air toxics may mediate the observed associations is forthcoming.

O-OP-222 Exposure to Indoor Particulate Matter is Associated with Gastrointestinal and Respiratory Microbial Communities

Mx. Maximilian Bailey[1], Kevin Clark[1], Talat Islam[2], Tanya Alderete[1]
[1]Department of Integrative Physiology, University of Colorado Boulder, Boulder, USA, [2]Department of Population and Public Health Sciences, Keck School of Medicine, Los Angeles, USA

BACKGROUND AND AIM: Exposure to outdoor particulate matter (PM2.5) has been associated with the respiratory and gut microbiome. Despite this, it remains uncertain how PM2.5 exposure may impact these developing microbial communities in early life. This study aimed to characterize the associations between exposure to household PM2.5 and the infant gut and respiratory microbiota.

METHODS: This study included 80 infants (~6-months of age) from a pregnancy cohort in rural Bangladesh. PM2.5 exposure was assessed using in-home optical sensors and stool and nasal microbiota were characterized using 16S rRNA sequencing. Associations between PM2.5 and microbial taxa were examined using zero-inflated negative binomial regression and incidence rate ratios (IRR) and Benjamini-Hochberg Procedure adjusted p-values (FDRBH) are reported. PM-associated microbial profiles were identified using differential abundance analysis by examining the log-ratio of differentially ranked sub-operational taxonomic units (sOTUs). Associations between PM2.5 and diversity measures were examined via multivariable linear regression and Mantel tests. Analyses adjusted for antibiotic exposure and infant weight.

RESULTS: PM2.5 exposure was associated with 8 gut and 25 respiratory bacterial taxa (FDRBH < 0.1). for example, PM2.5 was associated with the gut bacterial class Fusobacteriia (IRR=1.02, FDRBH=0.08) and the genus Pseudoramibacter Eubacterium (IRR=0.92, FDRBH=0.004). Similarly, PM2.5 was associated with the respiratory bacterial family Planococcaceae (IRR=0.96, FDRBH=0.005) and the genus Arthrobacter (IRR=1.02, FDRBH=0.06). PM2.5 exposure was also associated with distinct gut bacterial profiles based on the log-ratio of differentially ranked sOTUs (R2=0.10, P=0.004). Further, PM2.5 was associated with gut microbial beta-diversity (P=0.03).

CONCLUSIONS: PM2.5 exposure was associated with the infant gut and respiratory microbiota. Several of these bacteria have been associated with the immune system. Namely, taxa within the class Fusobacteriia and Planococcaceae have proinflammatory and/or immunoregulatory effects. These results suggest that PM2.5 exposure may alter microbial communities with implications for immune function and inflammation.

O-OP-223 The Effects of Co-Exposure to Extremes Heat and Particulate Air Pollution on Mortality in California

Md Mostafijur Rahman[1], Rob McConnell[1], Hannah Schlaerth[2], Joseph Ko[2], Sam Silva[3], Frederick Lurmann[4], Lawrence Palinkas[1], Jill Johnston[1], Michael Hurlburt[1], Hao Yin[5], George Ban-Weiss[2], Erika Garcia[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [2]Department of Civil and Environmental Engineering, Viterbi School of Engineering, University of Southern California, Los Angeles, USA, [3]Department of Earth Sciences, University of Southern California, Los Angeles, USA, [4]Sonoma Technology, Inc., Petaluma, USA, [5]Department of Economics, University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Extremes of heat and particulate air pollution threaten human health and are becoming more frequent due to climate change. Understanding the health impacts of the co-exposure to extreme heat and air pollution is urgent.

METHODS: Death certificate data for California from January 1, 2014, to December 31, 2019 were used to identify all-cause, cardiovascular, and respiratory mortality. A case-crossover study with time-stratified matching and conditional logistic regression was used to estimate the mortality association with acute co-exposures to extreme heat and PM2.5. Several percentile-based threshold values (i.e., 90th, 95th, 97th, and 99th) were used to define a day as an extreme exposure day. for each case day (date of death) and its control days, daily average PM2.5, maximum and minimum temperature were assigned based on decedent's residence census tract. Age-stratified analyses were also conducted.

RESULTS: This study included 1.5 million all-cause, 0.5 million cardiovascular, and 0.14 million respiratory deaths. Based on a 99th percentile threshold, all-cause mortality risk increased 6.1% (95%confidence interval,CI: 4.1, 8.1) on extreme maximum temperature only days and 5.0% (95%CI: 3.0, 8.0) on extreme PM2.5 only days, compared to non-extreme days. Risk increased 21.0% (95%CI: 6.6, 37.3) on days with exposure to both extreme maximum temperature and PM2.5. Increased risk of cardiovascular and respiratory mortality on extreme co-exposure days were 29.9% (95%CI: 3.3, 63.3) and 38.0% (95%CI: -12.5, 117.7), respectively, and were more than the sum of individual effects of extreme temperature and PM2.5 only. A similar pattern was observed for co-exposure to extreme PM2.5 and minimum temperature; effect estimates were larger among those over age 75 years.

CONCLUSIONS: Short-term exposure to extreme heat and air pollution alone were individually associated with increased risk of mortality, but their co-exposure had larger effects beyond the sum of their individual effects.

KEYWORDS: extreme co-exposure, heat, air pollution, mortality

O-OP-224 Projection of combined vulnerability to air pollution and heat stress

Sourangsu Chowdhury[1], Kristin Aunan[1]
[1]*Cicero Center for International Climate Research, Oslo, Norway*

BACKGROUND AND AIM: Climate change caused by anthropogenic emissions is associated with increase in the frequency and intensity of climate extremes. Exposure to non-optimal temperature is related with 2-5 million deaths per year globally. In addition, air pollution has become a key concern for public health. Particulate matter less than 2.5 µm in diameter (PM2.5) is the largest environmental risk factor globally and is expected to worsen with projected increase in anthropogenic emissions. However, little is studied on vulnerability of combined exposure to these two environmental hazards under a changing climate.

METHODS: We use outputs from three CMIP6 models to project PM2.5 and Wet Bulb Global Temperature (WBGT) till end of the century under SSP126, 370 and 585 scenarios. We assessed the combined vulnerability of the exposed population, represented by vulnerability index(VI), to these two risk factors by factoring in the distribution of projected gross domestic product and education attainment (together termed socioeconomic indicator).

RESULTS: We find currently, 7% of the population (8% of the population above 65years) reside in regions with the highest vulnerability (mostly in Asia), which is projected to increase to 25% (and 32%) in 2050 under the SSP370 scenario. Globally, under all the three scenarios, percentage of population exposed to the most extreme VI was projected to increase till 2050, and decrease thereafter under SSP126, but under SSP585 and SSP370 scenarios, we found a significant increase in the population exposed to the most extreme VI.

CONCLUSIONS: To the best of our knowledge, we present the first results on projections of combined vulnerability from exposure to two of the most hazardous environmental risk factors,by identifying their collocational hotspots across the globe. Our results may be used to assist decision making targeted towards averting exposure and excess deaths from heat stress and air pollution in the future decades.

O-OP-225 Mediation of 8-hour Maximum Concentration of Ozone on Association between Temperature and Daily Mortality and Excess Mortality due to Climate Change in 7 Metropolitan Cities in Korea

Sanghyuk Bae[1], Youn-Hee Lim[2], Jongmin Oh[3], Ho-Jang Kwon[4]
[1]The Catholic University of Korea, Seoul, Republic of Korea, [2]University of Copenhagen, Copenhagen, Denmark, [3]Ewha Womans University, Seoul, Republic of Korea, [4]Dankook University, Cheonan, Republic of Korea

BACKGROUND AND AIM: Climate change is suspected to cause adverse health effects, and increased ozone concentration is one of proposed pathways. We examined the mediation of ozone on the association between temperature and daily mortality and estimated excess mortality due to increased temperature.

METHODS: Daily mean temperature, 8-hr maximum ozone concentration and daily number of non-accidental death from 7 metropolitan cities (Seoul, Busan, Daegu, Incheon, Daejeon, Gwangju and Ulsan) in Korea between Jan. 1, 2006 and Dec. 31, 2019 were used. The mediation of ozone was evaluated with Sobel test and causal mediation analysis. The causal mediation analysis with Poisson regression model was conducted in days with temperature over and under 25℃. Coefficients for temperature's direct effect and indirect effect mediated by ozone was estimated in each city and pooled to produce single exposure-response function. We calculated excess mortality due to direct and indirect effects of daily temperature exceeding average daily temperature of 1960 through 1990.

RESULTS: The daily mean temperature was 1.15±2.94℃ higher compared to average daily temperature of 1960 through 1990. The Sobel test in all 7 cities were significant. The pooled RR (for 1℃-increment) of direct effect in days with temperature over 25℃ was 1.2047 (95% confidence interval: 1.1101, 1.3174) and 1.0762 (1.0403, 1.1132) in days with temperature under 25℃. The RRs of indirect effects were 0.9994 (0.9987, 1.0001) and 1.0004 (1.0000, 1.0007) for over and under 25℃, respectively. The numbers of excess deaths during the study period were 63,430 and 81,906 due to direct effect in days over and under 25℃, respectively, and -223 and 462 due to indirect effect in days over and under 25℃, respectively.

CONCLUSIONS: In the present analysis, we observed mediation of ozone between temperature and daily mortality. There has been significant number of excess deaths due to climate change.

O-OP-226 Heat, Fine Particulates, and Diagnosis of Dementia: A Matched Case Control Study in North Carolina from 2003 to 2016

Erik Slawsky[1], Cavin Ward-Caviness[2], Joshua Moyer[2], Anne Weaver[2], Anne Weaver[2]
[1]Oak Ridge Associated Universities at the United States Environmental Protection Agency, Chapel Hill, USA, [2]United States Environmental Protection Agency, Research Triangle Park, USA

BACKGROUND AND AIM: Dementia continues to pose a serious health concern for aging populations around the world and may be affected by fine particulate (PM2.5) air pollution. As our planet warms and climates shift, environmental factors may contribute to chronic health outcomes, including dementia. We aim to determine if any association between prior year average temperature and diagnosis of dementia is discernable using available medical records data.

METHODS: Using a random sample of University of North Carolina (UNC) electronic health records, we identified 318 individuals with any diagnosis of dementia. We utilized a 4:1 matched case-control design to link each case with hospital-based controls by birth year, sex, race, Census 2010 income and education tertiles, and climate zone. Climate data was derived from PRISM Climate Group data. Prior year average air temperature (min=12.26°C max=18.50°C), relative humidity (min=58.18% max=75.74%), and apparent temperature (min=11.86°C max=19.86°C) were calculated based on patient zip code. We also examined associations with prior year PM2.5 (min=5.50 µg/m3 max=15.56 µg/m3) estimated using an ensemble machine learning model and first diagnosis of dementia or first non-dementia diagnosis for controls. We conducted multivariable logistic regression models to estimate odds ratios (OR) and 95% confidence intervals (CI) adjusted for our matching variables and urbanicity.

RESULTS: We observed significant positive associations between diagnosis of dementia and increased PM2.5 (OR 1.18; 95%CI 1.09-1.28) per 1 µg/m3, and for relative humidity (OR 1.06; 95%CI 1.01-1.11) per 1%. Air and apparent temperature showed similar patterns (OR 1.16; 95% CI 0.99-1.35 and OR 1.17; 95%CI 1.02-1.34) per 1°C.

CONCLUSIONS: Our findings indicate that there are associations between both PM2.5 and year prior heat exposures and dementia. These findings suggest that further investigation into the role of heat and dementia is warranted. This abstract does not reflect EPA policy.

KEYWORDS: dementia, heat, climate change, air pollution

O-OP-227 Ambient heat exposure and COPD hospitalisations in England: A nationwide case-crossover study during 2007-2018

Garyfallos Konstantinoudis[1]
[1]*Mrc Centre of Environment and Health/ Imperial College London, London, UK*

BACKGROUND AND AIM: There is emerging evidence suggesting a link between ambient heat exposure and chronic obstructive pulmonary disease (COPD) hospitalisations. Individual and contextual characteristics can affect population vulnerabilities to COPD hospitalisation due to heat exposure. This study quantifies the effect of ambient heat on COPD hospitalisations and examines population vulnerabilities by age, sex, and contextual characteristics.

METHODS: Individual data on COPD hospitalisation at high geographical resolution (postcodes) during 2007-2018 in England was retrieved from the small area health statistics unit. Maximum temperature at 1 km×1km resolution was available from the UK Met Office. We employed a case-cross over study design and fitted Bayesian conditional Poisson regression models. We adjusted for relative humidity and national holidays, and examined effect modification by age, sex, green space, average temperature, deprivation and urbanicity.

RESULTS: After accounting for confounding, we found a 1.47% (95% Credible Interval 1.19% to 1.73%), increase in the hospitalisation risk for every 1oC increase in temperatures above 23.2oC (lags 0-2 days). We reported weak evidence of an effect modification by sex and age. We found a strong spatial determinant of the COPD hospitalisation risk due to heat exposure, that was alleviated when we accounted for contextual characteristics. Assuming a causal effect, 22 214 (95% CrI 18 907 to 24 947) COPD hospitalisations were attributable to heat exposure.

CONCLUSIONS: Our study suggests that resources should be allocated to support the public health systems, for instance through developing or expanding heat-health alerts, to challenge the increasing future heat-related COPD hospitalisation burden.

KEYWORDS: climate change, respiratory admissions, spatial effect modification

O-OP-228 Interactive effects of heat and air pollution on mortality in Europe using small area data – Results of the exhaustion project

Francesca De Donato[1], Massimo Stafoggia[1], Susanne Breitner[2], Masna Rai[3], Siqi Zhang[3], Evangelia Samoli[4], Klea Katsouyanni[4], Sofia Zafeiratou[4], Antonio Gasparrini[5], Pierre Masselot[5], Liliana Vazquez-Fernandez[6], Alfonso Diz-Lois Palomares[6], Shilpa Rao[6], Kristin Aunan[7], Alexandra Schneider[3]

[1]Department of Epidemiology Lazio Regional Health Service, ASLRoma 1, Rome, Italy, [2]Institute for Medical Information Processing, Biometry, and Epidemiology, LMU Munich, Munich, Germany, [3]Institute of Epidemiology, Helmholtz Zentrum München (HMGU), Neuherberg, Germany, [4]Department of Hygiene, Epidemiology and Medical Statistics, Medical School, University of Athens, Athens, Greece, [5]Department of Public Health, Environments and Society, London School of Hygiene & Tropical Medicine, London, UK, [6]Norwegian Institute of Public Health, Oslo, Norway, [7]CICERO - Center for International Climate Research, Oslo, Norway

BACKGROUND AND AIM: Studies on the interactive short-term health effects of heat and air pollution are limited and mostly carried out in cities thus providing limited evidence at national level and on the effects in suburban and rural areas.

METHODS: We used daily data on natural, cardiovascular and respiratory mortality, air temperature, particulate matter (PM2.5, PM10) and ozone (O3) for administrative small areas (municipalities) in five regions of Europe (Norway, England and Wales, Germany, Italy, and the Attica Region, Greece) during the warm season. We applied a two-stage design, where area-specific data were analyzed in the first stage with over-dispersed Poisson regression models, and a random-effects meta-analysis was conducted in the second. The interaction between temperature and air pollutants was analysed by a response-surface model with a tensor smoother. The study reports the effects of air temperature for an increase from 75th to 99th percentile by levels of air pollutants (95th percentile=high, 50th=medium, 5th=low).

RESULTS: Overall results showed an effect modification by PM2.5 in the relationship between heat and mortality. for an increase in mean temperature, the overall risk of natural mortality increased by 6.6% (95% CI: -1.9%, 15.8%), 10.9% (95% CI: 2.7%, 19.7%), and 14.2% (95% CI: 4.5%, 24.9%) at the low, medium, and high levels of PM2.5, respectively. Stronger heat effects were observed for respiratory mortality with high PM2.5 levels (25.0%; 95%CI: 6.4%, 46.9%). for O3 we found a suggestion of effect modification in the relationship between heat and mortality, with a trend in effect estimates for increasing levels of O3. Among the five regions some heterogeneity in effect estimates and in the impact of effect modification by air pollution was observed.

CONCLUSIONS: Evidence of effect modification between heat and air pollutants on mortality during the warm period was found, with slightly heterogeneous patterns within regions.

ORAL PRESENTATIONS SESSION 42: Environment and health in low and medium income countries (2)

O-OP-230 The effect of landscape fires on child hospital visits and admissions: a time-series study in southern Mozambique

Ariadna Curto[1,2,3], Jovito Nunes[4,5], Xavier Basagaña[1,2,3], Llorenç Quintó[4,5], Carles Milà[1,2,3], Arsenio Nhacolo[5], Antònia Valentín[1,2,3], Francisco Saute[5], Manolis Kogevinas[1,2,3,8], Charfudin Sacoor[5], Quique Bassat[3,4,5,6,7], Cathryn Tonne[1,2,3]
[1]ISGlobal, Barcelona, Spain, [2]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [3]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [4]ISGlobal, Hospital Clínic–Universitat de Barcelona, Barcelona, Spain, [5]Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique, [6]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain, [7]Pediatric Infectious Diseases Unit, Pediatrics Department, Hospital Sant Joan de Déu, University of Barcelona, Barcelona, Spain, [8]IMIM (Hospital del Mar Medical Research Institute), Barcelona, Spain

BACKGROUND AND AIM: Epidemiological evidence linking exposure to landscape fires with child health remains limited. We assessed the association between day-to-day variation in landscape fires and child hospital visits and admissions in Manhiça district, Mozambique, an area affected by forest and cropland fires.

METHODS: We conducted a time-series analysis (2012-2020) using daily satellite-derived fire data (VIIRS 375m) and number of hospital visits and admissions from an ongoing pediatric morbidity surveillance system (children aged ≤ 15 years). Fires were extracted from the study area and a 100km surrounding buffer. We applied quasi-Poisson regression models controlling for temperature, day of the week, season and long-term trend, and offsetting by annual population-time at risk to examine associations between fires (lags 0-4) and hospital visits and admissions.

RESULTS: at least 114,443 fires (mean: 44/day; median: 13/day) and a total of 507,034 child hospital visits (mean: 154/day; 39.5% respiratory-linked) and 8,981 admissions (mean: 2.7/day; 26.7% respiratory-linked) occurred in 2012-2020. Almost half of the fires were forest fires. Fires explained 39% of temporal variability in PM2.5 from a local monitoring campaign. Comparing two days with identical values in the adjustment variables but differing by 40 fires (interquartile range) resulted in an increase of all-cause (0.95%; 95%CI: 0.46, 1.44) and respiratory-linked hospital visits (1.14%; 0.57, 1.69) the following day (lag 1). Significant associations were observed for other lags in fires including: lag 0-1 with all-cause (0.47%; 0.17, 0.77) and respiratory-linked visits (0.64%; 0.29, 0.99) and lag 2 with respiratory-linked visits (0.47%; 0.17, 0.77). We did not observe associations for hospital admissions.

CONCLUSIONS: Landscape fires were associated with all-cause and respiratory-linked hospital visits in children. Improved exposure assessment is needed to better quantify the contribution of air pollution due to landscape fires on child health in regions with limited air pollution monitoring.

KEYWORDS: Landscape fires, child health, Mozambique

O-OP-231 Effects of a liquefied petroleum gas stove intervention on gestational blood pressure: intention-to-treat and exposure-response findings from the Household Air Pollution Intervention Network (HAPIN) trial

INTRODUCTION: Approximately 3-4 billion people worldwide are exposed to household air pollution (HAP) from burning solid fuels. HAP has been linked to increased blood pressure (BP) in pregnant women, although the literature is sparse and inconsistent.

METHODS: We recruited 3195 pregnant women in Guatemala, India, Peru, and Rwanda and randomly assigned half of them to receive a liquified petroleum gas (LPG) stove/fuel intervention over the pregnancy, while those in the control group continued cooking with solid fuels. We measured gestational BP and personal exposure to PM2.5, black carbon (BC), and carbon monoxide (CO) three times during gestation: once at baseline and twice post-randomization. We conducted an intention-to-treat (ITT) analysis and an exposure-response analysis to determine if exposure to HAP during gestation was associated with an increase in BP at the final measurement compared to baseline.

RESULTS: In the intervention group, 24-hour PM2.5 dropped from 84 µg/m3 at baseline to 24 µg/m3 after the intervention; BC and CO decreased similarly. ITT analyses showed an increase over gestation (as expected) in systolic BP (SBP) and diastolic BP (DBP) in both arms, but the increase was greater in the intervention group for SBP (0.69 mmHg, 95% CI 0.03 - 1.35) and DBP (0.62 mmHg, 95% CI 0.05 - 1.19) than controls. Exposure-response analyses showed that higher HAP exposures were associated with modest increases in SBP and DBP, but none of these associations were significant.

CONCLUSIONS: We found a greater increase in BP over gestation in the intervention group in ITT analyses. This was contrary to what we expected, though the increases were not considered clinically significant. In exposure-response analyses, we found a slight increase in BP with higher exposure, although no increases were significant. Overall, the LPG stove/fuel intervention did not markedly affect gestational BP.

O-OP-232 Indoor air pollution and diet mediates the effects of social inequality on birth outcomes

Nusrat Jabin[1], Mostafijjur Rahman[1], Md.Towhid Salam[1], Meredith Franklin[1,2], Talat Islam[1]
[1]University of Southern California, Los Angeles, USA, [2]University of Toronto, Toronto, Canada

BACKGROUND AND AIM: The detrimental effect of social inequality on birth outcomes in the low to middle income countries (LMICs) can only be partially explained by lack of access to care and biomass fuel use. We aim to investigate other possible factors that can mediate the effects of SES on birth outcomes.

METHODS: The analyses were based on a pregnancy cohort of 723 mother-infant pairs with single live births between 2016-2017 in rural Bangladesh. Multivariable linear and logistic regressions, and mediation analysis were performed adjusting for demographic characteristics, maternal and infant-related factors, and air pollution from cooking sources. As potential mediating factors of SES (Lowest three quintiles of calculated Wealth Index were considered low SES), we considered other sources of indoor pollution (i.e., traditional lamp fuel and mosquito repellents), maternal diet, and stress during pregnancy.

RESULTS: Compared to households with high SES, adjusted mean birth weight was 64.2 g (95% confidence interval, CI: -121.6, -6.8) less and the odds of small for gestational age (SGA) was 40% (RR:1.40, 95% CI: 1.01, 1.99) higher among households with low SES. Exposure to other sources of indoor air pollution and lower amount of protein- and dairy-rich maternal diet during pregnancy mediated 50% and 25% of the effect of SES on birth weight and SGA, respectively. Indoor air pollution from non-cooking sources alone mediated 33% of the SES effect on birthweight and 18% on SGA.

CONCLUSIONS: This study highlights that non-cooking related household sources of air pollution and maternal diet are potential modifying factors in LMICs that can be addressed to reduce the effect of social inequity on birth outcomes.

KEYWORDS: Indoor air pollution, socioeconomic status, birth weight, low- and middle-income countries.

O-OP-233 Air pollution, physical activity, and incident gestational diabetes mellitus: a prospective cohort study

Wenyu Liu[1,2], Jian-rong He[1,2], Wei Bao[3], Jinhua Lu[1,2], Lifang Zhang[1,2], Chengrui Wang[1,2], Dongmei Wei[1,2], Huimin Xia[1,4], Xiu Qiu[1,2,4]

[1]Division of Birth Cohort Study, Guangzhou Women and Children's Medical Center, Guangzhou Medical University, Guangzhou, China, [2]Department of Women's Health, Provincial Key Clinical Specialty of Woman and Child Health, Guangzhou Women and Children's Medical Center, Guangzhou Medical University, Guangzhou, China, [3]Department of Life Science and Medicine, University of Science and Technology of China, Hefei, China, [4]Provincial Clinical Research Center for Child Health, Guangzhou, China

BACKGROUND AND AIM: Physical activity (PA) during pregnancy has been linked to decreased risk of gestational diabetes mellitus (GDM). However, engaging in PA may increase exposure to air pollutants. We aimed to examine whether and how exposure to air pollution may affect the protective effect of PA on GDM.

METHODS: This study included 21,545 pregnant women from the Born in Guangzhou Cohort Study, China. Exposure to ozone (O3), nitrogen dioxide (NO2), sulfur dioxide (SO2), particulate matter less than 10 microns in diameter (PM10), and less than 2.5 microns in diameter (PM2.5) were estimated by the inverse distance-weighted models. Information on PA was collected using a self-administrated questionnaire. We used generalized estimating equations to calculate covariate-adjusted relative risks (RRs) and 95% confidence intervals (CIs) for the associations of air pollution, PA, and the multiplicative interaction of the two with the risk of GDM.

RESULTS: The GDM risk was inversely associated with overall PA level (RR, 0.93; 95% CI: 0.89, 0.96). Per 10 μg/m3 increase in O3 concentration conferred a 12% (95%CI: 6%, 18%) increase in the risk of GDM. Higher overall PA was associated with a lower GDM risk among women with low O3 exposure (RR, 0.88; 95% CI: 0.81, 0.95), but not among women with high O3 exposure (RR, 0.97; 95% CI: 0.91, 1.04) (P interaction = 0.008). Exposure to other air pollutants did not modify the association between overall PA and GDM.

CONCLUSIONS: PA and exposure to air pollutants were associated with GDM risk in the opposite direction. O3 exposure, but not other air pollutants, attenuated the protective effect of PA on GDM. Our finding highlights the importance of improving air quality to keep the beneficial effect of PA.

KEYWORDS: air pollutants, gestational diabetes, physical activity, ozone

BACKGROUND AND AIM: Although there is evidence for the association between air pollution and decreased lung function in children, evidence for adolescents and young adults is scarce. for a peri-urban area in India, we evaluated the association of ambient and household air pollution with lung function for young adults who had recently attained their expected maximum lung function.

METHODS: We measured, using a standardized protocol, forced expiratory volume in the first second (FEV_1) and forced vital capacity (FVC) in participants aged 20-26 years from the third follow-up of the population-based APCAPCS cohort (2010-2012) in 28 Indian villages. We estimated annual average $PM_{2.5}$ outdoors at residence using land-use regression. Biomass cooking fuel (a proxy for levels of household air pollution) was self-reported. We fitted a within-between linear-mixed model with random intercepts by village, adjusting for potential confounders.

RESULTS: We evaluated 1,044 participants with mean age of 22.8 (SD=1) years (p25-p75: 22-24); 327 participants (31%) were female. Only males reported use of tobacco smoking (9% of all participants, 13% of males). The mean ambient PM2.5 exposure was 32.9 (SD=2.8) $\mu g/m^3$. 76% reported use of biomass as cooking fuel. The adjusted association between 1 µg/m3 increase in $PM_{2.5}$ was -27 ml (95%CI, -89 to 34) for FEV_1 and -5 ml (95%CI, -93 to 76) for FVC. The adjusted association between use of biomass was -112 ml (95% CI, -211 to -13) for FEV_1 and -142 ml (95%CI, -285 to 0) for FVC. The adjusted association was of greater magnitude for those with unvented stove (-158 ml, 95%CI, -279 to -36 for FEV_1 and -211 ml, 95%CI, -386 to -36 for FVC).

CONCLUSIONS: We observed negative associations between ambient and household air pollution and lung function in young adults who had recently attained their maximum lung function.

O-SY-128 Using spatial data for sampling prioritization and prediction of PFAS chemicals in fish tissue in the Columbia River Basin

Nicole DeLuca[1], Ashley Mullikin[1], Rachel Slover[1], Peter Brumm[2], Drew Pilant[1], Elaine Cohen Hubal[1]
[1]U.S. Environmental Protection Agency, Durham, USA, [2]U.S. Environmental Protection Agency, Denver, USA

BACKGROUND AND AIM: U.S. tribes and states are challenged with identifying and characterizing the extent of per- and polyfluoroalkyl substances (PFAS) contamination and human exposure to PFAS, as well as developing effective and cost-efficient ways to prioritize site investigation. In the Columbia River Basin (CRB), particularly in and around the region's tribal lands, the availability of PFAS occurrence data is limited and exposure is less characterized than in other parts of the country. This study aims to develop and pilot a predictive modeling workflow for prioritization of sampling locations that show potential for PFAS exposures in vulnerable populations in the CRB.

METHODS: AND

RESULTS: While previous studies have mainly developed predictive models for PFAS in groundwater, this study develops and evaluates predictive models for PFAS in fish tissue. Understanding PFAS levels in fish is particularly important in CRB because it can be a major component of tribal and indigenous peoples' diet. Existing spatial data in the region are leveraged including locations of known PFAS sources or contaminated sites and potential, yet unconfirmed, sources such as PFAS-related industry facilities, mining and refinery sites, airports, and landfills. Machine learning and statistical models employ these spatial data to predict PFAS concentrations in fish tissue in natural waters throughout the CRB and will be evaluated using empirical fish tissue occurrence data.

CONCLUSIONS: Model predictions help to identify areas in which high PFAS concentrations are likely to occur in fish tissue but sampling has not yet confirmed. This workflow for targeted prioritization of sampling investigations and the identification of contaminated natural resources will help U.S. tribes and states in the Columbia River Basin more efficiently manage waste, initiate clean-up activities, and identify opportunities for source reduction, thereby promoting healthy and resilient communities.

Modelling techniques for exposure assessment

O-OP-235 UK hyperlocal air pollution model – Use of inverse modelling to increase the spatial detail of air pollution predictions

Sean Beevers[1], Nutthida Kitwiroon[1], Nosha Assareh[1], Gregor Stewart[1], Andrew Beddows[1]
[1]*Imperial College London, London, UK*

BACKGROUND AND AIM: Air pollution models are increasingly able to provide forecasts of NOx, NO_2, O_3, $PM_{2.5}$ and PM_{10} at country scales (every 1-2km) and close to roads (every 10-20m). However, a significant limitation of these models is the lack of road traffic flow, speed and emissions.
AIM: To develop a hyperlocal model which predicts air pollution every 20m across all of UK's roads.

METHODS: Here we address the lack of detailed traffic counts, speed and emissions by utilising ~12,000 diffusion tube and local sensor measurements in the UK, with a road traffic emissions optimisation method (EOM). The EOM uses model sensitivity coefficients in Taylor series expansions of the models' response to varying emissions, allowing Monte Carlo emissions calibration to be performed at every monitoring location. This has allowed the creation of previously unavailable road emissions estimates, as well as the calibration of emissions on those roads that were already in the model. for other sources we used a combination of European, UK National Atmospheric Emissions Inventories. Air pollution was predicted using the WRF met. model and the CMAQ-urban coupled model.

RESULTS: The EOM has enabled an emissions calibration process of unprecedented scale – improving traffic emissions estimates and enabling air pollution predictions at 20m resolution for every road in the UK. The NOx, NO_2 and O_3 model performance compares favourably with out of sample measurements and the EOM addresses the uncertainty NOx, NO_2 emissions from road transport, which has hitherto been under predicted.

CONCLUSIONS: We have demonstrated what is possible with coupled CTM and local scale air pollution models, when combined with sufficiently detailed emissions inventories. This new approach is ideally suited for use with low cost sensor networks globally, providing data, including for $PM_{2.5}$ and PM_{10}, for local populations, policy development and health research, across entire cities and even countries.

O-OP-236 Assessing daily PM2.5 at every square kilometer of India over 2008-2020 using a machine learning framework

Siddhartha Mandal[1,2], Ajit Rajiva[1], Jyothi Menon[1], Kevin Lane[3], Heresh Amini[4], Amruta Nori-Sarma[3], Anubrati Dutta[1], Praggya Sharma[2], Kishore K Madhipatla[5], Itai Kloog[6], Poornima Prabhakaran[1], Petter Ljungman[7], Joel Schwartz[8], Dorairaj Prabhakaran[1]

[1]Public Health Foundation of India, Gurgaon, India, [2]Center of Chronic Disease Control, New Delhi, India, [3]Boston University School of Public Health, USA, [4]University of Copenhagen, Denmark, [5]Carnegie Mellon University, USA, [6]Ben Gurion University of the Negev, Israel, [7]Karolinska Institute, Sweden, [8]Harvard TH Chan School of Public Health, USA

BACKGROUND AND AIM: High levels of ambient particulate matter (PM) combined with sparse ground monitoring networks, specifically concentrated in urban areas in India, pose massive challenges to studying health effects of PM in India. Thus it is important to develop robust predictive models that provide exposure estimates at high spatiotemporal resolution across India.

METHODS: We used a machine-learning-based approach by ensemble averaging across four different learners to develop a model calibrated against ground-monitoring-based data from 1060 stations spanning 2008-2020. To counter the sparsity of available PM2.5, we also implemented a calibration model for the ratio of PM2.5 and PM10. Predictors encompassing all major areas such as, meteorology, land-use patterns, satellite observations, emissions inventories and chemical transport models were utilized. Overall cross-validation(CV) was conducted by leaving out monitors and performance was assessed at the daily level using R2, RMSE, bias and slope.

RESULTS: In the left-out 20% validation dataset, median estimated PM2.5 using ensemble averaging was 44.5 µg/m3 compared to the observed concentration of 45 µg/m3. The overall daily CV-R2 was 0.84 ranging between 0.73-0.92 across years, while daily RMSE ranged between 3.7-4.2 µg/m3. Among the learners, tree-based algorithms (gradient boosting, extreme gradient boosting and random forests) performed better than deeplearning, and ensemble averaging further improved the predictive performance. Among predictors, meteorology, reanalysis based PM2.5 and elevation were more predictive by the tree based learners while urban-rural classification and road density were high-rank predictors by the deeplearning algorithm.

CONCLUSIONS: We have developed a valuable resource for air pollution epidemiology in a LMIC scenario with both high levels of pollution and burden of disease. The resulting predictions can leverage existing, ongoing and future health studies all across India to accurately assess the burden of ambient PM2.5 on a multitude of health outcomes.

KEYWORDS: Particulate Matter, Machine learning, Ensemble averaging, India, Spatiotemporal

O-OP-237 Comparison of PM2.5 concentrations estimated using eleven different methods and their associations with cognitive outcomes in the ARIC cohort

Melinda Power[1], Katie Lynch[1], Erin Bennett[1], Qi Ying[2], Eun Sug Park[3], Xiaohui Xu[4], Richard Smith[5], James Stewart[6], Jeff Yanosky[7], Duanping Liao[7], Lianne Sheppard[8,9], Adam Spziro[9], Eric Whitsel[6]

BACKGROUND AND AIM: Evidence of associations between fine particulate matter (< 2.5 µm aerodynamic diameter) ($PM_{2.5}$) and dementia-related outcomes remains mixed. Existing studies have used a variety of methods to estimate exposure, but the literature comparing the impact of estimation method on exposure and health effects is limited. This study aims to assess agreement between $PM_{2.5}$ concentrations across 11 estimation methods and to compare estimated associations between $PM_{2.5}$ and dementia-related outcomes using data from the Atherosclerosis Risk in Communities (ARIC) study cohort, which recruited in 1987-1989 from four regional sites: Forsyth County, NC; Jackson, MS; the suburbs of Minneapolis, MN; and Washington County, MD.

METHODS: Using the ARIC cohort, we estimated address-based mean $PM_{2.5}$ concentrations (2000-2007) using 11 different

METHODS: We assessed agreement between method-specific $PM_{2.5}$ concentrations using descriptive statistics and plots, overall and by site. We used adjusted linear and logistic regression to estimate associations between method-specific $PM_{2.5}$ concentrations and Visit 5 (2011-2013) cognitive scores and brain MRI outcomes, stratified by study site and then combined with random-effects meta-analysis.

RESULTS: $PM_{2.5}$ concentrations from most estimation methods had good agreement across sites and lower agreement within each site. Within-site exposure variation was limited for some

METHODS: Point estimates for $PM_{2.5}$-cognitive outcome associations varied by method and generally did not support associations between $PM_{2.5}$ and cognitive (n=4,460) or MRI (n=1,427-1,441) outcomes. Small, but statistically significant effect estimates were found for a few exposure method-outcome associations, but these associations were null when using $PM_{2.5}$ estimates from most other

METHODS:
CONCLUSIONS: Exposure estimation approaches agreed more across ARIC sites than within each site. Variability between exposure estimation methods for $PM_{2.5}$ within sites likely contributed to heterogeneity in estimated associations with cognitive outcomes. Choice of estimation methods may influence estimated exposure and findings in epidemiological studies when participants are concentrated in small geographic areas.

O-OP-238 Sources of measurement error for indoor carbon monoxide exposure – A simulation model

Sophie Hamilton[1], Stefania Oliverio[2], Ariana Zeka[3], Rebecca Close[1], Giovanni Leonardi[1,4]
[1]Environmental Epidemiology, Radiation, Chemicals and Environmental Hazards Directorate, UK Health Security Agency, Chilton, Oxfordshire, UK, [2]Département Médecine Légale, Laboratoire national de santé, L-3555 Dudelange, Luxemburg, [3]College of Health and Life Sciences, Brunel University, London, UK, [4]Department of Public Health, Environments and Society, London School of Hygiene and Tropical Medicine, London, UK

BACKGROUND AND AIM: Carbon monoxide (CO) is toxic gas produced by incomplete combustion of carbon-based fuel. Random error in exposure measurements at the population level reduces the power of a study, making it more likely that real associations are not detected. The burden of CO poisoning and its related health effects are likely underestimated due to exposure misclassification. We reviewed exposure measurement methods used for indirect indoor CO measurement and identified key sources of error which could contribute to exposure misclassification. Using a simulation model, we aimed to quantify the impact that changes in error could have on relative risk (RR) health estimates.

METHODS: We identified potential sources of error associated with indoor CO monitoring methods used in studies based in Peru and the UK. Using error contribution data reported in the studies, and technical apparatus reports, we quantified the impact of error improvement on health risk estimates using a simulation model to calculate error contribution scenarios. Error contribution ranges of 5-15% and 10-50% were modelled for Peru and the UK respectively. for both studies, error improvement scenarios were modelled between 20-80%.

RESULTS: Monitor accuracy, positioning, inter-subject variability, and lack of detailed time activity patterns were identified as key sources of error. Under differing error contribution and improvement scenarios, the RR measures for the Peru and UK studies were improved by 0.32% and 1.13% at the lowest error contribution and improvement level to 3.99% and 26.28% at the highest error contribution and improvement level respectively.

CONCLUSIONS: Identification of sources of errors and quantification of their potential impact on measures of effect by simulation is feasible. We will apply this approach to design improved exposure assessment methods, with the aim to reduce misclassification and produce more valid estimates of CO effects on the population.

O-OP-239 Air Pollution Models of High Spatiotemporal Resolution for the State of California to Identify Exposure Disparities of the Disadvantaged Communities

Jason Su[1], Shadi Aslebagh[1], Stacey Jung[1], Emma Yakutis[1], Vy Vuong[2], Meredith Barrett[2]
[1]University of California, Berkeley, Berkeley, USA, [2]ResMed and Propeller Health, San Francisco, USA

BACKGROUND AND AIM: Disadvantaged communities face higher air pollution burden than advantaged communities, but current research has not developed high resolution daily air pollution models enabling to identify exposure disparities for disadvantaged communities across a highly populated state with large geographic scope. We aim to develop daily air pollution models and surfaces of high spatiotemporal resolution for the State of California – the most populous US state with more than 39.5 million people across 163,696 square miles (423,970 km2).

METHODS: We generated TBs of data from various platforms (including NASA and NOAA Remote Sensing data, Google Earth Engine data, and our research data), and integrated air pollution measurements from multiple instruments (e.g., Google Streetcar, government continuous monitoring and our research saturation monitoring) into a single modeling framework. We used the best-practice out-of-sample v-fold cross-validation Deletion/Substitution/Addition (D/S/A) technique to develop daily models of 30 m resolution for years 2012-2019 across California on nitrogen dioxide (NO2), fine particulate matter (PM2.5) and ozone (O3). We further identified exposure disparities for the disadvantaged communities based on census tract level race-ethnicity composition, socio-economic status and health endpoints.

RESULTS: With the integration of data in land use, land cover, traffic, remote sensing acquisition, daily weather conditions, plus their buffered statistics, we generated more than 2,000 covariates in modeling a single pollutant. Through data reductions strategy and the D/S/A modeling framework, we created air pollution models with a respectively adjusted R2 of 79.6%, 65.3% and 93.6% for NO2, PM2.5 and O3. We further identified significant air pollution exposure disparities for the disadvantaged communities.

CONCLUSIONS: We are the first in literature that generated TBs of high spatiotemporal air pollution surfaces through integrating TBs of data sources in a out-of-sample cross-validation machine learning algorithm for California.

KEYWORDS: Deletion/Substitution/Addition, nitrogen dioxide, fine particulate matter, ozone, State of California, disadvantaged, disparity.

O-OP-240 Personal exposures to PM2.5 in rural Beijing, China: Spatial-temporal variation patterns and modeling approaches

Xiaoying Li[1], Jill Baumgartner[1], Christopher Barrington-Leigh[1], Collin Brehmer[2], Sam Harper[1], Brian Robinson[1], Guofeng Shen[3], Mis. Talia Sternbach[1], Shu Tao[3], Xiang Zhang[1], Yuanxun Zhang[4], Ellison Carter[2]
[1]Mcgill University, Montreal, Canada, [2]Colorado State University, Fort Collins, USA, [3]Peking University, Beijing, China, [4]University of Chinese Academy of Sciences, Beijing, China

BACKGROUND AND AIM: Household air pollution is a leading health risk factor for global morbidity and mortality. However, studies with high quality personal exposure data in settings of household air pollution are very limited. To investigate the levels and patterns of personal exposures to $PM_{2.5}$ in rural Beijing and develop a personal exposure model, we conducted measurements in over 500 households in 50 villages in rural Beijing over two winters.

METHODS: Adults (> 40-year-old) from 10 randomly selected households in each village were recruited to wear a personal exposure sampler (Ultrasonic Personal Aerosol Samplers, UPAS) to measure 24-h exposures. Indoor $PM_{2.5}$ was concurrently monitored in 300 households using calibrated low-cost sensors (Plantower) and outdoor $PM_{2.5}$ was monitored at the community levels using the same sensors. We also administered a survey to collect household socio-demographic information, fuel use patterns, and general physical activity patterns. Mixed-effects models and quantile regression were applied to investigate distributional effects in indoor and outdoor $PM_{2.5}$ and temperature, heating energy use, and other socio-demographic factors on personal exposures.

RESULTS: Personal $PM_{2.5}$ decreased by 39 (95%CI: 3.8-74) $\mu g/m^3$ for participants who shifted from solid fuel to clean energy for heating between study years, but the reduction in participants who continued using solid fuel was only 27 (95%CI: 9.9-44) $\mu g/m^3$. Indoor and outdoor $PM_{2.5}$ explained the largest proportion of personal $PM_{2.5}$ variance. Less wealthy participants who were current smokers and used solid fuels for space heating tended to have higher exposures. In quantile regression, at high quantiles of personal exposure levels, the influences of indoor $PM_{2.5}$ on personal exposures enlarged.

CONCLUSIONS: Transitions to clean energy for space heating improved indoor air quality and personal exposures. The influence of different variables on personal exposures varied by exposure levels, and it is essential to model personal exposures by exposure levels.

ORAL PRESENTATIONS SESSION 44:
Risk communication and participatory epidemiology

O-OP-241 PM2.5 attributable health disparities and distributional benefits of alternative National Ambient Air Quality Standards in the continental United States

Ananya Roy[1], Henry Roman, William Raich, Maria Harris, Mindi DePaola, Taylor Bacon, Stefani Penn, Joseph Chang, Melanie Jackson
[1]*Environmental Defense Fund, Washington, USA*

BACKGROUND AND AIMS: Racial, ethnic, and socioeconomic disparities in exposure to PM2.5 in the United States is well known. However, there is limited understanding of the magnitude of disparities in PM-attributable health effects and distributional benefits of policies, such as potential alternative National Ambient Air Quality Standards (NAAQS) currently being considered by EPA.

METHODS: We use fine scale air pollution, mortality and morbidity data, as well as new race- ethnicity stratified concentration response functions as inputs for a health impact assessment to determine the distribution of PM2.5 health burdens across race/ethnicity and poverty categories throughout the United States in 2015. Using a rollback approach, we examine the potential distribution of benefits of a 10 μg/m3 and 8 μg/m3 annual standard. We also explore the sensitivity of the model outputs to the different inputs.

RESULTS: In 2015, Black Americans experienced three times as many PM2.5-attributable related deaths per capita compared to all other races. The burden of PM-attributable asthma ED visits for non-white Americans were up to six times higher compared to white Americans. We find that an 8 μg/m3 alternative standard could avoid nearly 19,000 premature deaths and 11,500 respiratory emergency room visits. Mortality benefits for the 8 μg/m3 standard are three to four times higher than those for the 10 μg/m3 alternative standard. Per-capita mortality risk reductions for Black Americans are three times the rate of all other races and individuals with incomes ≤ 2X poverty line experience 30% higher mortality benefits under more protective PM NAAQS.

CONCLUSIONS: These findings indicate that more protective NAAQS would provide some reduction in the magnitude of racial/ethnic and socioeconomic disparities in health burdens of air pollution exposure. Despite this, significant residual disparities would remain, suggesting that supplemental policy approaches would be needed to further alleviate the disparity in PM-attributable health burdens.

O-OP-242 Pathway to WHO: Achieving clean air in the UK - Modelling air quality costs and benefits

David Dajnak[1], Nutthida Kitwiroon[1], Nosha Assareh[1], Gregor Stewart[1], William Hicks[1], Dimitris Evangelopoulos[1,2], Dylan Wood[1,2], Heather Walton[1,2], Sean Beevers[1]
[1]Environmental Research Group, MRC Centre for Environment and Health, Imperial College, London, UK, [2]NIHR Health Protection Unit in Environmental Exposures and Health at Imperial College, London, UK

BACKGROUND AND AIM: The Clean Air Fund commissioned us to investigate whether the WHO interim target of 10 µg/m3 PM2.5 could be met by 2030 with assessment of the health benefits of these air pollution reductions, to inform consultation on targets for the UK Environment Bill.

METHODS: UK PM2.5 concentrations in 2030 were modelled from 2018 using CMAQ-Urban and emissions predictions from business as usual, electrification of vehicles Planned London specific policies (UK2030+LS1) or two further London scenarios (LS2/3) were added using the London, toolkit model.
Life-table analysis at ward level assumed 2030 concentrations were maintained until 2134. Morbidity outcomes from changes in NO2, PM10 and PM2.5 were quantified using summary estimates from the UK Committee on the Medical Effects of Air Pollutants, WHO and published meta-analyses. Monetary values were then applied.

RESULTS: for UK2030+LS1, concentrations in 2030 were below 10 µg/m3 across the UK except the centre of London, near major roads in cities, and industrial biomass burning locations. With LS2/3, the exceedances dropped to <1% of the area of London. Local authority population-weighted exposures above 10 µg/m3 reduced from 40% in 2018 to 1% in 2030 (UK2030+LS1) to 0% for LS2 and 3.
11.5 million life years were gained across the UK population from 2018–2134 for UK2030+LS1 compared with unchanged 2018 concentrations. 2 million life years were in London, increasing to 2.5 and 2.9 million life years for LS2/3.
Substantial health benefits were generated e.g. avoiding 388,000 asthmatic symptom days in asthmatic children and 3,077 new cases of coronary heart disease per year for UK2030+LS1.
The monetary benefits showed policies costing up to £383 billion between 2018-2134 would be justified.

CONCLUSIONS: The WHO interim target was met in most but not all locations by 2030 generating substantial health benefits.

KEYWORDS: PM2.5, WHO Guidelines, air pollution, health impact assessment.

O-OP-243 The impact of alternative fuel vehicles on health: a systematic review

Audrey Pennington[1], Cheryl Cornwell[1,2], Maria Mirabelli[1], Kanta Sircar[1,3]
[1]U.S. Centers for Disease Control and Prevention, Atlanta, USA, [2]Oak Ridge Institute for Science and Education, Oak Ridge, USA, [3]Commissioned Corps, USA Public Health Service, Rockville, USA

BACKGROUND AND AIM: Despite the increasing adoption of alternative fuel vehicles such as electric, hybrid, and clean diesel cars, trucks and buses, the health impacts of these vehicles (e.g., through changes in air quality) is largely unexplored. We reviewed the published literature to assess the state of the evidence on use of alternative fuel vehicles and health.

METHODS: We conducted a systematic literature search of MEDLINE, Embase, Global Health, CINAHL, Scopus, and Environmental Science Collection databases for articles published January 1990 to November 2021. We included articles presenting observed or modeled data on the association between alternative fuel vehicles and health-related outcomes. We abstracted data, categorized studies based on the type of alternative fuel and health outcomes studied, and summarized the results.

RESULTS: In our preliminary findings, 23 of 631 screened articles met our inclusion criteria. The most common vehicle types examined were electric or hybrid electric (n=18, 78%), clean diesel (n=5, 22%), and compressed natural gas (n=3, 13%). Overall, 17 articles (74%) assessed death as an outcome and 8 articles (35%) monetized health benefits. Only one study collected longitudinal data to assess the health impact on a population; the other articles all modeled data. All 23 articles observed some evidence of a positive health impact of adopting alternative fuel vehicles, although magnitudes varied. There was a paucity of information on the environmental justice implications of vehicle transitions (e.g., changing of the spatial distribution of air pollution, emphasis on adoption equity).

CONCLUSIONS: There is limited information, particularly real-world studies, on the health impact of adoption of alternative fuel vehicles. The current rapid transitioning of vehicle fleets to alternative fuels provides a unique opportunity to conduct natural experiments to quantify health impacts and assess environmental justice implications of alternative fuel adoptions.

KEYWORDS: alternative fuels, traffic, review

O-OP-244 Application of co-created citizen science in environmental epidemiology

Frederique Froeling[1], Gerard Hoek[1], Florence Gignac[2], Annibale Biggeri[3], Lucia Errandonea[6], Antonella Ficorilli[3], Bruna De Marchi[3], David Kocman[4], Sandra Andrusaityte[5], Regina Grazuleviciene[5], Roel Vermeulen[1]
[1]Universiteit Utrecht, Utrecht, Netherlands, [2]Barcelona Institute for Global Health, Barcelona, Spain, [3]Epidemiologia e Prevenzione "Giulio A. Maccacaro" Social Enterprise, Milan, Italy, [4]Jozef Stefan Institute, Department of Environmental Sciences, Ljubljana, Slovenia, [5]Department of Environmental Science, Vytautas Magnus University, Kaunas, Lithuania, [6]Ideas for Change, Barcelona, Spain

BACKGROUND AND AIM: Scientists and scientific institutions are adopting more extensive participatory models, hoping to bridge the gap between institutionalized science and society. Though citizen science has become more common in environmental monitoring, it is seldom utilized in environmental epidemiology. In the Cities-Health study, we co-created epidemiological studies with citizens in five European cities. The aim of this paper is to provide methodological insight into the application of co-created citizen science strategies in environmental epidemiology.

METHODS: We applied the CitieS-Health framework for citizen science, which is a framework that allows citizens to be involved throughout all the phases of the research projects, in five environmental epidemiology studies. Studies covered diverse environmental issues (e.g. urban air pollution, wood smoke, noise) in Spain, Italy, the Netherlands, Slovenia and Lithuania. Among other aspects this included co-identifying the research question, co-designing and submitting the research protocol for ethical clearance, co-collecting data, co-analyzing data, co-authoring scientific articles and further communication of results to diverse audiences.

RESULTS: Together with citizens, we were able to design and conduct environmental epidemiology studies reflecting their concerns and knowledge. Involvement of citizens occurred in all of the research phases with different levels of participation depending on the needs and characteristics of each pilot. Examples of citizens' impact on research done in the Dutch pilot study was the inclusion of an additional health outcome, exposure period analysis and interpretation of exposure settings. Online communication was a major component, affecting the number of citizens involved, but also study quality. Citizens remained interested and invested time throughout the duration of the projects, some even becoming pilot "community champions".

CONCLUSIONS: Integration of citizen science in environmental epidemiology is feasible and has the potential to improve the quality of research and civic trust in research and results.

KEYWORDS: Co- creation, citizen science, Participatory Epidemiology

O-OP-245 An Evaluation of the Air Quality Warning System for Vulnerable and Susceptible Individuals in South Korea

Youhyun Park[1,2], Jun Hyuk Koo[2], Dae Ryong Kang[2,3], Koh Sang-Baek[4], Tae-Hwa Go[5]

[1]Department of Biostatistics, Graduate School,Yonsei University, Seodaemun-gu, Republic of Korea, [2]Institute of National Health Big Data Clinical Research, Wonju College of Medicine, Yonsei University, Wonju, Republic of Korea, [3]Department of Precision Medicine & Biostatistics, Yonsei University, Wonju College of Medicine, Wonju, Republic of Korea, [4]Department of Preventive Medicine, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea, [5]Department of Biostatistics, Graduate School of Yonsei University, Seoul, Republic of Korea

BACKGROUND AND AIM: Since 1987, WHO has periodically published international air quality guidelines and standards, and governments around the world have set the Air Quality Index (AQI) to monitor air pollution according to the characteristics of individual countries. The set AQI is used for the operation of a forecast and alarm system for air quality. There are many studies on these forecast and warning systems, but evidence of their effectiveness is still limited.

OBJECTIVES: The purpose is to understand the effectiveness of the air quality alert system implemented in January 2015 through the change in the incidence rate of environmental diseases.

METHOD: The study adopted interrupted time series analysis with Poisson segmented regression to detect changes in the incidence rate of environmental diseases after implementing the Air Quality Warning System (AQWS) in Korea using data from 2010 to 2019. Seasonality, air pollutants (CO, NO2, SO2, PM10, and O3), temperature, and humidity are used for adjustment variables. The findings were validated using false policy study periods and digestive diseases as a control.

RESULT: After implementation of the AQWS, the incidence of COPD gradually decreased by 24% (relative risk (RR) 0.76, 95% confidence interval (CI) 0.65-0.88). Asthma and Heart Failure similarly tended to decrease (Asthma : RR 0.37 95%CI 0.21-0.65, HF : RR 0.37 95%CI 0.21-0.65), which was statistically significant. There was a gradual effect on the incidence rate of asthma in both children and the elderly, decreasing 44% and 22%, respectively. In the elderly, the same tendency was found in COPD (RR 0.81, 95%CI 0.70-0.94) and HF (RR 0.95, 95%CI 0.90-0.99).

CONCLUSION: In Korea, the AQWS was effective in most environmental diseases. It is expected that the health benefits of the policy can be maximized if AQWS warns the degree of risk reflecting the characteristics of vulnerable and sensitive individuals.

ORAL PRESENTATIONS SESSION 45: Maternal exposures and neurobehavioural outcomes

O-OP-246 Maternal per- and poly-fluoroalkyl substances exposures associated with higher depression scores among immigrant women in the San Francisco Chemicals in Our Bodies cohort

Max Aung[1], Stephanie Eick[2], Amy Padula[3], Sabrina Smith[4], June-Soo Park[4], Erin DeMicco[3], Tracey Woodruff[3], Rachel Morello-Frosch[5]

[1]University of Southern California, Los Angeles, USA, [2]Emory University, Atlanta, USA, [3]University of California San Francisco, San Francisco, USA, [4]California Environmental Protection Agency, Berkeley, USA, [5]University of California Berkeley, Berkeley, USA

BACKGROUND AND AIM: Exposure to per- and poly-fluoroalkyl substances (PFAS) remains an important public health issue, due to their widespread detection in environmental media, slow metabolism in humans, and potential impacts on physiological processes such as neurological signaling. Maternal depression is highly prevalent in pregnancy and is an important neurological outcome that is potentially sensitive to PFAS. The health risks of PFAS may be further amplified in historically marginalized communities, including immigrant women.
OBJECTIVE: We evaluated maternal concentrations of PFAS in association with depression symptoms during pregnancy and stratified by US born and immigrant women.

METHODS: Our sample included 263 United States (US) born and 213 non-US born pregnant people recruited in the Chemicals in Our Bodies cohort (San Francisco, CA). Serum samples were collected in the 2nd trimester to measure seven PFAS chemicals. Depression symptoms were assessed using the Center for Epidemiologic Studies Depression. Single pollutant associations were estimated using linear regression, adjusting for maternal age, education, and pre-pregnancy body mass index. Cumulative PFAS associations were estimated using quantile g-computation.

RESULTS: On average, all PFAS were lower in immigrant participants compared to US participants, which may be due to shorter time spent in the US. A natural log unit increase in two PFAS was associated with higher depression scores among all participants, and stratified analyses showed that this association persisted only among immigrant women ([95% confidence interval]: perfluorooctane sulfonic acid (1.25 [0.14-2.36]) and methyl-perfluorooctane sulfonamide acetic acid (1.68 [0.58-2.77]). Quantile g-computation estimated higher cumulative PFAS exposure was associated with modestly increased depressive symptoms among immigrant women (0.96 [-0.22, 2.15]) compared to US born women (0.003 [-0.94, 0.95]).

CONCLUSIONS: Findings provide new evidence that PFAS are associated with higher depression symptoms among immigrant women during pregnancy. Results can inform efforts to address environmental factors that may affect depression among US immigrants.

O-OP-247 Associations of exposure to phenols during pregnancy with non-nutritive suck in full-term infants in two US birth cohorts

Megan Woodbury[1,2,3,4], Emily Zimmerman[1,5], Andréa Aguiar[4,6], Max Aung[7], Sarah Geiger[4,8], Deborah Watkins[9], Shukhan Ng[4], Antonia Calafat[10], José Cordero[11], John Meeker[9], Akram Alshawabkeh[1,2], Susan Schantz[4,6]

BACKGROUND AND AIM: Phenols are endocrine disrupting chemicals found in many consumer products. We examined the relationship between pregnancy exposure and non-nutritive suck (NNS), an early indicator of central nervous system integrity, in two diverse populations.

METHODS: The study involved two prospective birth cohorts in the national Environmental influences on Child Health Outcomes (ECHO) Program: Illinois Kids Development Study (IKIDS, n=49) and ECHO Puerto Rico (ECHO-PROTECT, n=145). In IKIDS, phenols were quantified in a pool of five maternal urine samples collected across pregnancy. In ECHO-PROTECT, urinary phenols were measured 1-3 times in pregnancy, and the geometric mean of each phenol was calculated for each participant. NNS was sampled from 1- to 8-week-olds using a pacifier attached to a pressure transducer for ~5 minutes. Associations of 2,4-dichlorophenol, 2,5-dichlorophenol, bisphenol-A (BPA), bisphenol-S (BPS), and bisphenol-F) with NNS were assessed using generalized linear models adjusted for child sex and assessment age and maternal age and education.

RESULTS: Only associations for the combined analyses were examined for the present analyses, although future work will also compare these relationships with those observed within IKDS and ECHO-PROTECT individually. Both 2,5-dichlorophenol and BPA were associated with longer NNS bursts (time sucking before pausing for breath; β[95%CL]: 2,5-dichlorophenol=7.72[-0.83,16.3], BPA=23.0[3.73,42.2]), greater NNS intraburst frequency (number of sucks/second within a burst; 2,5-dichlorophenol=7.84[-0.73,16.4], BPA=23.3[3.97,42.6]), more bursts/minute (2,5-dichlorophenol=8.04[-0.50,16.6], BPA=23.4[4.16,42.6]), and more suck cycles/burst (2,5-dichlorophenol=4.34[0.53,17.6], BPA=9.81[3.51,42.0]). BPA was also associated with more cycles/minute (β=22.0[2.59,41.3]), but BPS was associated with lower amplitude (sucking strength; β=-21.8[-45.4,1.72]).

CONCLUSIONS: Pregnancy exposure to some phenols (or their precursors) may be related to altered NNS patterning in infants. Future work will examine how NNS is related to later neuropsychological function. These results indicate NNS measures could allow for earlier detection of exposure-related neurological deficits which would allow for earlier intervention.

KEYWORDS: neurodevelopment, phenols, BPA, BPS, 2,5-dichlorophenol

O-OP-248 Prenatal exposure to endocrine disrupting chemicals and the association to behavioural outcomes in children at age seven in the SELMA study

Marlene Stratmann[1], MD Fatih Özel[1,3,9], Louise Persson[1], Christian Lindh[4], Maria Marinopoulou[7,8], PhD, MD Maria Unenge Hallerbäck[1,5,6], Carl-Gustaf Bornehag[1,2]

[1]Department of Health Sciences, Karlstad Universitet, Karlstad, Sweden, [2]Icahn School of Medicine at Mount Sinai, New York, USA, [3]Department of Organismal Biology, Uppsala Universitet, Uppsala, Sweden, [4]Division of Occupational and Environmental Medicine, Lund Universitet, Lund, Sweden, [5]School of Medical Science, Örebro Universitet, Örebro, Sweden, [6]Centre for Clinical Research and Education, Region Värmland, Sweden, [7]Gillberg Neuropsychiatry Centre, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Göteborg, Sweden, [8]Child and Adolescent Habilitation, Region Värmland, Karlstad, Sweden, [9]Centre for Women's Mental Health during the Reproductive Lifespan – WOMHER, Uppsala University, Uppsala, Sweden

BACKGROUND AND AIM: Endocrine disrupting chemicals (EDCs) can interfere with the hormone action and are able to cross the placenta and thereby expose the foetus. If the foetus is exposed, it can have an effect on the development of the nervous system with neurobehavioral consequences. Thus, the aim of this study is to estimate the association between prenatal exposure to EDCs and neurobehaviour in children.

METHODS: Based on the pregnancy cohort Swedish Environmental Longitudinal, Mother and Child, Asthma and Allergy (SELMA) study, 700 mother-child pairs were selected to estimate associations between prenatal exposure to EDCs and neurobehavioural outcomes using the Strengths and Difficulties Questionnaire (SDQ). Associations were estimated for the total SDQ score and a 90th percentile cut-off to identify cases that might be of clinical importance. Linear, logistic and weighted quantile sum (WQS) regressions were used to estimate betas (β), odds ratios (ORs) and 95% confidence intervals (95% CI). The models were adjusted for urinary creatinine concentration, mother's education, smoking status, age and parity and child's sex and age at outcome assessment.

RESULTS: Prenatal levels of MBzP (methylbenzylphthalate) measured in the pregnant mothers' urine were found to be associated with significantly higher SDQ scores (more problems) in adjusted analyses: linear regressions (β 1.49, 95% CI 0.64-2.33) and logistic regression (OR 1.95, 95% CI 1.03-3.70). Further, MBzP was the chemical with the highest weight in the adjusted mixture analyses (WQS), in both the linear (β 0.49, 95% CI 0.22-0.75) and logistic regression (ORs 1.35, 95% CI 1.10-1.64). There were no sex differences in any of the analyses.

CONCLUSIONS: MBzP, a phthalate used in vinyl flooring and adhesives, seems to be a chemical of concern when assessing indicators for neurobehavioural outcomes in children. Further studies are needed to explain a possible biological mechanism behind these findings.

KEYWORDS: Endocrine disrupting chemicals, neurobehaviour

O-OP-249 Joint Effects of Indoor Air Pollution and Maternal Psychosocial Stress During Pregnancy on Trajectories of Early Childhood Psychopathology

Grace Christensen[1], Michele Marcus[1], Aneesa Vanker[2], Susan Malcom-Smith[2], Shakira Suglia[1], Howard Chang[2], Heather Zar[2], Dan Stein[2], Anke Huels[1]
[1]Emory University, Atlanta, USA, [2]University of Cape Town, Cape Town, South Africa

BACKGROUND AND AIM: Identifying modifiable risk factors for childhood psychopathology can increase quality of life for children and prevent adult psychopathology. Previous studies have shown that indoor air pollution (IAP) and maternal psychosocial stress (MPS) during pregnancy separately influence psychopathology, but their joint effects are not well understood. Here, we use environmental mixture methodology to estimate joint effects of IAP and MPS during pregnancy on trajectories of early childhood psychopathology.

METHODS: We used data from the Drakenstein Child Health Study (N=360), a South African birth cohort. Exposure to IAP and MPS was measured during the second trimester of pregnancy. The Childhood Behavior Checklist (CBCL) was administered at ages 2, 3.5, and 5 years to assess child psychopathology. CBCL trajectories were created using latent class linear mixed effects models. Joint effects of IAP and MPS were summarized using principal component (PC) analysis. Individual effects of IAP and MPS and their joint effects were estimated using polytomous logistic regression models, adjusted for maternal age, sex, ancestry, and socioeconomic status.

RESULTS: Three distinct classes of CBCL trajectory were identified (class 1 (reference): lowest, class 2: highest and increases, class 3: stable at a medium-high). We consistently observed adverse associations between IAP (e.g., toluene for class 3: OR [95% CI]; 1.35 [1.00, 1.80]) and MPS (e.g., intimate partner violence for class 3: 1.44 [1.03, 1.99)) and CBCL. In the joint effects analysis, PC2 (accounted for 13% of risk factor variation) was significantly associated with class 3 (1.23 [1.03, 1.46]) and class 2 (1.27 [1.04, 1.55]) compared to class 1.

CONCLUSIONS: Exposure to IAP and MPS during pregnancy was associated with CBCL trajectories indicating increased risk for psychopathology. Estimating joint effects of IAP and MPS is important to identify vulnerable subgroups for intervention to prevent childhood psychopathology.

O-OP-250 Air pollution during perinatal period and neurodevelopment in children: a national population study in Taiwan

Ping Shih[1,9], Tung-liang Chiang[2], Chih-Da Wu[3,4], Bih-Ching Shu[5], For-Wey Lung[6,7], Yue Leon Guo[1,4,8]
[1]Department of Environmental and Occupational Medicine, National Taiwan University (NTU) and NTU Hospital, Taipei, Taiwan, [2]Institute of Health Policy and Management, College of Public Health, National Taiwan University, Taipei, Taiwan, [3]Department of Geomatics, National Cheng Kung University, Tainan, Taiwan, [4]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli, Taiwan, [5]Institute of Allied Health Sciences, Department of Nursing, College of Medicine, National Cheng Kung University, Tainan, Taiwan, [6]Calo Psychiatric Center, Pingtung, Taiwan, [7]Graduate Institute of Medical Science, National Defense Medical Center, Taipei, Taiwan, [8]Institute of Environmental and Occupational Health Sciences, College of Public Health, National Taiwan University, Taipei, Taiwan, [9]Department of Environmental and Occupational Medicine, National Taiwan University Hospital Hsin-Chu Branch, Hsinchu City, Taiwan

BACKGROUND AND AIM: Air pollutants have been associated with several neurodevelopment outcomes, including autism spectrum disorder- and attention deficit-related phenotypes, language delay, intelligence and mood disorders. This study aimed to evaluate the association between ambient PM2.5 during prenatal and postnatal period and infant neurodevelopmental parameters.

METHODS: We conducted a population-based birth cohort study using Taiwan Birth Cohort Study, recruiting representative 12% of all newborn in 2005. Participants were assessed for developmental conditions through home interviews and structured questionnaires at 6 and 18 months of age. Exposure to air pollutants during gestational and postnatal period was estimated using hybrid kriging/land-use regression based on data from the air monitoring stations. Logistic regression was then conducted to determine adjusted odds ratios (aORs) of neurodevelopmental delay in relation to PM2.5 adjusting for infant factors (gender, low-birthweight and birth order), maternal factors (education, age, breastfeeding and perinatal smoking), and household factors (urban living and family income).

RESULTS: A total of 17,046 term singletons without congenital malformations were included in the final analysis. PM2.5 during second trimester was associated with increased risks of delays in gross-motor neurodevelopmental milestones [aOR=1.087 per 10 μg/m3, 95% confidence interval (CI)=1.034-1.144 for walking with support; aOR=1.096, 95% CI=1.044-1.151 for walking steadily]. Personal and social neurodevelopmental milestones were related to PM2.5 exposure in the second and third trimester [aOR=1.11, 95% CI =1.052-1.17; aOR=1.057, 95% CI=1.006-1.111 for approaching when called upon, and also early gestational period [aOR=1.054, 95% CI=1.006-1.103 for drinking with both hands]. Fine-motor development was not found to be related to perinatal exposure to air pollutants.

CONCLUSIONS: Exposure to ambient PM2.5 during pregnancy was significantly related to the occurrence of delay in gross-motor and personal/social development in this population-based study.

KEYWORDS: neurodevelopmental delay, air pollution, PM2.5, prenatal and postnatal exposure

O-OP-251 Prenatal exposure to polycyclic aromatic hydrocarbons and behavioral problems in preschool and early school-aged children

Erin Wallace[1], Erin Buth[1], Adam Szpiro[1], Yu Ni[1], Christine Loftus[1], Erin Masterson[1], Drew Day[2], Bob Sun[1], Alexis Sullivan[3], Emily Barrett[4], Ruby Nguyen[5], Morgan Robinson[6], Kurunthachalam Kannan[6], Sheela Sathyanarayana[1,2], Nicole Bush[3], Kaja LeWinn[3], Catherine Karr[1]

[1]University of Washington, Seattle, USA, [2]Seattle Children's Research Institute, Seattle, USA, [3]University of California, San Francisco, San Francisco, USA, [4]Rutgers University, New Brunswick, USA, [5]University of Minnesota, Minneapolis, USA, [6]New York University School of Medicine, New York, USA

BACKGROUND AND AIM: Epidemiological study findings are inconsistent regarding associations between prenatal polycyclic aromatic hydrocarbon (PAH) exposures and childhood behavior. This study examined the associations of prenatal PAH exposure with behavior at age 4-6 years in a large, diverse, multi-region prospective cohort. Secondary aims included examination of PAH mixtures and effect modification by child sex, breastfeeding, and child neighborhood opportunity.

METHODS: The ECHO PATHWAYS Consortium pooled 1113 mother-child dyads from three prospective pregnancy cohorts in six U.S. cities. Seven PAH metabolites were measured in prenatal urine. Child behavior was assessed at age 4-6 using the Total Problems score from the Child Behavior Checklist (CBCL). Neighborhood opportunity was assessed using the socioeconomic and educational scales of the Child Opportunity Index. Multivariable linear regression with log2-transformed metabolite concentrations was used to estimate associations per 2-fold increase in each PAH metabolite, adjusted for demographic, prenatal, and maternal factors. Associations with PAH mixtures were estimated using Weighted Quantile Sum Regression (WQSR).

RESULTS: The mean child age at outcome assessment was 5.1 years (SD=1.0); 51% identified as non-White or Multiracial. In fully adjusted models, 2-hydroxynaphthalene was associated with a lower Total Problems score (Beta= -0.80, 95% CI = -1.51, -0.08). Associations were stronger in boys (Beta= -1.10, 95% CI = -2.11, -0.08) and among children breastfed 6+ months (Beta= -1.31, 95% CI = -2.25, -0.37), although there was no statistically significant evidence for interaction by child sex, breastfeeding, or neighborhood child opportunity. Associations were null for all other PAH metabolites, and there was no evidence of associations with PAH mixtures from WQSR.

CONCLUSIONS: In this large, diverse, and well-characterized prospective study of mother-child pairs, we did not observe evidence to support our hypothesis that prenatal PAH exposure was associated with adverse child behavior scores at age 4-6 years.

KEYWORDS: polycyclic aromatic hydrocarbons; behavior; neurodevelopment

ORAL PRESENTATIONS SESSION 46: Environmental health and the COVID pandemic

O-OP-252 Association between long-term exposure to ambient air pollution and COVID-19 severity - A prospective cohort study of confirmed SARS-CoV-2 cases in Ontario, Canada

Chen Chen[1], John Wang[2], Jeff Kwong[2], JinHee Kim[2], Aaron Van Donkelaar[3], Randall Martin[3], Perry Hystad[4], Yushan Su[5], Eric Lavigne[6], Megan Kirby-McGregor[7], Jay Kaufman[7], Tarik Benmarhnia[1], Hong Chen[2,6]

[1]University of California San Diego, La Jolla, USA, [2]Public Health Ontario, Toronto, Canada, [3]Department of Energy, Environmental, and Chemical Engineering, Washington University in St. Louis, St. Louis, USA, [4]College of Public Health and Human Studies, Oregon State University, Corvallis, USA, [5]Ontario Ministry of the Environment, Conservation and Parks, Toronto, Canada, [6]Environmental Health Science and Research Bureau, Health Canada, Ottawa, Canada, [7]Department of Epidemiology and Biostatistics and Occupational Health, McGill University, Montreal, Canada

BACKGROUND AND AIM: Coronavirus disease 2019 (COVID-19) is causing a tremendous health burden globally. Identification of the determinants of COVID-19 severity is important for prevention and intervention. This study aims to explore long-term exposure to ambient air pollution as a potential contributors to COVID-19 severity given its known impact on the pulmonary system.

METHODS: Using a cohort of all confirmed severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) cases aged ≥20 years and not residing in a long-term care facility in Ontario, Canada during 2020, we evaluated the association between long-term exposure to fine particulate matter (PM2.5), nitrogen dioxide (NO2), and ground-level ozone (O3) and risk of COVID-19-related hospitalization, intensive care unit (ICU) admission and death separately. Participants' long-term exposures to each air pollutant were ascertained based on their residential addresses from 2015 to 2019. We used logistic regression and adjusted for confounding and selection bias using various individual and contextual covariates obtained through data linkage.

RESULTS: Among the 151,105 confirmed SARS-CoV-2 cases in 2020, we observed 8,630 hospitalizations, 1,912 ICU admissions and 2,137 deaths related to COVID-19. for each interquartile range increase in exposure to PM2.5 (1.70 μg/m3), we estimated ORs of 1.06 (95% confidence interval (CI): 1.01 to 1.12), 1.09 (95% CI: 0.98 to 1.21) and 1.00 (95% CI: 0.90 to 1.11) for hospitalization, ICU admission and death, respectively. Estimates were smaller for NO2 but larger for O3.

CONCLUSIONS: In this large population-based study in Ontario during 2020, we found that chronic exposure to air pollution may contribute to severe outcomes following SARS-CoV-2 infection, with stronger evidence found with O3.

KEYWORDS: COVID-19 severity, long-term exposure to air pollution, death, hospitalization, intensive care unit admission

O-OP-253 Solving the short-term NO2 exposure and mortality dilemma: a natural experiment during the COVID-19 lockdowns

Yiqun Ma[1], Federica Nobile[2], Massimo Stafoggia[2], Susanne Breitner[3], Anne Marb[3], Patrick Kinney[4], Robert Dubrow[1], Kai Chen[1]

[1]Yale School of Public Health, New Haven, USA, [2]Lazio Region Health Service ASL Roma 1, Rome, Italy, [3]Ludwig-Maximilians-Universität München – IBE-Chair of Epidemiology, Munich, Germany, [4]Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: Current evidence is insufficient to establish an independent causal relationship between short-term exposure to nitrogen dioxide (NO_2) and mortality, mainly due to the usually moderate-to-high correlation between NO_2 and fine particulate matter ($PM_{2.5}$). Unprecedented lockdown measures were implemented worldwide to control the COVID-19 pandemic, leading to substantial decreases in NO_2 concentrations; however, changes in $PM_{2.5}$ concentrations were inconsistent among locations, with reductions comparable to those of NO_2, smaller reductions, or even increases. These disproportionate changes in pollutant concentrations provide a unique opportunity for a "natural experiment" study to disentangle the short-term effects of NO_2 versus $PM_{2.5}$ on mortality.

METHODS: We focused on regions that witnessed air pollution changes but limited COVID-19 cases during the lockdowns from January to May 2020: Jiangsu Province, China, and central-southern Italy. Counties or municipalities were divided into two groups: a treated group (considerable reduction in NO_2, but little to no reduction in $PM_{2.5}$) and a control group (changes in NO_2 and $PM_{2.5}$ comparable). A triple-difference (TD) approach was applied to assess the difference between the estimates for NO_2 in the treated and control groups, which captures the change in mortality risk induced by NO_2 alone. This method controlled for all temporal and spatial confounders and cancelled out the confounding effects that vary both over time and space.

RESULTS: Each 10-$\mu g/m^3$ increase in the 5-day moving average of NO_2 concentrations was significantly associated with increases of 11.21% (95% confidence interval [CI]: 1.60%, 21.73%) and 27.28% (95% CI: 14.51%, 41.46%) in daily all-cause mortality in Jiangsu and central-southern Italy, respectively. As negative controls, the TD estimates using 2019 data were close to null.

CONCLUSIONS: Our findings indicate that NO_2 exposure is an independent cause of increased mortality risk, not simply a surrogate for $PM_{2.5}$ exposure.

KEYWORDS: air pollution, mortality, causal inference, COVID-19

O-OP-254 COVID-19 national lockdown in morocco: Impacts on air quality andpublic health

Kenza Khomsi[1,2], Houda Najmi[1], Hassan Amghar[1], Youssef Chelhaoui[1], Zineb Souhaili[2]
[1]General Directorate of Meteorology, Casablanca, Morocco, [2]Faculty of Medicine and Pharmacy, Hassan II University, Casablanca, Morocco

BACKGROUND AND AIM: On the 20th April 2020, the end of the first strict lockdown in Morocco, 2403410 cases of corona Virus were confirmed globally. The number of Morocco confirmed cases attended 2990 and 143 deaths were announced. All avoidable activities in the country were prohibited since the kingdom announced the general lockdown on 20th March 2020. This study aims at comparing air quality in Casablanca and Marrakech from Morocco, before the pandemic and during the confinement to show whether COVID-19 compelled lockdown may have saved lives by restraining air pollution than by preventing infection.

METHODS: We used the difference-in-difference and the Theil and Sen non-parametric approaches for univariate time series. We defined the before quarantine period as between the 16th February and the 19th March and the during quarantine as between the 20th March and 20th April. We assessed changes in air quality during vs. before the quarantine period in 2020 and compared these with corresponding changes in the same lunar calendar periods in 2016-2019. We calculated the avoided cause-specific mortality attributable to the decreases in NO2 and PM2.5 based on the available concentration-response functions.

RESULTS: We found that NO2 dropped by -12 µg/m³ in Casablanca and -7 µg/m³ in Marrakech. PM2·5 dropped by -18 µg/m³ in Casablanca and -14 µg/m³ in Marrakech. CO dropped by -0.04 mg/m³ in Casablanca and -0.12 mg/m³ in Marrakech. This air pollution reduction had created human health benefits and had reduced mortality and saved lives mainly from cardiovascular diseases.

CONCLUSIONS: Our results are in complete agreement with the worldwide studies. They should be interpreted carefully because of the potential common impacts NO2 and PM2·5 may have on health. Further investigation may be undertaken to explore the reduction in the concentrations of industry-related pollutants.

O-OP-255 Urban greenspace and risk of mental illness following the COVID-19 lockdown – Results from the COVICAT-study, Spain

Matilda van den Bosch[1], Gemma Castaño-Vinyals[1], Ana Espinosa[1], Payam Dadvand[1], Kurt Straif[1], Judith Garcia-Aymerich[1], Rafael de Cid[2], Manolis Kogevinas[1], Ximena Goldberg[1]

[1]Barcelona Institute for Global Health, Barcelona, Spain, [2]GCAT laboratory, Germans Trias i Pujol Research Institute, Barcelona, Spain

BACKGROUND AND AIM: The COVID-19 pandemic has taken a substantial toll on mental health. Greenspace exposure is generally found to prevent mental illness, but the protective impact during the COVID-19 pandemic is insufficiently understood. We analysed if low exposure to and lack of greenspace views from home were associated with increased risk of depression following the COVID-19 lockdown.

METHODS: The COVICAT Study is a population cohort of over 10,087 individuals from northern Spain (Catalunya) who were recruited pre-pandemic and re-contacted after the confinement in 2020. The depression subscale (HADD) of the Hospital Anxiety and Depression Scale was used to measure mental health. Greenspace exposures were assessed by self-reports on views from home and by percentage of greenspace in residential buffer zones of 300, 500, and 1,000 m. We used log-binominal regression models to test the association between lack of greenspace views or low percentage and risk of moderate and severe depression, controlling for individual- and area-level covariates.

RESULTS: In our sample, 5.9% reported severe and 21.4% moderate depression. We found an increased risk of moderate (RR=1.37; 95%CI=1.22, 1.53) and severe depression (RR= 2.46, 95%CI=1.71, 3.56) among participants with lack of greenspace views from home. Low neighbourhood percentage of greenspace was related to higher risk of moderate depression in 300m and 1,000m buffer zones (RR=1.16; 95%CI=1.05, 1.28 and RR=1.14; 95%CI=1.03, 1.27 respectively), but no association was found to severe depression.

CONCLUSIONS: Our study suggests that, in particular, lack of greenspace views but also low percentage of greenspace, may increase risk of depression during the COVID-19 pandemic. This may be due to missing out on greenspaces' stress reducing impact, which can contribute to improved coping with challenging life situations, such as a lockdown. The findings should be considered in urban planning to support coping strategies during future pandemics.

KEYWORDS: Greenspace, COVID-19, depression

O-OP-256 Changes in health risks of pest control and disinfection workers after the COVID-19 outbreak in South Korea

Yun-Hee Choi[1,2], Lita Kim[1,2], Sang ji Lee[1], Da-An Huh[3], Yun-Hee Choi[1,2,4]
[1]Department of Health and Safety Convergence Science, Korea University, Seoul, Republic of Korea, [2]BK21 FOUR R & E Center for Learning Health System, Korea University, Seoul, Republic of Korea, [3]Institute of Health Sciences, Korea University, Seoul, Republic of Korea, [4]Department of Health and Environmental Science, Korea University, Seoul, Republic of Korea

As the exposure patterns of pest control and disinfection workers have changed with the outbreak of COVID-19, the health risks of the workers have also changed. However, no studies have confirmed the health risks of pest control and disinfection workers before and after the COVID-19 outbreak. This study aims to identify the exposure patterns of biocides used by pest control and disinfection workers and compare the risks before and after the COVID-19 outbreak. A survey was conducted to evaluate the chemical exposure and clinical symptoms of workers before and after the COVID-19 outbreak. The health risks were compared by calculating the risks according to inhalation and dermal exposures by work type pre- and post-outbreak of COVID-19. Compared to before the COVID-19 outbreak, the non-carcinogenic and carcinogenic risks of all chemical substances during inhalation and dermal exposure have increased. In the worst exposure scenario (95th quartile), ADBAC/BKC (C12-16) had a hazard quotient of less than 1 before the onset of COVID-19, but greater than 1 after the outbreak of COVID-19 in both inhalation and dermal exposure. The carcinogenic risk of dichlorvos for inhalation and dermal exposure was above acceptable levels both before and after the outbreak and increased further after the outbreak. In addition, the number of workers who experienced clinical symptoms increased after the outbreak compared to before ($p<0.05$), with the most common symptoms in the order of muscle lethargy, Skin and face stinging, breath shortness, and neck pain. This study suggests that exposure patterns of pest control and disinfection workers have changed and that the health risks by chemical exposure have increased compared to before the COVID-19 outbreak.

KEYWORDS: health risk assessment, COVID-19, pest control, disinfection, occupational exposure

ORAL PRESENTATIONS SESSION 47: Water quality and health

O-OP-257 Socioeconomic vulnerability and public water arsenic concentrations across the US

Anne Nigra[1], Adina Cazacu-De Luca[1], Ana Navas-Acien[1]
[1]*Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA*

BACKGROUND AND AIM: Inorganic arsenic is known human carcinogen and is routinely detected in community water systems (CWSs) across the US. Significant inequalities in CWS arsenic concentrations exist across broad sociodemographic subgroups of the US population. We evaluated the county-level association between socioeconomic vulnerability and CWS arsenic concentrations across the conterminous US.

METHODS: We evaluated previously developed, population-weighted, county-level CWS arsenic concentrations (2006-2011), the Centers for Disease Control and Prevention's county-level socioeconomic vulnerability score (range: 0-1), median household income, and the proportion of adults with a high school diploma for 2,604 conterminous US counties. We used spatial lag models and evaluated the adjusted geometric mean ratio (GMR) of county-level CWS arsenic concentrations per interquartile range increase in socioeconomic vulnerability domain and in flexible spline models. We also stratified by region and by United States Department of Agriculture Rural-Urban Continuum Codes to assess potential effect measure modification by region and rurality.

RESULTS: Associations between socioeconomic vulnerability and CWS arsenic were modified by region, rurality, and socioeconomic domain. The fully adjusted GMR (95% CIs) of CWS arsenic per interquartile range increase in the proportion of adults with a high school education was 0.83 (0.71, 0.98) or 17% in the Southwest, 0.82 (0.71, 0.94) or 18% in the Eastern Midwest, and 0.65 (0.31, 1.36) or 35% in New England. Higher overall socioeconomic vulnerability was significantly associated with lower CWS arsenic, but only in counties in the Central Midwest and those with total populations less than 20,000.

CONCLUSIONS: Higher educational attainment was associated with lower CWS arsenic in the Southwest, Eastern Midwest, and New England regions. Findings likely reflect regional/local differences in both socioeconomic/socio-cultural context and regulated drinking water contaminant concentrations. Region-specific analyses at finer geographic resolutions evaluating components of overall socioeconomic vulnerability are needed to adequately characterize the association.

O-OP-258 Are current drinking water standards for nitrate sufficient for preventing adverse birth outcomes and childhood cancer– Findings from a cohort of over one million children in Denmark

Leslie Stayner[1], Anja Søndergaard Jensen[2], Betina Trabjerg[3], Marie Pedersen[4], Jørn Olsen[5], Birgitte Hansen[6], Jörg Schullehner[7,8], Carsten Pedersen[8], Torben Sigsgaard[7,8]

[1]University of Illinois at Chicago, Chicago, USA, [2]Centre for Integrated Register-based Research, Aarhus University, Aarhus, Denmark, [3]Department of Economics and Business Economics, National Centre for Register-Based Research (NCRR), Aarhus University, Aarhus, Denmark, [4]Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [5]Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus, Denmark, [6]Department of Groundwater and Quaternary Geology Mapping, Geological Survey of Denmark and Greenland, Aarhus, Denmark, [7]Department of Public Health, Aarhus University, Aarhus, Denmark, [8]Department of Economics and Business Economics, National Centre for Register-Based Research (NCRR), Aarhus, Denmark

BACKGROUND AND AIM: Current standards for nitrate in drinking water in EU and the US are based on preventing methemoglobinemia a condition that occurs at high levels of exposure. There is growing evidence that exposure to nitrate in water is associated with adverse birth outcomes. Our aim is to summarize the findings from our nationwide studies of the population exposed to levels below the current standards in Denmark.

METHODS: We studied a cohort of all singletons liveborn to Danish-born parents from 1991–2013 (N=1,018,914). Data on birth weight, head circumference, body length, gestational age, birth defects and childhood cancer were obtained from Danish registers. Nitrate levels were estimated at the individual residential level. The analyses presented here were restricted to women who had pregnancy average exposures during their pregnancy that were lower than the current EU limit (50 mg/L N03).

RESULTS: Prenatal exposure to nitrate was found to be significantly associated with a decrease in birth weight ($p<0.001$), body length ($p<0.01$), and increased risk of small-weight-for-gestational age ($p=0.002$), all markers of fetal growth restriction. However, we did not observe evidence of an effect on head circumference or term low birth weight. Significant evidence of an exposure-response relationship was also observed for preterm births ($p<0.04$), eye cataracts ($p=0.004$), and for nervous system ($p=0.003$) and ear, face and neck ($p=0.01$) birth defects among women <25 years of age. A trend was not observed for childhood cancers, but a significant increase in central nervous system cancers was observed for the highest exposure group (>25 mg/L) with which was strongest for the preconception period (OR=1.82, 95%CI:1.09 to 3.04).

CONCLUSIONS: Our findings along with the results from other recent studies suggest that nitrate exposure from drinking water is associated with adverse birth outcomes and childhood CNS cancers at currently allowable levels.

KEYWORDS: nitrate, birth outcomes

O-OP-259 Private drinking water wells in Denmark: monitoring and predicting nitrate levels

Jörg Schullehner[1,2], Denitza Voutchkova[2], Julian Koch[2], Birgitte Hansen[2]
[1]Department of Public Health, Aarhus University, Aarhus, Denmark, [2]Geological Survey of Denmark and Greenland, Aarhus, Denmark

BACKGROUND AND AIM: Private wells are often not or poorly regulated while simultaneously supplying inferior drinking water quality. Therefore, exposure assessments of private well users are crucial when identifying highly-exposed groups. Here, we explore the available monitoring data for private wells in Denmark focusing on nitrate and apply a machine-learning approach to predict nitrate levels in unmeasured wells.

METHODS: We accessed information on private well location, abstraction depth, aquifer type, and, when available, nitrate samples, from the national monitoring database Jupiter. We used a gradient boosting decision tree algorithm to predict nitrate levels in unmeasured wells based on a suite of explanatory variables related to soil texture, geology, topography characteristics, water body proximity, land cover, redox conditions, nitrate leaching and hydrological simulations. We stratified our prediction model by abstraction depth and used an output resolution of 100x100 m.

RESULTS: The majority of private wells used aquifers in Quaternary sandy deposits, followed by carbonate fractured rocks and pre-Quaternary sandy deposits with relative shallow depths (median ± median absolute deviation: 24.5 ±11.1 m). of 49,821 private wells in Jupiter, 59% had at least one nitrate sample registered. for 28%, it was possible to establish a link to abstraction depth. In measured private wells, 60% had a significant nitrate contamination (>3 mg/L). The most important explanatory variables in the prediction model were georegion, topology, thickness of aquifer and Quaternary layer, and depth to redox interface. In unmeasured private wells, 64% were predicted to have nitrate levels >3 mg/L. We created probability maps stratified by abstraction depth layers.

CONCLUSIONS: Nitrate in Danish private wells is poorly monitored, but machine learning models can help predict levels, allowing exposure assessments of this highly-exposed group in epidemiological studies on health effects of drinking water nitrate.

O-OP-260 Inorganic arsenic in drinking water and breast cancer risk: a case-control study in Northern Chile

Estela Blanco[1], Craig Steinmaus, Catterina Ferreccio
[1]*Universidad Catolica, Chile, SANTIAGO, Chile*

BACKGROUND AND AIM: Exposure to arsenic in drinking water is a well-established cause of lung, bladder and skin cancer, however the relation between arsenic and breast cancer is less clear. Between 2014-2018, we conducted a breast cancer incident case-control study in Northern Chile, where from 1950-1970 the population was exposed to high levels of arsenic in drinking water (up to 900 µg/l).

METHODS: We analyzed 703 breast cancer cases and 491 population-based female controls with data collected on lifetime exposure to As and potential confounders. Using logistic regression, we tested whether exposure to higher levels of arsenic in drinking water related to differential risk of breast cancer. Initial causal models adjusted for age and education. Additional models included other known risk factors for breast cancer and several sensitivity analyses evaluated different exposure windows.

RESULTS: Both cases and controls were around 58 years of age and about half had finished high school or had additional studies. Cases, compared to controls, were exposed to lower median concentrations of arsenic (µg/L): 60 [interquartile range (IQR), 11-636] versus 70 (40-299). Adjusted odds ratios for category of highest single-year arsenic concentrations in water (<49, 50-199, 200-799, and ≥ 800 µg/L) were 1.00, 0.70 [95% confidence interval (CI), 0.52-0.94], 0.71 (0.51-1.01), and 1.02 (0.72-1.44), respectively. Results were similar after various adjustments, using different metrics of arsenic exposure, and windows of exposure.

CONCLUSIONS: Compared with women with the lowest levels of exposure to arsenic in drinking water, those with higher (up to 799 µg/L) arsenic exposure, had lower odds of breast cancer, in accordance with evidence implying a potentially therapeutic effect of arsenic exposure. Differential arsenic sensitivity of breast cancer cell types may explain differences in the direction of the effect and lack of precision for some exposure groups.

KEYWORDS: arsenic, breast cancer, drinking water

O-OP-261 Microplastic Pollution in Two Urban Rivers and an Associated Water Treatment Plant in Bangladesh

Mahfuza Mirza Sadia[1], Anika Nawar Ishika[1], Rabeya Miazi[1], Farzana Yasmin[2], Saif Shahrukh[3], Gazi Nurun Nahar Sultana[2], Mohammad Enayet Hossain[1]

[1]Department of Soil, Water and Environment, University of Dhaka, Dhaka, Bangladesh, [2]Centre for Advanced Research in Sciences, University of Dhaka, Dhaka, Bangladesh, [3]Bangladesh Council of Scientific and Industrial Research, Dhaka, Bangladesh

BACKGROUND AND AIM: Microplastics in freshwater environments are less well understood than in marine environments. The present study is the first of its kind in Bangladesh which was aimed at providing the first description of the abundance and distribution of microplastics in two rivers, namely the Buriganga and Shitalakhya. The study also examined the abundance of microplastics in a drinking water plant, which receives water from these two rivers.

METHODS: Twelve (12) water samples were collected from two rivers and the water treatment plant. The samples were first treated with the wet peroxidation method and then characterized and quantified according to color, shape, and size using a light microscope and a scanning electron microscope (SEM). Several representative microplastics were also isolated for polymer identification using the Attenuated Total Reflectance–Fourier Transform Infrared (ATR–FTIR) spectroscopy.

RESULTS: The average abundance of microplastic was found to be 11,639 particles/m3 in the collected water samples. Over 90% of them were found to be less than 0.5 mm. The most frequent types of microplastic were microfilm (70.94%), followed by microfibre (15.76%) and microfragment (2.95%) and the dominant color was transparent (68.47%). The common polymer types were polyethylene terephthalate, polypropylene, polyethylene, polyvinyl chloride, and polystyrene. Interestingly, there were no significant ($p>0.05$) differences between the river water and the water sampled from the inlet and outlet of the water treatment plant vis-à-vis microplastic abundance.

CONCLUSIONS: This study reveals the contamination levels and characteristics of microplastics in the Buriganga and Shitalakhya rivers. The study also provides insights into the microplastic pollution in water treatment plants in the country. Further research is needed to find ways to reduce the abundance in freshwater niches and to develop technologies dedicated to microplastic removal in the water treatment plant.

O-SY-132 Association of arsenic and uranium concentrations in private wells and community water systems with urinary biomarkers in American Indian adults: The Strong Heart Family Study

Maya Spaur[1], Melissa Lombard[2], Wil Lieberman-Cribbin[1], Carolyn Hayek[3], Kevin Patterson[1], Benjamin Bostick[4], Ana Navas-Acien[1], Anne Nigra[1]

[1]Columbia University Mailman School of Public Health, New York, USA, [2]New England Water Science Center, USA Geological Survey, Pembroke, USA, [3]Columbia Water Center, New York, USA, [4]Lamont-Doherty Earth Observatory of Columbia University, Palisades, USA

BACKGROUND AND AIM: Chronic exposure to inorganic arsenic (iAs) and uranium (U) has been associated with adverse health risks. High As and U levels occur in unregulated private wells and regulated community water systems (CWSs) serving tribal communities in the Southwest, Central Midwest, and Northern Plains. Our objective was to examine the contribution of CWS and private well As and U concentrations to urinary biomarkers of total internal dose in American Indian adults in the Strong Heart Family Study (SHFS).

METHODS: 2,688 SHFS participants had dietary recall information and spot urine concentrations of U and iAs, estimated as the sum of inorganic and methylated species, collected between 2001-2003. We assigned participants zip code level area- and population- weighted CWS and private well As and U estimates based on previously developed nationwide estimates derived from US Environmental Protection Agency and US Geological Survey datasets, respectively. We used generalized linear mixed models to evaluate the geometric mean ratio (GMR) of urinary iAs or U concentrations per log unit increase in water As or U, respectively. Models were adjusted for sex, age, reported intake of As- and U- containing foods, and smoking status. Random effects were applied for zip code and family group.

RESULTS: In fully adjusted models, the GMR of estimated iAs and U per log µg/L increase in CWS As and U was 1.11 (1.08-1.14) and 1.26 (1.15-1.39), respectively. The fully adjusted GMR of estimated iAs per unit (100%) increase in the probability of private well As >10 µg/L was 1.81 (1.35-2.41). Per log µg/L increase in mean private well U, the GMR of urinary U was 1.04 (0.91-1.19).

CONCLUSIONS: Both regulated CWSs and unregulated private wells are important sources of iAs and U exposure for tribal communities in the SHFS, as reflected in urinary biomarkers.

KEYWORDS: arsenic, uranium, environmental epidemiology

O-OP-054 Air Pollution, Climate Conditions and Risk of Psychotic Hospitalization in U.S. Residents

Xinye Qiu[1], Yaguang Wei[1], Marc Weisskopf[1], Avron Spiro[2], Liuhua Shi[3], Edgar Castro[1], Brent Coull[1], Petros Koutrakis[1], Joel Schwartz[1]

[1]Harvard University, Cambridge, USA, [2] Boston University, Boston, USA, [3]Emory University, Atlanta, USA

OBJECTIVE: The physical environmental risk factors for psychotic disorders are poorly understood. This study aimed to examine the associations between residential exposure to ambient air pollution, key climate measures and risk of psychotic hospitalization in the U.S. general population and uncover potential disparities by demographic and community factors.

METHODS: Using data from Health Cost and Utilization Project (HCUP) State Inpatient Databases (SIDs), we applied zero-inflated negative binomial regression to obtain the relative risks of psychotic hospitalization associated with increases in residential exposure to ambient air pollution (fine particulate matter, PM2.5; nitrogen dioxide, NO2), temperature and cumulative precipitation. All the exposures were aggregated to ZIP code level, and later merged with admission data by ZIP code of residence and calendar year. The analysis covered all-age residents in eight U.S. states over the period of 2002 – 2016. We additionally investigated modification by age, sex, area-level poverty, percent of blacks and Hispanics via stratified models.

RESULTS: Over the study period and among the covered areas, we identified 1,211,100 psychotic admissions. for each interquartile (IQR) increase in exposure to PM2.5 and NO2, we observed a relative risk (RR) of 1.11 (95% CI = 1.09, 1.13) and 1.27 (95% CI = 1.24, 1.31), respectively. for each 1 ºC increase of temperature, the RR was 1.03 (95% CI = 1.03, 1.04). We did not find significant associations with precipitation in the total population. Older age residents (>= 30 yrs.) were more sensitive to PM2.5 and ambient temperature. Population living in economically disadvantaged areas were more affected by air pollution. Area percent of Hispanics level modified the associations in different directions depending on the exposure.

CONCLUSIONS: The study findings suggest that living in areas with higher levels of air pollutants and ambient temperature could contribute to additional risk of psychotic hospitalization in a U.S. general population.

ORAL PRESENTATIONS SESSION 48: Health consequences of extreme events

O-OP-263 Heat-related deaths and ambulance transports after typhoon-triggered power outages: a quasi-experimental study in the metropolitan areas of Japan

Lisa Yamasaki[1,2], Takuma Kamada[3], Chris Fook Sheng Ng[1], Yoonhee Kim[1], Yuya Takane[4], Ko Nakajima[4], Yasushi Honda[5], Kazuki Yamaguchi[6], Kazutaka Oka[5], Masahiro Hashizume[1]

[1]The University of Tokyo, Tokyo, Japan, [2]Nagasaki University, Nagasaki, Japan, [3]Osaka University, Osaka, Japan, [4]National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan, [5]National Institute for Environmental Studies, Tsukuba, Japan, [6]Tokyo Electric Power Company Holdings, Inc., Tokyo, Japan

BACKGROUND AND AIM: Air conditioning use is an effective adaptation measure to prevent heat-related health problems. Any electricity supply disruptions can expose a population to non-optimal temperatures with ill effects. This study examined the mortality and morbidity impacts of sudden disruption to electricity caused by a typhoon Faxai that affected the metropolitan areas of Japan on 9th September 2019.

METHODS: We collected data on the daily counts of heat-related illness ambulance transport (HIAT) and all-cause deaths in 7 prefectures from July to September 2019. We used the difference-in-differences method to estimate the average treatment effect on the treated of blackout, and effect modification analysis to examine the association of heat with daily HIAT and all-cause deaths by different intensities of electricity reduction using electricity consumption data. Possible nonlinear and delayed effects of temperatures were accounted for using the distributed lag non-linear model with quasi-Poisson regression.

RESULTS: A total of 14,921 HIAT and 74,064 all-cause deaths were recorded during the study period. In the first three days (9th-11th September) of the blackout, the incidence rate ratio between the blackout and non-blackout areas for HIAT and all-cause deaths were 2.5 (95% confidence interval (CI): 1.8, 3.3) and 1.1 (95% CI: 1.0, 1.2), respectively. Comparing 20% reduction of electricity to no reduction, the ratio of relative risks for heat exposure (95th vs. 50th percentile temperature) was 2.3 (95% CI: 1.4, 3.8) for HIAT and 1.1 (95% CI: 0.9, 1.3) for all-cause deaths.

CONCLUSIONS: Typhoon-triggered reduction of electricity by 20% was associated with two times higher risk of HIAT attributable to summer heat in the metropolitan areas of Japan, while there was no evidence for all-cause deaths. Our findings suggest that emergency preparedness against blackouts in hot temperature must be activated in the face of climate change.

O-OP-265 Long-term Drought and Diarrhea among Children under Five and the Role of Water, Sanitation, and Hygiene Practices

Pin Wang[1,2], Ernest Asare[3], Virginia Pitzer[3], Robert Dubrow[1,2], Kai Chen[1,2]
[1]Department of Environmental Health Sciences, Yale School of Public Health, New Haven, USA, [2]Yale Center on Climate Change and Health, Yale School of Public Health, New Haven, USA, [3]Department of Epidemiology of Microbial Diseases and the Public Health Modeling Unit, Yale School of Public Health, New Haven, USA

BACKGROUND AND AIM: Climate change is projected to intensify drought conditions, which may increase the risk of diarrheal diseases in children. However, evidence on the association between drought and diarrhea risk is scarce. This study aimed to quantify this association among children under five in 51 low- and middle-income countries (LMICs).

METHODS: Data on childhood diarrhea during 1990-2019 were obtained from the Demographic and Health Surveys program. Drought was represented by the 6-to-24-month scale Standardized Precipitation Evapotranspiration Index at ~9km resolution and was further dichotomized into mild or severe drought. Log-binomial generalized linear mixed models with random effects for survey cluster were constructed to examine the association, adjusting for sociodemographic characteristics. The mediating and interacting effects of water, sanitation, and hygiene-related (WASH) practices were evaluated.

RESULTS: Exposure to 6-month mild or severe drought was associated with an increased diarrhea risk of 5% (95% confidence interval 3%–7%) or 8% (5%–11%), respectively. The strongest association for severe drought was observed at the timescale of 6 months, whereas the association for mild drought exhibited a light, graded increase across 6 to 24 month timescales. WASH mediated 11.6% or 19.5% of the association with 6-month mild or severe drought, respectively. The association was stronger among children living in a household that needed longer time to collect water or had no access to water or soap/detergent for handwashing. The association for 24-month drought was strong in dry zones but weak or null in tropical or temperate zones, whereas for 6-month drought the association was only observed in tropical or temperate zones.

CONCLUSIONS: We observed associations between exposure to long-term drought and elevated diarrhea risk among children under five in LMICs. Our results suggest that the risk could be reduced through improved WASH practices.

O-OP-266 Wildfire Smoke Exposure During Pregnancy and Preterm Birth in California

Sally Picciotto[1], Rachel Sklar[2], ShihMing Huang[3], Fred Lurmann[3], Nathan Pavlovic[3], Dana Goin[2], Elisabeth Noth[1], Rachel Morello-Frosch[1], Amy Padula[2]

[1]University of California Berkeley, Berkeley, USA, [2]University of California San Francisco, San Francisco, USA, [3]Sonoma Technology Inc., Petaluma, USA

BACKGROUND AND AIM: Owing to climate change and fire suppression policy, wildfires in the Western United States are a significant source of air pollution that threatens to reverse decades of progress in air pollution reduction; effects of wildfires on preterm birth (PTB) are not well understood. We assessed associations between prenatal exposure to wildland fire (wildfire and prescribed fire) smoke and risk of PTB in California.

METHODS: The population included all live singleton births in California, 2007-2015. PTB was defined as gestational age <37 weeks. We assigned wildland fire smoke exposure to geocoded maternal residence at birth with weekly average concentrations of particulate matter ≤2.5 microns attributable to fires from USEPA's Community Multiscale Air Quality Model (fire PM2.5) and smoke frequencies (smoke days) from National Oceanic and Atmospheric Administration's Hazard Mapping System. We used logistic regression to estimate odds ratios (OR) for PTB associated with exposures in the final 6 weeks of pregnancy and Cox proportional hazard models to estimate hazard ratios (HR) for PTB in relation to weekly exposures. Models adjusted for maternal age, education, race/ethnicity, season, medical insurance, and smoking.

RESULTS: Our study included 3,342,267 births. A one-smoke day increase in any of the final 6 weeks of the pregnancy was associated with increased odds of PTB, ranging from OR=1.01 (95%CI:1.01-1.02) in the final week of pregnancy to OR=1.03 (95%CI:1.02-1.03) 5 weeks before birth. A 10µg/m3 increase in fire PM2.5 in the final 6 weeks was associated with ORs ~1.04 (95%CIs covered 1.02-1.06). In survival analyses, HR=1.01 (95%CI:1.01-1.02) for a one-day increase in smoke frequency and HR=1.03 (95%CI:1.02-1.04) for a 10µg/m3 increase in fire PM2.5.
CONCLUSION: Wildland fire smoke is modestly associated with PTB. Results can inform efforts to slow climate change, manage forests, and reduce wildfire smoke exposure to pregnant people.

KEYWORDS: wildfire; pregnancy; preterm birth; climate; air pollution

O-OP-267 The Effects of Hurricane Matthew on Racial Disparities in Birth Outcomes

Zachary McCann[1], Stefniae Ebelt[1], Noah Scovronick[1], Rohan D'Souza[1], Howard H. Chang[1]
[1]*Emory University, Atlanta, USA*

BACKGROUND AND AIM: Stressful events during pregnancy can have negative effects on birth outcomes. Further, there are well documented racial disparities in birth outcomes in the United States. It is likely the case that climate-sensitive stressors, like exposure to severe hurricane impact may worsen birth outcomes. We explore the relationship between hurricane exposure and adverse birth outcomes, specifically preterm births (PTBs) and low-weight births (LWBs), using vital data from Florida before and after Hurricane Matthew. We establish hurricanes as a potential mechanism in exacerbating racial disparities in birth outcomes.

METHODS: We combined vital records in Florida for the period between January 2015 and February 2017, county-level demographic data, and disaster declarations to create a novel longitudinal dataset. Difference-in-difference models compare weekly rates of LWBs and PTBs in counties that did not receive a FEMA disaster resolution to counties that received public assistance only (PA) and public and individual assistance. Models were run for the full cohort and then stratified by race.

RESULTS: Hurricane exposure was not associated with rates of LWBs or PTBs in the overall cohort. However, black mothers exposed to Hurricane Matthew in counties that received PA after Hurricane Matthew experienced higher rates of LWBs (IRR = 2.64, 95% CI = 1.09, 6.37) and PTBs (IRR = 2.25, 95% CI = 1.02, 4.96) in the week following the storm. Compared to unexposed Hispanics mothers, Hispanic mothers in counties that received public assistance only experienced decreased rates of PTBs (IRR = 0.33, 95% CI = 0.11, 0.98) immediately after Hurricane Matthew followed by a faster increase.
CONCLUSION: Our study suggests that hurricane exposure may be an important driver of short-term racial disparities in birth outcomes. Future research should continue to investigate the intersection of climate-sensitive hazards and birth outcomes disparities.

KEYWORDS: Hurricane, Race, Birth Outcomes, Health Disparities

O-SY-125 Climate change and health system preparedness: it never rains but it pours

Nick Julien Baumgart[1], Cato Dambre[1,2], Sarah Feron[1], Arianna Rotulo[1,3], Valentina Gallo[1]
[1]University of Groningen, Leeuwarden, Netherlands, [2]University of Ghent, Ghent, Belgium, [3]Queen Mary University of London, London, UK

BACKGROUND AND AIM: Climate change is posing an increased burden on human health through both its long term consequences and its acute manifestations. National health systems need to increase their preparedness to these consequences. The geographical distribution of the manifestation of climate change is thought to widen inequalities in health system quality and accessibility already present across countries. The aim of this research is to assess the association between climate change impact and health system preparedness at country level, worldwide.

METHODS: All data was extracted from publicly available sources. Impact of climate change was measured with two variables: the Global Climate Risk Index (GCRI), which measures exposure and vulnerability of a country connected to weather-related loss events that have a socio-economic impact, and the Notre-Dame Global Adaptation Initiative index (ND-GAIN), measuring wider vulnerability to climate change. To assess healthcare system preparedness the Self Party Assessment Report Score (SPAR) was used, which measures healthcare system capacity to prepare for public health risks and emergencies. Regression models were adjusted for gross domestic product (GDP) per capita), Human Development Index, Peace Index, age structure of the population.

RESULTS: Preliminary results suggest a negative association between GCRI and SPAR suggesting that health systems worldwide are adapting well their preparedness to climate-related vulnerability as the preparedness was highest in those countries more frequently affected by climate-related events. A full analysis and interpretation of data will be presented.
CONCLUSION: Climate change consequence on human health are widening inequalities across countries. Lack of health system preparedness might contribute to the further widening of such inequalities and should be tackled by the international community and the World Health Organisation as matter of priority. This research will provide some important data to map existing resources and threats, and to inform public health priorities.

ORAL PRESENTATIONS SESSION 49: Impacts of exposure to chemicals on maternal and child health

O-OP-269 Variability of per- and polyfluoroalkyl substances concentrations among pregnant African American women and newborns

Youran Tan[1], Anne L. Dunlop[2], Dana Barr[1], Stephanie M. Eick[1], Morgan Robinson[3], Kurunthachalam Kannan[3], Kaitlin Taibl[1], Che-Jung Chang[4], Carmen Marsit[1], P. Barry Ryan[1], Donghai Liang[1]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Department of Gynecology and Obstetrics, School of Medicine, Emory University, Atlanta, USA, [3]Departments of Pediatrics and Environmental Medicine, New York University School of Medicine, New York, USA, [4]National Institute of Environmental Health Sciences (NIEHS), Chapel Hill, USA

BACKGROUND AND AIM: Longitudinal trends in PFAS levels across pregnancy have not been thoroughly examined, despite emerging evidence linking prenatal PFAS exposures with adverse birth outcomes. We sought to characterize variability of longitudinal PFAS concentrations during pregnancy and to examine maternal-fetal transfer rate of PFAS among African Americans (AA).

METHODS: We quantified serum concentrations of four PFAS in 376 participants and additional eight PFAS in 301 participants during early (8-14 weeks) and late (24-30 weeks) gestation, as well as levels of four PFAS in dried blood spots (DBS) from 199 paired newborns in the Atlanta AA Maternal-Child cohort (2014-2018). We characterized the variability of PFAS levels across gestation using intraclass correlation coefficients (ICC) and transfer rate. Multivariable linear regression models were fit to assess how maternal early or late serum PFAS concentrations predict newborn DBS PFAS levels.

RESULTS: Perfluorohexane sulfonic acid (PFHxS), perfluorooctane sulfonic acid (PFOS), perfluorooctanoic acid (PFOA), and perfluorononanoic acid (PFNA) were detected in >95% of both maternal and newborn samples, with PFHxS and PFOS having the highest median concentrations. All PFAS median concentrations increased across pregnancy, except for PFOA and N-methyl perfluorooctane sulfonamido acetic acid (NMFOSAA), which decreased. Prenatal PFAS were weakly to moderately correlated with newborn PFAS ($-0.11 < r < 0.54$). Compared to late pregnancy, maternal PFAS in early pregnancy can better predict newborn PFAS while adjusting for covariates. We observed high variability in PFAS levels across pregnancy (ICC: 0.001-0.59), with the greatest change in PFHxS (ICC=0.001). The mean maternal-fetal transfer rate of PFAS decreased with increasing carbon chain length.

CONCLUSIONS: In AA mother-newborn dyads, we found most PFAS concentrations increased across pregnancy, and the magnitude of variability differed by PFAS species. Future studies are needed to understand the within-person variability of PFAS during and after pregnancy in relation to birth outcomes.

KEYWORDS: PFAS; pregnancy; variability; transfer rate.

O-OP-270 Mixtures of persistent and non-persistent chemicals and associations with pregnancy outcomes in the Atlanta African American Maternal Child Cohort

Stephanie Eick[1], Dana Barr[1], Youran Tan[1], Parinya Panuwet[1], Volha Yakimavets[1], Grace Lee[1], P. Barry Ryan[1], Priya D'Souza[1], Anne Dunlop[2], Donghai Liang[1]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Department of Gynecology and Obstetrics, School of Medicine, Emory University, Atlanta, USA

BACKGROUND AND AIM: African Americans (AAs) experience high rates of adverse pregnancy outcomes relative to whites. Differential in utero exposure to environmental chemicals may partially explain these health disparities, as AAs are disproportionately exposed to environmental hazards. Few studies have examined the effects of multiple classes of non-persistant and persistant organic pollutants (POPs) together, which may better reflect real life exposures. Here, we examined the joint exposure effects of multiple POPs and non-POPs on gestational age and birthweight for gestational age z-scores among AAs.

METHODS: POPs and non-POPs were measured in 1st trimester serum or urine samples collected from 102 participants within the Atlanta African American Maternal-Child cohort. POPs included four per-and polyfluoroalkyl substances (PFOA, PFOS, PFHxS, PFNA), two polybrominated diphenyl ethers (PBDE-47, BDE-99), and two organochlorine insecticides (HCB, ppDDE), while non-POPs included eight urinary phthalates metabolites (MEP, MBP, MiBP, MBzP, MEHP, MEOHP, MEHHP, MECPP) and bisphenol A. Single pollutant associations were estimated using linear regression and mixture associations were estimated using quantile g-computation and Bayesian kernel machine regression (BKMR), adjusting for confounding factors and covariates.

RESULTS: An interquartile range increase in PFNA (β=-0.11, 95% confidence interval [CI]=-0.22, 0.00), BDE-47 (β=-0.19, 95% CI=-0.35, -0.04), and HCB (β=-0.17, 95% CI=-0.34, 0.00) was associated with lower birthweight z-scores in adjusted single pollutant models. Using quantile g-computation, the point estimate of effect for increasing all POPs and non-POPs by one quantile suggested a negative effect on gestational age and birthweight z-scores, although confidence intervals included the null. BKMR similarly showed that increasing all exposures in the mixture was associated with a modest decrease in gestational age and birthweight z-scores.
DISCUSSION: Using targeted exposure assessment and mixture analysis, we found that prenatal exposure to multiple classes of POPs and non-POPs may be associated with lower birth weight and gestational age at birth.

O-OP-271 Mixture analysis of air pollution and endocrine disrupting chemicals in relation to Vitamin D concentrations in pregnancy

Kimberly Berger[1], Victor Poon[2], Marty Kharrazi[1], Darryl Eyles[3], Kristen Lyall[4], Heather E. Volk[5], Lisa A. Croen[6], Gayle Windham[7], Michelle Pearl[7]

[1]Sequoia Foundation, Berkeley, USA, [2]Genentech, South San Francisco, USA, [3]Queensland Brain Institute, University of Queensland, Brisbane, Australia, [4]A.J. Drexel Autism Institute, Drexel University, Philadelphia, USA, [5]Department of Mental Health, Johns Hopkins University, Baltimore, USA, [6]Division of Research, Kaiser Permanente Northern California, Oakland, USA, [7]Environmental Health Investigations Branch, California Department of Public Health, Richmond, USA

BACKGROUND AND AIM: Over two-thirds of pregnant women in the U.S. have insufficient Vitamin D, which can adversely impact fetal health. Several environmental pollutants may affect Vitamin D concentrations, but they have not been examined as mixtures.

METHODS: We analyzed data from 336 general population controls from the case-control Early Markers for Autism study of children born in Southern California in 2000-2003. Maternal serum was assayed for Vitamin D and environmental chemicals; eleven polychlorinated biphenyls (PCBs), two organochlorine pesticides, six per- and polyfluoroalkyl substances, and six brominated flame retardants (BFRs) were detected in ≥ 60% of specimens and included in the study. Vitamin D was analyzed as a continuous variable, and concentrations <75 nMol/L were dichotomized as insufficient. Particulate matter <=10 microns (PM10) and <=2.5 microns, nitric oxide, nitrogen dioxide, and ozone data for 30 days preceding specimen collection were downloaded from monitoring stations near maternal addresses. Bayesian Kernel Machine Regression and Bayesian Hierarchical Modeling were used to assess an overall mixture effect of all chemicals and associations accounting for co-exposures, respectively, adjusting for demographic characteristics.

RESULTS: In the context of the mixture, PM10, BFRs as a group, and organochlorine trans-nonachlor were associated with lower continuous Vitamin D concentrations, while ozone was associated with higher concentrations. BFRs were also associated with increased odds of insufficient Vitamin D. Higher quantiles of combined exposures were associated with lower mean Vitamin D with wide credible intervals. Several null associations were also found.

CONCLUSIONS: We found associations of environmental pollutants with both lower and higher Vitamin D, though cumulative exposure was associated with lower concentrations. Some findings differed from non-mixture regressions, highlighting the importance of mixtures approaches for estimating real-world associations.

Eyriey, A. Licinia, A. Vellement (Groupe Hospitalier Mutualiste, Grenoble), I. Pin, P. Hoffmann, E. Hullo, C. Llerena (Grenoble University Hospital, La Tronche), X. Morin (Clinique des Cedres, Echirolles), A. Morlot (Clinique Belledonne, Saint-Martin d'Hères), J. Lepeule, S. Lyon-Caen, C. Philippat, I. Pin, J. Quentin, V. Siroux, R. Slama (Inserm, CNRS, University Grenoble Alpes IAB research center), Grenoble, France

BACKGROUND AND AIM: Previously we showed associations between elevated maternal urinary concentrations of triclosan in French pregnant women and increased placental DNA methylation in male fetuses, an effect potentially mediated by placental cell composition. Using a more recent cohort with improved exposure assessment, we aimed to replicate these findings and perform an exploratory study.

METHODS: We assessed triclosan in two pools of 21 urine samples each, collected during the second and third trimester among 395 pregnant women from the SEPAGES cohort. We used Infinium MethylationEPIC arrays to measure DNA methylation in placenta collected at delivery. We used adjusted linear regressions on 500 previously identified candidate CpGs and investigated differentially methylated regions (DMRs) within CpGs overlapping with our previous study. Additionally, we performed an exploratory epigenome-wide association study and DMR analysis on all CpGs available in the assay.

RESULTS: In the sex-stratified replication study, we found 75 triclosan-associated genes (three for males and 72 for females including imprinted FBRSL1, KCNQ1, RHOBTB3, and SMOC1). The effect estimates showed a similar pattern to our previous study for females but not males (correlation coefficient rho = 0.75 and 0.07, respectively), with most associations being positive but weaker. When both sexes were considered, 18 triclosan-associated genes were identified. The correlation with effect estimates of our previous study was 0.6. As previously, we showed that placental heterogeneity could mediate the associations between triclosan concentrations and DNA methylation. In the exploratory analysis, we identified only a few isolated sex-specific associations.

CONCLUSIONS: We observed several positive associations between pregnancy triclosan and placental DNA methylation similarly to our previous study, however most of the associations were identified for females but not males. Our results suggest that pregnancy exposure to triclosan could affect placenta through DNA methylation and that female placentas may be particularly vulnerable.

KEYWORDS: placenta, methylation, pregnancy triclosan, pooled biospecimens

O-OP-273 Relationships between levels of endocrine-disrupting chemicals and immune markers in maternal circulation during mid-pregnancy

Jennifer Ames[1], Stacey Alexeeff[1], Paul Ashwood[2], Kimberly Berger[3], Ghassan Hamra[4], Martin Kharrazi[3], Kristen Lyall[5], Judy Van de Water[6], Heather Volk[4], Lauren Weiss[7], Gayle Windham[3], Robert Yolken[4], Cathleen Yoshida[1], Lisa Croen[1]

[1]Kaiser Permanente Northern California, Oakland, USA, [2]MIND (Medical Investigations of Neurodevelopmental Disorders) Institute, University of California, Davis, Davis, USA, [3]Sequoia Foundation, La Jolla, USA, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, USA, [5]A.J. Drexel Autism Institute, Drexel University, Philadelphia, USA, [6]Department of Public Health Sciences, Division of Rheumatology, Allergy and Clinical Immunology, University of California, Davis, Davis, USA, [7]University of California San Francisco Weill Institute for Neurosciences, San Francisco, USA

BACKGROUND AND AIM: Prenatal exposure to endocrine-disrupting chemicals (EDCs) has been linked to child neurodevelopmental disorders. Maternal immune activation during pregnancy is associated with adverse child developmental outcomes. Whether EDCs influence maternal immune physiology is unclear.

METHODS: We analyzed data from general population controls (n=439) of the Early Markers for Autism (EMA) Study, a case-control study of children born during 2000-2003 in Southern California. Eleven polychlorinated biphenyls (PCBs), 6 brominated flame retardants (BFRs), 2 organochlorine pesticides (OCPs), 6 polyfluoroalkyl substances (PFAS), and 22 cytokines/chemokines were measured in maternal serum samples collected 15-20 weeks into pregnancy. We assessed individual relationships between log-transformed EDC levels and immune markers with spearman correlations and adjusted linear regression models. We further explored overall associations of EDC mixtures with specific immune markers using Bayesian kernel machine regression (BKMR).

RESULTS: After adjustment for false-discovery rate, 28 correlations between EDCs and maternal immune markers were statistically significant (spearman rho ranging from -0.25 to 0.24). These top correlations comprised 14 chemicals (9 PCBs, 3 PFAS, 1 BFR, and 1 OCP), and 8 immune markers. In adjusted linear models, all PCBs were inversely associated with levels of soluble interleukin-2 receptor alpha (sIL-2ra), with PCB99 showing the strongest relationship (adj-β[95%CI]: -0.48[-0.69, -0.27]). In BKMR, increasing all congeners in the PCB mixture from their 50th to their 95th percentiles was associated with decreased sIL-2ra (adj-β[95%CrI]: -0.43[-0.84, -0.02] and PCB99 had the highest relative importance in this mixture. Among other EDCs, p,p´-DDE, an OCP, was inversely associated with multiple markers (IL-12p40, IL-13, and IL-1ra). In contrast, others, such as Et-FOSAA, a PFAS, were positively associated with multiple immune markers, including IL-12p70, GM-CSF, IL-1ra, and IL-10.

CONCLUSIONS: These findings suggest that specific EDCs may affect diverse immune and inflammatory pathways during pregnancy. These relationships may have implications for child development.

KEYWORDS: EDCs; prenatal; immune;

O-OP-274 Urinary phthalate metabolites and phenolics in women of childbearing age and their association with thyroid hormones: a comparison study of fasting status

Inae Lee[1], M.D. Min Joo Kim[2], Sohyeon Choi[3], M.D. Min Kyong Moon[4], M.D. Young Joo Park[5], Jeongim Park[6], Kyungho Choi[7]

[1]Seoul National University, Seoul, Republic of Korea, [2]Seoul National University College of Medicine, Seoul, Republic of Korea, [3]Soonchunhyang University, Asan, Republic of Korea, [4]Seoul National University College of Medicine, Seoul, Republic of Korea, [5]Seoul National University College of Medicine, Seoul, Republic of Korea, [6]Soonchunhyang University, Asan, Republic of Korea, [7]Seoul National University, Seoul, Republic of Korea

BACKGROUND AND AIM: Exposure to parabens and phthalates has been associated with thyroid hormones in humans. Epidemiologic observations, however, are often inconsistent depending on population, probably due to different susceptibility or other factors such as exposure misclassification. Fasting status may influence the urinary levels of many chemicals, especially when their major exposure pathways are related to diet. In the present study, we assessed the associations of urinary phthalate metabolites and phenolics with thyroid hormones in non-pregnant women of child-bearing age in Korea (20-49 years of age), considering fasting status.

METHODS: As a fasting population, we recruited women (n=254) who visited four hospitals after >9 hr of fasting between 2015 and 2016. From the fasting women, we measured phthalate metabolites and parabens in urine, and thyroid hormones in serum. Non-pregnant women of the same age group, who were not asked to fast, was chosen from KoNEHS Cycle 3 (2015-2017) (phthalate metabolites (n=341) and phenolics (n=340)).

RESULTS: Urinary concentrations of MEHHP, MEOHP, MBzP, and BPA were >2 folds higher in the non-fasting women, and those of MeP were higher in the fasting women. Regardless of fasting status, MeP and EtP levels showed significant negative association with both total and free T4. DEHP metabolites also showed negative associations with free T4 but positive associations with total T3. However, associations of MBzP and BPA with thyroid hormones varied by the fasting status, which might be due to the influence of diet on their urinary concentrations.
CONCLUSION: While certain chemicals like EtP and to lesser extent DEHP are known to be delivered through dietary factors, consistent associations with altered thyroid hormones regardless of fasting status are noteworthy.

KEYWORDS: thyroid hormones; fasting; phthalates; phenolics

O-OP-162 Greenspace, air pollution and asthma exacerbations

Jian Cheng, Shilu Tong[1], Zhiwei Xu
[1]*Shanghai Children's Medical Center, Shanghai, China*

OBJECTIVE: Emerging evidence suggests a protective effect of greenspace against the adverse health effects of air pollution but the associations of greenspace and air pollution with asthma remain unclear. This study aimed to examine if greenspace modifies the effect of air pollution on asthma exacerbations.

METHODS: A time-stratified case-crossover design was used to quantify the association between air pollutants (PM2.5, PM10, NO2, and O3) and hospitalizations for asthma in Brisbane from 1st January 2013 to 31st December 2015. The modification effect of suburb-level greenspace on the association between air pollutants and asthma hospitalization was explored with a linear regression model. Greenspace was measured with normalized difference vegetation index (NDVI).

RESULTS: There were 6,226 asthma hospitalizations during the study period, with 3,098 occurring in children aged 0-14 years and 2,945 in males. Each 10μg/m3 increase in the concentrations of NO2 and O3 was associated with 19% (95% confidence interval (CI): 6%, 34%) and 7% (95% CI: 0%, 15%) increased risk of asthma hospitalizations, respectively. Individuals living in suburbs with low NDVI appeared to be more vulnerable to the effect of NO2 on the risk of asthma hospitalizations.

CONCLUSIONS: Our study shows that exposure to NO2 and O3 could increase the risk of asthma exacerbations, and greenspace may ameliorate the adverse effect of NO2 on asthma exacerbations, but there is no apparent modification effect of greenspace on the O3-asthma relationship.

ORAL PRESENTATIONS SESSION 50: Child health and metals exposure

O-OP-275 Prenatal heavy metals exposure and neurodevelopmental disorders in the Boston Birth Cohort: examining risk and protective factors

Giehae Choi[1], Xiaobin Wang[1], Jessie Buckley[2]
[1]*Department of Environmental Health and Engineering, Bloomberg School of Public Health, Johns Hopkins, Baltimore, USA,* [2]*Department of Population, Family and Reproductive Health, Center on the Early Life Origins of Disease, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA*

BACKGROUND AND AIM: Although heavy metals are well-known neurotoxicants, few studies have assessed multiple neurodevelopmental disorders (NDs) or identified vulnerable sub-populations.
Aim: We aimed to assess independent effects of metals on an array of clinician-diagnosed NDs and identify effect modifiers.

METHODS: We measured lead, mercury, cadmium, manganese, and selenium in maternal red blood cells obtained 24-72 hours post-partum, in Boston Birth Cohort born in 2002-2012. We abstracted children's ever diagnoses of attention-deficit hyperactivity disorder (ADHD), autism spectrum disorder (ASD), conduct disorder (CD), learning disability (LD), and developmental delay (DD) from electronic medical records. We estimated odds ratios (OR) of each ND compared to typically developing children (neurotypical) per interquartile range (IQR) increase in metals using logistic regression, adjusting for maternal age, education, obesity/diabetes, race/ethnicity, pregnancy fish intake, and sex. We assessed modification by pregnancy characteristics, preterm birth (PTB), and sex.

RESULTS: of 483 neurotypical and 520 children with NDs (184 ADHD, 53 ASD, 199 CD, 95 LD, 517 DD), majority were non-Hispanic Black (66%) or Hispanic (24%). An IQR increase in lead was associated with an LD OR of 1.27 (95% CI: 1.02, 1.57) and DD OR of 1.12 (0.97, 1.28) among boys, however, associations were not notable in total population. PTB and stressful pregnancies were vulnerable to higher cadmium and manganese, particularly for LD and DD. Mercury was consistently negatively associated with NDs, possibly due to residual confounding by fish consumption. Selenium was positively associated with NDs, particularly LD among boys (2.07 [1.35, 3.18]). We did not observe notable differences by folate.

CONCLUSIONS: In this traditionally understudied US minority birth cohort, prenatal exposure to toxic metals were widespread and associated with NDs, particularly LD and DD. Sex, PTB, stress, and fish intake modified some associations. These findings, if further confirmed, may inform the design of potential interventions to reduce metals neurotoxicity.

O-OP-276 Prenatal Trace Metal Exposures and Genetic Variants Inform Birth Weight-related Placental Isoform Expression

Maya Deyssenroth[1], Promita Bose[1], Shouneng Peng[2], Ke Hao[2], Carmen Marsit[3], Jia Chen[2]
[1]Columbia University, New York, USA, [2]Icahn School of Medicine at Mount Sinai, New York, USA, [3]Emory University, Atlanta, USA

BACKGROUND AND AIM: Placental gene expression patterns are increasingly recognized as functional targets associated with birth outcomes. However, studies to date do not capture transcript-level specification, an important resource for adaptive responses during fetal development. In this study, we conducted a genome-wide analysis to characterize differential transcript usage (DTU) in the placenta with respect to prenatal trace metal exposure, genetic variants, and birth weight.

METHODS: RNA sequencing was performed in placenta samples from the Rhode Island Child Health Study (n=199). A panel of essential and nonessential metals were measured in maternal toenails (Al, As, Cd, Cr, Cu, Fe, Mn, Mo, Ni, Pb, Sb, Se, Sn, U, V, Zn) and placenta (Ca, Cd, Co, Cu, Fe, K, Mg, Mn, Mo, Na, P, S, Se, Zn) using ICP-MS. DTU was assessed using the DRIMSeq R package to contrast infants small (SGA) and appropriate (AGA) for gestational age and infants above and below median trace metal exposure levels. Genetic variants that influence transcript usage were identified using the sQTLseeker R package.

RESULTS: We identified 82 genes demonstrating DTU in association with SGA status at an FDR < 0.05. Among the trace metals, placental transcript expression levels were most sensitive to Sn (n=377 genes) and Cd (n=73 genes) exposures measured in maternal toenails. Transcript proportions of LAMTOR4, a lysosome regulator implicated in neurodegenerative diseases, varied in association with SGA status, Sn and Cd levels measured in toenails, Ca levels measured in placenta, and genotypes across three local genetic variants (rs10231604, rs12878, and rs3736591).
DISCUSSION: We report a comprehensive genome-wide characterization of placental transcript usage and associations with prenatal trace metal exposure, genetic variants, and fetal growth restriction. These results highlight the utility of interrogating the transcriptome at transcript-level resolution to identify novel placental biomarkers of outcomes jointly impacted by genetic polymorphisms and environmental exposures.

O-OP-278 Exposure to a metal mixture is associated with decreased tremor in Italian adolescents

Alexa Friedman[1], Samantha Schildroth[1], Victoria Fruh[1], Roberto G Lucchini[2,3,4], Donald Smith[5], Robert Wright[5], Megan Horton[4], Donatella Placidi[3], Maxine Krengel[6], Yorghos Tripodis[7], Roberta F. White[1,6], Birgit Claus Henn[1]
[1]Boston University School of Public Health, Boston, USA, [2]Department of Environmental Health Sciences, Florida International University, Miami, USA, [3]Department of Medical and Surgical Specialties, Radiological Sciences, and Public Health,University of Brescia, Brescia, Italy, [4]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [5]Department of Microbiology and Environmental Toxicology, University of California, Santa Cruz, USA, [6]Department of Neurology, Boston University School of Medicine, Boston, USA, [7]Department of Biostatistics, Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: Children living near ferroalloy industry are commonly exposed to metals including manganese (Mn), copper (Cu), lead (Pb), and chromium (Cr). These metals are associated with adverse neurodevelopment outcomes, with evidence of non-linear associations for essential metals. Metals target brain regions involved in motor function, but motor function remains an understudied neurodevelopmental domain and little is known about the joint effects of metal mixtures.

METHODS: We used cross-sectional data from 618 adolescents (10-14 years; 51% female) to estimate associations between a metal mixture and postural tremor. Metal concentrations were quantified in hair and blood using inductively coupled plasma mass spectrometry. Neuropsychologists administered the Tremor Pen Test from the Coordination Ability Test System, which measures intensity and regularity of tremor in both hands at rest. We quantified joint associations between metals and adolescent tremor using quantile-based g-computation (qgComp) and Bayesian kernel machine regression (BKMR), adjusting for age, biological sex, and socioeconomic status.

RESULTS: The metal mixture was associated with decreased tremor intensity: using qgComp, a one quartile increase in the metal mixture was associated with 0.18 (95% CI: -0.29, -0.08) and 0.22 (95% CI: -0.33, -0.12) SD decrease in tremor intensity of the dominant and nondominant hands, respectively. Using BKMR, increasing levels of the mixture were associated with less intense tremor in the dominant hand (e.g., when all metals were at their 75th percentiles, compared to their 50th percentiles, β= -0.13 SD, 95% CI: -0.27, 0.01). Associations were driven by Cr and consistent between methods.

CONCLUSIONS: Increasing levels of the metal mixture were associated with smaller tremor magnitude, and associations were driven by Cr. Few epidemiological studies have examined the role of Cr in neurodevelopment, but our findings suggest that Cr may be beneficial for some aspects of motor function in adolescence.

KEYWORDS: metals, mixtures, motor function, neurodevelopment, chromium

O-OP-279 Associations of Prenatal Metals Exposure with Kidney Injury Biomarkers in Children

Maria D. Politis[1], Meizhen Yao[1], Chris Gennings[1], Marcela Tamayo-Ortiz[2], Damaskini Valvi[1], Seunghee Kim-Schulze[3,4], Jingjing Qi[3], Chitra Amarasiriwardena[1], Ivan Pantic[5,6], Mari Cruz Tolentino[7], Guadalupe Estrada-Gutierrez[8], Jason H. Greenberg[9], Martha M. Tellez-Rojo[5], Robert O. Wright[1], Maria Jose Rosa[1], Alison P. Sanders[10,11]

BACKGROUND AND AIM: Prenatal exposure to toxic metal(loid)s, including arsenic (As), cadmium (Cd), mercury (Hg), and lead (Pb) during development may have nephrotoxic effects in children. We assessed associations between prenatal metal exposure and urinary kidney injury biomarkers in children.

METHODS: Analyses included 418 children participating in the PROGRESS birth cohort study in Mexico City. Concentrations of As, Cd, Pb, and Hg (urine only) were quantified in maternal second trimester (2T) blood and urine. Kidney parameters were assessed at 8-10 years of age. We examined associations between individual metals and 1) kidney injury biomarkers using linear regression and 2) a multi-protein kidney index using weighted quantile sum (WQS) regression. Associations of separate urine and blood metal mixtures with individual kidney injury biomarkers were assessed via WQS. Covariates included child's age, sex, body mass index z-score, urine creatinine, 2T socioeconomic status, and 2T smoking exposure.

RESULTS: In single metal analyses, doubling of urine Cd was associated with higher urinary TIMP metallopeptidase inhibitor 1 (TIMP1), alpha-1-microglobulin (A1M), clusterin, and cystatin C. Within the multi-protein index, the association with increased urinary As was predominated by albumin, fatty acid binding protein 1 (FABP1), and interferon gamma-induced protein 10 (IP10), and the association with increased urinary Cd was predominated by albumin, A1M, TIMP1, lipocalin, and FABP1. Decile increases in urine metal mixture was associated with increased urinary albumin, IP10, and cystatin C. Urinary As and Cd comprised 60-96% of the metal mixture weights contributing to the associations.

CONCLUSIONS: Prenatal urinary metals, individually and as a mixture were associated with increased urinary kidney injury biomarkers in healthy children. Prenatal metals exposure may lead to subclinical glomerular or tubular injury in school age children. Further research is required to ascertain resolution or worsening of subclinical kidney injury at later life stages.

O-OP-280 Early pregnancy metal exposure and epigenetic aging biomarkers at birth and in childhood in a US cohort

Anne Bozack[1], Sheryl L Rifas-Shiman[2], Andrea A Baccarelli[3], Robert O Wright[4], Diane R Gold[5,6], Wei Perng[7], Zach Laubach[8], Emily Oken[2], Marie-France Hivert[2,9], Andres Cardenas[1,10]

[1]Division of Environmental Health Sciences, School of Public Health, University of California, Berkeley, Berkeley, USA, [2]Division of Chronic Disease Research Across the Lifecourse, Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA, [3]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA, [4]Department of Environmental Medicine and Institute for Exposomic Research, Icahn School of Medicine at Mount Sinai, New York, USA, [5]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital, Boston, USA, [6]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Harvard University, Boston, USA, [7]Department of Epidemiology, Colorado School of Public Health, Aurora, USA, [8]Ecology and Evolutionary Biology, University of Colorado, Boulder, Boulder, USA, [9]Diabetes Unit, Massachusetts General Hospital, Boston, USA, [10]Center for Computational Biology, University of California, Berkeley, Berkeley, USA

BACKGROUND AND AIM: Epigenetic aging is a strong predictor of mortality and morbidity, potentially linking environmental exposures to health. We analyzed the extent to which prenatal metals were associated with epigenetic age acceleration (EAA) at birth and in childhood in the Project Viva cohort.

METHODS: Metal concentrations (As, Ba, Cd, Cr, Cs, Cu, Hg, Mg, Mn, Pb, Se, Zn) were measured in maternal erythrocytes. DNA methylation was measured in cord blood (N=361) and leukocytes in early (N=92, median=3.2 years) and mid-childhood (N=333, median=7.7 years). We calculated epigenetic clocks for gestational age (GA) (Bohlin clock), early- and mid-childhood age (Horvath and skin & blood clocks), and respective EAA measures. Horvath intrinsic EAA adjusting for estimated cell types was also calculated. We evaluated associations between each metal and EAA at each period using linear models and across ages using linear mixed effects models, adjusting for biologically relevant covariates.

RESULTS: Epigenetic GA (Bohlin clock) strongly predicted chronological GA ($r=0.80$, $p<0.001$) while the Horvath and skin & blood epigenetic age estimates were moderately correlated with chronological age in childhood (Horvath early childhood $r=0.48$, mid-childhood $r=0.43$; skin & blood early childhood $r=0.68$, mid-childhood $r=0.56$; $p<0.001$). Higher prenatal As was associated with greater Bohlin GA acceleration (B=0.40 days per doubling in concentration, $p=0.03$), early childhood Horvath EAA (B=0.14 years per doubling in concentration, $p=0.03$), early childhood Horvath intrinsic EAA (B=0.14, $p=0.03$), and Horvath intrinsic EAA across ages in longitudinal analyses (B=0.07, $p=0.02$). We also observed associations between prenatal Cs and early childhood Horvath EAA (B=0.41, $p=0.04$) and Horvath intrinsic EAA (B=0.41, $p=0.03$).

CONCLUSIONS: Prenatal As and Cs are associated with epigenetic biomarkers of accelerated aging, particularly for those independent of age-related immune changes or intrinsic aging, at birth and in childhood. Future studies may provide insight to the relationship between EAA and health in early life.

ORAL PRESENTATIONS SESSION 51: Air pollution, ultrafine particles, radon and various health outcomes

O-OP-281 Renal function and ambient air pollution at low exposure levels

Karl Kilbo Edlund[1], Eva M Andersson[1], Yiyi Xu[1], Florencia Harari[1,2], David Segersson[3], Peter Molnár[1,2], Petter Ljungman[4], Leo Stockfelt[1,2]

[1]University of Gothenburg, Göteborg, Sweden, [2]Region Västra Götaland, Göteborg, Sweden, [3]Swedish Meteorological and Hydrological Institute, Norrköping, Sweden, [4]Karolinska Institute, Stockholm, Sweden

BACKGROUND AND AIM: Increasing evidence connects exposure to air pollution to decreased renal function. This has important public health implications, since chronic kidney disease is both an increasing global health threat and a risk factor for cardiovascular disease. In this study we investigate associations between low-level exposure to ambient air pollution and renal function.

METHODS: The Swedish CArdioPulmonary Study (SCAPIS, n = 30154) is a large population-based cohort of middle-aged men and women from six Swedish cities and includes extensive medical data. In these preliminary analyses, we use data from the Gothenburg subcohort (n = 6265). Longitudinal residential exposure to particulate matter (PM2.5 and PM10) and nitrogen oxide (NOx) was assigned from high-resolution dispersion models and averaged over 15, 5, and 2 year time-frames. We estimated the association between air pollutant exposure and estimated glomerular filtration rate (eGFR) and prevalence of a low eGFR, using multivariate-adjusted robust Poisson and linear regression.

RESULTS: In the SCAPIS Gothenburg subcohort average long-term exposure to PM2.5, PM10, and NOx was 8.19, 10.2 and 33.0 µg/m3, respectively, and median eGFR was 91.5 mL/min/1.73 m2. We did not find statistically significant associations between air pollutant exposure and renal impairment. However, there was a trend towards a negative association between two-year average exposure and eGFR (e.g., -0.29% (95% CI: -0.69–0.11%) lower eGFR per 10 µg/m3 higher two-year NOx). We found stronger associations in males, and in participants with low education level and with high alcohol consumption.

CONCLUSIONS: The results indicate an association between air pollution and lower renal function also at low exposure levels, although estimates were not statistically significant. Expanding the analysis to the entire SCAPIS cohort will permit analyses with higher power, greater exposure contrasts, and source-specific exposures.

KEYWORDS: Air pollution; Renal function; eGFR; Cross-sectional study

O-OP-282 Impact of ultrafine particles and total particle number concentration on natural-, cardiovascular, and respiratory mortality in three German cities

Maximilian Schwarz[1,2], Alexandra Schneider[1], Josef Cyrys[1], Susanne Bastian[3], Annette Peters[1,2,4], Susanne Breitner[1,2]

[1]Institute of Epidemiology, Helmholtz Zentrum München GmbH - German Research Center for Environmental Health, Neuherberg, Germany, [2]Institute for Medical Information Processing, Biometry and Epidemiology, Medical Faculty, Ludwig-Maximilians-Universität München (LMU), Munich, Germany, [3]Saxon State Office for Environment, Agriculture and Geology (LfULG), Dresden, Germany, [4]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Exposure to ambient particulate air pollution has been associated with adverse effects on morbidity and mortality. However, the evidence for ultrafine particles (UFP; 10-100nm) remains inconsistent, and study designs vary considerably. We aimed to examine short-term exposures to UFP and total particle number concentrations (PNC; 10-800nm) and the risk of cause-specific mortality in the three German cities Dresden, Leipzig, and Augsburg.

METHODS: for these cities, we included daily counts of non-accidental, cardiovascular, and respiratory mortality between 2010 and 2017. We collected daily averages of UFP, PNC, and routinely monitored air pollutants (e.g., fine particulate matter and nitrogen dioxide) at four urban background and two roadside/traffic monitoring sites. We applied site-specific confounder-adjusted Poisson regression models. We investigated effects of air pollutants at aggregated lags (0-1, 2-4, 5-7, and 0-7) and used meta-analytical methods to pool the results across the sites. Additionally, we investigated effect modification by age, sex, and season and assessed interdependencies between pollutants using two-pollutant models.

RESULTS: for respiratory mortality, we found a delayed increase in relative risk of 4.32% [95% confidence interval (CI): 1.63%, 7.09%] per 3,207 particles/cm³ increase 5 to 7 days after UFP exposure. Effects for PNC and other lags showed smaller but comparable results. Two-pollutant models indicated independent effects of fine particulate matter. Effect modification analysis showed higher risks for women. We did not find any associations for cardiovascular or non-accidental mortality.

CONCLUSIONS: Consistent with previous studies from the same region, we found significant delayed effects for respiratory mortality after short-term exposure to UFP and PNC. To avoid greater heterogeneity between study designs and allow better comparison of evidence, future research should be guided by the good practice statements for UFP devolved and published by the World Health Organization in 2021.

O-OP-283 Exposure to ultrafine particles and mortality in the Netherlands

Femke Bouma[1], Nicole Janssen[2], Joost Wesseling[2], Sjoerd van Ratingen[2], Maciek Strak[2], Jules Kerckhoffs[1], Ulrike Gehring[1], ir. Roel Vermeulen[1,3], ir. Gerard Hoek[1]

[1]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, [2]National Institute for Public Health and the Environment, Bilthoven, Netherlands, [3]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands

BACKGROUND AND AIM: Epidemiologic research on long-term exposure to ultrafine particles (UFP) is limited. The aim of this study was to investigate the association between long-term UFP exposure and natural and cause-specific mortality (including cardiovascular disease (CVD), respiratory disease and lung cancer) in the Netherlands.

METHODS: A Dutch national cohort of 10.8 million adults aged 29+ years was followed from 2013 until 2019. Annual average UFP concentrations were estimated at the home address at baseline, using land-use regression models based on a nationwide mobile monitoring campaign. Cox proportional hazard models were applied, stratified by sex, with age as the underlying time scale and adjustment for potential individual and area-level socio-economic status confounders. Two-pollutant models with NO2, PM2.5, PM10 and elemental carbon based on dispersion modelling were additionally assessed.

RESULTS: A total of 945,615 cases of natural mortality occurred during 71,008,209 person-years of follow-up. The correlation of UFP concentration with other pollutants ranged from 0.59 (PM2.5) to 0.81 (NO2). We found a significant association between annual average UFP exposure and natural mortality [HR 1.012 (95% CI 1.010 – 1.015), per IQR (2723 particles/cm3) increment]. The association attenuated but remained significant when adjusting for co-pollutants in two pollutant models, e.g., HR 1.009 (1.006 – 1.013) after adjustment for NO2. Associations were weaker for CVD mortality [HR 1.005 (1.000 – 1.011)], whereas stronger for respiratory disease mortality [HR 1.022 (1.013 – 1.032)] and lung cancer mortality [HR 1.038 (1.028 – 1.048)].

CONCLUSIONS: Annual average UFP exposure was independently associated with natural and cause-specific mortality among adults in the Netherlands.

Paris-Sud, Inserm, Équipe d'Épidémiologie respiratoire intégrative, CESP, Villejuif, France, [2]French Environment and Energy Management Agency, Angers, France, [3]Université Paris-Saclay, Université de Paris, UVSQ, Inserm, Cohortes Epidémiologiques en population, UMS 11, Villejuif, France, [4]Charité, Universitätsmedizin Berlin, Humboldt-Universität zu Berlin, Berlin, Germany, [5]Comprehensive Allergy Center, Department of Dermatology and Allergy, Berlin Institute of Health, Berlin, Germany, [6]Centre Hospitalier Universitaire, Montpellier, France, [7]MASK-air, Montpellier, France, [8]Swiss Tropical and Public Health Institute, Basel, Switzerland, [9]University of Basel, Basel, Switzerland, [10]Univ Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) - UMR_S 1085, Rennes, France

BACKGROUND AND AIM: Asthma and rhinitis are two related respiratory conditions. However, studies that investigated their associations with air pollution have considered them separately. We aimed to study the association between exposure to air pollution and phenotypes of current rhinitis (CR) and current asthma (CA) in Constances, a large French population-based adult cohort.

METHODS: CR was defined by the report of sneezing, runny or blocked nose in the last 12 months. CA was defined by the report of lifetime asthma plus having in the last 12 months: taken asthma medication or had an asthma attack, wheezed, woken up with breathing discomfort, been short of breath at rest or exercise, or woken up with shortness of breath. Four categories were considered: non-CR/non-CA, CR/non-CA, non-CR/CA, and CR/CA. Annual exposure to nitrogen dioxide (NO2), particulate matter ≤2.5 µm (PM2.5) and black carbon (BC) was estimated at the participants' residential address by land-use regression models. Cross-sectional analyses at inclusion were performed between air pollutants and the four phenotypes using a multinomial logistic model adjusted for age, sex, smoking, education level and French deprivation index.

RESULTS: Among the 173,805 participants included in this analysis (mean age: 47, 54% women), 108,637 (63%) were classified as non-CR/non-CA, 48,712 (28%) CR/non-CA, 6,282 (4%) non-CR/CA, and 10,174 (6%) CR/CA. Using non-CR/non-CA as reference, an increase of an interquartile range of BC (0.86 10-5m-1) was significantly associated with CR/non-CA (OR (CI95%): 1.17 (1.15-1.20)), non-CR/CA (1.10 (1.05-1.15)), and CR/CA (1.12 (1.08-1.16)). Similar associations were observed for PM2.5, NO2, and BC residuals. Regardless of pollutant, associations were significantly higher for the CR/non-CA than for the other groups.

CONCLUSIONS: Our results suggest that CR/non-CA phenotype may be more sensitive to the effects of air pollution and that among traffic related air pollutants, BC may be of special interest.

KEYWORDS: rhinitis, asthma, air pollution

O-OP-285 A prospective cohort study on the association between residential radon exposure and melanoma incidence in Switzerland

Seçkin Boz[1,2], Claudia Berlin[3], Murielle Bochud[4], Jean-Luc Bulliard[4], Marcel Zwahlen[3], Martin Röösli[1,2], Danielle Vienneau[1,2]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]University of Basel, Basel, Switzerland, [3]Institute of Social and Preventive Medicine (ISPM), University of Bern, Switzerland, [4]Centre for Primary Care and Public Health (Unisanté), University of Lausanne, Lausanne, Switzerland

BACKGROUND AND AIM: Radon is radioactive noble gas found in earth crust. It tends to accumulate in buildings, and is estimated to account for half of the ionizing radiation dose received by humans. Skin is the second most exposed organ to ionizing radiation from radon. The aim of this study was to evaluate the association between residential radon exposure and melanoma incidence in selected Swiss cantons.

METHODS: The study included 1.3 million adults (20+ years) from the Swiss National Cohort (SNC) who were residents in the cantons of Vaud, Neuchâtel, Valais, Geneva, Fribourg, and Ticino at the study baseline (04.12.2000). Cases of primary tumours (ICD-O-3: 8720-8790/3+ melanoma) were identified using data from these cantonal cancer registries, linked to the SNC. Long-term residential radon and ambient ultraviolet exposure from sun were assigned to each individual's addresses at baseline. We used Cox proportional hazard models with age as the underlying time scale and adjusted for birth cohort, canton, sex, socioeconomic position, educational attainment, civil status, mother tongue, outdoor occupation with potential sun exposure as fixed explanatory variables and stratified by follow-up period. Potential effect modifiers were also tested.

RESULTS: Among the study population, we observed 4937 incident cases of melanoma during an average 8.9 years of follow-up. The adjusted hazard ratio for per 100 Bq/m³ increase in residential radon levels at age 45 was 1.11 (95% CI: 1.00, 1.23). Radon effect was higher at younger ages and became null at higher ages. Ambient long-term UV exposure was not associated with melanoma incidence across all ages.

CONCLUSIONS: Residential radon exposure might be a relevant risk factor for melanoma incidence, especially for people at younger ages. Accumulation of radon gas is preventable via built-in solutions applicable to dwelling. Such measures are important for public health.

O-OP-286 The Association of ventilation device in kitchen with the reported respiratory symptoms of adults

Xiaocheng Xu[1], Zhanlu Lv[2], Bin Luo[3], Han Zhang[1], Lingchuan Guo[2], Jinliang Zhang[1]

[1]State Key Laboratory of Environmental Criteria and Risk Assessment, Chinese Research Academy of Environmental Sciences, Beijing, China, [2]Center for the Risk Assessment and Research, Chinese Research Academy of Environmental Sciences, Beijing, China, [3]Institute of Occupational Health and Environmental Health, School of Public Health, Lanzhou University, Lanzhou, China

OBJECTIVE: To investigate the benefits of ventilation device in kitchen on respiratory symptoms of rural adults and to provide scientific evidences for indoor air pollution controlling and health promotion in rural China.

METHODS: We selected the information on the ventilation device in kitchen, the reported respiratory symptoms and the sociodemographic status from the database for the questionnaire investigation in 7 counties in Huaihe River Basin. The participants were local residents aged 20-75. The respiratory symptoms were investigated by the revised questionnaire based on American Thoracic Society's Division of Lung Disease and Logistic Regression Model was used to complete the analyses of the relationship.

RESULTS: Totally 11134 participants finished the survey and 1548 of them (13.9%) reported that there were ventilation devices in their kitchens. The reported rates of cough, chronic cough, expectoration, chronic expectoration, wheeze and shortness of breath were 15.4%, 9.6%, 15.1%, 10.8%, 9.9% and 22.9%, respectively. These rates among people with ventilation device in kitchen was significantly lower than those without ventilation device in kitchen (P<0.001). After adjusted the age, gender, education years, marriage status, farmer, smoking and family income, the multivariate logistic regression analysis showed that ventilation device in kitchen could significantly reduce the risk of chronic cough (OR=0.64, 95% CI:0.50~0.81), chronic expectoration (OR=0.61, 95%CI:0.48~0.77), wheeze (OR=0.70, 95%CI:0.55~0.88) and shortness of breath (OR=0.80, 95%CI:0.69~0.94).

CONCLUSIONS: The use of ventilation device in kitchen was associated with the decreasing of the reported respiratory symptoms among adults, which will benefit the human respiratory health.

Monday, September 19

PECHA KUCHA SESSION 01:
Air pollution (from ambient and indoor sources) and health

THEMATIC 03: Air pollution (ambient & indoor) and Sources

O-PK-01 Associations between short-term ambient PM2.5, oxidant gases and respiratory hospitalizations in children: effect modification by PM2.5 transition metals, sulfur and oxidative potential

Jill Korsiak[1], Eric Lavigne[2], Hongyu You[2], Krystal Pollitt[3], Ryan Kulka[2], Marianne Hatzopoulou[4], Greg Evans[5], Richard T. Burnett[6], Scott Weichenthal[1]

[1]Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, Canada, [2]Air Health Science Division, Health Canada, Ottawa, Canada, [3]Department of Environmental Health Sciences, Yale School of Public Health, New Haven, USA, [4]Department of Civil and Mineral Engineering, University of Toronto, Toronto, Canada, [5]Department of Chemical Engineering and Applied Chemistry, University of Toronto, Toronto, Canada, [6]Population Studies Division, Health Canada, Ottawa, Canada

BACKGROUND AND AIM: Exposure to particulate and gaseous pollutants impair the respiratory health of children. Mass-based measures of PM2.5 do not capture spatiotemporal variability in particle composition/toxicity. The aim of this study is to examine whether associations between short-term ambient PM2.5 or oxidant gases and respiratory hospitalizations in children are modified by metals or sulfur content in PM2.5, or particle oxidative potential.

METHODS: This is a case-crossover study of 10,500 children (0-17 years) in Canada. Daily PM2.5 mass concentration and the combined weighted oxidant capacity of NO2 and O3 (Ox) were collected. Monthly estimates of transition metals (copper, iron, nickel, manganese, zinc) and sulfur in PM2.5, and three metrics of particle oxidative potential (OPAA, OPGSH, OPDTT) were measured at each monitoring site. Conditional logistic regression models were used to estimate associations between PM2.5 or Ox and respiratory hospitalizations, above and below median metals, sulfur, and particle oxidative potential.

RESULTS: Without stratifying above and below median metals, sulfur, or particle oxidative potential, there were no associations between PM2.5 mass and respiratory hospitalizations (OR and 95% CI per 10 μg/m3 increase in PM2.5: 1.004 [0.955, 1.056]). However, when the analyses were performed above/below median metals, sulfur, and oxidative potential, positive associations were observed when metals, sulfur and OPGSH were above the median. for example, when copper was above the median, the OR and 95% CI per 10 μg/m3 increase in PM2.5 was 1.084 [1.007, 1.167], while the OR and 95% CI was 0.970 [0.929, 1.014] when copper was below the median. Stronger associations between Ox and respiratory hospitalizations were also observed when metals, sulfur and oxidative potential were above the median.

CONCLUSIONS: Stronger associations between short-term PM2.5, oxidant gases and respiratory hospitalizations in children were observed when metals, sulfur and particle oxidative potential were elevated.

KEYWORDS: PM2.5, respiratory health, children, oxidant gases

O-PK-02 The Spatial Modification of the Non-Linear Effects of Ambient Oxides of Nitrogen during Pregnancy on Birthweight in a South African Birth Cohort

Aweke A. Mitku[1,2], Temesgen Zewotir[1], Delia North[1], Rajen N. Naidoo[1], Prakash Jeena[1], Kareshma Asharam[1], Sheena Muttoo[1]

[1]University of KwaZulu-Natal, Durban, South Africa, [2]Bahir Dar University, Bahir Dar, Ethiopia

BACKGROUND: Birthweight is strongly associated with infant mortality and is a major determinant of infant survival. Several factors such as maternal, environmental, clinical, and social factors influence birthweight, and these vary geographically, including across low, middle, and economically advanced countries. The aim of the study was to investigate the geographical modification of the effect of oxides of nitrogen exposure on birthweight adjusted for clinical and socio-demographic factors.

METHODS: Data for the study was obtained from the Mother and Child in the Environment birth cohort study in Durban, South Africa. Pregnant females were selected from public sector antenatal clinics in low socioeconomic neighborhoods. Land use regression models were used to determine household level antenatal exposure to oxides of nitrogen (NOx). Newborns were assessed at the local hospitals by doctors or qualified midwives. Six hundred and seventy seven births were analysed, using the geoadditive model with Gaussian distribution and identity link function. Continuous covariates were modelled by thin-plate regression splines and smoothing was estimated by the generalized cross validation.

FINDINGS: A total of 677 births were analyzed. The newborns in the cohort had mean birthweight of 3106·5g (standard deviation (SD):538·2g and maternal mean age was 26 years (SD: 5·7). The mean prenatal exposure to NOx was found 31·5µg/m3 with standard deviation of 8·6 µg/m3. A spatially modified NOx exposure-related effect on birthweight was found across two geographic regions in Durban. Prenatal exposure to NOx was also found to have a non-linear effect on the birthweight of infants. The geoadditive model adjusted for maternal age, weight gain, and body mass index showed significant non-linear influences.

CONCLUSION: The study suggested that incorporating spatial variability is important to understand and design appropriate policies to reduce air pollution in order to prevent risks associated with birthweight and child development.

O-PK-03 Short-term effects of particulate matter and desert dust on mortality in Southern Europe, the Middle East and Eastern Asia

Massimo Stafoggia[1], Jorge Pey[2], Chris Fook Sheng Ng[3], Sara Basart[4], Carmen Iñiguez[5], Aurelio Tobías[6], MCC Collaborative Group

[1]Lazio Region Health Service - Asl Roma 1, Rome, Italy, [2]ARAID-Instituto Pirenaico de Ecología, Spanish Research Council, Zaragoza, Spain, [3]Department of Global Health Policy, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [4]Barcelona Supercomputing Center, Barcelona, Spain, [5]Department of Statistics and Operational Research, Universitat de Valencia, Valencia, Spain, [6]Institute of Environmental Assessment and Water Research, Spanish Research Council, Barcelona, Spain

BACKGROUND: Desert dust represents a threat to health, but the evidence is limited, as past studies were localised and adopted different exposure metrics and/or statistical approaches. We aim to evaluate the short-term effects of desert dust episodes and particulate matter (PM) on natural mortality in multiple cities from different geo-climatic zones.

METHODS: Daily death counts were collected for 21 cities in southern Europe (France, Greece, Italy, Portugal, Spain), the Middle East (Iran, Kuwait) and Eastern Asia (China, Japan, South Korea, Taiwan) from 2003-2018. Dust advection days were identified using satellite data, operational models and back-trajectories. Daily mean concentrations of PM10 (PM<10µm) and PM2.5 (<2.5µm) were available for 21 and 16 cities, respectively. City-specific quasi-Poisson regression models were fitted, adjusted for time trends and meteorology, and city-specific estimates were combined using random-effects meta-analysis.

RESULTS: The frequency of dust days ranged from 5% in Northern Italy to 61% in Northern China, with highest levels of PM10 and PM2.5 raised in Kuwait (191 µg/m3) and Xian (182 µg/m3). Overall, dust (yes/no), PM10 and PM25 (10 µg/m3) increased mortality at the same day by 0.52% (95% confidence interval: 0.04, 1.01), 0.14% (0.07,0.21) and 0.16% (0.02, 0.31), respectively. We found differential effects of PM on non-dust versus dust days: on non-dust days 10 µg/m3 increases in PM10 and PM25 increased mortality by 0.20% (0.11, 0.29) and 0.26% (0.05, 0.46) in non-dust days, while in dust days they increased mortality by 0.06% (95% confidence interval: 0.01, 0.10) and 0.05% (-0.04, 0.15), respectively.

CONCLUSIONS: Desert dust may have independent adverse health effects. Further investigation is needed to disentangle the complex role of dust on air quality and health. On-going analyses on a broader set of cities within the MCC network provide a promising opportunity for this purpose.

KEYWORDS: Desert dust; particulate matter; short-term effects; mortality

O-PK-04 Effects of a Liquefied Petroleum Gas Stove and Continuous Fuel Distribution Intervention on Anthropometric Outcomes at Birth

Hina Raheel, Ashley Younger, Sheela Sinharoy, Jiantong Wang, Shirin Jabbarzadeh, Marilu Chiang, Adly Castañaza, Anaite Diaz-Artiga, Sarada Garg, Florien Ndagijimana, Gloriose Bankundiye, Miles A. Kirby, Kalpana Balakrishnan, John P. McCracken, Ghislaine Rosa, Aris Papageorghiou, Thomas F. Clasen, Jennifer Peel, William Checkley, Lisa M. Thompson

BACKGROUND AND AIM: Air pollution may contribute to childhood stunting and impaired cognitive development. Potential anthropometric markers of poor growth and cognition include head circumference and length at birth. The Household Air Pollution Intervention Network (HAPIN) trial in India, Guatemala, Peru, and Rwanda was a randomized controlled field trial among 3200 pregnant women that assessed the effect of liquefied petroleum gas (LPG) stove and continuous free fuel intervention compared to cooking with biomass on health outcomes. We conducted an intention-to-treat analysis of the LPG intervention delivered during pregnancy starting at 9-19 weeks of gestation on head circumference and length at birth among offspring.

METHODS: Length and head circumference were measured in centimeters within 24 hours of birth. Birth length and head circumference z-scores were calculated using INTERGROWTH-21st standards which accounts for gestational age at birth. Separate linear regression models (adjusted for 10 strata, representing settings in Guatemala (1 site), Rwanda (1 site), India (2 sites) and Peru (six sites)) were created for head circumference, head circumference z-score, birth length and birth length z-score.

RESULTS: A total of 3060 live births were included in the analysis. The intervention had small or no effect on birth length (β=0.14, 95% CI -0.01 to 0.29), birth length Z-scores (β=0.09, 95% CI 0.01 to 0.16), head circumference (β= -0.01, 95% CI -0.11 to 0.09) and head-circumference Z-scores (β= -0.01, 95% CI -0.08 to 0.07). More than 90% of the women had a full-term pregnancy (94.6% in control and 94.1% in intervention group), and the mean (SD) time with the intervention was 21.23 weeks (3.67 weeks).

CONCLUSION: Our intervention strategy aimed at reducing household air pollution during pregnancy had small or no effects on length and head circumference at birth among offspring.

KEYWORDS: Household air pollution, liquefied petroleum gas, biomass fuel, head circumference, birth length, newborn

O-PK-05 Ambient fine particulate matter exposure and lung cancer risk in the NIH-AARP Diet and Health Study

Jared Fisher[1], Ian Buller[1], Neal Freedman[1], Linda Liao[1], Joel Kaufman[2], Debra Silverman[1], Rena Jones[1]
[1]National Cancer Institute, Rockville, USA, [2]University of Washington, Seattle, USA

BACKGROUND AND AIM: Fine particulate matter (PM2.5) is an established cause of lung cancer; however, few studies have evaluated risk by histologic subtype.

METHODS: We estimated outdoor PM2.5 concentrations at the residential enrollment (1995-1996) address for 494,728 participants of the NIH-AARP Diet and Health Study, a cohort located in 6 states (California, Florida, Louisiana, New Jersey, North Carolina, and Pennsylvania) and 2 metropolitan areas (Atlanta, Georgia, and Detroit, Michigan). We used annual estimates from a national spatiotemporal model to assess PM2.5 concentrations for a 5-year pre-enrollment period (1990-1994). We used Cox regression to estimate hazard ratios and 95% confidence intervals (HR[CI]) for risk of incident lung cancer overall and by histologic subtype per 10µg/m3 increase in PM2.5. Models were adjusted for demographic characteristics, smoking status and intensity, and census-tract median household income. We also examined models stratified by smoking status, sex, and study catchment area at baseline, and we tested for statistical interaction via Wald tests.

RESULTS: 16,766 lung cancers were diagnosed in follow-up through 2011. We observed a small, nonsignificant increased risk for lung cancer overall (HR=1.02[0.96-1.08] per 10µg/m3). Associations were stronger for adenocarcinoma (HR=1.10[1.00-1.21]) and squamous cell carcinoma (HR=1.08[0.94-1.24]), whereas we found no association for small cell carcinoma (HR=0.98[0.83-1.15]). No significant differences in risk were noted by smoking status or sex (p-interaction all >0.05). Associations between PM2.5 and lung cancer overall varied widely among the 8 cohort catchment areas (p-interaction <0.01). State-specific associations for lung cancer ranged from HR=0.78[0.46-1.30] in Louisiana to HR=1.60[1.27-2.01] in Pennsylvania.

CONCLUSIONS: Our findings from this large U.S. cohort indicate that risk of lung cancer increases with PM2.5, particularly for adenocarcinoma and squamous cell carcinoma subtypes. Associations varied by region, suggesting that PM2.5 constituency may influence differences in lung cancer risk.

KEYWORDS: lung cancer, outdoor air pollution, particulate matter

O-PK-06 Prescribed Fires, Smoke Exposure, and Hospital Utilization Among Heart Failure Patients

Henry Raab[1], Cavin Ward-Caviness[1], Joshua Moyer[1], Sadia Afrin[2,3], Fernando Garcia Menendez[3]
[1]Center for Public Health and Environmental Assessment, US Environmental Protection Agency, Chapel Hill, USA, [2]MIT Laboratory for Aviation and the Environment, Massachusetts Institute of Technology, Cambridge, USA, [3]Department of Civil, Construction, and Environmental Engineering, North Carolina State University, Raleigh, USA

BACKGROUND AND AIM: Prescribed burns are used for land management, but their environmental health risks have been infrequently studied. We contrasted the health effects of prescribed burns and smoke exposure on heart failure (HF) patients in North Carolina.

METHODS: We used electronic health records from a North Carolina hospital-based cohort diagnosed with HF between 2014-2016. Prescribed fire data was obtained using the Satellite Mapping Automatic Reanalysis Tool for Fire Incident Reconciliation and the National Emissions Inventory. Smoke density data came from NOAA's Hazard Mapping System and was linked to patients based on the zip code of residence. Exposures were the number of prescribed burns within 1 km of the primary residence and the number of days of smoke exposure. Outcomes were the number of hospital visits and 30-day readmissions after HF diagnosis. We used a cross-sectional study design and quasi-Poisson models to model the number of hospital visits and zero-inflated Poisson models to model 30-day readmissions. Models were adjusted for age, sex, race, smoking status, urbanicity, poverty, education level, unemployment, median household value, and public assistance, and included an offset for follow-up time. Results presented are the percent change and associated 95% confidence interval (CI).

RESULTS: The number of prescribed burns within 1 km of a patient's residence showed weak evidence for an association with total hospital visits (-4.5%; 95% CI: -13.7%, 5.2%) and was not associated with 30-day readmissions. However, exposure to an additional medium or heavy smoke day was associated with an increase in both hospital visits (1.3%; 95% CI: -0.2%, 2.7%) and 30-day readmissions (5.3%; 95% CI: 2.3%, 8.5%).

CONCLUSIONS: Smoke exposure is associated with increased hospital utilization among HF patients, but no positive association with prescribed burns was seen. This work does not necessarily represent the views or policies of the US Environmental Protection Agency.

O-PK-07 DNA methylation as a potential mediator of the association between indoor air pollution and neurodevelopmental delay in a South African birth cohort

Dakotah Feil[1], Grace M. Christensen[1], Sarina Abrishamcar[1], Aneesa Vanker[2], Nastassja Koen[3,4,5], Anna Kilanowski[1,6,7,8], Nadia Hoffman[3,4], Kirsten A. Donald[2,3], Michael S. Kobor[9,10,11], Heather J. Zar[2,5], Dan J. Stein[3,4,5], Anke Hüls[1,12]

BACKGROUND AND AIM: Prenatal exposure to indoor air pollution (IAP) has been linked to neurodevelopmental delay in toddlers. Changes in DNA methylation (DNAm) have been independently associated with both prenatal air pollution exposure and delayed neurodevelopment. Investigating DNAm as a mediator may help to elucidate the biological pathways driving the association between IAP and neurodevelopmental delay. In this study, we aim to identify differentially methylated CpG sites and gene regions that mediate this association.

METHODS: We analyzed data from 142 mother-child pairs enrolled in the South African Drakenstein Child Health Study. DNAm from cord blood was measured using the Infinium MethylationEPIC and HumanMethylation450 arrays. Particulate matter with an aerodynamic diameter of 10□m or less (PM10) was measured inside participants' homes during the second trimester of pregnancy. Neurodevelopment was assessed at age 2 years using the Bayley Scales of Infant and Toddler Development III in four domains (cognitive function, general adaptive behavior, language, and motor function). We used three high-dimensional mediation analysis techniques (HIMA, DACT and gHMA) to identify potential mediators, complemented with causal mediation analysis to assess the robustness of our results.

RESULTS: Differential methylation at 29 CpG sites and 4 gene regions (GOPC, RP11-74K11.1, DYRK1A, RNMT) was found to significantly mediate the association between prenatal PM10 exposure and cognitive neurodevelopment. Estimated proportion mediated (95%-confidence interval) ranged from 0.29 (0.01,0.86) for cg00694520 to 0.54 (0.11,1.56) for cg05023582.

CONCLUSIONS: DYRK1A and several of the genes our CpG sites mapped to, including CNKSR1, IPO13, IFNGR1, LONP2, and CDH1 are associated with biological pathways implicated in neurodevelopment and three of our identified CpG sites (cg23560546, cg22572779, cg15000966) have been previously associated with fetal brain development. These findings suggest that DNAm may mediate the association between prenatal PM10 exposure and cognitive neurodevelopment.

KEYWORDS: particulate matter, neurodevelopment, cord blood, epigenetics, newborn DNA methylation.

O-PK-08 Particle Components and Risk of Psychiatric Hospitalization in the U.S.

Xinye Qiu[1], Yaguang Wei[1], Heresh Amini[2], Cuicui Wang[1], Marc Weisskopf[1], Petros Koutrakis[1], Joel Schwartz[1]
[1]Harvard University, Cambridge, USA, [2]University of Copenhagen, Copenhagen, Denmark

OBJECTIVE: This study examined the associations between long-term exposure to ambient particle components and total psychiatric hospital admission risk among the U.S. general population.

METHODS: Using Health Cost and Utilization Project (HCUP) State Inpatient Databases (SIDs), we analyzed the relative risk of psychiatric hospitalization associated with increased exposure to 14 particle components in eight U.S. states over the period of 2002-2018. The particle components data was based on super-learning models. Exposure data was matched with each residential address based on ZIP code of residence and admission year. Single component models were conducted via fitting zero-inflated negative binomial regression on counts of admission per ZIP code per year for each component separately. A multi-components regression was modeled by including the four main mass components (organic carbon (OC), elemental carbon (EC), nitrate and sulfate). We also applied Nonnegative Matrix Factorization (NMF) to identify particle source factors and obtain the source-specific effect estimates. Generalized Weighted Quantile Sum (gWQS) Regression was applied to obtain an overall mixture effect.

RESULTS: Sulfate, Fe, Pb and Zn were associated with the largest risk increases in single-component models. for each interquartile (IQR) increase in OC and sulfate, we observed a relative risk (RR) of 1.10 (95% CI, 1.07 - 1.12) and 1.14 (95% CI, 1.12 - 1.16) respectively. Significant harmful associations were observed for multiple particle sources with the metal industry source (high loadings of Pb and sulfate) being the most influential. for one quartile increase in the WQS score of the components mixture, we observed an increased RR of 1.24 (95% CI, 1.21 - 1.26) adjusting for covariates.

CONCLUSIONS: Living in areas with higher annual average levels of particle components was associated with increased risk of psychiatric hospitalization among residents in eight U.S. states. Certain components (i.e. Pb, sulfate) and sources (metal industry) were the most related.

O-PK-09 Long-term exposure to air pollution, cause-specific mortality and incidence of stroke and acute coronary heart disease in the Rome Longitudinal Study: the BIGEPI project

Federica Nobile[1], Paola Michelozzi[1], Nicola Caranci[2], Claudio Gariazzo[3], Sara Maio[4], Giovanni Viegi[4], Nicolas Zengarini[5], Massimo Stafoggia[1], on behalf of the BIGEPI collaborative Group

[1]Department of Epidemiology, Lazio Region Health Service / ASL Roma 1, Rome, Italy, [2]Regional Health and Social Care Agency, Emilia-Romagna Region, Bologna, Italy, [3]Italian National Institute for Insurance against Accidents at Work (INAIL), Rome, Italy, [4]Institute of Clinical Physiology, National Research Council, Pisa, Italy, [5]Unit of Epidemiology, Regional Health Service ASL TO3, Grugliasco, TO, Italy

BACKGROUND AND AIM: Long-term air pollution exposure increases cause-specific mortality and incidence of cardiovascular diseases. Within the BIGEPI project, we aimed to investigate the association between long-term exposure to air pollutants, cause-specific mortality, incidence of coronary heart diseases and stroke in 6 large Italian administrative cohorts. We report preliminary results for Rome.

METHODS: We enrolled 1,739,277 adults from the Rome Longitudinal Study at 2011 census, and followed them up until 2018. We analysed natural, cardiovascular and respiratory mortality, stroke and acute coronary heart disease (CHD) incidence. We assigned annual mean concentrations of particular matter <10 µm (PM_{10}), PM <2.5 µm ($PM_{2.5}$), nitrogen dioxide (NO_2) and warm-season ozone (warm-O_3) at baseline residential addresses from satellite-based spatiotemporal models. We applied Cox proportional hazards models adjusted for individual and area-level covariates, in single- and two-exposure models. We investigated effect modification by age, sex, educational level, employment status and socioeconomic deprivation index.

RESULTS: We observed 167,300 deaths from natural causes (62,368 cardiovascular, 12,286 respiratory), 42,241 CHD incident cases and 24,835 cases of incident stroke. $PM_{2.5}$ was positively associated with natural, cardiovascular, respiratory mortality and stroke incidence: interquartile range (IQR) increases of 1.69 µg/m³ were associated with hazard ratios (HR) of 1.007 (95% confidence interval: 1.000-1.014), 1.018 (1.006-1.030), 1.028 (1.001-1.056) and 1.025 (1.007-1.044), respectively. We found positive associations between NO_2 and cardiovascular mortality (HR=1.021; 1.007-1.034 per IQR=11.53 µg/m³) and between warm-O_3 and CHD incidence (HR=1.024; 1.011-1.037 per 3.57 µg/m³). Associations tended to attenuate in two-exposure models. The effects were stronger for females and in the age group 30-64 years, with no major differences by individual or area-level socioeconomic indicators.

CONCLUSIONS: We estimated consistent associations between long-term air pollution exposure and cause-specific mortality and CVD incidence. Similar analyses will be conducted in other 5 administrative cohorts.

KEYWORDS: air pollution, cause-specific mortality, stroke, acute coronary heart disease.

O-PK-10 Mobile monitoring of air pollutants; performance evaluation of a mixed-model framework in relation to number of drive days

Jules Kerckhoffs[1], Gerard Hoek[1], Roel Vermeulen[1]
[1]*Utrecht University, Utrecht, Netherlands*

BACKGROUND AND AIM: Because of the implicit uncertainty of mobile measurements due to the short-term nature of the measurements, most studies to date have used empirical modeling to stabilize predicted concentrations, thereby losing local spatial information. In a previous paper, we demonstrated that a mixed-model can stabilise the measurements by a land use regression (LUR) model, while allowing street segments to deviate from the LUR prediction based on between-segment variation of the measurements as a random effect. We analysed how many drive-days are needed for the mixed-effect model to improve predictions from LUR models and data-only mapping.

METHODS: We used black carbon data from the Air View study in Oakland, where every street segment was measured at least 50 times. We selected one drive day per street segment and compared the measurement, the LUR prediction and the mixed-model prediction with the average concentration based on 50 drive days of that street segment. We assumed that driving 50 times on a street segment reflects a robust long-term average concentration. We then sequentially added drive days to the dataset and computed the explained variance (R^2) and RMSE.

RESULTS: With one drive day on every street segment, the LUR model explained 63% of the variation, with very limited improvement in performance with increasing number of drive-days (65% for 50 drive days). The data-only map predicts less than 30% for one drive-day and more than 90% of the variance after 15 drive days, surpassing the LUR model in explained variance at 4-5 drive days. The mixed model outperformed the data-only and LUR model estimates, with 75% explained variance after 2 drive days and 90% after 12 drive days.

CONCLUSION: The mixed-model improves predictions compared to LUR and data already with two drive days and updates the model when more drives become available.

O-PK-11 Blood and urinary metal levels among exclusive marijuana users in the National Health and Nutrition Examination Survey (2005-2018)

Katlyn McGraw[1], Anne Nigra[1], Joshua Klett[1], Marisa Sobel[1], Xin Hu[2], Elizabeth Oelsner[1], Ana Navas-Acien[1], Tiffany Sanchez[1]

[1]Columbia University, New York, USA, [2]Emory University, Atlanta, USA

BACKGROUND AND AIM: Marijuana is the third most used drug in the world behind tobacco and alcohol; as more states legalize marijuana, recreational use continues to grow. Because cannabis, the marijuana plant, is a known scavenger of heavy metals, we hypothesized that individuals who use marijuana have higher metal biomarker levels compared to those who do not.

METHODS: To examine the relationship between marijuana use and metal exposures, we acquired and combined seven cycles of data from the National Health and Nutrition Examination Survey (2005-2018) for n=7,254 participants. Five metals were measured in blood and 16 in urine using inductively coupled plasma-mass spectrometry; urinary metals were adjusted for urinary creatinine. Individuals were grouped by: non-marijuana/non-tobacco use, current exclusive marijuana use, current exclusive tobacco use, and dual use; and by recent marijuana use: in the last 7 days, 30 days, or year. We built generalized linear models with non-marijuana/non-tobacco use as the reference.

RESULTS: We found 0.22µg/L (0.11, 0.34) and 0.18µg/g (0.06, 0.31) higher cadmium levels and 0.27µg/dL (0.07, 0.5) and 0.21 µg/g (-0.006, 0.50) higher lead levels in blood and urine, respectively, in participants reporting current marijuana use compared to non-marijuana/non-tobacco use when adjusting for sociodemographic factors, eGFR, and NHANES cycle year. We found 0.23µg/L (0.12, 0.35) and 0.20µg/g (0.03, 0.39) higher cadmium levels and 0.39µg/dL (0.11, 0.75) and 0.31µg/g (0.01, 0.70) higher lead levels in blood and urine, respectively, in those who had used in the last week compared to participants reporting no marijuana use.

CONCLUSIONS: Our results suggest that marijuana is a significant source of cadmium and lead exposure. Regulations regarding cannabis contaminants, particularly for metals, need to be addressed at the national level in order to address safety and public health concerns related to the growing number of cannabis users in the US.

KEYWORDS: metals, marijuana, cannabis

O-PK-12 Serum half-life of PFOA after end of exposure: a highly exposed community in the Veneto Region

Erich Batzella[1], Cristina Canova[1], Gisella Pitter[2], Francesca Russo[4], Tony Fletcher[3]
[1]Unit of Biostatistics, Epidemiology and Public Health, Department of Cardio-Thoraco-Vascular Sciences and Public Health, Padua, Italy, [2]Screening and Health Impact Assessment Unit, Azienda Zero-Veneto Region, Padua, Italy, [3]London School of Hygiene and Tropical Medicine, London, UK, [4]Directorate of Prevention, Food Safety, and Veterinary Public Health-Veneto Region, Venice, Italy

BACKGROUND AND AIM: Perfluoroalkyl substances (PFAS) are widely used, ubiquitous and highly persistent man-made chemicals. Groundwater of a vast area of the Veneto Region (North-Eastern Italy) was found to be contaminated by PFAS from a manufacturing plant active since the late 1960s. As a result, residents were exposed to PFAS through drinking water until autumn 2013. The aim of the present study was to estimate the decline rates in serum PFAS, and their corresponding serum half-lives, while characterizing their determinants.

METHODS: The population investigated in this study is a subgroup of the Regional health surveillance program target population consisting of subjects who enrolled in the second surveillance wave (n=2,619). The two blood samples were collected between January 2017 and December 2021. Four of the twelve measured PFAS were detected in greater than 50% of participants: PFOA (100%), PFOS (99.89%), PFHxS (99.01%) and PFNA (61.82%). Serum PFAS excretion rates and half-lives were estimated based on linear mixed effect models, adjusting for a set of contributing factors on PFAS pharmacokinetics such as age, sex, BMI, smoke-habit and eGFR.

RESULTS: Median initial serum concentrations were 62.6 ng/mL for PFOA, (range:0.6-1064), 4.6 ng/mL (range:0.5-142) for PFOS, 4.9 ng/mL (range:0.5-109.2) for PFHxS and, 0.6 (range:0.5-0.8) PFNA, with median declines of 61.18%, 36.96%, 40.82% and 41.67%, respectively. The median estimated PFOA's half-life was 2.90 years (95%CI:2.83-2.95). We found suggestive evidence that half-lives varied when stratified by gender and tertile of exposure, with more rapid elimination in men and higher tertiles of exposure.

CONCLUSIONS: Drinking water was the dominant route of exposure for PFOA so this study, the largest on PFOA half-life, offers great potential for studying interactions and risk modifications. Other PFAS longer half-lives than reported in other studies might be due to ongoing exposure to PFAS via other routes.
KEYWORDS: perfluoroalkyl substances; contaminated water; half-life.

O-PK-13 The challenge of assessing exposure to fast-elimination endocrine disruptors: When collecting? Which matrix? How many samples?

Brice Appenzeller[1], François Faÿs[1], Paul Palazzi[1]
[1]*Luxembourg Institute of Health, Strassen, Luxembourg*

BACKGROUND AND AIM: The assessment of human exposure to fast-elimination endocrine disruptors (FEED) such as phthalates, bisphenols or pesticides is usually based on urinary biomarkers. The variability of biomarkers concentration, due to rapid elimination from the body combined with frequent exposure is however pointed out as a major limitation to obtain reliable information. Collecting samples at specific times of the day, or increasing the number of samples have been suggested to improve the quality of exposure assessment. In parallel, the use of hair, less sensitive to short-term variations in the exposure, have also been proposed as a possible alternative. No consensus has however been reached yet on these points and providing a reliable information on exposure to FEED remains highly challenging.

METHODS: Urine and hair samples were repeatedly collected from 16 volunteers over a 6 months follow-up. 92 hair samples and 805 urines samples were collected and analyzed for 16 phthalate metabolites, 4 bisphenols and 8 pesticides metabolites.

RESULTS: 21 biomarkers were more frequently detected in urine, 6 in hair, and 1 was equivalent. Biomarkers were much more variable in urine, with intraclass correlation coefficients (ICC) ranging from 0.09 to 0.51, compared to 0.1 to 0.8 in hair. No preferred moment between first urine of the day, morning, afternoon and evening could be identified for urine collection. Algorithms demonstrated that between 10 (for monobenzyl phthalate) and 31 (for bisphenol S) samples were necessary to correctly classify 87.5% of the subjects into quartiles according to their level of exposure.

CONCLUSIONS: The study illustrates the complexity of assessing exposure to FEED and documents the respective advantages and limitations of urine and hair. These results provide new insights in exposure assessment based on biological matrices and will help to better design future biomonitoring strategies.

O-PK-14 Spatiotemporally resolved daily relative humidity predictions across Germany during 2000-2021: a Random Forest approach

Nikolaos Nikolaou[1,2], Laurens Bouwer[3], Marco Dallavalle[1,2], Kathrin Wolf[1], Mahyar Valizadeh[1], Massimo Stafoggia[4,5], Annette Peters[1,2], Alexandra Schneider[1]

[1]Institute of Epidemiology, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany, [2]Institute for Medical Information Processing, Biometry, and Epidemiology, Pettenkofer School of Public Health, LMU Munich, Munich, Germany, [3]Climate Service Center Germany (GERICS), Helmholtz-Zentrum Hereon, Hamburg, Germany, [4]Department of Epidemiology, Lazio Regional Health Service, Rome, Italy, [5]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

BACKGROUND AND AIM: The lack of high-resolution relative humidity (RH) datasets and the limited ability of available weather stations to fully capture the spatiotemporal RH variability might lead to errors in exposure assessment for epidemiological studies and biased health effects estimates. We aimed to predict German-wide 1×1 km daily mean RH during 2000-2021 by using a machine learning approach.

METHODS: We used data from multiple sources, including RH observations, modelled precipitation and wind speed as well as remote sensing elevation, vegetation and the visible red, green and blue light bands. Our main predictor for estimating RH was modelled daily mean air temperature that we previously estimated in 1×1 km across Germany through a multi-stage regression-based approach incorporating two linear mixed models. Additionally, we included date in our RH model, capturing the day-to-day variation of the response-explanatory variables relationship. All the aforementioned predictors were included in a Random Forest (RF) model, which was separately developed for each year.

RESULTS: Ten-fold cross validation showed that the RF model achieved high accuracy (R^2=0.81) and low errors (Root Mean Square Error (RMSE)=5.26%). We also compared our output with an independent dataset from a dense monitoring network in Augsburg metropolitan area (R^2=0.81, RMSE=5.42%). Our models displayed high RH overall (21y-average RH=78.8%) and high spatial variability within a year across the country, exceeding 12.1% on average. RH distribution followed spatial patterns including urbanization, mountains, rivers and coastlines. for instance, the Alps and the North Sea coast were areas with elevated RH, while extended urban cores or individual cities were less humid than the surrounding rural settings.

CONCLUSIONS: Our findings indicate the proposed RF model as suitable for countrywide RH modeling at high spatiotemporal resolution, providing a reliable dataset for subsequent epidemiological analyses and other research purposes.

KEYWORDS: relative humidity, spatiotemporal modeling, random forest, exposure assessment

O-PK-15 Exposure Differences Between Measures of Residential and Smartphone Mobility Derived Greenness in the US-Based Nurses' Health Study 3 Cohort

Grete Wilt[1], Charlotte Roscoe[1,2], Cindy R. Hu[1], Hari Iyer[3], Isabel Holland[1,2], Brent Coull[4], Jaime Hart[1,2], Steven Gortmaker[5], Francine Laden[1,2], Peter James[1,6]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Division of Population Sciences, Dana-Farber Cancer Institute, Boston, USA, [4]Department of Biostatics, Harvard T.H. Chan School of Public Health, Boston, USA, [5]Department of Social and Behavioral Sciences, Harvard T.H. Chan School of Public Health, Boston, USA, [6]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA

BACKGROUND AND AIM: Studies of greenness and health often rely on buffer-based residential measures which miss potential exposure occurring outside the home environment. We compared greenness measures obtained from traditional residence-based buffers and novel smartphone mobility-based estimates.

METHODS: We used data from the US-based Nurses' Health Study 3 mHealth study, which followed 348 participants who completed four 7-day sampling periods to capture seasonal variability across the year. We used Landsat Normalized Difference Vegetation Index (NDVI) data (30mx30m resolution) for both traditional and mobility-based greenness measures. We assessed two annual average residence-based estimates: 270m and 1230m. Mobility-based greenness exposure was calculated as seasonal NDVI values at GPS points captured every 10 minutes averaged across all four seasonal sampling periods. We compared measures using descriptive statistics, Bland Altman tests, and Generalized Additive Models.

RESULTS: Mean NDVI values from traditional residential buffers (270m=0.40, SD =0.12, 1230m=0.40, SD=0.12) were higher than those obtained using mobility derived NDVI (mean = 0.32, SD=0.11). The Bland Altman agreement bias was larger by 8.0% (95% CI: 7.0%, 9.0%) using the 270m residential measure and 7.3% (95% CI: 6.0%, 8.0%) using the 1230m residential measures compared to mobility derived NDVI. Spearman's rank correlations comparing the mobility and residential NDVI were 0.57 and 0.55 for the 270m and 1230m buffer respectively. The two residential buffers had a Spearman's rank correlation of 0.88. Lastly, for each 10% increase in both 270m and 1230m NDVI, was associated with 0.06 increase in mobility based NDVI (95% CI: 0.05, 0.07).

CONCLUSIONS: Results from our study indicate traditional residential estimates of greenness are higher than mobility derived metrics. These findings contribute to discussions surrounding the choice of an optimal spatial scale for greenness exposure.

O-PK-16 Biological and Environmental Sampling at ATSDR PFAS Exposure Assessment Sites

Karen Scruton[1], LCDR Bradley Goodwin[1], CAPT Peter Kowalski[1], Ana Pomales[1], Rachel Rogers[3], Elaine Cohen Hubal[2], Kent Thomas[2], Jeffrey Minucci[2]
[1]CDC/ATSDR, Atlanta, USA, [2]U.S. EPA/ORD, Research Triangle Park, USA, [3]NCEH/ATSDR, Atlanta, USA

BACKGROUND AND AIM: The Agency for Toxic Substances and Disease Registry (ATSDR) conducted biomonitoring exposure assessments (EAs) in communities near U.S. military installations that have documented PFAS in drinking water. PFAS in drinking water were mitigated prior to initiation of the EAs.

METHODS: EAs were conducted in ten communities using a community sampling design to evaluate PFAS serum concentrations in communities with PFAS in drinking water. PFAS in urine was measured in a subset of participants. PFAS in indoor dust and tap water were evaluated in a subset of households. All participants completed a questionnaire to gather information to characterize exposure and the responses were evaluated to identify demographic and exposure characteristics associated with PFAS levels in serum.

RESULTS: The relationships between PFAS levels in drinking water and concentrations of PFAS in serum will be presented for two locations, Hampden County Massachusetts and New Castle County Delaware. The primary PFAS elevated in serum included PFHxS, PFOS, and PFOA which were associated with drinking water exposure. PFAS levels in serum were compared to CDC's National Health and Nutritional Examination Survey (NHANES). Males had higher PFAS serum levels than females at both locations; additional site-specific findings regarding serum levels and demographic and exposure characteristics information will be presented. Dust sampling results indicated that non-drinking water sources of PFAS may contribute to exposure.

CONCLUSIONS: The results of testing at the PFAS EA locations presented indicate that levels of PFAS in drinking water are associated with increased levels of PFAS in serum. Additional environmental sampling is being conducted in partnership with U.S. EPA in Delaware and Massachusetts to evaluate potential non-drinking water exposures to PFAS.

KEYWORDS: Exposure, PFAS

The findings and conclusions in this presentation have not been formally disseminated by CDC/ATSDR and should not be construed to represent any agency determination or policy.

O-PK-17 Associations of prenatal exposure to per- and polyfluoroalkyl substances (PFAS) with measures of cognition in 7.5-month-old infants

Stephanie Eick[1], Elizabeth Enright[2], Andrea Aguiar[3], Amy Padula[4], Sarah Geiger[3,5], Tracey Woodruff[4], Rachel Morello-Frosch[4,6], Susan Schantz[3,7]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Department of Psychology, St. Mary's College of Maryland, St Mary's City, USA, [3]Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign, Champaign, USA, [4]Program on Reproductive Health and the Environment, Department of Obstetrics, Gynecology and Reproductive Sciences, University of California, San Francisco, San Francisco, USA, [5]Department of Kinesiology and Community Health, University of Illinois at Urbana-Champaign, Champaign, USA, [6]Department of Environmental Science, Policy and Management and School of Public Health, University of California, Berkeley, Berkeley, USA, [7]Department of Comparative Biosciences, University of Illinois at Urbana-Champaign, Champaign, USA

BACKGROUND: Per- and polyfluoroalkyl substances (PFAS) are man-made chemicals that are of health concern given their persistence in the environment and human body, and transmission to offspring during pregnancy. Studies examining the relationship between PFAS and neurodevelopment are inconclusive and largely have been conducted in older children. In the present study, we examined whether prenatal exposure to a mixture of PFAS was related to cognitive function in infancy.

METHODS: Pregnant participants were enrolled in the Chemicals in Our Bodies cohort and Illinois Kids Development Study, which together make up the ECHO.CA.IL cohort. Seven PFAS were previously measured in 2nd trimester maternal serum samples and were natural log transformed for analyses. Infant cognition was assessed at 7.5 months using a visual recognition memory task that tracks infant looking behavior using an infrared eye tracker. From the eye-tracking data, we calculated two measures of attention (based on infants shifting their looking between two stimuli, and the time it took them to reach cumulative looking criterion), information processing speed (based on how long infants looked at the stimuli before looking away) during the familiarization trial, and recognition memory (based on infants' looking at novel compared to the familiar stimulus) in the test trial. Bayesian kernel machine regressions (BKMR) were used to assess joint associations between multiple PFAS and individual cognitive outcomes (N=160).

RESULTS: Unexpectedly, prenatal exposure to the PFAS mixture was modestly associated with better attention, as indicated by faster shifts between stimuli, with PFNA, PFOS, PFHxS, and PFUdA contributing the most to the overall mixture effect. Increasing exposure to the PFAS mixture was weakly associated better information processing speed and attention although credible intervals include the null value.

CONCLUSIONS: Using a visual recognition memory task, we observed little evidence that prenatal PFAS exposure is associated with cognitive function.

KEYWORDS: PFAS, mixtures, neurodevelopment

O-PK-18 Effects of Artificial Light at Night on Body Mass Index and Islet Autoimmunity Development in Children in Bavaria, Germany

Mahnaz Badpa[1,2,3], Kathrin Wolf[1], Alexandra Schneider[1], Christiane Winkler[3,4], Florian Haupt[3,4], Annette Peters[1,5], Anette-Gabriele Ziegler[3,4,6]

[1]Institute of Epidemiology, Helmholtz Zentrum Munchen, Munich, Germany, [2]Institute for Medical Informatics, Biometrics and Epidemiology, Ludwig-Maximilians-Universität (LMU) Munich, Munich, Germany, [3]German Center for Diabetes Research (DZD), Munich, Germany, [4]Institute for Diabetes Research, Helmholtz Diabetes Center at Helmholtz Zentrum München, Munich, Germany, [5]Chair of Epidemiology, Faculty of Medicine, Ludwig-Maximilians-Universität München, Munich, Germany, [6]Forschergruppe Diabetes, Technical University Munich at Klinikum rechts der Isar, Munich, Germany

BACKGROUND AND AIM: Worldwide, incidence of childhood obesity and early-onset type 1 diabetes (T1D) has risen over the past decades. Epidemiological studies have shown that in addition to genetic predisposition, environmental factors such as air pollution and temperature are associated with body mass index (BMI), T1D and its presymptomatic stage of autoimmunity to pancreatic islet cells. This study aimed to investigate the effect of exposure to light at night (LAN) on standardized BMI and islet autoimmunity (having 2 or more islet autoantibodies) in children in Bavaria, Germany.

METHODS: Exposure to LAN at baseline was assigned to the residential addresses of 52,636 children (<6 years of age) participating in the Fr1da study from 2015 to 2019. Information on demographic characteristics was extracted from self-administered questionnaires. We investigated the association of LAN with standardized BMI using linear regression and with islet autoimmunity using generalized additive models, segmented regression and quartile analysis. All models were adjusted for sex, age, family history of diabetes and area-level socioeconomic status (SES).

RESULTS: The mean standardized BMI was 0.12 ± 1.04 and 225 children showed islet autoimmunity. A 10 nW/cm2/sr increase in LAN was significantly associated with a 2.14% increase in standardized BMI (95% confidence interval (CI): 0.86-3.45). Also, LAN exposure was linearly associated with a significantly higher odds of islet autoimmunity in children with exposure levels up to 11 nW/cm2/sr (Odds ratio (OR): 1.98; 95% CI: 1.14-3.45). Similar, quartile analyses showed a greater risk of islet autoimmunity especially for the third quartile (Q3: 5.2-11.6 nW/cm2/sr) of LAN compared to the lowest quartile (Q1: 0.0-2.0 nW/cm2/sr; OR: 1.71; 95% CI: 1.19-2.47).

CONCLUSION: Exposure to LAN might be a further environmental risk factor contributing to higher BMI and islet autoimmunity in children.

KEYWORDS: Light at night, light pollution, body mass index, islet autoimmunity

O-PK-20 The association between ambient temperature exposure during infancy and overweight at age two years

Neora Alterman[1], Ronit Calderon-Margalit[1], Michael Hauzer[2], Itai Kloog[3], Raanan Raz[1]
[1]The Hebrew University of Jerusalem, Jerusalem, Israel, [2]Clalit Health Services, Israel, [3]Ben-Gurion University of the Negev, Beer-Sheva, Israel

BACKGROUND AND AIM: Childhood overweight and obesity is increasing in prevalence globally and is a risk factor for metabolic disease in adulthood. We have previously described an association between exposure to higher ambient temperatures during infancy and rapid infant weight gain. We aimed to examine the association between ambient temperature exposure during the first year of life and overweight at age two years.

METHODS: A population-based cohort study using data from the Israeli network of public maternal and child health clinics from 2011 to 2018. The study population was restricted to children born with birthweight ≥2500g (N=579,404). We assessed exposure to ambient temperature using a high-resolution spatio-temporal model and calculated the average annual exposure during the first year of life for each infant based on daily temperature at their address. Overweight at two years was defined as >85th percentile in World Health Organization age and sex-adjusted body mass index. We calculated relative risks using log-linear models and fitted general additive models with thin plate regression splines while adjusting for sub-district, neighbourhood socio-economic index, ethnicity, month and year of birth and average ambient temperature during pregnancy.

RESULTS: We found a positive association between ambient temperature exposure and risk of overweight at age two years. Children exposed to the highest temperature quintile (≥22.0°C) had an adjusted relative risk of 1.16 (95% CI 1.12, 1.19) compared to those exposed to the lowest quintile (<19.6°C). Modelling temperature as a continuous variable using general additive models showed an increase in risk with higher temperature exposure up to approximately 23°C when the risk levelled out.

CONCLUSIONS: Exposure to higher ambient temperatures during infancy is associated with increased risk of overweight at age two years in Israel. Future studies should explore this association in other populations and examine possible biological mechanisms.

KEYWORDS: temperature, child health, climate

O-PK-21 Prenatal Exposure to Air Pollution and Childhood Lipid Levels: The Rhea Birth Cohort (Greece)

Theano Roumeliotaki[1], Katerina Margetaki[1], Minas Iakovides[2], Euripides Stephanou[2], Manolis Kogevinas[3], Leda Chatzi[4], Marina Vafeiadi[1]

[1]Department of Social Medicine, School of Medicine, University of Crete, Heraklion, Greece, Heraklion, Greece, [2]Environmental Chemical Processes Laboratory (ECPL), Department of Chemistry, University of Crete, Heraklion, Greece, [3]ISGlobal, Barcelona, Spain, [4]Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Abnormal blood lipid profiles in childhood are an important precursor to atherosclerosis and cardiovascular disease. Air pollution has been associated with lipid levels in animal models; however, evidence from human studies remains insufficient and inconclusive. We evaluated the associations of pregnancy exposure to air pollution with serum lipid profiles during childhood in the Rhea birth cohort, Greece.

METHODS: Residential exposure to particulate matter <10 μm (PM10) and <2.5 μm (PM2.5) during pregnancy was estimated with temporally adjusted land-use regression models. We measured triglycerides (TG), total cholesterol (TC), HDL- and LDL- cholesterol at 4, 6, and 11 years. Abnormal lipid levels in children were defined according to the US NHLBI guidelines. We assessed associations with multivariate regression models and effect modification by sex.

RESULTS: Prenatal PM2.5 and PM10 levels ranged between 13.0 and 18.7 μg/m3 and 34.9 and 54.6 μg/m3, respectively. PM10 concentrations over the 4th quartile were associated with lower TG levels overall (β= -5.25 mg/dL, 95% CI: -10.38, -0.11) and lower TC and TG levels in girls (β= -6.87 mg/dL, 95% CI: -13.78, 0.05; β= -9.03 mg/dL, 95% CI: -17.05, -1.01 respectively) at 4 years. at 11 years, higher prenatal PM10 levels were associated with both higher levels of TC and LDL (β= 7.75 mg/dL, 95% CI: -0.17, 15.68; β= 7.40 mg/dL, 95% CI: 0.36, 14.45) but also higher risk for elevated TC and LDL. Associations at 11 years were stronger in girls, indicating a sex-dependent effect. Associations with PM2.5 were in the same direction but not significant. No associations were observed at 6 years.

CONCLUSIONS: These results shed new light on the importance of controlling air pollution, which can contribute to abnormal blood lipid levels during childhood, an independent risk factor for adult cardiovascular disease.

KEYWORDS: prenatal, air pollution, lipids, children

O-PK-22 The relationship between pregnancy phthalate exposure and language development at 2 years of age

Megan Woodbury[1,2,3], Kelsey Dzwilewski[2,3], Patricia Cintora[2], Shukhan Ng[2], Antonia Calafat[6], Pamela Hadley[4], Susan Schantz[3,5]

[1]PROTECT Center, College of Engineering, Northeastern University, Boston, USA, [2]Neuroscience Program, University of Illinois at Urbana-Champaign, Urbana, USA, [3]Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign, Urbana, USA, [4]Department of Speech and Hearing Science, University of Illinois at Urbana-Champaign, Urbana, USA, [5]Department of Comparative Biosciences, University of Illinois at Urbana-Champaign, Urbana, USA, [6]National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA

BACKGROUND AND AIM: Phthalates are endocrine disrupting chemicals found in many consumer products. Pregnancy exposure has been associated with adverse neurodevelopmental outcomes, but few studies have examined their association with language development. Even less is known about replacements for commonly used phthalates.

METHODS: The MacArthur-Bates Communicative Development Inventories (CDI) was used to evaluate language development in 300 2-year-old children (average age of 27 months; 149 males, 151 females) in the Illinois Kids Development Study. Phthalate metabolites were quantified in a pool of five maternal urine samples collected across pregnancy. Associations of monoethyl phthalate (MEP) and the sums of metabolites of di(2-ethylhexyl) phthalate (ΣDEHP), di(isononyl) phthalate (ΣDINP), antiandrogenic phthalates (ΣAA), and di(2-ethylhexyl) terephthalate (ΣDEHTP) with each CDI outcome were assessed using generalized linear models. Models were adjusted for child age and sex, delivery type, and maternal age, education, verbal IQ, and parity.

RESULTS: Most mothers were white, non-Hispanic, college educated, approximately 30 years old, and gave birth vaginally. Most children were firstborn. All phthalate exposure biomarkers were associated with changes in vocabulary scores. MEP and ΣDEHTP were also associated with the mean of the three longest utterances (M3L) and with language complexity scores. MEP and ΣDEHTP were both associated with lower vocabulary scores (MEP β=-12.16,95% CI:-21.15,-3.17; ΣDEHTP β=-21.09,95%CI:-38.83,-3.36), M3L scores (MEP β=-0.12,95%CI:-0.25,0.02; ΣDEHTP β=-0.28,95%CI:-0.54,-0.02), and complexity scores (MEP β=-0.67,95%CI:-1.33,-0.02; ΣDEHTP β=-1.15,95%CI:-2.45,0.16). Associations of other biomarkers with vocabulary were specific to male children. ΣAA (β=-31.86,95%CI:-67.47,3.74) and ΣDEHP (β=-19.89,95%CI:-41.96,2.18) were associated with lower vocabulary scores in males while ΣDINP (β=12.50,95%CI:0.63,24.36) was associated with higher vocabulary scores in males.

CONCLUSIONS: Pregnancy exposure to some phthalates, particularly DEP and DEHTP, a replacement for DEHP, may be related to poorer language outcomes at 2 years of age, especially in male children.

KEYWORDS: language development, phthalates, neurodevelopment

O-PK-23 Big Data-Driven Korean CHildren's ENvironmental health Study (Ko-CHENS): Big-CHENS

Jongmin Oh[1], Whanhee Lee[1,2], Jueun Lee[3], Suejin Kim[3], Choonghee Park[3], Seulbi Lee[4], Su Young Kim[5], Eunhee Ha[1,2,6], Ko-CHENS Study group[7,8]

[1]Department of Environmental Medicine, School of Medicine, Ewha Womans University, Seoul, Republic of Korea, [2]Institute of Ewha-SCL for Environmental Health (IESEH), College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [3]Environmental Health Research Division, National Institute of Environmental Research, Incheon, Republic of Korea, [4]Department of Big Data Strategy, National Health Insurance Service, Wonju, Republic of Korea, [5]Department of Preventive Medicine, College of Medicine Jeju University, Jeju, Republic of Korea, [6]Graduate Program in System Health Science and Engineering, Ewha Womans University, Ewha Medical Research Institute, College of Medicine, Seoul, Republic of Korea, [7]Core Center,, [8]Supportive Center,

BACKGROUND AND AIMS: The Korean CHildren's ENvironmental health Study (Ko-CHENS) has been established in May 2015 and has recruited a total of 70,000 nationally-representative mothers with its two enrollment tracks (65,000 in the Main Cohort and 5,000 in the Core Cohort) from Jun 2015 through Feb 2021. Concurrently, we have launched a cohort titled "Big CHildren's ENvironmental health Study (Big-CHENS)" including all newborns and mothers in Korea, which is the target population of Ko-CHENS. Prior to Ko-CHENS, Big-CHENS commenced its mother registration in Jan 2015 and completed it in Dec 2021. Big-CHENS aims to investigate the nationwide association between environmental exposures and children's health.

METHODS: Big-CHENS is primarily based on medical records on delivery of mothers ("delivery code") provided by the National Health Insurance Service (NHIS) covering the entire Korean population, along with all Ko-CHENS participants. Based on the NHIS delivery code and PIN, Big-CHENS obtains medical records on newborns (up to 18 y) and parents (from 3-year before delivery to 1-year after delivery), and this registration procedure is expected to collect 97% of total births. Furthermore, Big-CHENS constructs the integrated-database including NHIS eligibility, medical utilization, periodic health screenings (up to 71 months), and neonatal deaths, via data linkages with NHIS, the Ministry of Education, and Statistics in Korea.

RESULTS: Since Jan 2015, over 1.7 million mother-child pairs (with 53,185 pairs from Ko-CHENS) have been registered in Big-CHENS, and 0.91 million male children and 0.86 million female children are included. Preterm birth and low birth weight rates were 7.1% and 6.1%. Big-CHENS also has been revealing the associations of environmental exposures with delivery and children's health outcomes.

CONCLUSIONS: The population-based Big-CHENS birth cohort is expected to identify the national effects of environmental exposures on health in childhood and provide scientific evidence for evidence-based life-course-persistent interventions for environmental health in childhood.

O-PK-25 Quantification of waste in schools: A case study in Danang City, Vietnam

Nguyen Xuan Huong[1], Nguyen Tran Anh Vu[2], Nguyen Thi Thuy Nga[2], Tran Minh Huan[1], Ngo Hoang Anh Ngoc[2], Ho Nguyen Kim Tram[2], Hoang Nguyen Nhat Linh[1]

[1]Da Nang University of Medical Technology and Pharmacy, Da Nang City, Vietnam, [2]Center for Adaptive Capacity Building Research, Da Nang city, Vietnam

BACKGROUND AND AIM: Waste is a major problem that can affect the environment and health; especially in developing countries where there is often a lack of an appropriate system for waste treatment. Understanding the current situation of waste, its common type and amount are important to develop appropriate strategies for waste control, especially in a school-based setting. This study has been conducted to identify common types of waste that are disposed in schools and quantify such waste.

METHODS: This study used an audit method to identify the common types of waste and quantify such waste in Da Nang city in 2021.

RESULTS: There were four schools with a total number of 3064 students were participated in this study. The average total volume of waste that schools discharge in a day is 460kg (accounting for 7542 litres of storage volume); in which, organic waste has the largest volume of 261kg (57% of total volume) accounting for 2262 litres (30% of total volume); non-recyclable waste weights 175kg (38% of the total volume) with a maximum volume of 4524 litres (60% of the total volume); recyclable waste has a weight of only 22kg (5% of total volume) accounting for 719 litres (10% of total volume); The remaining types of waste are insignificant. This study also showed the presence of a large number of plastic bags (2128 pieces), multi-layer packaging (2036 pieces), milk cartons (1047 boxes), straws (772 pieces), plastic bottles (670 bottles), foam boxes (531 pieces), plastic spoons (400 pieces), polypropylene plastic cups (327 pieces) in the total waste produced in one day in these schools.

CONCLUSIONS: Schools are emitting a large amount of waste, significantly plastic waste. Intervention programs in the school-based setting are needed to reduce the amount of waste toward ensuring health for children and protecting the environment.

O-PK-27 High Ambient Temperatures and Child/Young Adult Injury Emergency Department Visits in NYC

Blean Girma[1], Bian Liu[2], Ellen J. Kinnee[3], Leah H. Schinasi[4,5], Jane Clougherty[4], Perry E. Sheffield[1]
[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York, USA, [3]University Center for Social and Urban Research, University of Pittsburgh, Pittsburgh, USA, [4]Department of Environmental and Occupational Health, Drexel University Dornsife School of Public Health, Philadelphia, USA, [5]Drexel University Urban Health Collaborative (UHC), Drexel University Dornsife School of Public Health, Philadelphia, USA

BACKGROUND AND AIM: Despite a growing literature on effects of ambient temperature and climate change on health, there remains little research quantifying associations between ambient temperature and violence-related or unintentional injury, particularly among children and adolescents. Here, we examined associations between ambient minimum daily temperature (Tmin) and emergency department (ED) visits for pediatric injury during warm months in New York City (NYC).

METHODS: We examined all ED visits among patients 0-25 years, during May-September 2010, with primary injury diagnosis (ICD-9) (n=108,447). We performed conditional logistic regression, in a case-crossover design, using distributed lag non-linear functions (DLNMs), adjusting for long-term time trends and daily relative humidity. We modeled the lag-response curve across lag days 0-5, estimating cumulative odds ratios (OR) across lag days, compared to odds at observed minimum-injury temperature (MIT, 42° F)). We also stratified analyses by age and injury type.

RESULTS: Across all ages and injury type, case-day Tmin was significantly associated with increased odds of injury, though associations were inconsistent across lag days. Across five-year age groups, children aged 5-9 (n =17,810) had the highest odds of injury [adj OR = 1.66 (95% CI: 1.24 - 2.24)] for days with Tmin >95th percentile (78 °F) compared to the MIT, with elevated risks of violence-related and unintentional injury (OR =1.74 (95% CI: 1.18-2.57) and OR = 1.66 (95% CI: 1.42-1.93, respectively)).

CONCLUSIONS: Elevated ambient temperature was associated with higher risk of ED visits for injury among ages 0-25. Future analyses will explore variation in effects of heat by socio-economic position and discriminatory race-based policies (e.g., redlining) over an extended observation period.

O-PK-28 Injury occurrence and gender-related factors among child workers in Nicaragua: a crossectional study

Steven Cuadra[1], Rosa Noemi Fuertes Toledo[2], Martha Gallo[2]
[1]Universidad de Occidente (UdO Managua), Managua, Nicaragua, [2]Casa Emilia Salud, Managua, Nicaragua

BACKGROUND AND AIM: Few studies have explored the effect of gender on injuries occurrence among child workers, despite multiple studies indicating gender often dictates occupations, tasks, and working conditions of boys and girls in developing countries. We aimed to assed the influence of gender-related factors on non-work-related (non-WRI) and work-related injuries (WRI) occurrence in child workers in Nicaragua.

METHOD: We performed a crossectional study among children (3 to 17 years of age) working in agriculture (n=120), street working children (n=108), and non-working referents (n=140) in 2019. We investigated self-reported non-WRI and WRI during the previous 12 months. Incidence rate (IR) per 1000 person-days, rate ratios (RR), and 95% CI were calculated by multivariate Poisson regression.

RESULTS: Child workers had a higher global incidence of injury than nonworking children (3.8 vs 0.7; p=0.001). Street workers had a higher incidence of WRI than agricultural workers (2.1 vs 1.6; p=0.022). When we analyzed only injuries occurring at work boys have a higher incidence than girls (2.3 vs 1.8; p=0.43) but when we included injuries that occurred when performing household chores girls had a higher incidence than boys (3.3 vs 2.2; p<0.0001). Moreover, girls had a higher incidence of severe injuries than boys (1.5 vs 0.9; p=0.012), Factors that increased the risk of WRI among all children, but with a higher impact among girls, were age ≤10 years), the number of working hours at work and home, single-parent family, living on the streets, out of school, alcohol or drug consumption, and pregnancy or parenthood.

CONCLUSION: Our data suggest girls are at higher risk of WRI than boys, especially for severe injuries, and that relevant risk factors are modifiable. A deeper gender analysis of injury occurrence and determinants may allow for more effective targeting of prevention efforts.

THEMATIC 19: Reproductive outcomes

O-PK-19 Prenatal Exposure to Ambient Particle Radioactivity and Fetal Growth in Eastern Massachusetts

Veronica Wang[1], Michael Leung[1,2], Longxiang Li[1], Anna M. Modest[3], Michele R. Hacker[2,3], Joel Schwartz[1], Brent Coull[4], Petros Koutrakis[1], Stefania Papatheodorou[2]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [2]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [3]Department of Obstetrics and Gynecology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, USA, [4]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Particle radioactivity (PR) is a property of particulate matter (PM) originating from attached radon decay radionuclides. After PM is inhaled, radiation can continue to be emitted locally in the lungs or it can translocate to other parts of the body. PR has been previously associated with adverse pregnancy outcomes, and we investigated its association with fetal growth.

METHODS: We included singleton births with routine obstetric ultrasounds at an academic medical center in Massachusetts from 2011 through 2016. PR was represented by particle gross β-activity (mBq/m3) estimated from an ensemble model and was assigned based on residential zip-code. We considered two exposure windows: first 16 weeks of pregnancy and conception until fetal growth measurement (cumulative PR). Standardized (z-score) biparietal diameter (BPD), head circumference, femur length (FL), and abdominal circumference (AC) were examined on anatomic scans (<24 weeks' gestation) and growth scans (≥24 weeks' gestation), and weight was measured at birth. We used linear mixed models adjusted for PM ≤2.5 μg/m3, maternal risk factors, meteorological variables, and long-term trends.

RESULTS: Among 9.409 pregnancies, an interquartile range increase in cumulative PR was associated with reduced BPD (-0.07 [95% CI: -0.12, -0.01]) and FL (-0.07 [95% CI: -0.12, -0.01]) on anatomic scans and birth weight (-0.06 [95% CI: -0.11, -0.002]). While the association with AC was positive in early growth scans, it decreased with gestational age and was negative after week 35. First 16 weeks of gestation was not a critical window of exposure.

CONCLUSIONS: Prenatal PR was associated with fetal growth independently of particle mass, where the direction of the association depended on the fetal growth measure and the gestational age at measurement. Our findings are consistent with patterns previously observed among pregnancies with gestational diabetes and bring awareness to a novel environmental exposure.

KEYWORDS: air pollution, fetal growth, pregnancy

O-PK-24 Ambient Air Pollution and Preeclampsia Onset in Massachusetts, USA

Yi Zheng[1], David Cantonwine[2], Thomas McElrath[2,3], Hui Hu[1]

[1]Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [2]Division of Maternal Fetal Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Ambient particulate matter and gaseous air pollution have been linked to preeclampsia. However, despite the recognition that preeclampsia is likely a heterogenous syndrome with distinct pathogenic mechanisms, few studies have examined the association between air pollution and subtypes of preeclampsia. Our objective was to examine differential impacts of air pollution on early- vs. late-onset (i.e., diagnosed in or after 34th gestation week) preeclampsia among pregnant women in the Boston, Massachusetts based biorepository, LIFECODES.

METHODS: Preeclampsia was diagnosed according to the American College of Obstetrics and Gynecologists guidelines and each case was reviewed by a panel Maternal–Fetal Medicine–certified physicians. Women's exposures to ozone and fine particulate matter (PM2.5) during pregnancy were estimated based on geocoded residential addresses using U.S. Environmental Protection Agency's Fused Air Quality Surface Using Downscaling Files. Cox proportional hazards models and multinomial logistic regression were used to examine the associations of ozone and PM2.5 with preeclampsia and its onsets. Hazard ratio (HR), odds ratio (OR), and 95% confidence interval (95% CI) for each interquartile range increase in exposures were reported.

RESULTS: A total of 3,316 pregnant women were included. In the cox model, higher exposures to ozone during pregnancy were associated with higher hazard being diagnosed with preeclampsia (HR: 1.67, 95% CI: 1.16, 2.40). In the multinomial logistic regression model, ozone was significantly associated with early-onset preeclampsia (OR: 2.50, 95% CI: 1.48, 4.21) but not late-onset preeclampsia (OR: 1.34, 95% CI: 0.96, 1.88), and PM2.5 was significantly associated with both early- (OR: 1.62, 95% CI: 1.07, 2.45) and late-onset preeclampsia (OR: 1.32, 95% CI: 1.02, 1.71).

CONCLUSIONS: Exposures to ozone and PM2.5 were significantly associated preeclampsia. This association was significant with respect to ozone exposure in the earlier onset, but not later onset, preeclampsia. This study highlights the importance of assessing the heterogeneity in preeclampsia.

O-PK-26 Peri-conceptional exposure to ambient air pollution increases risk of gestational diabetes among pregnant participants in the Maternal and Developmental Risks from Environmental and Social Stressors (MADRES) study

Zhongzheng Niu[1], Rima Habre[1], Tingyu Yang[1], Brendan H. Grubbs[2], Claudia Toledo-Corral[1], Jill Johnston[1], Genevieve F. Dunton[1], Deborah Lerner[3], Laila Al-Marayati[2], Fred Lurmann[4], Nathan Pavlovic[4], Theresa M. Bastain[1], Carrie V. Breton[1], Shohreh F. Farzan[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [2]Department of Obstetrics and Gynecology, University of Southern California, Los Angeles, USA, [3]Eisner Health, Los Angeles, USA, [4]Sonoma Technology, Inc, Petaluma, USA

BACKGROUND: Exposures to air pollution potentially disrupt maternal metabolic adaptation during pregnancy. However, influences of preconception and prenatal exposures to ambient air pollution on gestational diabetes mellitus (GDM) remain unclear, and even less is known about sensitive windows for these exposures' effect on GDM.

METHODS: In 617 pregnant participants enrolled the Maternal and Developmental Risks from Environmental and Social Stressors (MADRES) study, we estimated daily levels of ambient particulate matter (PM_{10}; $PM_{2.5}$), nitrogen dioxide (NO_2), ozone (O_3) using spatial interpolation. GDM was ascertained from medical records by physician diagnosis or defined as abnormally high glucose challenge and tolerance test results. We used distributed lag models (DLM) with Poisson regression to identify sensitive exposure windows by estimating weekly associations of exposures from pre-conception week (PcW) 12 to gestational week (GW) 24 with GDM risk, adjusting for maternal and meteorological factors. Analyses were additionally stratified by median prenatal Perceived Stress Scale (PSS, 14), median pre-pregnancy body mass index (BMI, 27.5 kg/m^2), median age (28 years), and newborn sex to explore differential susceptibility to exposure effects.

RESULTS: Sixty (9.7%) participants were diagnosed with GDM. We identified sensitive peri-conceptional exposure windows for $PM_{2.5}$, PM_{10}, and NO_2 ranging from PcW5 to GW3 associated with increased GDM risk. An IQR increase in each pollutant was associated with 5% (95%CI: 3.3-6.7%), 6% (5.9-7.4%), and 11% (9.3-12.2%) increased GDM risk, respectively. In stratified analyses, effects of PM_{10} and NO_2 in the identified sensitive windows were greater among those ≥28 years old, with BMI≥27.5 kg/m^2, or with PSS≥14.

CONCLUSIONS: Peri-conception exposures to ambient air pollutants were associated with increased risk of GDM. Stronger effects in the identified sensitive windows were seen in participants who were older, had higher BMI, or higher perceived stress.

PECHA KUCHA SESSION 04: Climate change and health

THEMATIC 07: Climate change and Health

O-PK-29 Premature mortality due to temperature changes by 2050 in Chile

Luis Abdón Cifuentes[1], Daniela Quiroga[2], Jose-Miguel Valdes[2], Camila Cabrera[1]
[1]*Pontificia Universidad Católica De Chile, Santiago, Chile,* [2]*Greenlab/DICTUC, Santiago, Chile*

BACKGROUND AND AIM: Increases in daily average temperatures and in the intensity and frequency of heatwaves are expected to have several effects in the health of the population, including premature mortality, but it can vary by climate types. Due to its geography, Chile has 10 Koppen types of climates, from hot arid to ice caps.

METHODS: Groups of similar climate municipalities with more than 100.000 inhabitants were obtained through cluster analyses and exposure-response functions were fitted using DLNM models. A representative exposure-response function was developed for each of 6 climatic regions via meta-analysis.

RESULTS: The ER functions for each region of the country varied accordingly to their climate.
In the north, there was no effect of low temperatures. In the central zones, a U shape ER was obtained, with a higher risk for low and high temperatures. In the south and Austral regions, there was only an increase in risk for lower temperatures.
The increase in premature mortality by 2050 varied according to the region. In the north region, the increase was observed only in the warm season. In the central regions, the decrease in deaths in the cold season could not offset the increase in the warm season. Finally, in the southern regions, the net effect was a reduction in premature mortality due to the warming in the cold season. for the whole country a decrease of 650 (-1220 to -70) in the cold season, and an increase of 1,430 (210 to 2,660) deaths was compted, with a net effect of 790 (-150 to 1,700)

CONCLUSIONS: The impact of climate change on premature mortality varies in hot and mild climates there is a net increase, while in colder climates the opposite was observed. This has important implications for adaptation measures.

KEYWORDS: Climate change, temperature increase, heat waves, premature mortality

O-PK-30 Inclement Weather and Risk of Missing Scheduled Hemodialysis Appointments

Hyeonjin Song[1,2], Richard Remigio[2,3], Xin He[1], Jochen Raimann[4], Peter Kotanko[4,5], Frank Maddux[4], Amir Sapkota[2]
[1]Department of Epidemiology and Biostatistics, University of Maryland College Park, College Park, USA, [2]Maryland Institute for Applied Environmental Health, University of Maryland College Park, College Park, USA, [3]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, USA, [4]Research Division, Renal Research Institute, New York, USA, [5]Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: Non-adherence to dialysis treatments results in health complications that are associated with increased morbidity and mortality in hemodialysis patients. We examined the association between different types of inclement weather conditions and missed dialysis treatments.

METHODS: We obtained health records on end-stage kidney disease (ESKD) patients who received hemodialysis at Fresenius Kidney Care (FKC) clinics across the Northeastern U.S. during 2001-2019. County-level daily meteorological data on rainfall, hurricane events, snowfall, snow depth, and wind speed were extracted through the National Oceanic and Atmosphere Agency (NOAA) database. A time-stratified case-crossover study design with conditional Poisson regression was employed to estimate the effect of inclement weather exposures on hemodialysis treatment adherence. We applied distributed lag non-linear model (DLNM) framework to estimate the delayed effect of inclement weather for up to one week.

RESULTS: We studied 28,620 ESKD patients from 27 northeastern counties who had any missed hemodialysis appointment. Overall, the missed appointment rate was higher for all of the inclement weather type (rainfall, hurricane, snowfall, snow depth, and wind advisory) compared to non-inclement weather days. The risk of missed appointment was highest at lag 0 for 10mm increase of rainfall (RR=1.027, 95% CI: 1.021, 1.032), snowfall (RR=1.019, 95% CI: 1.017, 1.021), and snow depth (RR=1.014, 95% CI: 1.013, 1.016). Hurricane events showed the highest RR at lag 5 (RR=1.163, 95% CI: 1.016, 1.332). Wind advisory showed sustained higher risk compared to non-exposure days through up to lag 5.

CONCLUSIONS: All types of inclement weather events showed increased risk of missed hemodialysis appointments. Since inclement weather events are projected to increase due to ongoing climate change, our findings suggest the need for enhanced climate readiness by health care delivery systems that include early warning systems disaster response plans for delivering uninterrupted dialysis-related health services.

KEYWORDS: inclement weather, climate change, hemodialysis

O-PK-31 Wildfire exposure and health care use among people who use durable medical equipment in Southern California

Heather McBrien[1], Sebastian Rowland[1], Tarik Benmarhnia[2], Sara Tartof[3], Joan Casey[1]
[1]Columbia University Medical Center, [2]University of California San Diego, [3]Kaiser Permanente Southern California,

BACKGROUND: Climate change-induced wildfires cause trauma, stress, and injury in affected communities, while exposing 70% of the US population to smoke particulate matter (PM2.5) annually and exacerbating cardiorespiratory disease. Few studies examine wildfire smoke exposure in vulnerable populations, and none evaluate residence near a fire.

METHODS: We identified 236,732 Kaiser Permanente Southern California members who used electricity-dependent durable medical equipment (DME). DME use is associated with respiratory illness and disability, indicating vulnerability to smoke exposure and difficulty evacuating disaster zones. Daily counts of outpatient, inpatient, and emergency healthcare visits made by DME users from 2016-2020 were linked with daily estimates of wildfire generated PM2.5 by residential ZIP code. We used historical maps to identify ZIPs within 20 km of the the 2018 and 2019 Getty and Woolsey fires. We performed negative binomial regression analyses using direct and lagged effects of wildfire PM2.5 and difference-in-differences analyses to evaluate the association between direct wildfire exposure and health care visit frequency. We adjusted for temperature, temporal effects, non-wildfire PM2.5, and spatial confounders.

RESULTS: Residence within 20 km of the Woolsey Fire was associated with fewer outpatient and more inpatient visits (RR = 0.98, 95% CI: 0.78, 0.87, RR = 1.45, 95% CI: 1.01, 2.11), while Getty Fire evacuation exposure was not associated with visit frequency. In contrast, increases in wildfire PM2.5 were associated with small and constant increases in outpatient visits 2-6 days after a change. Wildfire PM2.5 was not associated with frequency of inpatient or emergency visits at any lag.

CONCLUSION: DME users, presumed vulnerable to wildfire smoke exposure, may have sheltered in place during fires or took other precautions. However, the Woolsey Fire (which was 10 times larger than the Getty) may have produced health concerns in those directly affected when evacuation was necessary and sheltering in place impossible.

O-PK-32 Effect of different heat wave timing on non-accidental mortality in 20 French cities

Anna Alari[1], Noemie Letellier[2], Tarik Benmarhnia[2]
[1]Barcelona Institute for Global Health, ISGlobal, Barcelona, Spain, [2]Scripps Institution of Oceanography, UC San Diego, San Diego, USA

BACKGROUND AND AIM: Previous epidemiological evidence suggests that the impact of heat waves on mortality may change over time (within and between summer seasons). The consideration of heat wave timing could help to optimize the alert systems, especially under a warming climate. The aim of this study was to explore the effect of heat wave timing on mortality risk during the summer season in France.

METHODS: Summertime daily mortality data for 20 French cities from 2000 to 2015 were obtained from the French National Institute of Health and Medical Research. Heat waves were defined according to the official definition of Météo France. The order of heat wave over time, from June to September, was assessed. To quantify mortality risk for the first and second heat waves, quasi-Poisson with distributed-lag models were performed for each city.

RESULTS: Overall, we found that, compared with non-heat wave days, the first heat wave of the summer season was associated with a higher risk ratio (RR) for cardiovascular mortality (RR: 1.32, 95% Confidence Interval [CI]:1.18-1.47) as compared to subsequent heat waves within the same summer (RR, 95% CI: 1.28, 1.14-1.44). We found the opposite pattern for respiratory mortality with RRs of 1.59 (95%CI:1.35-1.88) and 1.66 (95%CI: 1.32-2.07) for the first and second heat waves respectively. We identified important heterogeneity in such patterns across all cities. for cities such as Paris or Nancy, the first heatwave of the season resulted in a greater mortality risk. In contrast, for cities such as Lille, Marseille, or Rouen, the second heat wave was more impactful regarding mortality risk.

CONCLUSIONS: The timing of heat waves events modulates heat-related risks in France. Such information could be used to update local heat action plans to optimize health benefits across French cities.

O-PK-33 The impact of weather changes on air quality and health in Brazil

Weeberb Réquia[1], Francisco Castelhano[1], Ana Clara Neme Pedroso[1], Igor Cobelo Ferreira[1], Rafael Borge[2], Henrique Roig[3], Matthew Adams[4], Heresh Amini[5], Petros Koutrakis[6]
[1]Fundação Getúlio Vargas, Brasília, Brazil, [2]Universidad Politécnica de Madrid, Madrid, Spain, [3]University of Brasilia, Brasilia, Brazil, [4]University of Toronto Mississauga, Mississauga, Canada, [5]University of Copenhagen, Copenhagen, Denmark, [6]Harvard TH Chan School of Public Health, Boston, EUA

BACKGROUND AND AIM: Weather changes affect air quality that is also a leading contributor to disease burden. The current evidence on the relationship between weather changes and air pollution is mainly based on the environmental processes occurring in North America and Europe. As a response to this gap in knowledge, in this study, we quantified the past weather-related changes in ambient air pollution in Brazil over 16 years (2003-2018). Then we estimated the excess mortalities associated with this impact of long-term weather changes on air quality.

METHODS: We applied generalized additive models (GAMs) to fit adjusted (with meteorological variables) and unadjusted models. The difference of slopes estimated by the models without and with adjusting for these meteorological variables represents the impact of weather changes on pollutant trends, defined in our study as “weather penalty”.

RESULTS: Overall, ambient air pollution levels in Brazil during the period 2003-2018 have decreased in most of the Brazilian regions. We estimated significant trends in meteorological variables, indicating an increase in temperature, relative humidity, and wind speed in all Brazilian regions over the 16-study period. Our findings suggest that PM2.5 was the pollutant most impacted by weather changes. for the 16-year period of analysis, we estimated a weather penalty ranging from 1.58 µg/m−3 (CI 95%:1.25;1.91) to 0.41 µg/m−3 (CI 95%:0.28;0.53) among the different Brazilian regions. If weather parameters had remained constant, PM2.5 would have decreased by 1.10 µg/m3 (95%CI: 0.74; 1.46) in the South and by 2.25 µg/m3 (95%CI: 2.72; 1.79) in the Midwest. Over the 16-year study period, the weather impact on PM2.5 in Brazil was associated with over 6,500 excess deaths.

CONCLUSIONS: The evidence of historical weather penalty should be of interest to policy makers to devise future strategies related to environmental health and climate change.

O-PK-34 Associations between short-term ambient temperature exposure and kidney-related diseases in New York State: The influence of exposure spatial resolution and adaptation adjustment

Lingzhi Chu[1], Kai Chen[1], Susan Crowley[2,3], Robert Dubrow[1]
[1]Yale School of Public Health, New Haven, USA, [2]Yale School of Medicine, New Haven, USA, [3]Veterans Administration Health Care System of Connecticut, West Haven, USA

BACKGROUND AND AIM: Findings on the relationship between short-term temperature exposure and kidney diseases are divergent. Furthermore, the roles of temperature spatial resolution and climate adaptation are unclear. This study aimed to evaluate associations between short-term ambient temperature exposure and kidney-related diseases, as well as the influence of spatial resolution and adaptation adjustment.

METHODS: We estimated daily mean temperature at 1-km resolution in New York State (NYS) from random forest models, and obtained health data from the NYS SPARCS dataset (2007-2016). We used a symmetric case-crossover design analyzed by conditional logistic regression with distributed lag non-linear models, and evaluated spatial resolutions of 1-km, 5-km, 10-km, 20-km, and 35-km. To evaluate the influence of adaptation, we compared one-stage and two-stage models using temperature on the absolute or relative scales.

RESULTS: This study included 1,209,934 non-elective adult kidney-related hospital visits. We observed similar estimates from models with different spatial resolutions. When controlling for adaptation in one-stage models using temperature on the relative scale at 20-km resolution, for the 95th percentile of daily mean temperature compared to the minimum morbidity temperature at lag 0-6 days, we found odds ratios of 1.14 for acute kidney failure (95% confidence interval [CI]: 1.07, 1.22), 1.10 for renal tubulo-interstitial diseases (95% CI: 1.02, 1.18), 1.21 for urolithiasis (95% CI: 1.16, 1.26), 1.25 for dysnatremia (95% CI: 1.14, 1.37), and 1.27 for volume depletion (95% CI: 1.23, 1.31), but no significant associations for chronic kidney disease (CKD) or glomerular diseases (GD). Models not considering adaptation generated consistent association patterns, but somewhat different effect estimates.

CONCLUSIONS: Short-term exposure to high temperature was associated with increased risk for kidney-related diseases (except CKD and GD). The influence of exposure spatial resolution was negligible and of adaptation adjustment was modest.

O-PK-35 Upstream oil and gas infrastructure and wildfire burn areas in the western U.S.: Assessing current and future risks

Joan Casey[1], Rachel Morello-Frosch[2], Leo Liu[1], Benjamin Steiger[1], David Gonzalez[2]
[1]Columbia University Mailman School of Public Health, New York, USA, [2]University of California, Berkeley, Berkeley, USA

BACKGROUND AND AIM: The extent and intensity of wildfires has worsened in recent years, a trend that is expected to continue as climate change worsens. The western U.S., a region with numerous oil basins, has a particularly high wildfire risk. Wildfires damage to oil and gas wells may result in emissions of air toxics and higher costs for safe well retirement. We aimed to determine the extent to which oil and gas wells were located within and near wildfire burn areas in the western U.S. in each year between 1984 and 2020 and to identify wells at high risk of wildfire exposure in present-day and under projected risk in mid- and late century

METHODS: We obtained oil and gas wells data from Enverus DrillingInfo, population data from the US Census Bureau, wildfire burn areas data from National Interagency Fire Center, and data on areas with high projected future wildfire risk from Argonne National Laboratory. We assessed which wells were inside or near (≤1 km) wildfire burn areas from 1984-2020 and estimated the number of people living near burn areas with wells. We then determined the count of active and plugged wells in areas with high current and projected wildfire risk.

RESULTS: We observed that an estimated 31,385 (1.9%) of the 1.65 million wells in the western U.S. were located in wildfire burn areas during the study period and an additional 52,815 (3.2%) were within 1 km of a burn area.

CONCLUSIONS: Wildfire damage to oil and gas wells may increase pollution in nearby communities, raise operator mitigation costs, and increase climate change through fugitive fossil fuel emissions. Policymakers may wish to consider wildfire risk in oil and gas operation regulation.

KEYWORDS: oil and gas, climate change, wildfire, exposure, spatial analysis

O-PK-36 Health impact assessment of climate change mitigation and adaptation policies

Dimosthenis Sarigiannis[1,2,3], Alberto Gotti[4], Spyros Karakitsios[1,2]
[1]Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]HERACLES Research Center on the Exposome and Health - CIRI, Aristotle University of Thessaloniki, Thessaloniki-Thermi, Greece, [3]University School for Advanced Study IUSS, Pavia, Italy, [4]EUCENTRE Foundation, Pavia, Italy

BACKGROUND AND AIM: Current climate policy focuses on two key aspects: the relevance and extent of mitigation measures to avoid crossing the point of no return; and the necessity for adaptation measures considering socio-economic state and dynamics across the globe. Assessing properly the health benefits of policy measures geared towards adapting to climate change is a key requirement for accurate impact assessment of climate action.

METHODS: The climate exposome is the exposome of human population considering the climate change aspects relevant to the life course. The methodological framework for unravelling the climate exposome is presented and examples demonstrating its applicability and usefulness in climate policy are given. The new generation of integrated assessment models entail a model scheme based on enhanced data fusion and on the concept of ensemble modelling, supported by big data analytics for filling data gaps.

RESULTS: Drivers pertaining to direct impacts on climate are increased temperatures; precipitation extremes; extreme weather events; and sea level rise. To better understand the impacts of climate change, the environmental and institutional context is accounted for including land use change; ecosystem change; condition of the infrastructure; geography; agricultural production and livestock use. The social and behavioural context including age and gender; race and ethnicity; poverty; housing and infrastructure; education; discrimination; access to shared and community health infrastructure is a significant modifier of the impacts associated with climate change.

CONCLUSIONS: The climate exposome addresses interactions among activity sectors and the changing environment; exposure and effects of chemical, physical and biological stressors and waste; interactions among these stressors. Refined tools for understanding the impacts using high dimension biology techniques are crucial. The interplay between vulnerabilities and socio-economic factors affecting exposure profiles and individual susceptibility to these complex exposures determine the ultimate relationship between climate change and health.

KEYWORDS: climate change, health, exposome

O-PK-37 Long-term exposure to ambient fine particulate elements and leukocyte epigenome-wide DNA Methylation in older men: the Normative Aging Study

Cuicui Wang[1], Zongli Xu[2], Xinye Qiu[1], Heresh Amini[3], Yaguang Wei[1], Allan Just[4], Jonathan Heiss[4], Lifang Hou[5], Yinan Zheng[5], Brent Count[1], Anna Kosheleva[1], Petros Koutrakis[1], Andrea Baccarelli[6], Joel Schwartz[1]

[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]National Institute of Environmental Health Sciences, Durham, USA, [3]University of Copenhagen Department of Public Health, Copenhagen, Denmark, [4]Icahn School of Medicine at Mount Sinai, New York, USA, [5]Northwestern University Feinberg School of Medicine, Chicago, USA, [6]Columbia University Mailman School of Public Health, New York, USA

BACKGROUND AND AIM: Several epigenome-wide association studies of ambient fine particulate matter (PM2.5) have been reported. However, none have been done on long-term exposure to PM2.5 elements (PEs). We hypothesized that significant changes in DNA methylation (DNAm) may vary by long-term exposure to PEs.

METHODS: We repeatedly collected blood samples in the Normative Aging Study and measured leukocyte DNAm with the Illumina HumanMethylation450K BeadChip. We predicted 15 PEs based on an ensemble of machine-learning algorithms. The spatial resolution was 50m × 50m for urban areas (majority in this study) and 1km × 1km for non-urban areas. We applied median regression with subject-specific intercepts for each of the 15 PEs and DNAm at individual cytosine-phosphate-guanine site, adjusting for PM2.5 mass. Significantly differentially methylated probes (DMPs) were identified by Bonferroni correction. We further conducted regional analyses and pathway analyses to identify differentially methylated regions (DMRs) and pathways. We also used nonnegative matrix factorization to identify source factors and obtained the source-specific effect estimates.

RESULTS: We included 672 men with 1,181 visits between 1999 and 2013. The significant DMPs, DMRs, and pathways varied by PEs. for example, lead was associated with one DMP and one pathway whereas organic carbon was associated with 45 DMPs and 30 pathways. The identified pathway by lead was involved in cardiovascular disease, whereas the pathways associated with organic carbon were related with reproductive function, nervous system, inflammation, etc. In addition, we identified four independent source factors, which had varied associations with DMPs, DMRs, and pathways. for example, source factor 1 (nitrate, ammonium) was associated with 43 pathways involved in cardiovascular disease, cancer, diabetes, aging, inflammation, etc.

CONCLUSIONS: Long-term exposure to different PEs were differentially associated with DNAm changes at multiple probes, regions, and along multiple pathways.

O-PK-38 Outdoor air pollution and risk of incident adult hematologic cancer subtypes in a large US prospective cohort

W. Ryan Diver[1,2,3], Lauren R. Teras[3], Emily L. Deubler[3], Michelle C. Turner[1,2]
[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [3]Department of Population Science, American Cancer Society, Atlanta, USA

BACKGROUND AND AIM: Outdoor air pollution and airborne particulate matter (PM) have been classified as Group 1 carcinogens for lung cancer. Previous research on childhood leukemias and adult cancer mortality suggest associations of outdoor air pollutants with blood cancers, which are etiologically diverse. However, detailed examinations of major air pollutants by histologic subtypes of incident adult hematologic cancers are lacking.

METHODS: The American Cancer Society Cancer Prevention Study-II Nutrition Cohort was used to examine associations of outdoor air pollutants with risk of incident hematologic cancers. Residential address at enrollment was used to assign census block-group level annual predictions of PM10, PM2.5, NO2, O3, SO2, and CO concentrations. Cox proportional hazard regression was used to estimate multivariable-adjusted hazard ratios (HR) and 95% confidence intervals (CI) for associations per each fifth percentile-mean difference in 1992-2015 average pollutant concentrations with risk of incident Hodgkin lymphoma (HL), non-Hodgkin lymphoma (NHL), myeloid leukemia and eleven specific histologic subtypes.

RESULTS: There were 2,659 total incident hematologic cancer cases identified among 108,002 participants followed from 1992-2017. Positive HRs were observed for several residential outdoor air pollutants and incident HL (n=54), with statistically significant elevated HRs observed for both NO2 (HR per 6.4 ppb=1.42; 95% CI=1.05-1.90) and SO2 (HR per 1.6 ppb=1.41, 95% CI 1.07-1.85). There were no clear positive associations observed for either NHL (n=2,276) or myeloid leukemias (n=329) and there was an inverse association observed for the chronic lymphocytic leukemia/small lymphocyte lymphoma subtype. In analyses by gender, the positive associations observed with incident HL strengthened among women.

CONCLUSIONS: Overall, there were few positive associations of outdoor particulate or gas residential air pollution concentrations and incident adult hematologic cancers observed. However, subtype analyses revealed some evidence for positive associations with HL, particularly among women, which require further investigation.

KEYWORDS: outdoor air pollution, particulate matter, lymphoma, leukemia

O-PK-39 Mortality and Morbidity Risk and residential exposure to municipal waste landfills in Italy: the ERAS-2 Lazio project

Lisa Bauleo[1], Francesca Mataloni[1], Paola Michelozzi[1], Marina Davoli[1], Carla Ancona[1]
[1]*Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*

BACKGROUND AND AIM: Evidence of health effects associated with living nearby municipal waste (MW) landfills is still controversial. Nine MW landfills have been operating in the Lazio region (Central Italy) for several decades. We evaluated the potential health effects associated with contamination from MW landfills using hydrogen sulphide (H2S) concentration as proxy of airborne contamination.

METHODS: A cohort of residents within 5 km of MW landfills was enrolled (residents on 1 January 1996 and those who subsequently moved into the areas until 2008) and followed up for mortality and hospitalizations until 31 December 2018. Assessment of exposure to the landfill (H2S as a tracer) was performed for each participant residential address at enrolment by using a Lagrangian dispersion model. The potential confounding effect of gender, age, socioeconomic position, outdoor PM10 concentration, and distance from busy roads and industries was considered. Cox regression analysis was performed [HRs, 95% CIs].

RESULTS: The cohort included 242,409 individuals. H2S exposure was associated with mortality from non-accidental causes (HR=1.02, 95% CI 0.97-1.08), total cancer (HR 1.07, 95% CI 0.98-1.07), and lung cancer (HR 1.24, 95% CI 1.04-1.49) when comparing 75° percentile vs <25° percentile of H2S concentrations. We also found associations with all cause hospitalization (HR 1.04, 95% CI 1.02-1.07), kidney cancer (HR 1.68, 95% CI 1.18-2.39), and respiratory diseases (HR=1.06, 95% CI 1.00–1.11) when comparing 75° percentile vs <25° percentile of H2S concentrations.

CONCLUSIONS: H2S Exposure was associated with non-accidental mortality and morbidity for respiratory diseases. The link with respiratory disease is plausible and coherent with previous studies, whereas the associations with cancers deserves confirmation through the study of cancer incidence.

O-PK-40 Long-term exposure to elemental components of fine particulate matter and natural and cause-specific mortality in a Danish nationwide administrative cohort

Rina So[1], Jie Chen[2], Massimo Stafoggia[3,4], Kees de Hoogh[5,6], Youn-Hee Lim[1], Steffen Loft[1], Evangelia Samoli[7], Bert Brunekreef[2], Gerard Hoek[2], Zorana Andersen[1]

[1]Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [2]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands, [3]Department of Epidemiology, Lazio Region Health Service/ASL Roma 1, Rome, Italy, [4]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [5]Swiss Tropical and Public Health Institute, Basel, Switzerland, [6]University of Basel, Basel, Switzerland, [7]Department of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

BACKGROUND AND AIM: Fine particulate matter ($PM_{2.5}$) is an established risk factor for premature death, but it remains unclear which components and sources are most responsible. We investigated the associations between long-term exposure to $PM_{2.5}$ components and mortality from all-natural causes, cardiovascular disease (CVD), respiratory diseases (RD), lung cancer, diabetes, chronic kidney disease (CKD), dementia, and psychiatric disorders in a Danish nationwide administrative cohort.

METHODS: We followed all Danish residents aged ≥30 at January 1, 2000 (3,081,244) until December 31, 2017. Residential annual mean exposure $PM_{2.5}$ components levels (copper, iron, zinc, sulfur, nickel, vanadium, silicon, and potassium) were estimated by Europe-wide land-use regression models at a 100×100m scale, developed within the "Effects of Low-Level Air Pollution: A Study in Europe" project, with two modeling approaches: supervised linear regression (SLR) and random forest (RF). We used Cox proportional hazard models to evaluate the associations between each component and mortality, adjusting for demographic, socioeconomic factors, and $PM_{2.5}$ mass.

RESULTS: The cohort accumulated 46,992,890 person-years, and 803,373 died from natural causes. for natural mortality, we observed significant positive associations [hazard ratios (HRs); 95% confidence intervals per interquartile range increase] with SLR-silicon (1.04; 1.03-1.05) and SLR-potassium (1.03; 1.02-1.04) and with RF-iron (1.02; 1.01-1.02), RF-zinc (1.02; 1.01-1.03), RF-nickel (1.01; 1.00-1.02), RF-vanadium (1.02; 1.01-103), RF-silicon (1.01; 1.00-1.02), and RF-potassium (1.06; 1.05-1.07). Potassium and silicon were most strongly associated with all causes of death except CKD and diabetes, respectively, with the highest HRs observed for psychiatric disorders. Furthermore, iron was associated with RD, lung cancer, CKD, and psychiatric disorders, zinc with RD, CKD, and lung cancer, and nickel and vanadium with lung cancer.

CONCLUSIONS: We present novel findings that different $PM_{2.5}$ components were relevant to different causes of death. Potassium and silicon seemed most consistently associated with mortality in Denmark.

KEYWORDS: Long-term exposure, $PM_{2.5}$ components, mortality

POSTER DISCUSSION SESSIONS

Monday, September 19

POSTER DISCUSSION SESSION 01: Advances in Epidemiology and Statistical Methods | Exposure assessment

THEMATIC 01: Advances in Epidemiology and Statistical

P-0003 Application of High Spatiotemporal Air Pollution Surfaces and Participants' Activity Space for Identification of the Instantaneous Effect of Air Pollution on Rescue Medication Use for California Residents

Jason Su[1], Shadi Aslebagh[1], Stacey Jung[1], Emma Yakutis[1], Vy Vuong[2], Meredith Barrett[2]
[1]*University of California, Berkeley, Berkeley, USA,* [2]*ResMed and Propeller Health, San Francisco, USA*

BACKGROUND AND AIM: Previous studies often used individuals' residential addresses as locations of exposure. Air pollution exposure can occur in the community, at work, at home, and at school. Digital sensors fitted onto inhalers can capture the date, time, and location of rescue inhaler use. The sensors also send out "heartbeats" every 3-4 hours and records the Global Positioning System (GPS) locations when paired with a smartphone. Evaluating the signals of all heartbeats and rescue inhaler uses over time can help characterize an individual's exposure space. The goal of this research was to identify the impacts of air pollution, modeled at high spatiotemporal resolution, on sub-acute respiratory disease symptoms represented by rescue inhaler use for California residents 01/01/2012-12/31/2019.

METHODS: The daily air pollution surfaces of nitrogen dioxide (NO2), fine particulate matter (PM2.5) and ozone (O3) of 30m spatial resolution were assigned to 3,386 participants' daily activity space. R packages random forest and glmmTMB with capability of dealing with excessive zeros and overdispersion were used to identify associations of daily air pollution exposure with daily rescue inhaler use.

RESULTS: Both advanced linear mixed models and random forest models identified that all the three pollutants had significant ($p < 0.001$) and positive associations with daily rescue inhaler use. In the linear mixed model, we identified that 10 ppb, 10 ug m-3 and 30 ppb increase in exposure to NO2, PM2.5 and O3 would result in, respectively, a 2.5%, 9.1% and 17.2% increase in daily rescue puffs.

CONCLUSIONS: The results of this project will help California policy makers characterize the health effects of regulatory programs. More importantly, the project will also provide the information needed to include respiratory disease symptoms as a new endpoint for California's health analysis.

KEYWORDS: rescue medication use, air pollution, linear mixed model, random forest model, State of California.

P-0006 Development of environmental risk score of the biomarker for chronic kidney disease in residents exposed to pollutant mixtures

Hyun A Jang[1,3], Hyuna Jang[2], Yong Min Cho[3], Young Seoub Hong[4]
[1]Department of Statistics, Sookmyung Women's University, Seoul, Republic of Korea, [2]Department of Preventive Medicine, Dankook University College of Medicine, Cheonan, Republic of Korea, [3]Institute of Environmental Health, Seokyeong University, Seoul, Republic of Korea, [4]Department of Preventive Medicine, School of Medicine, Dong-A University, Busan, Republic of Korea

BACKGROUND AND AIM: To develop an environmental risk score (ERS) of biomarkers for chronic kidney disease (CKD) in residents exposed to multipollutant.

METHODS: Multipollutant with nine metals, four PAH metabolites, and four VOC metabolites measured in urine was constructed from the Forensic Research via Omics Markers (FROM) study in Korea (n=298). Beta-2-microglobulin (β2-MG), N-acetyl-β-D-glucosaminidase (NAG), and estimate glomerular filtration rate (eGFR) were used as CKD markers. Optimal models were selected among elastic net models (ENET), adaptive elastic net models (AENET), weighted quantile sum regression (WQS), Bayesian weighted quantile sum regression (BWQS), Bayesian kernel machine regression (BKMR), Bayesian additive regression tree (BART), and super learner (SL) by comparing mean squared error adjusted for sex and age. The selected models were stratified with a history of occupational chemical exposure (OCE) and additionally adjusted for urinary cotinine level. Variable importance (VI) was estimated to evaluate the associations between each pollutant and biomarkers of CKD.

RESULTS: The performance of ERS based on BKMR was the best-fitting model and ERS based on SL or BART performed better than other models. The model with BKMR could not be used due to overfitting as the number of covariates increased. When stratified with a history of OCE, the most effective metabolites for β2-MG, NAG, and eGFR were Sb (VI=0.47), Hg (VI=0.13), and Pb (VI=0.34) in the non-OCE group, and V (VI=0.39), Hg (VI=1.19), and 1-ohp (VI=0.10) in the OCE group, respectively.
CONCLUSION: This study suggests that ERS, especially the SL and BART model, stratified with a history of OCE were fitted when evaluating the association between multipollutant and CKD.

KEYWORDS: Metals, multipollutant, environmental risk score, machine learning, kidney disease

P-0019 Capture of local sources variation using a hierarchical Bayesian spatiotemporal model for the spatial prediction of air pollution levels

Maria A. Barceló[1,2], Dominic Roye[2,3], Diego Varga[1,2,4,5], Aurelio Tobías[6], Marc Saez[1,2]

[1]Research Group on Statistics, Econometrics and Health (GRECS), University of Girona, Girona, Spain, [2]CIBER of Epidemiology and Public Health (CIBERESP), Madrid, Spain, [3]Department of Geography, University of Santiago de Compostela, Santiago de Compostela, Spain, [4]Landscape Analysis and Management Laboratory, University of Girona, Girona, Spain, [5]Department of Geography, University of Girona, Girona, Spain, [6]Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Barcelona, Spain

BACKGROUND AND AIM: The spatial predictions obtained from models based on land use regression (LUR), even the most advanced ones, do not fully capture local variations in the levels of air pollutants. This is because they do not control for unobserved variation, including spatial and temporal dependencies. Our objective is to present a hierarchical Bayesian spatiotemporal model for the spatial prediction of air pollution levels that, considering unobserved variation, both spatial heterogeneity and spatio-temporal dependence, controls for fine scale spatial variability.

METHODS: We use information on the hourly levels of air pollution for 2018-2019 from 116 monitoring stations located throughout Catalonia, Spain. The pollutants we are interested in for making spatial predictions are PM10, PM2.5, NO2 and O3. We carried out the spatial predictions at a point level. We specified a hierarchical spatiotemporal model using the Stochastic Partial Differential Equations of the integrated nested Laplace approximation. As predictors we use the levels of other air pollutants, both measured at the monitoring stations and high-resolution satellite and reanalysis data, and land use variables (altitude of the monitoring station, NDVI, land cover, density). We control for unobserved variation, both spatial heterogeneity (using unstructured random effects) and spatial and temporal dependence (using structured random effects), considering them non-independent but separable.

RESULTS: As preliminary results, the predictions using our model are much better than using an advanced LUR model. The mean absolute percentage error (MAPE, in %) and the root mean squared prediction errors (RMSPE, µg/m3) of our model are: PM10: 7.55-2.62 (MAPE-RMSPE), PM2.5: 9.99-4.50, NO2: 4.37-2.14; and O3: 6.83-2.78, while those of the LUR models are: 10.66-5.26, 15.99-5.61, 13.090-2.181, 33.21-13.85, respectively.

CONCLUSIONS: By controlling for unobserved variation, both heterogeneity and space-time dependency, our model can capture variation at the fine spatial scale and thus achieve more accurate spatial predictions.

P-0020 Benchmark dose in the presence of co-exposure to melamine and di-(2-ethylhexyl) phthalate and urinary renal injury markers in pregnant women

Chu-Chih Chen[1], Yin-Han Wang, Hui-Ju Tsai, Chia-Jung Hsieh, Shu-Li Wang, Mei-Lien Chen, Chia-Fang Wu, Chia-Chu Liu, Tusty-Jiuan Hsieh, Ming-Tsang Wu
[1]*National Health Research Institutes, Zhunan, Taiwan*

Environmental exposures to mixtures of toxic chemicals are known to have potential interaction effects that may lead to hazard index exceeding one. However, current regulation levels such as tolerable daily intake (TDI) are mostly based on experimental studies on single chemical compound. In this study, we assessed the relationships between melamine and di-(2-ethylhexyl) phthalate (DEHP) exposures and their co-exposure on early renal injury markers N-acetyl -D-glucosaminidase (NAG), albumin/creatinine ratio (ACR), and microalbuminuria in 1236 pregnant women. We derived the benchmark dose (BMD) and the corresponding one-sided 95% confidence bound BMDL based on the estimated (covariate-adjusted) average daily intake of melamine and DEHP metabolites measured in spot urine of the women collected during third trimester. Various generalized linear models with interaction terms and Bayesian kernel machine regression model were used for the (co-)exposure response associations. Given a benchmark response of 0.1, the BMDL level of melamine (DEHP) exposure on NAG (ACR, microalbuminuria) was 2.67 (11.20, 4.45) μg/kg_bw/day ignoring mixture effect, and decreased to as low as 1.46 (3.83, 2.73) μg/kg_bw/day when considering co-exposure to DEHP (melamine) at 90th percentile. Both the exposure threshold levels of melamine and DEHP for early renal injuries in pregnant women were several-folds to one order lower than the current recommended TDIs by WHO and the US FDA and EPA, and were even lower considering co-exposure. Because of concurrent exposures in real-world environment, more conservative regulation levels are suggested for potential synergetic mixture effects.

P-0030 Comparison of machine learning methods for the prediction of cardiovascular mortality from environmental and socio-economic neighbourhood factors

Sahar Behzadi[1], Mahyar Valizadeh[1], Jeroen Staab[2,3], Marco Dallavalle[1,4], Nikolaos Nikolaou[1,4], Annette Peters[1,4], Alexandra Schneider[1], Hannes Taubenböck[2,5], Kathrin Wolf[1]

[1]Helmholtz Zentrum München, Institute of Epidemiology, Neuherberg, Germany, [2]German Aerospace Center (DLR),German Remote Sensing Data Center, Geo-Risks and Civil Security, Oberpfaffenhofen, Germany, [3]Geography Department, Humboldt-University Berlin, Berlin, Germany, [4]Institute for Medical Information Processing, Biometry and Epidemiology - IBE, Medical Faculty, Ludwig-Maximilians-Universität München, Munich, Germany, [5]Institute for Geography and Geology, Julius-Maximilians-Universität Würzburg, Würzburg, Germany

BACKGROUND AND AIM: Several environmental and socio-economic neighbourhood factors have been reported to majorly impact human health, but their interplay is not yet well understood as simultaneous analyses are sparse. We aimed to identify the driving contextual factors and assess their predictive ability for cardiovascular disease (CVD) mortality in a neighbourhood setting by comparing several machine learning methods.

METHODS: We obtained the number of CVD deaths per county for entire Germany for 2017. Most socio-economic factors (e.g. proportion of unemployed, foreigners, household income, deprivation index) were also only available on a county level, whereas most environmental factors (e.g. imperviousness, greenness, air pollution, noise, building density) could be gained on a higher spatial resolution (10m-2.4km). All data was aggregated to a 5km*5km grid to compile compliant prediction maps. In addition to traditional linear and additive regression models, we applied one neighbour-based method and several statistical, ensemble and deep learning approaches using a random search strategy for hyper-parameter tuning. Variable importance was assessed by SHapely Additive exPlanations (SHAP) values.

RESULTS: CVD mortality for the 5km grid ranged from 2.5 to 8.1 per 10,000 residents with a mean of 4.7 (standard deviation 1.0). The models performed well in the training phase with R^2 between 0.85-1.00, mean squared error (MSE) between 0.001-0.005, and moderate to well in our test data (R^2: 0.27-0.66; MSE: 0.011-0.024). Most models identified the deprivation index as the most important predictor followed by the proportion of foreigners, unemployed, median income and air pollution. Comparison of our predicted and observed CVD mortality rates showed high correlations for all models (Spearman r: 0.69-0.82), though prediction maps indicated heterogeneity in spatial patterns.

CONCLUSIONS: The selected approaches differed in their predictive ability but identified similar predictors as the main drivers for CVD mortality.

THEMATIC 13: Exposure assessment

P-0818 Simultaneous assessment of chemical and biological contaminants in settled house dust

Kiyoung Lee[1], Donghyun Kim[1]
[1]*Seoul National University, Seoul, Republic of Korea*

BACKGROUND AND AIM: Settled house dust (SHD) is a reservoir for various contaminants, including endocrine-disrupting chemicals (EDCs), trace metals, and house dust mite allergens. This study aimed to characterize various chemical and biological contaminants in SHD and identify determinants of the indoor contaminants.

METHODS: In total, 106 SHD samples were collected from 106 houses in Seoul and Gyeonggi Province, Korea in 2021. Thirty of the 106 houses were recruited for collecting bedding dust samples. All participants completed a questionnaire comprised of housing and lifestyle-related factors. Samples were analyzed for 18 organophosphate flame retardants (OPFRs), 16 phthalates, five alternative plasticizers (APs), seven trace metals, and two house dust mite allergens (Dermatophagoides farinae type 1 [Der f1] and Dermatophagoides pteronyssinus type 1 [Der p1]). A multiple regression analysis was conducted to identify the determinants governing the concentrations and profiles of various contaminants.

RESULTS: OPFRs, phthalates, APs, and trace metals were detected in all SHD samples, indicating ubiquitous contamination in indoor environments. Among the three EDC groups, APs were detected most frequently with the highest concentrations, followed by phthalates and OPFRs. Der f1 was detected in all bedding dust samples with significantly higher levels than Der p1. The concentrations of OPFRs, plasticizers, and trace metals in SHD were significantly associated with the type and number of electronic appliances and combustion activities. Der f1 was significantly associated with the number of occupants and water penetration. Ventilation, vacuum cleaning, and wet cleaning or dry mopping significantly reduced the levels of most contaminants in SHD.

CONCLUSIONS: As residents are persistently exposed to a wide array of pollutants, comprehensive and adequate measures are required to prevent potential exposures.

KEYWORDS: Settled house dust; OPFR; Plasticizer; Alternative plasticizer; House dust mite allergens

P-0819 Comparison of PM2.5 air pollution exposure estimates at WHIMS participant locations based on different modelling approaches and impact on health effects estimation

Melinda Power[1], Erin E. Bennett[1], Katie M. Lynch[1], James D. Stewart[2], Xiaohui Xu[3], Eun Sug Park[3], Qi Ying[3], Richard Smith[2], William Vizuete[2], Helene G. Margolis[4], Ramon Casanova[5], Robert Wallace[6], Lianne Sheppard[7], Marc Serre[2], Adam Szpiro[7], Jiu-Chiuan Chen[8], Jeff Yanosky[9], Duanping Liao[9], Gregory Wellenius[10], Joel Kaufman[7], Eric Whitsel[2]
[1]George Washington University, Washington, USA, [2]University of North Carolina, Chapel Hill, USA, [3]Texas A&M, College Station, USA, [4]University of California, Davis School of Medicine, Davis, USA, [5]Wake Forest, Winston-Salem, USA, [6]University of Iowa, Iowa City, USA, [7]University of Washington, Seattle, USA, [8]University of Southern California, Los Angeles, USA, [9]Pennsylvania State University, Hershey, USA, [10]Boston University, Boston, USA

BACKGROUND AND AIM: Many approaches to quantifying air pollution exposures for use in epidemiologic analyses have been developed. However, whether exposure estimates from different approaches are comparable and whether choice of approach affects reported associations with health-related outcomes remains unclear. We compare PM2.5 concentrations at addresses from participants of the Women's Health Initiative Memory Study (WHIMS) derived using multiple estimation approaches and assess differences in associated health effects estimates.

METHODS: We linked annual PM2.5 exposure estimates from 1999 to 2004 from 12 different approaches to WHIMS participant addresses from across the continental United States and restricted analyses to data from participants with stable addresses within each calendar year. Approaches included geo-statistical interpolation approaches, geographic information system (GIS)-based statistical models, air dispersion and chemical transport models, and hybrid models. We used descriptive statistics and visualizations to assess relative and absolute agreement of exposure estimates from different approaches across space and time and examined the impact of estimation approach on associations between PM2.5 and non-accidental mortality, CVD-related mortality, and incident CVD events.

RESULTS: Annual PM2.5 exposure estimates were reasonably similar across approaches, although the specific shapes and ranges of the distributions varied. Interquartile ranges tended to be similar, though ranges were more variable. Relative agreement was consistently higher than absolute agreement. After controlling for putative confounders, associations of PM2.5 with mortality and CVD were similar regardless of estimation approach.

CONCLUSIONS: Agreement across different air pollution estimation approaches for PM2.5 was generally high when considering participants drawn from a broad geographic area, suggesting that all models predicted similar between-area differences. The implications of fine-scale variability between exposure estimation approaches warrants further investigation.

P-0824 A Comparison of Measured Airborne and Self-Reported Secondhand Smoke Exposure in the MADRES Pregnancy Cohort Study

Karl O'Sharkey[1], Yan Xu[1], Tingyu Yang[1], Thomas Chavez[1], Mark Johnson[1], Jane Cabison[1], Marisela Rosales[1], Meredith Franklin[1,2], Myles Cockburn[1], Shohreh Farzan[1], Theresa Bastain[1], Carrie Breton[1], Rima Habre[1]
[1]University of Southern California, Alhambra, USA, [2]University of Toronto, Toronto, Canada

BACKGROUND: Secondhand smoke (SHS) exposure during pregnancy is associated with several adverse birth outcomes, including reduced birthweight and preterm birth. Questionnaires are commonly used to assess SHS exposure; however, the wording of questions and their ability to capture true exposure can vary, limiting researchers' ability to harmonize SHS measures. Therefore, we compared the association of SHS self-reported exposure in the MADRES pregnancy cohort with measurements of SHS in particulate matter ($PM_{2.5}$) personal samples collected in the 3rd trimester.

METHODS: We measured SHS on 48-hour integrated personal $PM_{2.5}$ Teflon filters collected from 204 pregnant women using optical transmissometry. Self-reported SHS related to presence, intensity, and duration of exposure was ascertained via a 3rd trimester questionnaire and an exit survey at the time of personal monitoring. Descriptive statistics were calculated for SHS measures overall and by key demographics and environmental factors. Analysis of variance tests were conducted to test group differences in SHS concentrations by self-reported SHS exposure.

RESULTS: Participants were predominately Hispanic (81%), with a mean (SD) age of 28.2 (6.0) years. Geometric mean (SD) personal SHS concentrations were 0.14 (9.41) $\mu g/m^3$. There was a significant difference in mean SHS by education ($p = 0.015$), with participants with lower education having higher measured SHS. Mean SHS concentrations differed by reported time with windows open (none/a little of the time: 0.10 $\mu g/m^3$ vs. most/all of the time: 0.19 $\mu g/m^3$; $p = 0.047$). There was no association between measured SHS and self-reported SHS exposure; however, asking about the number of smokers nearby in the 48-hour monitoring period was most correlated with measured SHS (Two+ smokers: 0.30 $\mu g/m^3$ vs. One: 0.12 $\mu g/m^3$ and Zero: 0.15 $\mu g/m^3$; $p = 0.230$). CONCLUSION: Overall, self-reported SHS exposure was not associated with measured airborne SHS in personal $PM_{2.5}$ samples.

P-0826 Integrating Time-Activity and Air Sensors into Smartphone-based PM2.5 and Ozone Exposure Model for Epidemiologic Studies

Michael Breen[1], Vlad Isakov[1], Caroline Chivily[2], Carsten Skarke[3], Catherine Seppanen[4], Sarav Arunachalam[4]
[1]US Environmental Protection Agency, Research Triangle Park, USA, [2]Center of Excellence in Environmental Toxicology (CEET), University of Pennsylvania, Philadelphia, USA, [3]Institute for Translational Medicine and Therapeutics, University of Pennsylvania, Philadelphia, USA, [4] Institute for the Environment, University of North Carolina at Chapel Hill, Chapel Hill, USA

BACKGROUND AND AIM: Epidemiologic studies of fine particulate matter (PM2.5) and ozone (O3) often use outdoor concentrations as exposure surrogates, which can induce measurement error. The goal of this study was to improve PM2.5 and O3 exposure assessments for a repeated measurement study with 20 individuals in Philadelphia, Pennsylvania by applying a smartphone-based exposure model called TracMyAir.

METHODS: We developed TracMyAir, which is a smartphone (iPhone, Android) application that determines multiple tiers of individual-level exposure metrics in real-time for ambient and non-ambient PM2.5 and O3 using outdoor concentrations, home building characteristics, weather, time-locations, and time-activities. In this study, we extended TracMyAir by including (1) outdoor concentrations from an air quality model (CMAQ), (2) indoor and outdoor PM2.5 concentrations from low-cost air sensors (PurpleAir) and a building infiltration model, (3) a microenvironment model (MicroTrac) based on time-resolved smartphone geolocations, and (4) inhaled ventilation models based on physical activity data from smartphone and smartwatch accelerometers and heart rate sensors. The five tiers of exposure metrics with increasing information needs and model complexity include: residential air exchange rates (AER, Tier 1), infiltration factors (Finf_home, Tier 2), indoor concentrations (Cin_home, Tier 3), exposures (E, Tier 4), and inhaled doses (D, Tier 5). We applied TracMyAir to determine hourly PM2.5 and O3 exposure metrics for three consecutive days for 20 participants consisting of two age groups (18-30 years old, n=10; 55-75 years old, n=10).

RESULTS: The TracMyAir predictions showed considerable temporal and house-to-house variability of AER, Finf_home, and Cin_home (Tiers 1-3), and person-to-person variability of E and D (Tiers 4-5).

CONCLUSIONS: Our study demonstrates the capability of extending TracMyAir with air pollutant and time-activity sensors and models to estimate individual-level PM2.5 and O3 exposure metrics for an epidemiologic study, in support of improving risk estimation.

P-0839 Heavy metal contamination of soil in informal foundries and surrounding homes in South Africa

Busisiwe Shezi[1,3,4], Renee Street[2,3], Nokulunga Cele[2], Sipho Ndabandaba[2], Angela Mathee[1,4,5]
[1]Environment and Health Research Unit, South African Medical Research Council, Johannesburg, South Africa, [2]Environment and Health Research Unit, South African Medical Research Council, Durban, South Africa, [3]University of KwaZulu-Natal, Discipline of Occupational and Environmental Health, School of Nursing and Public Health, Durban, South Africa, [4]Department of Environmental Health, Faculty of Health Sciences, University of Johannesburg, Johannesburg, South Africa, [5]Department of Environmental Health, School of Behavioural and Lifestyle Sciences, Faculty of Health Sciences, Nelson Mandela University, Gqeberha, South Africa

BACKGROUND AND AIM: Despite the economic benefits, the growing informal sector in residential areas has a significant environmental impact. The present study aimed to determine heavy metals and evaluate the health risks caused by heavy metals in informal foundries and surrounding residential homes situated in rural and urban communities of South Africa.

METHODS: Five informal foundries and thirty-three surrounding residential homes were selected for this study. Four composite samples of soil were collected in each informal foundry. One composite sample was taken from a minimum of five houses situated around each of the selected informal foundries. Contamination levels were evaluated using a geoaccumulation index (Igeo), enrichment factor (EF), contamination factor (CF) and pollution load index (PLI). Sources of heavy metals and the correlation among metals were assessed using factor analysis and Pearson correlation, respectively. The measured concentrations of metals were used to estimate the health risk for children and adults.

RESULTS: The average levels for copper (Cu), iron(Fe), lead (Pb), manganese (Mn), nickel (Ni), strontium (Sr) and Zinc (Zn) were 280, 23980, 137, 493, 129, 459 and 1124 mg/kg, respectively for informal foundries; and 54, 26325, 31, 485, 172, 237 and 74 mg/kg respectively for residential homes. According to Igeo, EF, CF and PLI, contamination exist in the selected study sites. Factor analysis and Pearson correlation coefficient point to the potential roles of informal foundry activities. The health index (HI) for non-carcinogenic effects showed the ingestion route as the main contributor to the total risk, with the accumulative carcinogenic risk exceeding the maximum acceptable level.
CONCLUSION: This study provides evidence of the need to strengthen environmental and occupational health policies related to informal industrial operations. This will help protect individuals from exposure to potentially toxic elements and the associated health risks.

P-0844 Citizen science approach to mapping background radiation for environmental epidemiology

Ben Spycher[1], Jessica E Laine[1], Cristophe L Folly[1]
[1]*University of Bern, Bern, Switzerland*

BACKGROUND AND AIM
Volunteered geographic information from citizen scientists can provide alternatives to traditional exposure assessment for environmental epidemiological studies; whereby, facilitating access to data, providing continuous monitoring, improving exposure awareness for participants and the community, among others. Safecast is a participatory, open-source, citizen science centered radiation surveying project where international volunteers collect and openly share data on environmental radiation collected through mobile sensors. However, information is lacking on the potential use of the collected measurements for epidemiological research, especially regarding their validity for exposure assessment. We aimed to develop and validate maps of gamma radiation (GR) for Denmark and Switzerland, as part of a larger European-wide consortium, using measurements collected by the Safecast community.

METHODS: Spatial Bayesian mixed-effects models were fit to GR measurements from Safecast, using predictors of soil class, geology, land cover, and elevation from maps. Pointwise posterior means from these models were used to predict GR for the territory of each country at a resolution of 1x1km2. Internal validity was assessed using cross-validation (CV) with random assignment of either the measurements (random-CV) or area blocks defined by square grids (different cell sizes) to folds (spatial-CV). We also validated maps for Switzerland against personal exposure measurements (dosimeters worn over five consecutive days) in 149 children using linear regression and calculated the coefficient of determination(R2) and mean squared error.

RESULTS: Spatial variations in GR exposure was observed for each country. Predictors of GR from Safecast were associated with ambient dose rates, where models fit the data well, for example with a R2 of 0.5 in random-CV, with 0.77 model fit in Denmark.

CONCLUSIONS: Results highlight the potential for using open citizen science data for exposure assessments in radiation research. The association between GR and childhood cancers will be assessed.

P-0856 Land Use Regression modelling of airborne microbial markers in the vicinity of livestock farms: evaluation of stepwise linear regression and random forest modelling approaches

Myrna De Rooij[1], Beatrice Cornu Hewitt[1], Warner van Kersen[1], Jules Kerckhoffs[1], Alex Bossers[1], Inge Wouters[1], Lidwien Smit[1], Gerard Hoek[1]
[1]*Utrecht University, Utrecht, Netherlands*

BACKGROUND
Whilst being of likely public health relevance, microbial air pollution related to livestock farming is understudied. for epidemiological studies, it is important to accurately predict residential exposure. Thus far, exposure assessment has mainly focused on endotoxin, while residents living near livestock farms are exposed to a wide array of microbial agents. We evaluated different modelling approaches to predict residential exposure to airborne microbial markers in the vicinity of livestock farms.

METHODS: Residential exposure measurements were performed at 61 sites in a livestock-dense area in 2014-2015. at each site, three to four 14-day PM10 samples were collected. Quantitative-PCR was used to assess DNA concentrations in air of commensal Gram-negative Escherichia coli and Gram-positive Staphylococcus spp. as well as indicator antimicrobial resistance (AMR) genes (tetW, mecA). A local reference site was used for temporal variation adjustment. Modelling was performed using livestock-related characteristics of the surroundings. Two approaches were evaluated using 10-fold Cross Validation: stepwise linear regression (SLR) and random forest (RF).

RESULTS: for all four microbial markers, both approaches explained an acceptable percentage of spatial variation in residential exposure concentrations. RF models had a higher training R-squared compared to SLR (E.coli: 0.89vs0.65; Staph.: 0.64vs0.36; tetW: 0.82vs0.44; mecA: 0.74vs0.47). However, this did not equate to higher 10-fold CV R-squared except for tetW (0.31vs0.14) while performance was similar for E.coli and Staph. (approximately 0.38, 0.15, respectively) and lower for mecA (0.30vs0.41). This shows that one approach did not outperform the other.

CONCLUSIONS: Both modelling approaches, stepwise linear regression and random forest, had acceptable predictive ability for livestock-related microbial markers in ambient air. Application of these models seems promising for residential exposure estimation for epidemiological studies, enabling more insights into relevance of exposure to specific microbial air pollutants.

Agricultural air pollution, ambient air, residential exposure, microbial emissions, Land Use Regression modelling.

P-0868 Investigating Population Exposure Assignment Methods for Air Pollution from Google Street View Polyline Data in Copenhagen, Denmark

Heresh Amini[1], Seyed-Mahmood Taghavi-Shahri[1], Tom Cole-Hunter[1], Jibran Khan[2,3], Jules Kerckhoffs[4], Youn-Hee Lim[1], Marie Bergmann[1], Laust Mortensen[1,5], Theis Lange[1], Ole Hertel[6], Thomas Ellermann[2], Kees Meliefste[4], Rasmus Reeh[7], Christian Gaarde Nielsen[7], Gerard Hoek[4], Rudi Westendorp[1], Steffen Loft[1], Joel Schwartz[8], Roel Vermeulen[4], Zorana J. Andersen[1]

[1]University of Copenhagen, Copenhagen, Denmark, [2]Department of Environmental Science, Aarhus University, Aarhus, Denmark, [3]Danish Big Data Centre for Environment and Health (BERTHA), Aarhus University, Roskilde, Denmark, [4]Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, The Netherlands, [5]Statistics Denmark, Copenhagen, Denmark, [6]Department of Ecoscience, Aarhus University, Aarhus, Denmark, [7]City of Copenhagen and Copenhagen Solution Lab, Copenhagen, Denmark, [8]Harvard TH Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Google Street View (GSV) cars provide air pollution (AP) data across thousands of streets in multiple cities. Various methods exist for linkage of such vector data with populations. While rasterization or near-analysis are possible methods, multiple streets often surround residences; thus, a composite value can be assigned for geo-locations. We aimed to identify best geospatial method for exposure assignment from such data.

METHODS: Long-term mean AP [ultra-fine particles (UFP), nitrogen dioxide (NO2), and black carbon (BC)] predictions across 30,312 streets (length = 15-60 m) were obtained from GSV-based mixed-effects LUR models developed for Copenhagen, Denmark. A near-analysis was used where Euclidean distances between each residence (out of ~77,000) and surrounding streets were calculated, nearest street was identified, and its AP values were assigned. Predictions were also assigned to mid-street centroid; using a systematic algorithm data were split to train (24,061; ~80%) and test sets (3,031; ~10%). Spatial averaging (SA), inverse distance weighting (IDW), ordinary kriging (OK), and natural neighbor (NN) models with multiple configurations for weighting and cell-size were developed. The coefficient of determination (R2) and RMSE were calculated on the test sets.

RESULTS: The mean (SD) of UFP, NO2, and BC were, respectively, 14,120 (8,849) particles/cm³, 16.8 (8.3) µg/m³, and 1.1 (0.4) µg/m³. Overall, 9 SA, 27 IDW, 45 OK, and 3 NN models were developed. NN with a cell-size of 15m was the best performing model. The R2 and RMSE for NN on the test sets were, respectively, 0.92 and 2543 pt/cm3 for UFP, 0.87 and 3.1 µg/m3 for NO2, and 0.88 and 0.15 µg/m3 for BC. The Spearman correlation between residential predictions from NN and near-analysis assignment method was 0.97 for UFP, 0.95 for NO2, and 0.93 for BC.

CONCLUSIONS: Although high correlation was observed for NN and near-analysis, the latter overestimated the concentrations.

P-0899 A Bayesian Spatio-temporal Multisource Air Pollution Exposure Model for the UK

Abi Riley[1]
[1]*Imperial College London, London, UK*

BACKGROUND AND AIM: New 2021 WHO Global Air Quality Guideline levels follow mounting evidence of premature deaths from air pollution exposure, give rise to an increased need for high-quality air pollution modelling strategies. Currently, many areas of the UK exceed the recommended annual PM2.5 level of 10 µg/cm3; however, ground monitoring stations for PM2.5 remain sparse. The aim of this study is to produce a 1km x 1km monthly-estimated PM2.5 exposure map for the UK between 2005-2020, from AURN ground monitored data, the Pollution Climate Mapping model, and corrected satellite-derived Aerosol Optical Depth, with additional climate covariates from the HadUK-Grid.

METHODS: Taking a Bayesian hierarchical approach, the model tackles firstly the misalignment issue from using multi-source data by fitting a spatio-temporal geostatistical model at the ground monitoring site locations. Then a Gaussian process-based approach is used to predict PM2.5 across the regions where AOD is available. The usual global stationarity assumption is restrictive for this purpose, so a new regionally-stationary approach has been considered. Finally, interpolation methods, for areas with missing AOD data, will be compared to formulate a complete exposure model.

RESULTS: Preliminary results from a locally-stationary Greater London model display clear spatial variability in ground monitored PM2.5, with different trends identified across site types; as well as a moderate non-linear relationship with temperature humidity and precipitation, creating an overall seasonality trend. The validation of the model via cross-validation technique is currently ongoing.

CONCLUSIONS: This model will be used to quantify the effects of air pollution exposure on mental health outcomes in the UK Biobank cohort. Through the use of a Bayesian approach, measurement and modelling uncertainties can be propagated from the exposure model to the mental health effect model. Extensions of this model could involve multiple pollutants and further environmental covariates.

P-0414 Exposure to Surrounding Greenness and Air Pollution Related to Nasal Microbiota Among Asthmatic Children

Aji Kusumaning Asri[1], Chih-Da Wu[1], Tsung-Lin Liu[2], Hui-Ju Tsai[3], Jiu-Yao Wang[4], Wen-Chi Pan[5]

[1]Department of Geomatics, National Cheng Kung University, Tainan City, Taiwan, [2]Department of Biotechnology and Bioindustry Sciences, National Health Research Institutes, Tainan City, Taiwan, [3]Institute of Population Health Sciences, National Health Research Institutes, Miaoli County, Taiwan, [4]Department of Pediatrics, National Cheng Kung University, Tainan City, Taiwan, [5]Institute of Environmental and Occupational Health Sciences, National Yang Ming Chiao Tung University, Taipei City, Taiwan

BACKGROUND AND AIM: Environmental exposures such as greenness and air pollution have been widely associated with asthma among children. However, the potential mechanisms have rarely been studied. Considering the nasal microbiota whose interactions influence asthma, we aimed to investigate the linkage between surrounding greenness and air pollution (fine particulate matter [PM2.5]; nitrogen dioxide [NO2]; ozone [O3]) and nasal microbiota among asthmatic children in Tainan City, Taiwan.

METHODS: The normalized difference vegetation index was used to estimate greenness exposure in each children's location. Spatiotemporal air pollutions variations were predicted using the integrated hybrid kriging-LUR with XG-Boost algorithm. The nasal microbiota was collected from 47 children during the recovery phase. A generalized additive model was applied to evaluate exposure-outcome associations. Several covariates such as personal information and home environment were also considered in the model adjustment. A sensitivity test was then performed to evaluate the robustness of the model estimates.

RESULTS: Considering short-term exposure, a significant negative association was found between air pollution with bacterial diversity of the microbiota, as 1 unit increment of PM2.5 and O3 significantly decreases the observed species (PM2.5: -0.59, 95%CI -1.13, - 0.05 and O3: -0.93, 95%CI -1.54, - 0.32) and species richness (PM2.5: -0.64, 95%CI -1.25, - 0.02 and O3: -0.68, 95%CI -1.43, - 0.07). However, considering the long-term effect, a significant positive association was identified for greenness related to observed species and species richness, as well as a significant negative association for all pollutants related to species richness.

CONCLUSIONS: This is a scarce investigation that confirmed the significant association between nasal microbiota and greenness also air pollution. The findings have the potential for further investigation of how environmental exposures might influence asthma phase trends.

KEYWORDS: air pollution; asthmatic children; nasal microbiota; recovery phase; surrounding greenness

P-0449 Pb, As, Cd and Hg mixture in cord blood and effects in birth outcomes – Bayesian analysis. PIPA Project - Brazil

Nataly De Figueiredo[2], Luiz Eduardo Gomes[1], Ronir Ragio Luiz[1], Volney de Magalhaes Câmara[1], Carmen Ildes Rodrigues Froes Asmus[1]

[1]Federal University of Rio De Janeiro, Rio de Janeiro, Brazil, [2]Souza Marques Medical School, Rio de Janeiro, Brazil

Lead, arsenic, cadmium and mercury have been the subject of studies regarding individual and combined effects. Both have been detected in umbilical cord blood and placenta, evidencing intrauterine exposure. Its effects on fetal and infant development can have consequences in childhood and adulthood. This study aimed to estimate the combined effect of exposure to Pb, As, Cd and Hg in umbilical cord blood on head circumference (HC) and birth weight (BW). This study is part of the PIPA project (Childhood and Environmental Pollutants Project). Data are from the pilot study, conducted between October 2017 and August 2018, a prospective cohort to investigate the effects of exposure to environmental pollutants on child health. Lead, arsenic, cadmium and mercury were measured in 117 umbilical cord samples and sociodemographic information on the mother and clinical data on the baby at birth were collected. for the concentrations of metals the natural log-transformation was performed. The well-established Bayesian kernel machine regression to estimate the joint effects. Convergence tests were performed to check agreement and convergence of two parallel chains starting from different values. The difference of the median multivariate exposure-response functions (EF) represents the estimated joint effect distance when all metals are fixed at a certain percentile and when all metals are fixed at their medians. The model has been adjusted for confounders. for BW EF P10 = 46.056 (IC 95% -176.112 268.223) while EF P90 = -85.827 (IC 95% -316.245 144.591). Regards HC, EF P10 = 0.852 (IC 95% 0.133 1.568) while EF P90 = -0.285 (IC 95% -1.061 0.491). Among the confounding variables considered, smoking had a negative impact on birth weight (-272.99 CI 95% -433.59, -111.39). The higher the joint concentration of metals, the smaller the baby's weight and head circumference.

P-0451 Urinary arsenic concentration and bronchial asthma prevalence in children from Arica, Chile

María Pía Muñoz[1], Marta Saavedra[3], Gina Saavedra[3], Ximena Cannobbio[3], Verónica Iglesias[2]
[1]Programa de Doctorado en Salud Pública, Instituto de Salud Poblacional, Facultad de Medicina, Universidad de Chile, Santiago, Chile, [2]Programa de Epidemiología, Instituto de Salud Poblacional, Facultad de Medicina, Universidad de Chile, Santiago, Chile, [3]Departamento de Salud Pública, Secretaría Regional Ministerial de Salud Arica y Parinacota, Arica, Chile

INTRODUCTION:
Bronchial asthma is the most common chronic inflammatory disease in children. Globally, the asthma prevalence is estimated to be 10.8% in children aged 6 to 7 years and 13.8% in 13 to 14 years. Environmental factors have been associated with asthma, including exposure to metals. In Arica city, northern Chile, arsenic levels in soils of natural and anthropocentric origin have generated exposure in the population. Our study aim was to examine the association between urinary arsenic concentration and bronchial asthma diagnosis in children and adolescents from Arica.

METHODS: Cross-sectional design. A database of 2,026 subjects under 18 years of age enrolled in the Environmental Health Center between 2009 and 2021 was analyzed. Arsenic exposure was obtained through a urine sample and; diagnosis of bronchial asthma from the computerized system of management of explicit health guarantees. The association between urinary arsenic and bronchial asthma adjusted for confounding variables was assessed by logistic regression models.

RESULTS: The prevalence of bronchial asthma was 7.4%, and the median inorganic arsenic was 15 µg/L (IQ range: 7.0 - 26 µg/L). Children with urinary arsenic concentrations above the median were more likely to develop bronchial asthma [Odds Ratio (OR): 1.91 95% CI 1.26 - 2.91)] adjusted for sex, age, ethnicity, and urinary creatinine. Also, the adjusted model revealed a higher chance of developing asthma at concentrations ≥ 22 µg/L of arsenic (OR 1.90, 95% CI 1.12 - 3.20).
CONCLUSION: This study reveals that urinary inorganic arsenic concentration might be associated with the development of bronchial asthma in children and adolescents. Despite the inherent limitations of cross-sectional data analysis, it is necessary to reduce arsenic exposure to prevent possible chronic health effects in children.

P-0454 Cord blood transcriptome-wide association study identifying genes associated with metabolic disrupting chemicals and infant growth

Anran Cai[1,2], Virissa Lenters[3], Lützen Portengen[1], Gokhan Ertaylan[2], Juliette Legler[1], Roel Vermeulen[1,3], Sylvie Remy[2], on behalf of the GOLIATH consortium

[1]Institute for Risk Assessment Sciences, Department of Population Health Sciences, Utrecht University, Utrecht, The Netherlands, [2]VITO Health, Flemish Institute for Technological Research (VITO), Mol, Belgium, [3]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, The Netherlands

BACKGROUND AND AIM: Prenatal exposure to metabolic disrupting chemicals (MDCs) has been linked to childhood obesity, however, the underlying mechanism is not clear. The first two years of life are critical for the development of childhood obesity, with adverse consequences including adult obesity, diabetes, and non-communicable diseases. We aimed to elucidate the role of cord blood transcriptomic influence in prenatal MDC-induced increased infant growth.

METHODS: Cord blood samples were obtained from 192 Belgian mother-singleton pairs, and mRNA was profiled for gene expression using Agilent Whole Human Genome Microarray 4x44K. A linear regression-based transcriptome-wide association study (TWAS) was performed to identify transcriptomic features associated with prenatal MDCs [including dichlorodiphenyldichloroethylene (p,p'-DDE), polychlorinated biphenyls congener 153 (PCB-153), perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS)], measured in cord blood, and with infant growth, defined as body mass index z-score change between birth and 2 years. A triangulation approach, consisting of mediation analysis, pathway enrichment analysis and transcription factor enrichment analysis, was conducted to assess the functional activity of transcriptomics in the relationship between MDCs and infant growth.

RESULTS: TWAS identified 521 features associated with infant growth, and 940, 242, 711, 206 features associated with p,p'-DDE, PCB-153, PFOA, PFOS, respectively. Mediation analysis identified 58 genes mediating the indirect effects of MDCs on infant growth. Particularly, IL34 gene expression was found to mediate both p,p'-DDE and PFOA. No overlapping pathways or transcription factors were associated with MDCs and with infant growth.

CONCLUSIONS: Mediating effects of certain gene expressions on the associations between MDCs and infant growth were identified. This is the first study to investigate the relationship between prenatal MDCs and infant growth by exploring transcriptomic profiling in cord blood, and the triangulation approach provides new insights into the underlying mechanisms.

P-0461 Arsenic exposure and respiratory outcomes during childhood in the INMA study

Antonio José Signes Pastor[1], Susana Díaz-Coto, Pablo Martinez-Camblor, Manus Carey, Raquel Soler-Blasco, Miguel García-Villarino, Ana Fernández-Somoano, Jordi Julvez, Paula Carrasco, Aitana Lertxundi, Loreto Santa Marina, Maribel Casas, Andrew A. Meharg, Margaret R. Karagas, Jesús Vioque-Lopez

[1]Unidad de Epidemiología de la Nutrición. Universidad Miguel Hernández., San Joan d'Alacant, Spain, [2]CIBER de Epidemiología y Salud Pública (CIBERESP), Instituto de Salud Carlos III (ISCIII), Madrid, Spain, [3]Instituto de Investigación Sanitaria y Biomédica de Alicante (ISABIAL), Alicante, Spain

BACKGROUND AND AIM: Ingested inorganic arsenic (iAs) is a human carcinogen that is also linked to other adverse health effects, such as respiratory outcomes. Yet, among populations consuming low-arsenic drinking water, the impact of iAs exposure on childhood respiratory health is still uncertain. Here, it is investigated the association between iAs exposure and respiratory outcomes assessed at 4 and 7 years of age in children living in Spain. In Spain, low-arsenic drinking water is usually available and ingestion of iAs from food is considered the major source of exposure.

METHODS: Our study population of 400 children come from the INMA cohort study (INfancia y Medio Ambiente). The summation of 4-year-old children's urinary iAs, monomethylarsonic acid (MMA), and dimethylarsinic acid (DMA) was used as a biomarker of iAs exposure (∑As) (median of 4.92 µg/L). Children's occurrence of asthma, eczema, sneeze, wheeze, and medication for asthma and wheeze at each assessment time point (i.e., 4- and 7-year) was assessed with maternal interviewer-led questionnaires. Crude and adjusted Poisson regression models using Generalized Estimating Equation (GEE) were performed to account for the association between natural logarithm transformed (ln) urinary ∑As at 4 years and repeated assessments of respiratory symptoms at 4 and 7 years of age adjusting for covariates.

RESULTS: The GEE - splines function using Poisson regression showed an increased trend of the overall expected counts of respiratory symptoms with urinary ∑As. The adjusted expected counts (95% confidence intervals) at ln-transformed urinary ∑As 1.57 (average concentration) and 4.00 (99th percentile) were 0.63 (0.36, 1.10) and 1.33 (0.61, 2.89), respectively.

CONCLUSIONS: These findings suggest that even relatively low-iAs exposure levels, relevant to the Spanish and other populations, may relate to an increased number of respiratory symptoms during childhood.

P-0479 Nitrate exposure from drinking water during pregnancy and risk of small-for-gestational-age in infants from a population-based study in Denmark

Anja Søndergaard Jensen[1], Vanessa R. Coffman[2], Betina B. Trabjerg[3], Carsten B. Pedersen[4], Birgitte Guldberg Hansen[5], Jørn Olsen[6], Marie Pedersen[7], Jörg Schullehner[5], Torben Sigsgaard[8], Leslie T. Stayner[2]

[1]Centre for Integrated Register-based Research (CIRRAU), Aarhus University, Aarhus, Denmark, [2]Division of Epidemiology and Biostatistics, University of Illinois at Chicago, Chicago, USA, [3]National Centre for Register-Based Research (NCRR), Aarhus University, Aarhus, Denmark, [4]Big Data Centre for Environment and Health (BERTHA), Aarhus University, Aarhus, Denmark, [5]Department of Groundwater and Quaternary Geology Mapping, Geological Survey of Denmark and Greenland, Aarhus, Denmark, [6]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, [7]Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [8]Department of Public Health, Aarhus University, Aarhus, Denmark

BACKGROUND AND AIM: Nitrate is commonly found in drinking water due to leaching from agricultural activity into the groundwater. Drinking-water nitrate has been linked to several adverse birth outcomes, such as fetal growth restriction, preterm birth and birth defects. However, only one prior study has examined the impact of drinking-water nitrate on small-for-gestational-age (SGA). We aim to investigate the association between prenatal exposure to nitrate in drinking water and SGA in a population-based cohort in Denmark, a country with extensive national registers and where drinking water is solely groundwater based.

METHODS: We linked a cohort of 1,078,892 Danish singleton live births from 1991-2015 from Danish-born parents where the mother resided in Denmark throughout the pregnancy to individual-level household estimates of nitrate in drinking water. Exposure was modelled categorically and as an ln-transformed continuous variable. SGA was defined as the bottom 10% of births by birth weight per sex and gestational age, while severe SGA was defined as the bottom 5%. Using multiple logistic regression with generalized estimating equations, we accounted for births from the same mother.

RESULTS: We found an increased risk of SGA in the second category of nitrate (>2-5 mg/L) (OR=1.04, 95% CI: (1.03, 1.06)) and in the third category (>5-25 mg/L) (OR=1.02, 95% CI: (1.00, 1.04)) compared to the referent category (≤2 mg/L), but not in the highest. There was strong (p=0.002) evidence of an increase in SGA with nitrate in the model with continuous exposure. Restricting to those with nitrate levels at or below current European Union regulatory standards (≤50 mg/L) showed no meaningful changes.

CONCLUSIONS: Given the ubiquity of nitrate, these findings suggest that the current regulatory standards for nitrate in drinking water may put unborn children at risk of SGA.

KEYWORDS: nitrate, drinking water, small for gestational age, SGA, severe small for gestational age

P-0481 Prenatal Exposure to Ambient Air Pollution and Offspring Cerebral Palsy in Ontario, Canada: A Population-Based Cohort Study

Yuhong Hu[1], Yu Zhang[1], Robert Talarico[2,3], Xinye Qiu[1], Joel Schwartz[1,4], Deshayne B. Fell[3,5,8], Maryam Oskoui[6,7], Eric Lavigne[2,3,8], Carmen Messerlian[1,4,9]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Heath, Boston, USA, [2]Air Sectors Assessment and Exposure Science Division, Health Canada, Ottawa, Canada, [3]School of Epidemiology and Public Health, University of Ottawa, Ottawa, Canada, [4]Department of Epidemiology, Harvard T. H. Chan School of Public Health, Boston, USA, [5]Children's Hospital of Eastern Ontario Research Institute, Ottawa, Canada, [6]Department of Pediatrics, McGill University, Montreal, Canada, [7]Department of Neurology and Neurosurgery, McGill University, Montreal, Canada, [8]ICES, Ottawa, Canada, [9]Massachusetts General Hospital Fertility Center, Department of Obstetrics and Gynecology, Boston, USA

BACKGROUND AND AIM: Air pollution has been linked with structural brain changes, disruption of neurogenesis, and elevated risk of adverse neurodevelopment. However, no study investigated the influence of air pollutants on risk of cerebral palsy (CP), the most common motor disability in childhood. This study aimed to evaluate the association between prenatal exposure to ambient air pollution and the risk of CP in children born at term gestation.

METHODS: This study included 1,587,935 singleton term births with valid outcome information between 2002 and 2017 from all hospitals at Ontario, Canada. Annual $PM_{2.5}$ (1 × 1 km), NO_2 (10 × 10 km), and O_3 (21 × 21 km) were estimated and spatiotemporally interpolated to obtain weekly average concentrations at the postal code level for maternal residence during pregnancy. CP cases were ascertained by a single inpatient hospitalization diagnosis or at least two outpatient diagnoses for children from birth to 16 years of age. Multi-pollutant Cox proportional hazard models were performed with distributed lags to estimate the covariate-adjusted weekly hazard ratios (HRs) of CP per interquartile range (IQR) increase in prenatal exposure to each pollutant.

RESULTS: We identified 3,170 (2.0‰) CP cases during the study period. We found significant associations between exposures to $PM_{2.5}$ over gestational weeks 10 - 20 and increased CP risk, with a cumulative HR of 1.11 (95% CI: 1.03, 1.12) per IQR increase (2.7 μg/m3) across pregnancy (up to 37 weeks). No associations or windows of susceptibility were found for NO_2 or O_3 in relation to CP.

CONCLUSIONS: $PM_{2.5}$ exposure during early- and mid-pregnancy was associated with an increased risk of CP. Further studies are needed to explore this association and its potential mediators, which could advance knowledge of the environmental risk factors of CP during early fetal life.

KEYWORDS: Air Pollution; Cerebral Palsy; Neurodevelopment; Windows of Susceptibility

P-0520 Attendance Benefits of the EPA's School Bus Rebate Program: A Randomized Design

Meredith Pedde[1], Adam Szpiro[2], Richard Hirth[1], Sara Adar[1]
[1]*University of Michigan, Ann Arbor, USA,* [2]*University of Washington, Seattle, USA*

BACKGROUND AND AIM: While buses remain the safest school transport from an accident perspective, older buses can expose students to high levels of diesel exhaust. Since these exposures adversely impact health and can cause missed school, the US Environmental Protection Agency (EPA) has spent millions of dollars to transition school bus fleets to cleaner vehicles. We leveraged the randomized allocation of the EPA's 2012-2017 School Bus Rebate Program funding to causally assess the district attendance impacts of upgrading buses.

METHODS: We used classical intent-to-treat analyses for randomized controlled trials to compare changes in school district attendance rates after vs before the 2012-2017 lotteries by funding selection status. We evaluated heterogeneity of effect by quartiles of estimated ridership and model years (MY) of the replaced buses since emissions standards have strengthened over time.

RESULTS: Within our analytical sample, 383 of the 2,816 EPA applicants were selected for funding. We found that districts selected for funding had, on average, a 0.06 percentage point (pp) higher attendance rate in the year after the lottery (95% CI: -0.01, 0.13) compared to unselected districts. Impacts were larger for districts with the highest estimated ridership on applicant buses (0.14 pp; 95% CI: -0.05, 0.32) and who replaced the oldest buses (pre-1990 MY replacement: 0.45 pp; 95% CI: 0.26, 0.65). In the first year after the funding lotteries we estimate there were 350,000 (95% CI: -70,000, 770,000) additional student-days of attendance due to these EPA funds. Extrapolation of our results suggests that replacement of all pre-2000 MY buses nationwide would lead to 1.3 million additional student-days of attendance each year (95% CI: 250,000, 2,400,000).

CONCLUSIONS: We find evidence that the EPA's School Bus Rebate Program has improved student attendance, especially in districts that had high levels of ridership on the impacted buses and removed the oldest buses.

P-0538 Dose-response relation between maternal exposure to arsenic in drinking water and risk of congenital heart disease in offspring – A nationwide cohort study

Annette Ersbøll[1], Frida Richter, Stine Kloster, Kirstine Wodschow, Birgitte Hansen, Jorg Schullehner, Søren Kristiansen, Mette Mains, Katrine Strandberg-Larsen
[1]*University of Southern Denmark, København K, Denmark*

BACKGROUND AND AIM: Prenatal exposure to arsenic is suspected to increase the risk of birth defects including congenital heart disease.
The aim of the study was to examine the association between maternal exposure to arsenic in drinking water and risk of congenital heart disease in the offspring with focus on the dose-response relationship.

METHODS: A nationwide register-based cohort study was performed. All liveborn children in Denmark in the study period 1997-2014 was included. Arsenic concentrations in drinking water were available through the national well database (Jupiter) managed by the Geological Survey of Denmark and Greenland. Maternal addresses at fetal age 4 weeks were linked with arsenic concentration in drinking water in the water supply areas. Four categories of maternal exposure to arsenic in drinking water were applied (<0.5 µg/L, 0.5-0.9 µg/L, 1.0-4.9 µg/L, ≥5 µg/L). The outcome was congenital heart disease diagnosed within the first year of life overall and stratified as severe, septal defects, and valvular heart defect.
The association between maternal exposure to arsenic in drinking water and risk of congenital heart disease was examined using a logistic regression analysis. The association was adjusted for year of birth, mother's educational level and ethnicity.

RESULTS: A total of 1,042,413 children was included in the study. The number of children born with a congenital heart disease increased from 9.2 per 1,000 births at maternal exposure <0.5 µg/L to 12.3 per 1,000 births at maternal exposure ≥5 µg/L. Similar findings was seen for septal defects. The associations were similar for girls and boys.
CONCLUSION: The study showed that maternal exposure to arsenic in drinking water increased the risk of congenital heart disease in the offspring even at low concentrations (i.e., 0.5–0.9 µg/L).

KEYWORDS: arsenic concentration, drinking water, congenital heart disease, nationwide study

P-1182 Associations of per- and polyfluoroalkyl substances (PFAS) and their mixture with oxidative stress biomarkers during pregnancy

Kaitlin Taibl[1], Tracey J. Woodruff[2], Max Aung[3], Amy Padula[2], Sarah Geiger[4], June-Soo Park[5], Ginger Milne[6], Susan Schantz[7], Rachel Morello-Frosch[8], Stephanie Eick[1]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Program on Reproductive Health and the Environment, Department of Obstetrics, Gynecology and Reproductive Sciences, University of California, San Francisco, San Francisco, USA, [3]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [4]Department of Kinesiology and Community Health, University of Illinois at Urbana-Champaign, Champaign, USA, [5]Environmental Chemistry Laboratory, Department of Toxic Substances Control, California Environmental Protection Agency, Berkeley, USA, [6]Division of Clinical Pharmacology, Department of Medicine, Vanderbilt University Medical Center, Nashville, USA, [7]Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign, Champaign, USA, [8]Department of Environmental Science, Policy and Management and School of Public Health, University of California, Berkeley, Berkeley, USA

BACKGROUND AND AIM: Oxidative stress, caused by environmental insults, may interfere with redox signaling during pregnancy and is a known contributor to preterm birth. In vivo and in vitro studies indicate that PFAS generate reactive oxygen species, but this has been minimally investigated in humans and has not been examined during pregnancy. We investigated the effects of prenatal PFAS exposure on oxidative stress biomarkers, hypothesizing that PFAS would be positively associated with oxidative stress.

METHODS: Our analytic sample included participants enrolled in the Illinois Kids Development Study and Chemicals In Our Bodies prospective pregnancy cohorts between 2014 and 2019 (N=428). Seven PFAS were quantified in 2nd trimester serum. Urine levels of 8-isoprostane-prostaglandin-F2α, PGF2α, 2,3-dinor-8-iso-PGF2α, and 2,3-dinor-5,6-dihydro-8-iso-PGF2α were measured in the 2nd and 3rd trimesters as biomarkers of oxidative stress. We fit linear mixed-effects models to estimate the associations between single PFAS with one or two measurements of oxidative stress biomarkers. We used quantile g-computation and Bayesian kernel machine regression (BKMR) to assess mixture associations between multiple PFAS and oxidative stress biomarkers. All models were adjusted for cohort, maternal age, parity, education, and pre-pregnancy body mass index.

RESULTS: Linear mixed-effects models showed that an interquartile range increase in perfluorooctane sulfonic acid (PFOS) was associated with a 4.08% increase in 8-iso-PGF2α (95% confidence interval [CI]= -3.20, 11.91). Using quantile g-computation, a one-quartile increase in all PFAS concentrations was associated with a modest increase in 8-iso-PGF2α (β=0.09, 95% CI= -0.07, 0.25). In both quantile g-computation and BKMR, and across all oxidative stress biomarkers, PFOS contributed the most to the overall mixture effect.

CONCLUSIONS: Our study is the first to investigate the effects of PFAS exposure on oxidative stress biomarkers during pregnancy. Findings were consistent across mixture methods and indicated PFOS is associated with elevated levels of oxidative stress among pregnant people.

P-1189 Synthetic pyrethroids exposure among women from fertility clinic and embryological outcomes- is there an association?

Joanna Jurewicz[1], Katarzyna Wieczorek[1], Dorota Szczęsna[1], Katarzyna Konieczko[1]
[1]*Nofer Institute of Occupational Medicine, Lodz, Poland*

INTRODUCTION: Pyrethroids exposure has been associated with adverse reproductive outcome. However, there is no study that explore the effect of environmental exposure and embryological outcomes. This question was addressed in the prospective cohort of couples undergoing fertility treatment.

METHODS: We included 450 women aged 25-45 undergoing assisted reproductive technology (ART) cycle at Infertility Clinic in Poland. A urine sample were collected at the time of fertility procedure(s) to assess four urinary synthetic pyrethroids concentrations (3-phenoxybenzoic acid (3PBA), cis-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropane carboxylic acid (cis-DCCA), trans-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropane carboxylic acid (trans-DCCA), cis-2,2-dibromovinyl-2,2-dimethylocyclopropane-1-carboxylic acid (DBCA)) using validated gas chromatography ion-tap mass spectrometry and calculated for cycle-specific for each metabolite. To evaluate effect of environmental exposure to synthetic pyrethroids and embryological outcomes (methaphase II (MII) oocyte yield, top quality embryo, fertilization rate, implantation rate) multivariable generalized linear mixed analyses with random intercepts was prepared.

RESULTS: Urinary 3-PBA concentrations decrease MII oocyte count (p=0.007) in the four quartile (>75 percentyl) compared to women in the first quartile (≤ 25 percentyl). Additionally when 3-PBA was treated as continuous variable the negative association between exposure to pyrethroids and MII oocyte count was also observed (p=0.012). Exposure to other pyrethroids metabolities (CDCCA, TDCCA, DBCA) were not related to any of the examined embryological outcomes.

CONCLUSIONS: The exposure to synthetic pyrethroids may be associated with poorer embryological outcome among couples seeking fertility treatments. As this is the first study on this topic, the results need to be confirmed in further studies.

KEYWORDS: embryological outcomes, urinary pyrethroids concentrations, environmental exposure, IVF treatment

P-1191 Prenatal Mycoestrogen Concentrations in Relation to Placental and Birth Weights

Zorimar Rivera-Núñez[1,2], Carolyn Kinkade[2], Anita Brinker[2], Brian Buckley[2], Jessica Brunner[3], Richard K. Miller[3], Carolyn Salafia[4], Thomas G. O'Connor[3], Lauren M. Aleksunes[5], Emily S. Barrett[1,2,3]
[1]School of Public Health, Rutgers University, Piscataway, USA, [2]Environmental and Occupational Health Sciences Institute, Rutgers University, Piscataway, USA, [3]University of Rochester Medical Center, Rochester, USA, [4]Placenta Analytics, Larchmont, USA, [5]Ernest Mario School of Pharmacy, Rutgers University, Piscataway, 08854

BACKGROUND AND AIM: Zearalenone (ZEN) is an estrogenic mycotoxin or 'mycoestrogen' that contaminates global grain crops. Worldwide consumption has resulted in detectable concentrations of ZEN and its metabolites, including the synthetic version alpha-zearalanol (ZER), in human populations. Despite in vivo and in vitro evidence of endocrine disruption by ZEN, there is limited investigation of how mycoestrogens impact human health. The aim of this study was to examine markers of fetal growth following prenatal exposure to ZEN.

METHODS: Placental samples were collected from participants (n= 240) in the UPSIDE cohort (Rochester, NY, USA). ZEN and its metabolites were analyzed using high performance liquid chromatography and tandem mass spectrometry and values were log-transformed. Birth and placental weights were obtained from medical records and direct measurement, respectively; fetoplacental ratio (FPR) was calculated by dividing birthweight by placental weight. Generalized linear regression models were used to examine ZEN, ZER, and total mycoestrogens (sum of ZEN, ZER and their metabolites) in relation to fetal and placental size, adjusting for covariates.

RESULTS: ZEN and its metabolites were detected in 82% of placentas (median ZEN: 0.013 ng/g). Lower fetoplacental ratios were associated with placental concentrations of ZER (-0.45, 95%CI: -0.74,-0.16) and total mycoestrogens (-0.26, 95%CI: -0.42, -0.10). Although not statistically significant, placental ZEN (-31g, 95%CI: -115, 53) and ZER (-83g, 95%CI: -205, 40) were associated with lower birthweight and ZEN was associated with lower fetoplacental ratio (-0.19, 95%CI: -0.47, 0.08). No associations with placental weight were observed.

CONCLUSIONS: Results from this first epidemiological study of prenatal mycoestrogen exposure and child health suggest that ZEN and its metabolites may alter placental efficiency, resulting in lower birthweight. Ongoing work in this cohort will additionally quantify urinary mycoestrogens across pregnancy and evaluate maternal estrogens in relation to ZEN exposure.

P-1214 Associations of Urinary Phthalate Metabolites and Inflammatory Biomarkers Characteristic of the Preeclamptic Pathway Among Pregnant Women in Puerto Rico

Christine Lee[1], Amber Cathey[1], Deborah Watkins[1], Zaira Rosario-Pabón[2], Carmen Vélez-Vega[2], Akram Alshawabkeh[3], José Cordero[4], John Meeker[1]

[1]University of Michigan School of Public Health, Department of Environmental Health Sciences, Ann Arbor, USA, [2]University of Puerto Rico, Graduate School of Public Health, San Juan, USA, [3]Northeastern University, College of Engineering, Boston, USA, [4]University of Georgia, College of Public Health, Athens, USA

BACKGROUND AND AIM: Phthalates are a ubiquitous environmental exposure that may be implicated in inflammatory processes, as demonstrated by previous in vivo and in vitro studies. Few human studies have substantiated these observations. This study sought to examine whether maternal phthalate exposures impact inflammatory processes, as measured by circulating inflammatory biomarkers, in the PROTECT cohort in northern Puerto Rico.

METHODS: Circulating inflammatory biomarkers were collected from maternal serum samples during pregnancy. Inflammatory biomarkers included matrix metalloproteinases 1, 2, and 9 (MMPs), C-reactive protein (CRP), vascular cell adhesion molecule-1 (VCAM), and intercellular cell adhesion molecule-1 (ICAM). 19 phthalate metabolites were assessed in urinary samples measured at three study visits across pregnancy. Phthalates with <50% of measurements above the limit of detection were excluded from analysis. We utilized linear mixed effect models to estimate associations between interquartile range increases in phthalate metabolite concentrations and percent changes in inflammatory biomarkers.

RESULTS: Our results revealed significant associations between mono-n-butyl phthalate (MBP) and higher MMP1 by 7.86% (95% CI: 0.49, 15.76) and between mono oxononyl phthalate (MONP) and higher MMP2 by 8.30% (95% CI: 2.22, 14.75). We observed negative or null associations between phthalate metabolites and MMP2, MMP9, ICAM, VCAM, and CRP. Many results were significantly modified by fetal sex, particularly those between di-2-ethylhexyl phthalate (DEHP) metabolites and MMP1 (p-interaction: MEHHP=0.01, MEOHP= 0.04, MECPP= 0.01) and MMP2 (p-interaction: MEHHP=0.03, MEOHP=0.01, MECPP=0.01), for which associations were positive among only women carrying female fetuses.

CONCLUSIONS: MMPs have been previously investigated as preeclamptic biomarkers given their role in artery remodeling. Hence, our findings suggest a potential role for phthalates in mediating the maternal inflammatory response, as well as significant sexual dimorphism in these relationships, which has implications for preeclampsia and other adverse pregnancy outcomes.

P-1220 Fetal death: analysis of angiogenic factors during pregnancy

Luciana Duzolina Manfré Pastro[1], Mara Sandra Hoshida[1], Hillegonda Maria Dutilh Novaes[2], Márcia Furquim de Almeida[3], Nelson Gouveia[2], Rossana Pulcinelli Vieira Francisco[1]
[1]University of Sao Paulo Medical School - Department of Gynecology and Obstetrics, São Paulo, Brazil, [2]University of São Paulo - Departament of preventive Medicin, São Paulo, Brazil, [3]University of Sao Paulo School of Public Health, São Paulo, Brazil

BACKGROUND: Fetal mortality is still insufficiently studied.
Objectives: Analyze angiogenic factors (PlGF) in maternal-fetal interface and associate then with fetal mortality.

METHODS: This is part of a case control study from 15 public branch hospitals of Sao Paulo City were we selected fetal death and live births.
Inclusion criteria: Single pregnancy; fetus and live births: ≥ than 22 and ≤ than 45 weeks of gestation and/or birth weight ≥ 500g.
Exclusion criteria: Absence of judicial termination of pregnancy and of maternal death on birth room

RESULTS: We analized 23 patients case and 23 controls. Birth weight averaged was 2290 grams for case group and 3177 grams for control ($p < 0.001$) (Mann-Whitney). Gestational age ranged from 27 to 39 weeks in case group and from 32 to 42 weeks in control ($p < 0.001$) (Qui Square)
Maternal PlGF of case group had a mean of 433.9 and of the control had 132.6 ($p = 0.005$). Umbilical cord PlGF of case group had a mean of 358.2 and the control had 10.41 pg/mL ($p < 0.001$). Median PlGF of umbilical cord of pregnant women who had preterm birth was 358.7 and of those who had delivered at term was 15.1 ($p < 0.001$) (Mann-Whitney).
Comparing PlGF of the control group and the fetal death group (intrapartum or antepartum) we found difference between live births and mothers who had intrapartum fetal death. By Dunn's post hoc test, the difference for maternal PLGF is between live birth vs intrapartum ($p=0.012$), similarly for cord PLGF ($p<0.001$)

CONCLUSIONS: We found differences between the PlGF of the blood of the mother and the umbilical cord of the case and control. We intend to analyze the sFlt and relate them with the occurrence of fetal death and other obstetric parameters.

P-0519 The effect of COVID-19 lockdown/post-lockdown and season on children's exposure to PM2.5 and time expenditure by environment type

Natalie Crnosija[1], Josh Medrano[2], Richard W. Prather[2], Devon Payne-Sturges[1]
[1]Maryland Institute for Applied Environmental Health, School of Public Health, University of Maryland--College Park, College Park, USA, [2]Department of Human Development and Quantitative Methodology, University of Maryland--College Park, College Park, USA

BACKGROUND AND AIM: $PM_{2.5}$ concentration differs by environment type (indoor, outdoor, automobile). Elevated $PM_{2.5}$ exposure is associated with children's poor cognitive/mathematical performance, a strong predictor of poor later academic performance. The Bridging the Environment and Neurodevelopment for Children's Health Study provided low-cost personal air quality sensors to 30 Washington, D.C. metro-area children to investigate the relationship between daily air pollution exposures and children's cognitive performance. We investigated whether, between COVID-19 lockdown and post-lockdown periods, there were significant differences between measured location-specific (indoor, outdoor, automobile) $PM_{2.5}$ values and time spent in these locations, as well as these exposures' correlation with children's cognitive performance.

METHODS: Each data collection round included children (age 8-11) wearing the air quality sensor for 3 days during which parents recorded their activities; on day 3, children completed cognitive assessments. We collected data during winter 2020-2021 (Round 1) and spring/summer 2021 (Round 2). We used: Friedman tests to assess differences in average $PM_{2.5}$ and time spent by activity location for each round, Wilcoxon signed-rank tests to evaluate change over time and Spearman correlation tests to evaluate correlation between location-specific $PM_{2.5}$/time exposure and cognitive performance.

RESULTS: We found that there were significant differences in $PM_{2.5}$ exposure by activity type during the post-lockdown period--$PM_{2.5}$ exposure outside was significantly greater than that measured indoors or in an automobile (median outdoors = 5.11 $\mu g/m^3$; indoors = 3.25 $\mu g/m^3$; automobile = 2.66 $\mu g/m^3$). There were significant differences based on average time spent (logged in quarter-hour increments) in these locations rounds 1 vs. 2: outdoors (median=0.92 hours vs. 2.17 hours) and in automobiles (median=1.25 hours vs. 2.75 hours). These exposures weakly correlated with cognitive performance.
CONCLUSION: Our findings suggest seasonal effects of place-based $PM_{2.5}$ exposure and the effects of the cessation/the resumption of "normal life" during the COVID-19 pandemic's phases.

P-0643 Long term exposure to air pollution and COVID-19 incidence: a prospective population-based study in northern Italy

Giovanni Veronesi[1], Sara De Matteis[2,3], Giuseppe Calori[4], Nicola Pepe[4], Marco M Ferrario[1]
[1]Research Center in Epidemiology and Preventive Medicine, Department of Medicine and Surgery, University of Insubria, Varese, Italy, [2]Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy, [3]National Heart and Lung Institute, Imperial College London, London, UK, [4]ARIANET s.r.l., Milano, Italy

BACKGROUND AND AIM: Most of studies on air pollution and COVID-19 are limited to the first pandemic wave and by their ecological design. We investigate the association between long-term exposure to airborne pollutants and SARS-CoV-2 incidence up to March 2021 in Varese city, Lombardy Region, one of the most polluted areas of Europe.

METHODS: A prospective study of Varese adult citizens as of Dec31st,2019, linked by residential address to 2018 average annual exposure to outdoor concentrations of PM2.5, PM10, NO2, NO and O3 (FARM chemical-transport model), and to Regional datasets for age, sex, residential care home living, population density, comorbidities, and COVID-19 case ascertainment (positive nasopharyngeal swab specimens) until March 2021. We estimate rate ratios and additional number of cases for 1µg/m3 increase in air pollutants from single- and bi-pollutant Poisson regression models, reporting how sensible our estimates are to residual confounding through the E-value.

RESULTS: The 62848 residents generated 4408 cases. Yearly average PM2.5 exposure was 12.5µg/m3. In single-pollutant models adjusting for age, residential care home living, history of stroke, medications for diabetes, hypertension and obstructive airway diseases, PM2.5 was associated with 5.1% increase in COVID-19 rate (95%CI:2.7%-7.5%), corresponding to 294 additional cases per 100000 person-years. Further adjustment for area-based indicators of social deprivation and use of public transportation slightly attenuated the risk excess to 3.6% (95%CI:0.9%-6.4%). To explain away this estimated effect, an unmeasured confounder would need a rate ratio of 1.23 (E-value) with both exposure and outcome besides measured covariates. Bi-pollutant models confirmed the association. Results for PM10, NO2 and NO were similar. O3 was associated with a 2% decrease in disease rate, the association being reversed in bi-pollutant models.

CONCLUSIONS: Our prospective study provides solid evidence to the association between long-term exposure to low-levels of PM2.5 and increased COVID-19 incidence.

KEYWORDS: air pollution, COVID-19, prospective study

P-0644 Detection and quantitative assessment of SARS-CoV-2 in wastewater influent in Mazovian District, Poland

Agata Stobnicka-Kupiec[1], Małgorzata Gołofit-Szymczak[1], Rafał Górny[1]
[1]*Central Institute for Labour Protection - National Research Institute, Warsaw, Poland*

BACKGROUND AND AIM. Coronaviruses (CoVs; ssRNA) are responsible for human and animal respiratory and gastrointestinal infections. Although, CoVs are mainly transmitted through respiratory droplets, SARS-CoV-2 RNA has been detected in stool and urine samples of asymptomatic carriers and patients showing symptoms of COVID-19. Wastewater-based surveillance of the SARS-CoV-2 is used to monitor the population-level prevalence of the COVID-19 disease. The aim of this research was to assess the prevalence of SARS-CoV-2 in wastewater influent samples collected in wastewater treatment plants located in Mazovian District in Poland.

METHODS: Fifteen wastewater influent samples (1000mL) were collected into sterile glass containers in April 2021. The extraction of viral RNA was carried out with Kogene Power Prep Viral DNA/RNA Extraction Kit (Kogene Biotech, South Korea) according to the manufacturer's instructions to produce a final volume of 35 µL. Obtained RNA samples were stored in -20 °C until further analysis. RT-qPCR was performed using CFX96 real-time PCR thermocycler (BioRad, USA). The detection of SARS-CoV-2 was carried out with SARS-CoV-2 VIASURE Real-Time PCR Detection Kits (CerTest Biotec, Spain) with a detection limit of ≥ 10 RNA copies per reaction.

RESULTS: The performed RT-qPCR-based studies revealed the presence of SARS-CoV-2 and presumptive SARS-CoV-2 or other coronaviruses in 33.3% and 46.7% of samples, respectively. The concentration of viral nucleic acids in analyzed influent wastewater samples ranged between 1.57×104 gc/L and 6.12×104 gc/L for SARS-CoV-2 and 6.84×103 gc/L and 2.39×105 gc/L for presumptive SARS-CoV-2 or other coronaviruses.

CONCLUSIONS: The wastewater-based approach can provide an effective way for identifying community-level hotspots of the infection and may be useful as an early warning tool, providing extra time for actions to suppress the spread of infections before the availability of clinical surveillance information.

KEYWORDS: SARS-CoV-2, wastewater, RT-qPCR

P-0646 Predictive model for severe COVID-19 using SARS-CoV-2 whole genome sequencing and electronic health record data, March 2020-May 2021

Lei Zhu[1,2], Jane W Marsh[1,2], Marissa P Griffith[1,2], Kevin Collins[3], Vatsala Srinivasa[1,2], Kady Waggle[1,2], Daria Van Tyne[1,2], Graham M. Snyder[2,4], Tung Phan[5], Alan Wells[5], Oscar C Marroquin[3], Lee H Harrison[1,2]

[1]Microbial Genomic Epidemiology Laboratory, Center for Genomic Epidemiology, University of Pittsburgh, Pittsburgh, USA, [2]Division of Infectious Diseases, University of Pittsburgh School of Medicine, Pittsburgh, USA, [3]Healthcare Data and Analytics, University of Pittsburgh Medical Center, Pittsburgh, USA, [4]Department of Infection Prevention and Control, University of Pittsburgh Medical Center, Pittsburgh, USA, [5]Department of Pathology, University of Pittsburgh, Pittsburgh, USA

BACKGROUND AND AIM: We used SARS-CoV-2 whole-genome sequencing (WGS) and electronic health record (EHR) data to investigate the associations between viral genomes and clinical characteristics and severe outcomes among hospitalized COVID-19 patients.

METHODS: We conducted a case-control study of severe COVID-19 infection among patients hospitalized at a large academic referral hospital between March 2020 and May 2021. SARS-CoV-2 WGS was performed, and demographic and clinical characteristics were obtained from the EHR. Severe COVID-19 (case patients) was defined as having one or more of the following: requirement for supplemental oxygen, mechanical ventilation, or death during hospital admission. Controls were hospitalized patients diagnosed with COVID-19 who did not meet the criteria for severe infection. We constructed predictive models incorporating clinical and demographic variables as well as WGS data including lineage, clade, and SARS-CoV-2 SNP/GWAS data for severe COVID-19 using multiple logistic regression.

RESULTS: of 1,802 hospitalized SARS-CoV-2-positive patients, we performed WGS on samples collected from 590 patients, of whom 396 were case patients and 194 were controls. Age (p=0.001), BMI (p=0.032), test positive time period (p=0.001), Charlson comorbidity index (p=0.001), history of chronic heart failure (p=0.003), atrial fibrillation (p=0.002), or diabetes (p=0.007) were significantly associated with case-control status. SARS-CoV-2 WGS data did not appreciably change the results of the above risk factor analysis, though infection with clade 20A was associated with a higher risk of severe disease, after adjusting for confounder variables (p=0.024, OR=3.25; 95%CI: 1.31-8.06).

CONCLUSIONS: Among people hospitalized with COVID-19, older age, higher BMI, earlier test positive period, history of chronic heart failure, atrial fibrillation, or diabetes, and infection with clade 20A SARS-CoV-2 strains can predict severe COVID-19.

P-0649 SARS-CoV-2 infection is associated with functional changes in resting-state neural mechanisms among Italian adolescents and young adults: a longitudinal case control study

Azzurra Invernizzi[1], Elza Rechtman[1], Stefano Renzetti[3], Alessandra Patrono[8], Christoph van Thriel[9], Demetrios Papazaharias[1], Elena Colicino[1], Claudia Ambrosi[2], Lorella Mascano[2], Giuseppa Cagna[3], Roberto Gasparotti[3], Abraham Reichenberg[5], Cheuk Tang[6], Donald Smith[4], Donatella Placidi[3], Roberto Lucchini[1,3,7], Robert Wright[1], Megan Horton[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]ASST Spedali Civili Hospital, Brescia, Italy, [3]Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, University of Brescia, Brescia, Italy, [4]Department of Microbiology and Environmental Toxicology, University of California Santa Cruz, Santa Cruz, USA, [5]Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, USA, [6]Department of Diagnostic, Molecular, and Interventional Radiology, Icahn School of Medicine at Mount Sinai, New York, USA, [7]Department of Environmental Health Sciences, Robert Stempel College of Public Health and Social Work, Florida International University, Miami, USA, [8]Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy, [9]Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany

BACKGROUND: There is strong evidence for brain-related abnormalities COVID-19. Neurologic, cognitive, and olfactory deficits demonstrate the potential neurotoxic impact of the virus. Recent studies of covid-related brain changes focus on severe infection or older populations. To our knowledge, no studies have focused on brain changes in adolescents and young adults impacted mildly by COVID-19. We took a data-driven approach to identify functional brain changes in COVID-19 cases and controls from Lombardy, Italy, a global hotspot of COVID-19.

METHODS: From our ongoing longitudinal neuroimaging study of adolescents in Northern Italy (the Public Health Impact of Metals Exposure (PHIME) study), we selected 10 participants (age 16-25y) who tested positive for SARS-CoV-2 infection (confirmed via real-time reverse transcription polymerase chain reaction (RT-PCR) tests) and 11 age- and sex-matched non-infected controls (RT-PCR negative; no close-contact or self-reported symptoms). None of the 10 positive subjects were hospitalized or suffered from pneumonia. All participants completed resting state functional magnetic resonance imaging (rs-fMRI) studies prior to and after infection. Using graph theory metrics, we computed eigenvector centrality (EC) in 111 brain areas (Harvard Oxford Atlas) and computed ECdelta (i.e., the difference in EC values pre- and post-COVID-19). We used family wise error (FWE) corrected permutation statistics to quantify ECdelta differences between cases and controls.

RESULTS: ECdelta in four brain regions (right posterior temporal gyrus; right planum temporale; left insular cortex and left central opercular cortex; p= 0.034, 0.047, 0.016, 0.038, respectively) differed significantly between COVID-cases and matched controls.

CONCLUSIONS: To our knowledge, this is the first longitudinal imaging study of COVID-19 in adolescence where participants were scanned before and after SARS-CoV-2 infection. Our results show that key brain areas associated with the primary gustatory cortex (insula and opercular cortex) and the 'brain-fog' (temporal gyrus and planum temporale) have altered functional connectivity patterns in adolescents infected by SARS-CoV-2.

P-0651 Residential green space is associated with a buffering effect on stress responses during the COVID-19 pandemic in mothers of young children, a prospective study

Stijn Vos[1], Esmée Bijnens[1,2], Eleni Renaers[1], Hanne Croons[1], Charlotte Van Der Stukken[1], Dries Martens[1], Michelle Plusquin[1], Tim Nawrot[1,3]

[1]Centre for Environmental Sciences, Hasselt University, Diepenbeek, Belgium, [2]Department of Human Structure and Repair, Ghent University Hospital, Gent, Belgium, [3]Department of Public Health & Primary Care, Occupational & Environmental Medicine, KU Leuven, Leuven, Belgium

BACKGROUND AND AIM: Green spaces are associated with increased well-being and reduced risk of developing psychiatric disorders. In this study, we aimed to investigate how residential proximity to green spaces was associated with stress response buffering during the COVID-19 pandemic in a prospective cohort of young mothers.

METHODS: We collected information on stress in 766 mothers (mean age: 36.6 years) from the ENVIRONAGE birth cohort at baseline of the study (from 2010 onwards), and during the COVID-19 pandemic (from December 2020 until May 2021). Self-reported stress responses due to the COVID-19 pandemic were the outcome measure. Green space was quantified in several radiuses around the residence based on high-resolution (1 m2) data. Using ordinal logistic regression, we estimated the odds of better resistance to reported stress, while controlling for age, socio-economic status, stress related to care for children, urbanicity, and household change in income during the pandemic. In sensitivity analyses we corrected for pre-pandemic stress levels, BMI, physical activity, and changes in health-related habits during the pandemic.

RESULTS: We found that for an inter-quartile range contrast in residential green space 300 m and 500 m around the residence, participants were respectively 24% (OR = 1.24, 95%CI: 1.03 to 1.51) and 29% (OR = 1.29, 95%CI: 1.04 to 1.60) more likely to be in a more resistant category, independent of the aforementioned factors. These results remained robust after additionally controlling for pre-pandemic stress levels, BMI, physical activity, smoking status, urbanicity, psychological disorders, and changes in health-related habits during the pandemic.

CONCLUSION

This prospective study in young mothers highlights the importance of proximity to green spaces, especially during challenging times.

P-0656 Mental health dynamics during the national quarantine in China

Yimeng Song[1], Hung Chak Ho[2], Bin Chen[3], Michelle L. Bell[1]
[1]School of the Environment, Yale University, New Haven, USA, [2]Department of Urban Planning and Design, The University of Hong Kong, Hong Kong, [3]Division of Landscape Architecture, The University of Hong Kong, Hong Kong

BACKGROUND AND AIM: The COVID-19 pandemic and accompanying lockdown, pandemic fear, and economic collapse are widely believed to harm mental health. However, the spatio-temporal dynamics of public mental health status during national or regional quarantine have not been systematically examined due to data availability issues. This leaves a gap in evidence required to estimate socio-psychological risks for facilitating post-pandemic recovery in the population.

METHODS: By leveraging Baidu Index (index.baidu.com), a numeric rating score reflecting netizens' concerns for a specific issue, we characterized the magnitude of three mental health issues during the first wave of COVID-19-caused national quarantine in China, including anxiety, depression, and insomnia. The weekly variations of mental health issues are measured at national, provincial, and city levels by comparing the indexes across years. Bayesian regression models examined the relationships between COVID-19-related factors and mental health problems.

RESULTS: Compared to the same period in 2019, we observed that mental health issues became more severe around the 5th -9th week after the start of China's national quarantine, with a nearly 18% increase in well-being-related topic search terms. In particular, anxiety became more severe in 274 of the 289 selected major cities, depression in 235 cities, and insomnia in 257 cities during this period. Provinces including Hubei, Shangdong, and Hebei are the regions that have the most extended duration of heightened mental health issues. In addition, factors like cumulative confirmed cases, new deaths, and emergency response levels are found to have significant positive effects on the increase of mental health issues.

CONCLUSIONS: The COVID-19 pandemic has a pervasive negative impact on people's mental health, exhibiting significant spatio-temporal heterogeneity. A timely and accurate assessment of mental health dynamics is beneficial for effective interventions during major health events.

KEYWORDS: COVID-19; lockdown policy; anxiety; depression; insomnia

P-0684 Social environment, inequality, and COVID 19 in Nicaragua: did we underreport COVID-19 impact on those most highly vulnerable socioeconomic population groups?

Steven Cuadra[1], Rosa Noemi Fuertes Toledo[2], Martha Gallo[2]
[1]Universidad De Occidente (udo Managua) Nicaragua, Managua, Nicaragua, [2]Casa Emilia Salud, Managua, Nicaragua

BACKGROUND AND AIM: In Nicaragua, COVID-19 official figures are very limited for vulnerable socio-economic population groups. Therefore, we conducted a multiapproach study to investigate the health impact of the pandemic in such groups and to estimate underreporting of COVID-19 cases.
METHOD: We implemented both a web-based survey (n=8,200 respondents) and a face-to-face interview-based survey (n=321 respondents) to explore self-reports of suspected and confirmed cases of COVID-19. The health impact was assessed by calculating the COVID-19 years of life lost (YLLs) and the COVID-19 Disability-Adjusted Life Years. We also performed a national-level registry study of public official data, then by combining that information we created an underreporting index (UI) by region, age, and gender since official data are reported only according to those variables. We explored factors associated with underreporting and health impact through nonlinear multi regression analysis.

RESULTS: National level estimated percentage of underreporting varied between 60 to 90% of cases during the COVID-19 pandemic. The UI was higher among young females, people with disability, older adults living alone, older workers with no access to social security or limited ace to public health care, Afro-Caribbean ethnic groups, people living in rural areas, and belonging to low and very low socioeconomic strata. Also, the municipality with the highest national poverty index had the highest UI. Our data strongly suggest that the relative burdens of both the YLDs and DALYs were also higher among those groups with a higher UI.
CONCLUSION: The COVID-19 greatly impacts highly vulnerable population groups, however, this situation is not being reflected in the official figures. To make visible the true impact of the pandemic and establish effective measures to assist the most vulnerable groups, we need to start by making the situation of such groups visible to society.

KEYWORDS: COVID 19, underreporting, vulnerable groups, Nicaragua.

THEMATIC 16: Neurobehavioral changes in children/adults

P-1010 Prenatal metals exposure and pre-adolescents' emotional and behavioral problems

Manuel Lozano[1,2], Karin Broberg[3], Raquel Soler-Blasco[4], Mario Murcia[4], Gabriel Riutort-Mayol[4], Ferran Ballester[1,4,5], Ana Esplugues[1], Lara Manyes[1], Laura Escrivá[1], Juan Francisco Correcher[1], Juanjo Peiró[1], Maribel Casas[6,7], Mónica Guxens[6,7], Amaia Irizar[8,9], Nerea Lertxundi[8,9], Sabrina Llop[4,5]

[1]University of Valencia, Burjassot, Spain, [2]Epidemiology and Environmental Health Joint Research Unit, FISABIO–Universitat Jaume I–Universitat de València, Valencia, Spain, [3]Lund University, Lund, Sweden, [4]Foundation for the Promotion of Health and Biomedical Research of Valencia Region, Spain, [5]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Madrid, Spain, [6]Universitat Pompeu Fabra, Barcelona, Spain, [7]ISGlobal, Barcelona, Spain, [8]Biodonostia Health Research Institute, Donostia, Spain, [9]University of the Basque Country, Leioa, Spain

BACKGROUND AND AIM: Humans are regularly exposed to metals and most of them can cross the placental barrier which can lead to adverse effects on the developing foetus. Our aim was to study the association between maternal metals and trace elements exposure during gestation and preadolescent's emotional and behavioural problems at 9 years of age. Socio-demographic, environmental and dietary variables, as well as single nucleotide polymorphisms (SNPs) in brain- and metabolism-related genes, were considered.

METHODS: The study sample comprised Spanish mother-child pairs in the INMA (Environment and Childhood) cohort study recruited in the regions Valencia, Sabadell and Gipuzkoa (n=1027). Metals (Cd, Co, Cu, Mo, Ni, Pb, Sb, Se, Tl and Zn) were measured in urine samples collected during first and third trimesters of pregnancy. Arsenic (As) metabolites (monomethylarsenic acid, [MMA], dimethylarsenic acid, and inorganic As) were determined in a subsample (n=729). Behaviour was assessed at 9 years of age using the Child Behaviour Checklist (CBCL) composed of three scales: internalizing, externalizing and total problems. Sociodemographic, dietary and environmental variables were obtained through questionnaires. SNPs in APOE, BDNF, GSTP1, and PON1 were genotyped in cord blood DNA. Multivariate negative binomial models were built. The interaction with sex and genotypes was evaluated including interaction terms.

RESULTS: Increasing maternal urinary concentrations of Cu, MMA and Pb were associated with an increased incidence ratio risk (IRR 4.6-7.5%) in pre-adolescents for all three CBCL scales. Increasing Mo, Ni and Co concentrations were associated with higher IRR for internalizing problems (up to 8%), and Cd for the externalizing scale (6.7%). Modifications of sex and genotypes were found for several associations.

CONCLUSIONS: In our population, prenatal exposure to several metals was associated with worse scores on behavioral tests in pre-adolescents. Sex and genetic background may play a role in metals toxicity.

KEYWORDS: Metals, behavioral problems, prenatal exposure

P-1013 Intergenerational Transmission of Stress: Multi-domain Stressors from Maternal Childhood and Pregnancy Predict Children's Mental Health in a Racially and Socioeconomically Diverse, Multi-site Cohort

Nicole Bush[1,2], Amanda Norona-Zhou[2,3], Michael Coccia[3], Kristen Rudd[3], Shaikh Ahmad[2,3], Christine Loftus[4], Shanna Swan[5], Ruby Nguyen[6], Emily Barrett[7], Catherine Karr[4,8], Sheela Sathyanarayana[4,8,9], Kaja LeWinn[1]

[1]Department of Psychiatry and Behavioral Sciences, Weill Institute for Neurosciences, University of California, San Francisco (UCSF), San Francisco, USA, [2]Department of Pediatrics, UCSF, San Francisco, USA, [3]Center for Health and Community, UCSF, San Francisco, USA, [4]Department of Occupational and Environmental Health Sciences, University of Washington, Seattle, USA, [5]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [6]Department of Epidemiology and Community Health, University of Minnesota, Minneapolis, USA, [7]Department of Biostatistics and Epidemiology, Rutgers School of Public Health, New Brunswick, USA, [8]Department of Pediatrics, University of Washington, Seattle, USA, [9]Seattle Children's Research Institute, Seattle, USA

BACKGROUND AND AIM: Despite growing recognition that unfortunately common stress exposures during women's childhood and pregnancy may have intergenerational impacts, studies of children's mental health rarely take an intergenerational lifecourse approach. To identify modifiable risk factors, we examined associations of maternal exposure to adversity in childhood and pregnancy with children's mental health problems in a sociodemographically diverse, multi-site, sample.

METHODS: Participants were mother-child dyads in the ECHO-PATHWAYS consortium with harmonized data across three U.S. pregnancy cohorts drawn from 7 regions. Women reported on their own exposure to childhood traumatic events (CTE) and pregnancy stressful life events (PSLE), and their 4-6 year-old child's mental health problems using the Child Behavior Checklist (CBCL). Regression analyses estimated associations between maternal stressors and child Total Behavior Problems, adjusting for a wide range of confounders.

RESULTS: Among 1948 dyads (child age M=5.13 (SD=1.02) years; 38% Black, 44% White; 8.5% Hispanic), maternal history of CTE and PSLE were independently positively associated with children's Total Problems ([ßCTE=0.11, 95%CI [.06, .15]; ßSLE=0.22, 95%CI [.17, .27]) and also with greater odds of Clinical Levels of Problems (ORCTE=1.39; 95%CI [1.11, 1.76]; ORPSLE=1.37; 95%CI [1.24, 1.53]). Patterns of association were consistent across pooled analyses and within cohorts. Results held after adjustment for both confounders and variables on the mechanistic pathway (e.g., postnatal depression, birth outcomes).

CONCLUSIONS: Findings show consistent effects of maternal history of adversity during sensitive periods of her development on children's mental health, across region and cohort, within a large, socioeconomically and racially diverse sample, increasing confidence that mental health has intergenerational developmental underpinnings across populations. This is the first study to demonstrate independent contributions of maternal CTE and PSLE to children's mental health. Prevention and intervention programs that reduce childhood trauma and stress during pregnancy will likely positively impact women's and their children's health.

P-1015 Annoyance and sleep disturbance due to traffic noise: a comparison with WHO exposure-response functions

Karla Romero Starke[1], Melanie Schubert[1], Pauline Kaboth[1], Janice Hegewald[1], Matthias Reusche[2], Julia Gerlach[3], D. Friedemann[4], med. Steffi Riedel-Heller[5], med. Hajo Zeeb[6], med. Andreas Seidler[1]

[1]Institute and Policlinic for Occupational and Social Medicine (IPAS), Faculty of Medicine, Technische Universität Dresden, Dresden, Germany, [2]Institute for Medical Informatics, Statistics and Epidemiology, Faculty of Medicine, LIFE, Leipzig University, Leipzig, Germany, [3]Institute of Transport Planning and Road Traffic, Chair of Transport Ecology, Technical University Dresden, Germany, [4]cdf Schallschutz, Dresden, Germany, [5]Institute for Social Medicine, Occupational Medicine, and Public Health (ISAP), Faculty of Medicine, Leipzig Universit, Leipzig, Germany, [6]Leibniz-Institute for Research Prevention and Epidemiology - BIPS GmbH, Section Prevention and Evaluation, Bremen, Germany

BACKGROUND AND AIM: Traffic noise is omnipresent. Annoyance and sleep disturbance due to road, rail, and aircraft noise in Leipzig, Germany were investigated.

METHODS: Traffic noise-related annoyance and sleep disturbance were collected in the LIFE cohort study (2018-2021) and linked to address-specific traffic noise data (LDEN/LNight). Information on noise-related disturbances to falling asleep, sleeping at night, and staying asleep, as well as annoyance from each traffic noise source, were obtained using ISO/TS-15666 standards. Answers ranged from "not at all" to "extremely disturbed". "Highly" and "extremely disturbed" individuals were defined as "highly annoyed" and "highly sleep disturbed".
Logistic regressions were used for the association between high annoyance/sleep disturbance and traffic noise. The percentage of highly annoyed and sleep disturbed for all three traffic noise sources were modelled. Results were compared to WHO reviews for annoyance (Guski et al. 2017) and sleep disturbance (Basner & McGuire 2018).

RESULTS: The increase in risk (per 10 dB) was most pronounced for aircraft noise (annoyance (LDEN): ORair=12.65; 95% CI 9.37-17.10; sleep disturbance (LNight): ORair=19.66; 95%CI 11.47-33.71). Risk estimates for road and rail noise were increased for annoyance (ORroad=3.55; 95%CI 2.78-4.53; ORrail=3.31; 95%CI 2.77-3.97) and sleep disturbance (ORroad=2.86; 95%CI 1.92-4.28; ORrail=2.68; 95% CI 1.92-4.28).
Exposure-response curves for annoyance due to road and rail noise were lower than the corresponding curves in the WHO review, and were higher for aircraft noise. The curves for high sleep disturbance due to road noise were comparable, but the proportion of highly sleep-disturbed persons was lower for rail noise and higher for aircraft noise compared to the WHO review.

CONCLUSIONS: The higher proportion of highly annoyed and sleep disturbed at given aircraft noise levels compared with the WHO reviews may indicate changing noise effects over time. Our results underscore the need for improved noise control.

KEYWORDS: Annoyance, sleep disturbance, traffic noise

P-1021 Antenatal depression and environmental pollutants

Senhor. Patricia Pinheiro da Silva[1], Senhora Evelyn Guimarães[1], Senhora Rafaela Fernandes[1], Senhora Kato Kato[1], Senhora Marcelle Viana[1], Dra Nataly Figueiredo, Dra Carmen Asmus
[1]*Projeto Infância e Poluentes Ambientais - PIPA UFRJ, Rio de Janeiro, Brasil*

Mental health influences the experience of pregnancy. Antenatal Depression is a risk factor for mother-baby bond. Many factors can cause depression, including genetic, psychological and environmental factors.
The aim of this study is investigating associations between Perfluoroalkyl and Polyfluoroalkyl Substances (PFAS) and Metals exposure with depression in pregnancy.

METHODS: This study used data from Projeto Infância e Poluentes Ambientais (PIPA UFRJ) pilot study. That was accomplished at Federal University of Rio de Janeiro from 2017 to 2018. 131 pregnant women participated at this research. They answered questionnaires to collect sociodemographic, environmental pollutants exposure and mental health information. Maternal blood and urine sample were collected at third trimester of pregnancy to detect environmental pollutants.

RESULTS: The mean age of research participants was 27. All participants were in urban areas. The mean per capita income was R$ 891,80. All metals investigated by this study (4 metals) were detected in all participants. Perfluorooctane Sulfonate (PFOS) and Perfluorooctanoic Acid (PFOA) were detected in 73%. 6% of participants reported having depression. Higher mean PFOS exposure was detected in pregnant women with depression (With Depression= 1,1 ng/mL; CI 95% 0,74-1,56. No Depression= 0,79 ng/mL; CI 95% 0,76-0,84). The same was found in analysis of PFOA (WD= 0,82 ng/mL; CI 95% 0,55-1,48. ND= 0,59 ng/mL; CI 95% 0,55-0,63). Analyzing Metals exposure, higher mean Arsenic exposure was detected in participants with depression (WD= 10.3423 ng/mL; CI 95% 7,47-12,7). (ND= 9.805 ng/ mL; CI 95% 8,96-10,5).

CONCLUSIONS: These results suggest higher concentration in pregnant women with depression. However there is no statistical significance. The PIPA Project cohort is currently being developed. It will cooperate with greater statistical power in this discussion.

P-1229 Long-term exposure to ambient air pollution from multiple sources and associations with asthma incidence in children born in Denmark 1998-2016

Marie Pedersen[1], Shuo Liu[1], Zorana Jovanovic Andersen[1], Jørgen Brandt[2], Esben Budtz-Jørgensen[1], Klaus Bønnelykke[3], Lise Marie Frohn[2], Anne-Marie Nybo Andersen[1], Matthias Ketzel[2,4], Jibran Khan[2,5], Leslie Stayner[6], Bert Brunekreef[7], Steffen Loft[1]

[1]University of Copenhagen, Copenhagen K, Denmark, [2]Department of Environmental Science, Aarhus University, Roskilde, Denmark, [3]COPSAC, Copenhagen Prospective Studies on Asthma in Childhood, Herlev and Gentofte Hospital, University of Copenhagen, Gentofte Hospital, Copenhagen, Denmark, [4]Global Centre for Clean Air Research (GCARE), University of Surrey, Guildford, the UK, [5]Danish Big Data Centre for Environment and Health (BERTHA), Aarhus University, Roskilde, Denmark, [6]University of Illinois at Chicago, School of Public Health, the United States, [7]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, the Netherlands,

BACKGROUND AND AIM Asthma has been associated with ambient air pollution exposure, mainly in the urban environment. We examined the nationwide associations between early-life exposure and childhood asthma incidence.

METHODS: Asthma incidence was defined as the first record of a ICD-code for asthma collected from hospital admission, emergency room or outpatient contact among all liveborn singletons born in Denmark between 1998 and 2016. We linked registry data with monthly mean concentrations of particulate matter (PM2.5 and PM10), nitrogen dioxide (NO2), nitrogen oxides (NOX), elemental carbon (EC) and organic carbon (OC), sulphur dioxide (SO2), ozone (O3), sulphate (SO42-), nitrate (NO3-), ammonium (NH4+), secondary organic aerosols (SOA) and sea salt modelled at the home addresses. Associations were estimated with Cox proportional hazard models adjusted for potential confounders using fixed prenatal and time-varying postnatal exposure means.

RESULTS: Out of the 1,060,154 children included, 6.1% had asthma during the mean follow-up of 8.8 years. The risk of asthma increased with increasing prenatal exposure to all pollutants in adjusted models except for O3 and sea salt. Increased risks were also evident for postnatal exposure to most pollutants and for asthma after age 4. The hazard ratio associated with an interquartile range increase of 2.4 and 8.7 µg/m3 in prenatal exposure was 1.06 (95% CI 1.04-1.08) for PM2.5 and 1.04 (95% CI 1.02-1.05) for NO2. This association with PM2.5 was stable after adjustment for NO2, while it attenuated for NO2 to 1.01 (95% CI 0.99-1.03) after adjustment for PM2.5. OC, for which biomass burning is an important source, appeared to increase risk beyond its contribution to total PM2.5. for a 0.5-µg/m3 increase in the HR was 1.08 (95% CI 1.06-1.10) irrespective of adjustment for PM2.5.

CONCLUSIONS:The findings strengthen the evidence that early-life exposure to ambient air pollution from multiple sources contributes to asthma development.

P-1231 Maternal stressful life events during pregnancy and child asthma: an investigation of effect modification by postnatal neighborhood opportunity

Margaret Adgent[1], Erin Buth[2], Amanda Norona-Zhou[3], Adam Szpiro[2], Christine Loftus[2], Paul Moore[1], Rosalind Wright[4], Emily Barrett[5], Kaja LeWinn[3], Alex Mason[6], Ruby Nguyen[7], Sheela Sathyanarayana[2], Catherine Karr[2], Nicole Bush[3], Kecia Carroll[4]

[1]Vanderbilt University Medical Center, Nashville, USA, [2]University of Washington, Seattle, USA, [3]University of California San Francisco, San Francisco, USA, [4]Icahn School of Medicine at Mount Sinai, New York, USA, [5]Rutgers School of Public Health, Piscataway, USA, [6]University of Tennessee Health Sciences Center, Memphis, USA, [7]University of Minnesota, Minneapolis, USA

BACKGROUND AND AIM: Studies have linked prenatal maternal psychosocial stress and childhood wheeze/asthma, but have rarely investigated modifiable factors that may mitigate risks such as the postnatal environment. We investigated associations between prenatal stress and childhood wheeze/asthma, examining effect modification by postnatal neighborhood-level opportunity as a potential buffer of stress.

METHODS: Participants included 2056 mother-child dyads from ECHO PATHWAYS, a consortium of three prospective pregnancy cohorts (CANDLE, TIDES, GAPPS) from six U.S. cities. The number of maternal stressful life events (SLEs) experienced during pregnancy was reported retrospectively using the 14-item Pregnancy Risk Assessment Monitoring System SLE questionnaire (including traumatic, financial, emotional and relationship stressors). Parents reported child wheeze/asthma outcomes at age 4-6 (mean: 4.7 +/-0.7) years using a validated questionnaire: ever asthma, current wheeze (previous 12 months), current asthma (any two: ever asthma, current wheeze, or asthma-specific medication use), and strict asthma (ever asthma and either current wheeze or asthma-specific medications). We used modified Poisson regression to estimate risk ratios and 95% confidence intervals (95%CI), adjusting for confounders. We examined effect modification between SLEs and postnatal Child Opportunity Index (COI), a measure of neighborhood-level resources and conditions based on residence up to age 4, using interaction terms.

RESULTS: Median of maternally-reported SLEs was 1 event (interquartile range: 0-2). Per one-unit increase in SLE, adjusted risk ratios (95%CI) were 1.06 (0.99, 1.13) for ever asthma (prevalence: 11%); 1.09 (1.03, 1.14) for current wheeze (prevalence: 15%); 1.05 (0.98, 1.12) for current asthma (prevalence: 12%); and 1.05 (0.98, 1.13) for strict asthma (prevalence: 9%). We found no evidence of effect modification by COI (all p-interaction >0.20).

CONCLUSIONS: Childhood wheeze/asthma risk, particularly current wheeze, increases with increasing stress events experienced by women prenatally. In this study of women with few SLEs, these associations were not mitigated by postnatal neighborhood opportunity.

P-1238 PM2.5 and NO2 as Potential Modifiers of Clinical Trial Results on Asthma Exacerbation and Control

Lizbeth Gomez[1], Ellen J. Kinnee[2], Joel D. Kaufman[3], Dave T. Mauger[4], Fernando Holguin[5], Jane E. Clougherty[1]
[1]Drexel University Dornsife School of Public Health, Philadelphia, USA, [2]University of Pittsburgh Center for Social and Urban Research, Pittsburgh, USA, [3]University of Washington School of Public Health, Seattle, USA, [4]Department of Public Health Sciences, Penn State University, Hershey, USA, [5]University of Colorado School of Medicine, Denver, USA

BACKGROUND: Despite well-established associations between ambient air pollution and asthma exacerbations, few RCTs have considered variation in clinical outcomes or treatment efficacy by pollutant concentrations. Common clinical treatment for asthma includes inhaled corticosteroids (ICS) and long-acting beta-agonists (LABA), although treatment response is heterogeneous. Many patients are nonresponsive to this combination, despite treatment compliance. Here, we re-analyzed data from NIH AsthmaNet Best African American Response to Asthma Drugs (BARD) trial, to investigate the role of PM2.5 and NO2 in asthma exacerbation (AE) and annual asthma control days (AACD), across varying doses of ICS and LABA combination therapy.

METHODS: We reexamined data from 247 children sequentially randomized to: a double-ICS dose (2xICS), double-ICS with LABA (2xICS+1xLABA), quintuple-ICS (5xICS) and quintuple-ICS with LABA (5xICS+1xLAB A). Treatment preference was determined by AE and AACD during each treatment. We geocoded participants' residences, estimated treatment-period-specific PM2.5 and NO2 mean exposures, using validated national spatiotemporal models, and estimated associations for PM2.5 and NO2 with AACD and AE, using mixed models adjusted for treatment and trial site.

RESULTS: The original RCT findings showed that half the children responded better to increased ICS, and half responded better to the LABA addition, with no clear preference. We found that PM2.5 and NO2 exposures varied substantially across periods (2.28 - 15.3 µg/m3, 2.6 - 23.7 ppb, respectively), and that, among children, both PM2.5 and NO2 conferred more exacerbations [0.25 events (95% CI: 0.078 - 0.41), 0.15 events (95% CI: -0.03 - 0.33), respectively], though neither significantly altered treatment preference in these data.

CONCLUSIONS: We found that, among children, ambient PM2.5 and NO2 had a stronger association with asthma outcomes than did treatment, but neither significantly altered treatment preference or efficacy. Richer considerations of environmental context may help improve the design and interpretation of RCTs.

KEYWORDS: Asthma, PM2.5, NO2, ICS, RCT, LABA.

POSTER DISCUSSION SESSION 04: Aging and Environment | Non-communicable diseases including cancer, cardio-metabolic and neurological

THEMATIC 02: Aging and Environment

P-0044 The association between long-term PM2.5 exposure and late-life amyloid burden in the Atherosclerosis Risk in Communities (ARIC) study cohort

Erin Bennett[1], Xiaohui Xu[2], Katie Lynch[1], Eun Sug Park[3], Qi Ying[4], Richard Smith[5], James Stewart[5], Eric Whitsel[5,6], Thomas Mosley[7], Jeff Yanosky[8], Dean Wong[9], Duanping Liao[8], Rebecca Gottesman[10], Melinda Power[1]

[1]The George Washington University Milken Institute School of Public Health, Washington, USA, [2]Texas A&M School of Public Health, College Station, USA, [3]Texas A&M Transportation Institute, College Station, USA, [4]Texas A&M University, College Station, USA, [5]University of North Carolina Chapel Hill Gillings School of Global Public Health, Chapel Hill, USA, [6]University of North Carolina Chapel Hill School of Medicine, Chapel Hill, USA, [7]University of Mississippi Medical Center, Jackson, USA, [8]The Pennsylvania State University College of Medicine, Hershey, USA, [9]Washington University School of Medicine in St. Louis, St. Louis, USA, [10]National Institute of Neurological Disorders and Stroke, Bethesda, USA

BACKGROUND AND AIM: Mechanistic models suggest that particulate matter ≤ 2.5 um (PM2.5) may promote Alzheimer's disease, which is characterized by brain amyloid accumulation. This hypothesis has rarely been explored in epidemiologic studies, despite studies showing associations between long-term PM2.5 exposure and late-life cognitive impairment. We estimated the association between long-term PM2.5 exposure and late-life brain amyloid deposition in the Atherosclerosis Risk in Communities (ARIC) study cohort.

METHODS: We used a chemical transport model with data fusion to estimate PM2.5 concentrations (ug/m3) in 36-, 12-, 4-, and 1-km grid cells in ARIC study areas. We linked concentrations to geocoded participant addresses and calculated mean PM2.5 exposures from 2000 to 2007. We estimated amyloid deposition using florbetapir amyloid positron emission tomography (PET) scans in 346 participants with normal cognition or mild cognitive impairment in 2011-2014. We defined amyloid positivity as a global cortical standardized uptake value ratio (SUVR) ≥ the sample median of 1.2. We used logistic regression models to quantify the association between amyloid positivity and PM2.5 exposure after adjusting for potential confounders. We explored effect measure modification by APOE e4 allele status and tested whether effect estimates were consistent using alternate PM2.5 exposure methods.

RESULTS: Our analytic sample included 279 participants. at the time of amyloid-PET scans, their mean age was 78 years, 56% were female, 42% were Black, and 26% had mild cognitive impairment. After adjusting for age, sex, education, and race-study center, we found no significant association between brain amyloid positivity and long-term mean PM2.5 exposure. There was no evidence of effect measure modification by APOE e4 allele status. Results were consistent when we used alternate PM2.5 estimation methods.

CONCLUSIONS: PM2.5 may induce neurotoxic effects through non-amyloid, potentially vascular pathways, though we note the small sample size may have made us underpowered to detect a significant association.

P-0052 Newborn ribosomal DNA content as a potential early marker of genomic instability and longevity in association with prenatal air pollution exposure

Dries Martens[1], Paola Truzzu[1], Charlotte Van Der Stukken[1], Congrong Wang[1], Tim Nawrot[1]
[1]*Centre for Environmental Sciences, Hasselt University, Belgium, Diepenbeek, Belgium*

BACKGROUND AND AIM: Repetitive regions in the genome, including ribosomal DNA repeats, have essential functions in genome stability. Alterations in ribosomal DNA copy numbers (rDNAcn) associates with genome-wide methylation and gene-expression, and links with longevity, as proposed in the rDNA theory of aging. Prenatal air pollution exposures affect molecular markers of aging that may underly later life health effects. We studied the association between prenatal air pollution exposure and this novel potential aging marker (rDNAc) in newborns.

METHODS: Cord blood rDNAcn (45S rDNA) was measured in 177 newborns from the ENVIRONAGE birth cohort using ddPCR. Maternal residential exposure to PM10, PM2.5, NO2, and BC during pregnancy was estimated using a high-resolution spatial-temporal interpolation method. Using multivariable-adjusted distributed lag models, newborn rDNAcn was associated with average weekly air pollution exposures.

RESULTS: The mean cord blood rDNAcn was 245 (SD: 64). Higher prenatal exposure to PM10, PM2.5, and NO2 in early to mid-pregnancy (weeks 9-18) was associated with an increase in rDNAcn. Each SD increment in air pollutants was associated with an average increase of 22.5 (95%CI: 5.9 to 35.0) copy numbers. Higher exposure to PM10, PM2.5, NO2, and BC late in pregnancy (weeks 25-35) was strongly associated with a decrease in rDNAcn. Each SD increment in air pollutants was associated with an average decrease of –29.6 (95%CI: –49.9 to –9.4) copy numbers.

CONCLUSIONS: We studied for the first time rDNAcn in newborns and show that prenatal air pollution exposure is associated with rDNA repeats at birth. These results add evidence to the impact of air pollution on genome stability and early aging mechanisms. Evaluating the rDNA concept of aging in relation to diseases may further show the link between prenatal air, molecular alterations, and health later in life.

KEYWORDS: genome instability, aging, ribosomal DNA copy number, prenatal air pollution

P-0056 Ambient Air Pollution and Clinical Dementia: Systematic Review and Meta-analysis

Marc Weisskopf[1,2], Marwa Osman[1], Elissa Wilker[1,2]
[1]Harvard TH Chan School of Public Health, Dept of Environmental Health, Boston, USA, [2]Harvard TH Chan School of Public Health, Dept of Epidemiology, Boston, USA

BACKGROUND AND AIM: Air pollution exposure is a possible modifiable risk factor for dementia and epidemiologic evaluation of this relation has grown rapidly. We synthesize the existing literature, considering differences by study factors that could influence findings.

METHODS: Studies describing associations between EPA criteria air pollutants and proxies of traffic pollution were identified from Embase and PubMed through August 2021. Information on study characteristics and key findings were extracted for each study and results were meta-analyzed where at least three studies used comparable approaches. Differences in data source, study type, and variability in exposure reported were also explored.

RESULTS: Thirty-seven studies were identified and 11 could be meta-analyzed for PM2.5. Results were expressed per standard deviation or interquartile range. The overall HR for PM2.5 was 1.07 (95% CI: 1.04-1.10). The HR among 4 cohort studies was 1.20 (95% CI: 1.09-1.32) and among 6 studies using administrative data was 1.04 (95% CI: 1.00-1.07). Wider confidence intervals were observed for associations with NO2 (HR=1.04; 95% CI: 0.99-1.10; n=5 studies) and NOx (HR=1.08; 95% CI: 0.99-1.16; n=4 studies), and there was no clear association with O3 (HR=0.98; 95% CI: 0.93-1.04; n=3 studies).
CONCLUSION: The evidence suggests that PM2.5 is a risk factor for dementia. However, the meta-analyzed HRs are subject to limitations that require interpretation with great caution. Outcome ascertainment approaches differ across studies and each exposure assessment approach likely is only a proxy for etiologically relevant exposure as it relates to clinical dementia outcomes. Studies that evaluate critical periods of exposure, pollutants other than PM2.5, and that actively assess all participants for outcomes, are needed.

P-0068 Greater residential greenness is associated with reduced epigenetic aging in a population survey in North Carolina

Andrey Egorov[1], Shannon Griffin[2], Jennifer Styles[1], Jo Klein[1], Jason Kobylanski[1], Lindsay Wickersham[1], Edward Hudgens[1], Timothy Wade[1]

[1]U.S. Environmental Protection Agency, Chapel Hill, USA, [2]U.S. Environmental Protection Agency, Cincinnati, USA

BACKGROUND AND AIM. Epigenetic age acceleration (EAA) or the difference between DNA methylation-predicted age and chronological age is affected by environmental and social factors, and predictive of systemic diseases. This study assessed associations between residential greenness and EAA, and between EAA and systemic inflammation.

METHODS: This analysis applied three alternative EAA formulas proposed by Horvath (2013), Hannum et al. (2013), and Li et al. (2018) to Illumina EPIC DNA methylation data on 116 blood samples from adult participants of a cross-sectional survey in North Carolina. Inflammation score was based on a sum of 17 biomarkers including multiple cytokines, which were dichotomized at the 90th percentile of sample distribution. ELISA tests were applied to determine Helicobacter pylori, Toxoplasma gondii and cytomegalovirus IgG seropositivity, and calculate the number of chronic infections. Proportion of vegetated land cover (trees, shrubs, and grass) was calculated within 500 m of each residence using high resolution landcover data.

RESULTS: Li's epigenetic age formula [Li et al. 2018. Exposure to polycyclic aromatic hydrocarbons and accelerated DNA methylation aging; EHP 126] produced the strongest correlation between DNA methylation age and chronological age. Using this formula, an interquartile increase (23%) in vegetated land cover was associated with 2.3 (95% CI 1.2; 3.4) years reduction in predicted EAA in generalized additive regression analysis adjusting for obesity, sex, race, chronic infections, daily screen time and two-dimensional spline function of geographic coordinates. Individuals with three chronic infections had 10.3 (5.9; 14.7) years greater adjusted EAA than those with no infections. One extra year of EAA was predictive of 6.2% (2.5%; 10.2%) greater mean adjusted inflammation score in Poisson regression.
Conclusion. This study demonstrated that greater residential greenness is associated with reduced epigenetic aging.

THEMATIC 17: Non-communicable diseases including cancer, cardio-metabolic and neurological

P-1058 Long-term exposure to transportation noise and risk of type 2 diabetes: a cohort study

Mette Sørensen[1], Aslak Poulsen[1], Ulla Hvidtfeldt[1], Ole Raaschou-Nielsen[1]
[1]*Danish Cancer Society Research Center, Copenhagen O, Danmark*

BACKGROUND AND AIM: A few studies have reported associations between transportation noise and diabetes. This includes studies based on millions of participants, relying entirely on register-based confounder adjustment, which raises concern about residual confounding from lifestyle. We aimed to investigate associations between road and railway noise and risk of type 2 diabetes (T2D), including investigation of effects of increasing adjustment for register-based and lifestyle covariates.

METHODS: In a population-based cohort of 324,988 participants randomly selected across Denmark in 2010–2013 and followed up until December 2017, we identified 7,574 incident T2D cases using hospital and prescription registries. Based on historical address-information, we calculated 10-year time-weighted exposure to road noise at the most (LdenMax) and least (LdenMin) exposed façades and exposure to air pollution (PM2.5). We used Cox proportional hazards models to calculate hazard ratios (HR) with increasing adjustment for individual- and area-level register-based sociodemographic covariates (e.g. education and income) and lifestyle covariates assessed through questionnaires, including smoking, physical activity and alcohol.

RESULTS: We found that a 10 dB increase in road LdenMin was associated with HRs (95% CI) of 1.06 (1.02–1.10) in the crude model, 1.08 (1.04–1.13) after adjustment for register-based sociodemographic covariates and 1.07 (1.03–1.12) after further adjustment for lifestyle. for road LdenMax, the corresponding HRs were 1.07 (1.04–1.10), 1.05 (1.02–1.08) and 1.04 (1.01–1.07). After further adjustment for PM2.5, HRs were 1.06 (1.01–1.10) for LdenMin and 1.03 (1.00–1.07) for LdenMax. Railway noise was associated with HRs of 1.05 (0.98–1.11) for LdenMax and 1.04 (0.94–1.14) for LdenMin in fully adjusted models.

CONCLUSIONS: Long-term exposure to road and potentially railway noise was associated with T2D. Our results indicated that administrative cohort studies can produce reliable results if a broad register-based adjustment strategy is applied.

P-1060 Multidimensional sleep clusters and cardiometabolic risk factors in adolescents: Results from the GINIplus and LISA studies

Mingming Wang[1,2], Claudia Flexeder[1,3], Carla Harris[1,4], Elisabeth Thiering[1,4], Sibylle Koletzko[4,5], Carl-Peter Bauer[6], Andrea von Berg[7], Dietrich Berdel[7], Tamara Schikowski[8], Holger Schulz[1], Annette Peters[1,9], Marie Standl[1]
[1]Institute of Epidemiology, Helmholtz Zentrum München - German Research Center for Environmental Health, Neuherberg, Munich, Germany, [2]Institute for Medical Information Processing, Biometry and Epidemiology, Pettenkofer School of Public Health, LMU Munich, Munich, Germany, [3]Institute and Clinic for Occupational, Social and Environmental Medicine, University Hospital, LMU Munich, Munich, Germany, [4]Department of Pediatrics, von Hauner Children's Hospital, University Hospital, LMU Munich, Munich, Germany, [5]Department of Pediatrics, Gastroenterology and Nutrition, School of Medicine Collegium Medicum, University of Warmia and Mazury, Olsztyn, Poland, [6]Department of Pediatrics, Technical University of Munich, Munich, Germany, [7]Research Institute, Department of Pediatrics, Marien-Hospital Wesel, Wesel, Germany, [8]IUF-Leibniz Research Institute for Environmental Medicine, Düsseldorf, Germany, [9]Chair of Epidemiology, Ludwig Maximilians University of Munich, Munich, Germany

BACKGROUND AND AIM: Evidence of an association between sleep duration and body mass index is vast, but other sleep characteristics might also be relevant for cardiometabolic health. We aimed to identify sleep clusters based on multidimensional sleep characteristics, and to determine their associations with cardiometabolic risk markers in adolescents.

METHODS: A total of 1096 participants of the GINIplus and LISA birth cohorts, wearing accelerometers for one week during the 15-year follow-up, were included. K-means cluster analysis was performed based on twelve sleep characteristics including daily average and day-to-day variability, respectively, of total sleep time (TST), sleep efficiency, sleep-onset latency, sleep onset timing, time awake per hour after sleep onset, number of awakenings per hour. Cardiometabolic markers were dichotomized based on established cut-offs or sex-specific percentiles, including high fat mass index, prehypertension, high triglycerides, low high-density lipoprotein cholesterol, high C-reactive protein, and high homeostatic model assessment of insulin resistance (HOMA-IR). Cross-sectional, logistic regression models were run adjusting for potential confounders.

RESULTS: Five sleep clusters were identified: good sleep (n=391; average TST 7.7 hours), late but high-efficient sleep (n=224; 6.9 hours), irregular sleep (n=101; 6.9 hours), difficulty staying asleep (n=298; 6.8 hours), and difficulty falling asleep (n=82; 6.9 hours). Compared with "good sleep", the "irregular sleep" cluster was associated with higher odds of high triglycerides (odds ratio (OR) = 2.43, 95% confidence interval (CI) =1.29-4.60). Moreover, the "difficulty falling asleep" cluster was associated with increased odds of high HOMA-IR (OR=3.09, 95%CI=1.25-7.65). The "late but high-efficient sleep" and "difficulty staying asleep" clusters were not significantly associated with cardiometabolic markers.

CONCLUSIONS: Clusters describing "difficulty falling asleep" and "irregular sleep" patterns were associated with high insulin resistance and high triglycerides, respectively, in adolescents. Improving sleep quality and quantity in different sleep dimensions might benefit adolescents' cardiometabolic health.

KEYWORDS: Sleep, cardiometabolic markers, adolescents, cluster analysis, accelerometry

P-1061 Earthquake exposure and development of ischemic heart disease

Changwoo Han[1]
[1]*Chungnam National University, Daejeon, Republic of Korea*

BACKGROUND AND AIM: The Kyungju earthquake of Korea (moment magnitude of 5.8) occurred on 12 September 2016 and over 600 aftershocks continued for a year. The association between the series of earthquake experience and the development of ischemic heart disease is evaluated.

METHODS: The 10 years (2010-2019) of medical history of 540,858 residents living in Kyungju and control cities (Pohang, Gimpo, and Jeonju) was gathered from the national health insurance database. The difference-in-difference analysis adjusting for time trend and age structure was used to evaluate the risk of ischemic heart disease development before (reference: 2014.09-2015.08; period 1: 2015.09-2016.08) and after the earthquake (period 2: 2016.09-2017.08; period 3: 2017.09-2018.08; period 4: 2018.09-2019.08). The difference-in-difference estimate comparing Kyungju and each control city was meta-analyzed using a fixed effect model. Stratification analysis by sex, age (25-44, 45-64, and 65-), and income groups were conducted.

RESULTS: The monthly average incidences of ischemic heart disease were 39.5 (reference) and 38.4 (period 1) persons before the earthquake but increased to 58.5 (period 2) and 49.8 (period 3) persons after the earthquake. There was an increase in the risk of ischemic heart disease development after the earthquake when compared to control cities and period before the earthquake [relative risk (95% confidence intervals): period 1, 0.97 (0.88, 1.06); period 2, 1.58 (1.43, 1.73); period 3, 1.33 (1.21, 1.46); period 4, 1.15 (1.04, 1.27)]. The risk increase was greater in women, young adults (age 25-44), and low-income groups.

CONCLUSIONS: The 2016 Kyungju earthquake was associated with an increased risk of ischemic heart disease development in local residents. It is necessary to manage the long-term cardiovascular health of people who experienced a series of earthquakes.

KEYWORDS: ischemic heart disease; earthquake; difference-in-difference; seismic activity

P-1064 Association between Food Insecurity and Cardiometabolic Outcomes in the U.S. Adult Population

Sericea Stallings-Smith[1]
[1]*University of North Florida, Jacksonville, USA*

BACKGROUND AND AIM: To make progress toward the Sustainable Development Goals in the United States (U.S.), it is imperative to provide evidence to policymakers of the importance of achieving food security. The aim of this study was to examine the association between food insecurity and cardiometabolic outcomes among a representative sample of U.S. adults ages ≥20 years.

METHODS: Data were obtained from seven cycles of the National Health and Nutrition Examination Survey (NHANES), which spanned 14 years from 2005-2018. Multivariable logistic regression was utilized to investigate the association between food insecurity and laboratory-confirmed diabetes as well as self-reported measures of physician-diagnosed angina, heart attack, and stroke. Statistical models were adjusted for age, sex, and race. Stratified analyses were conducted by education level and body mass index. Survey weightings were applied to account for the complex design of NHANES.

RESULTS: The study population included 38,935 interview participants of whom 52% were female and 67% were Non-Hispanic White. Most interview participants (95%) underwent body measures analysis in a mobile examination center and 70% of those participants were classified as overweight or obese. When compared to participants with full and marginal food security, participants with low/very food security were 1.80 (95% CI: 1.62-2.02) times more likely to have laboratory-confirmed diabetes and were more likely to report a history of physician-diagnosed cardiometabolic outcomes including angina (adjusted OR [aOR]=2.48; 95% CI=1.92-3.20), heart attack (aOR=2.50; 95% CI=2.04-3.07), and stroke (aOR=2.71; 95% CI=2.22-3.31). Each of these associations was robust across all educational levels and significant among participants classified as normal weight, overweight, or obese.

CONCLUSIONS: Food insecurity is associated with multiple cardiometabolic health outcomes. Structural and environmental changes are needed to increase food security among the general U.S. adult population. Targeted clinical interventions should be implemented early for those who are food insecure.

KEYWORDS: Food insecurity; Cardiometabolic

P-1068 Association of multiple environmental risk factors with prevalent diabetes mellitus and obesity - Results from the population-based KORA FIT cohort in Augsburg, Germany

Fiona Niedermayer[1,2], Kathrin Wolf[1], Siqi Zhang[1], Marco Dallavalle[1,2], Alexandra Schneider[1], Annette Peters[1,2]
[1]Institute of Epidemiology, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany, [2]Institute for Medical Information Processing, Biometry and Epidemiology, Department of Epidemiology, Ludwig-Maximilians-Universität München, Munich, Germany

BACKGROUND AND AIM
Although a number of studies suggest an association of surrounding greenness, air pollution and temperature with metabolic diseases, potential joint effects of these environmental factors were not adequately taken into account. In this study, we aim to investigate the associations and interplay of multiple environmental exposures with diabetes mellitus and obesity using single- and multi-exposure models.

METHODS: We analyzed data of 3,034 participants from the German population-based KORA Fit survey (2018-2019). Residential exposures included annual mean air temperature, air pollutants (nitrogen dioxide (NO_2), particulate matter with diameters ≤10 µm (PM_{10}), ≤2.5 µm ($PM_{2.5}$), and between 2.5 and 10 µm (PMcoarse), absorbance of $PM_{2.5}$ ($PM_{2.5}$abs), particle number concentration (PNC), ozone (O_3)) and surrounding greenness represented by normalized difference vegetation index within a 1000m buffer ($NDVI_{1000}$). We performed linear and logistic regression models with multiple covariate-adjustment to assess associations of long-term environmental exposures with prevalent diabetes and obesity (defined as Body-Mass-Index (BMI) ≥30 kg/m²).

RESULTS: In KORA Fit, 244 (8%) participants reported a diabetes mellitus diagnosis and 909 (30%) were obese. After adjusting for age, sex, lifestyle factors and individual socioeconomic status, an interquartile range increase of annual mean air temperature was associated with diabetes (Odds Ratio (OR): 1.20, 95% confidence interval (CI): 1.00, 1.44). Associations with air pollutants were suggestive (e.g. $PM_{2.5}$: OR: 1.20; 95% CI: 0.99, 1.46) and there was no association with greenness. Moreover, there was no association of environmental factors with obesity or any continuous obesity measure, except for $NDVI_{1000}$ and BMI (ß: 0.25 kg/m2, 95% CI: 0.04, 0.54 kg/m²).

CONCLUSIONS: These preliminary findings indicate that mean air temperature and air pollution were associated with prevalent diabetes in middle to older-aged adults in single-pollutant models. The analysis gave no indication that these associations were mediated by BMI.

BACKGROUND AND AIM. The possibility that wireless (mobile and cordless) phone use might increase brain tumour (BT) risk, has long been a concern, particularly in young people. We studied the association between

wireless phone use and subsquently radiofrequency (RF) and extremely low frequency (ELF) electromagnetic fields (EMF) exposure) in childhood/adolescence with BT risk.

METHODS: MOBI-Kids, a 14-country case-control study, recruited 899 BT cases and 1910 hospital controls aged 10-24 years. Each participant answered a questionnaire on history of mobile communication devices use. Analyses were conducted both in relation to the history of use of wireless phones and to estimated RF and ELF dose from use of wireless phones (based on algorithms developed in the project), adjusting for parental education. Numerous substudies and sensitivity analyses were conducted to address potential biases.

RESULTS: Mean ages of cases and controls were 16.5 and 16.6 years, respectively. The vast majority of participants were wireless phones users, with substantial numbers of long-term (>10 years) users. Most tumours were neuroepithelial (NBT; n=671). The adjusted odds ratios (OR) of NBT appeared to decrease with increasing time since start of use of wireless phones, cumulative number of calls and cumulative call time, particularly in the 15-19 years old age group. A decreasing trend in ORs was also observed with increasing estimated cumulative RF specific energy and ELF induced current density. These decreasing trends are attributable mainly to differential recall by proxies and prodromal symptoms affecting phone use before case diagnosis. Results remain unchanged despite the large number of sensitivity analyses we conducted.

CONCLUSIONS: Our study provides no evidence of a causal association between wireless phone use and brain tumours in young people. However, possible residual biases prevent us from ruling out a small increased risk.
KEYWORKS: brain tumours, young people, wireless phones

P-1082 Historical redlining and modern-day cardiovascular disease across New York City

Pablo Knobel[1], MA Ellen Kinnee[2], Jamie L. Humphrey[3], Jane E. Clougherty[4]
[1]Icahn School of Medicine at Mount Sinai, New York, US, [2]University of Pittsburgh, Pittsburgh, US, [3]RTI International, US, [4]Drexel University, Philadelphia, US

BACKGROUND AND AIM: In 1938, the Home Owners' Loan Corporation (HOLC), a federal program, graded neighborhoods in U.S. cities from A ("best") to D ("hazardous"), based on racial, ethnic, and immigrant composition. This policy, known as "redlining," limited access to mortgage financing, an essential tool for wealth generation. Redlining has been associated with long-term negative impacts including air pollution and violence, and lower greenness and life expectancy. Here, we analyzed associations between redlining and modern-day cardiovascular disease (CVD) events across New York City neighborhoods. We hypothesized that place-based associations (context) would persist, even after adjustment for sociodemographic composition.

METHODS: We used negative binomial models to examine incidence rates for acute CVD events, across 1727 census tracts, using complete emergency department and hospitals data for 2005-2011 (n=843,958) from NYS Department of Health Statewide Planning and Research Cooperative System. CVD event rates were predicted as a function of HOLC grade, which we assigned to 2010 census blocks using shapefiles from the Mapping Inequality Project. We fit incremental models, sequentially adjusted for modern-day confounders and potential mediators, including American Communities Survey (ACS) 2007-11 sociodemographic data, tract-level annual average violent crime (derived from NYPD point-level data on all reported offenses 2009-2012), and both tree canopy and overall greenness for 2010, from NYC OpenData.

RESULTS: Worse redlining grade was consistently associated with higher CVD incidence rate ratios (IRR), even after adjusting for sociodemographics and other mediators. Fully-adjusted model IRRs (compared to A-grade) were: B-grade: IRR = 1.11 (95% CI: 0.98 - 1.24), C-grade: IRR = 1.16 (95% CI: 1.02 - 1.29), and D-grade IRR = 1.23 (95% CI: 1.08 - 1.37).

CONCLUSIONS: Historical redlining continues to impact specific neighborhoods, with stronger effects on CVD than would be predicted by sociodemographics alone. The precise mechanisms through which redlining influences modern neighborhood health need be further explored.

P-1084 Association between Air Pollution and Prostate Cancer in the US-based Health Professionals Follow-Up Study

Ilkania Chowdhury-Paulino[1], Rachel Nethery[2], Melissa Fiffer[3], Francine Laden[1,3,4], Lorelei Mucci[1], Jaime Hart[3,4]
[1]Department of Epidemiology, Harvard TH Chan School of Public Health, Boston, USA, [2]Department of Biostatistics, Harvard TH Chan School of Public Health, Boston, USA, [3]Department of Environmental Health, Harvard TH Chan School of Public Health, Boston, USA, [4]Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA

BACKGROUND AND AIM: Prostate cancer, the most diagnosed cancer and the second leading cause of cancer death in U.S. men, is a hormonally driven malignancy. Air pollution could impact prostate carcinogenesis via its role in endocrine disruption and inflammation. There is limited epidemiologic research on the association between air pollution and prostate cancer. We prospectively evaluated whether PM2.5 and NO2 exposure increases prostate cancer risk, particularly more aggressive forms of the disease.

METHODS: We followed 48,879 participants in the Health Professionals Follow-up Study from 1990 through 2016 through biennial questionnaires. We used spatiotemporal models to estimate PM2.5 and NO2 at all mailing addresses. Fatal prostate cancer is defined as death from prostate cancer and total as diagnosis of prostate cancer. Multivariable Cox models were used to estimate hazard ratios and 95% confidence intervals in single and multipollutant models, adjusting for prostate cancer risk factors, neighborhood SES (nSES), and population density.

RESULTS: Over 26 years of follow-up, we identified 5,418 total and 779 fatal prostate cancer cases. We found no association with PM2.5 in single or multipollutant models for either outcome. Each interquartile (9.62 ppb) increase in cumulative NO2 was associated with fatal prostate cancer, in single (HR: 1.06, 95% CI: 0.96, 1.17) and more strongly in multipollutant models (HR: 1.12, 95% CI: 1.01, 1.26). There was no association between NO2 and total prostate cancer in single (HR: 1.01, 95% CI: 0.97, 1.04) or multipollutant models (HR: 1.02, 95% CI: 0.98, 1.07).
CONCLUSION
Exposure to higher levels of NO2 is associated with increased risk of fatal prostate cancer. Future analyses will explore how this association varies by nSES, population density, and region.

P-1087 Long-term effects of air pollutant exposures on site-specific cancer incidence in elders

Yaguang Wei[1], Mahdieh Yazdi[1], Edgar Castro[1], Su Liu[1], Liuhua Shi[2], Joel Schwartz[1]
[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Emory University, Atlanta, USA

BACKGROUND AND AIM: As the second leading cause of death in the US, cancer has received much less attention in air pollution epidemiology. Currently, only lung cancer is well-studied. Evidence on other types of cancer is extremely limited. We aim to examine causal effects of long-term exposures to fine particulate matter (PM2.5), ozone, and nitrogen dioxide (NO2) on the incidence of common and understudied cancers in elders.

METHODS: We constructed an open cohort of all individuals aged ≥ 65 years with continuous enrollment in fee-for-service Medicare in the contiguous US during 2000–2016, with 146 million person-years of follow-up. We linked ambient pollutant predictions developed from high-resolution, well-validated models to each individual's residential ZIP Codes as proxy exposure measures. We used inverse probability weighting to adjust for confounders, with gradient boosting machine to account for nonlinearity and interactions and kernel density to relax the contentious assumption of the distribution of generalized propensity score. for each pollutant, we estimated independent effects of the moving average exposures over lag 0-2 year (current year and previous two years), lag 3-5 year, and lag 6-10 year on the hazard ratio (HR) for the incidence of breast, colorectal, endometrial, and prostate cancers.

RESULTS: The critical exposure window differed by pollutant and cancer site. Specifically, long-term PM2.5 exposure increased colorectal cancer incidence, with lag 0-2 exposure associated with the highest HR (1.040, 95% CI: 1.039, 1.042); long-term ozone exposure increased prostate cancer incidence, with lag 0-2 exposure associated with the highest HR (1.005, 95% CI: 1.004, 1.005); long-term NO2 exposure increased incidence of all cancer types, with the most susceptible window being mixed.

CONCLUSIONS: Long-term PM2.5, ozone, and NO2 exposures may initiate breast, colorectal, endometrial, and prostate cancer in a window of up to 10 years before diagnosis.

KEYWORDS: air pollution, common cancer incidence, causal modeling

P-1096 Metal exposures and risk of Parkinson's disease: a European prospective cohort (NeuroEPIC4PD)

Yujia Zhao[1], Anushree Ray[2], Karin Broberg[3], Paolo Vineis[4], Roel Vermeulen[1,4,5], Susan Peters[1], EPIC consortium
[1]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, [2]Graduate School of Life Sciences, Utrecht University, Utrecht, Netherlands, [3]Institute of Environmental Medicine, Karolinska Institute, Solna, Sweden, [4]School of Public Health, Imperial College London, London, UK, [5]Julius Center for Health Sciences and Primary Care, University Medical Centre Utrecht, Utrecht, Netherlands

BACKGROUND AND AIM: Metals are environmental concerns in the etiology of Parkinson's disease (PD). Existing studies might be subject to reverse causality due to retrospective assessment of metal exposure. We aimed to investigate the association between metal levels in prospectively collected blood samples and risk of PD.

METHODS: A nested case-control study was conducted within NeuroEPIC4PD, part of the prospective European EPIC population-based cohort. 362 incident PD cases were ascertained through clinical records confirmed by neurologists. One control per case was selected, matched by age at recruitment, sex and study center. Concentrations of metals (arsenic, cadmium, calcium, copper, iron, lead, magnesium, manganese, mercury, selenium, zinc) in erythrocytes, collected at recruitment, were measured by inductively coupled plasma-mass spectrometry. Odds ratios (ORs) were estimated for quartiles (Qs) of metal levels and PD risk by logistic regression.

RESULTS: Cadmium was suggested to be associated with a decreased risk of PD (OR (95% confidence interval (CI): Q2 0.59 (0.38-0.90), Q3 0.75 (0.48-1.15), Q4 0.70 (0.42-1.17), compared to Q1), which remained after excluding current smokers. for current smokers, we found a strong inverse association between lead levels and PD risk: Q2 OR=0.08 (0.01-0.45), Q3 OR=0.06 (0.01-0.35), and Q4 OR=0.06 (0.01-0.35), with p-value=0.007 for linear trend. Zinc showed an increased risk of PD, which became most pronounced among females (Q2 OR=1.56 (0.80-3.04), Q3 OR=2.32 (1.16-4.63), Q4 OR=1.52 (0.68-3.38)). for other metals, we did not observe any indication of associations with PD risk.

CONCLUSIONS: This is the largest study assessing blood metal levels prior to disease onset. Cadmium, lead and zinc might play a role in PD development. The effects of cadmium and lead are possibly confounded by smoking.

KEYWORDS: Parkinson's disease, metals, prospective exposure assessment, cohort study

P-1104 Residential exposure to airborne polychlorinated biphenyls and risk of cardiovascular diseases: A register-based cohort study

Laura Deen[1], Alice Clark[2], Karin Sørig Hougaard[3,4], Harald William Meyer[1], Marie Frederiksen[4], Ellen Bøtker Pedersen[1], Kajsa Kirstine Ugelvig Petersen[1], Esben Meulengracht Flachs[1], Jens Peter Bonde[1,3], Sandra Søgaard Tøttenborg[1,3]

[1]Department of Occupational and Environmental Medicine, Bispebjerg and Frederiksberg Hospital, Copenhagen University Hospital, Copenhagen, Denmark, [2]Department of epidemiology, Novo Nordisk, Copenhagen, Denmark, [3]Department of Public Health, The Faculty of Health Sciences, University of Copenhagen, Copenhagen, Denmark, [4]National Research Centre for the Working Environment, Copenhagen, Denmark

BACKGROUND AND AIM Polychlorinated biphenyls (PCBs) are biopersistent chemicals ubiquitously present in our environment. Although exposure to lower-chlorinated PCBs (LC-PCBs) evaporating from building materials to indoor air is relatively common, the long-term cardiovascular effects remain unknown. We aimed to examine the risk of cardiovascular disease (CVD) following residential exposure to PCBs in indoor air.

METHODS: The study builds on the register-based Health Effects of PCBs in Indoor Air (HESPAIR) cohort of 51,921 residents of two residential areas near Copenhagen: Farum Midtpunkt and Brøndby Strand Parkerne. Here, indoor air was contaminated with PCB in one third of the apartments. Indoor air measurements in subsets of apartments have documented large differences in PCB-concentrations between contaminated and uncontaminated apartments, dominated by LC-PCBs. Individual PCB-exposure was based on relocation dates from nation-wide registers and indoor air PCB-measurements and calculated as PCByear. CVD Information was retrieved from the Danish National Patient Register for the follow-up period 1977–2018. We estimated hazard ratios using Cox regression analyses with time-varying exposure adjusting for a priori identified potential confounders.

RESULTS: Residential exposure to airborne PCB was not associated with a higher overall risk for CVD (HR for highly exposed: 1.02, 95% CI 0.95-1.11). The same was the case for most of the specific cardiovascular diseases apart from acute myocardial infarction where a 17% higher risk was observed for residents exposed to ≥3300 ng/m3*year compared to the reference group (HR 1.17, 95% CI 1.01-1.36).

CONCLUSIONS:In this first study to examine CVD risk following residential exposure to PCBs in indoor air, we observed only limited support for cardiovascular effects of living in PCB-contaminated air. Considering the prevalence of exposure to airborne PCBs and lack of knowledge on their potential health effects, these findings need to be corroborated in future studies.

KEYWORDS: lower-chlorinated PCBs; cardiovascular toxicity; environmental epidemiology; environmental pollutants

POSTER DISCUSSION SESSION 05:
Air pollution (ambient & indoor) and Sources

THEMATIC 03: Air pollution (ambient & indoor) and Sources

P-0098 Combined Deep Learning and Land Use Regression Models for Ultrafine Particles and Black Carbon in Montreal and Toronto, Canada

Marshall Lloyd[1], Junshi Xu[2], Arman Ganji[2], Alessya Ventura[1], Leora Simon[1], Mingqian Zhang[2], Shoma Yamanouchi[2], An Wang[2], Alexandra Schmidt[1], Kris Y. Hong[6], Hong Chen[3], Paul Villeneuve[4], Joshua Apte[5], Eric Lavigne[8], Rick Burnett[6], Michael Tjepkema[7], Marianne Hatzopoulou[2], Scott Weichenthal[1]

[1]McGill University, Montreal, Canada, [2]University of Toronto, Toronto, Canada, [3]Health Canada, Ottawa, Canada, [4]Carleton University, Ottawa, Canada, [5]University of California Berkeley, Berkeley, USA, [6]Consultant, [7]Statistics Canada, Ottawa, Canada, [8]University of Ottawa, Ottawa, Canada

BACKGROUND: Ambient ultrafine particles (UFP; <100nm) and black carbon (BC) have been associated with adverse health outcomes including cardiovascular disease and brain tumour incidence. Estimating population exposures for these pollutants is a challenge since both exhibit high within-city spatial variability. In this study, our aim was to develop new models for annual average outdoor UFP particle number concentrations (PNC), UFP size, and BC concentrations in Montreal and Toronto, Canada using several approaches.

METHODS: We conducted large-scale mobile monitoring campaigns across both cities throughout 2020-2021 including all days of the week, most times of day, and all four seasons. Land use regression (LUR) models were developed using geographic information systems and Convolutional Neural Network (CNN) models were developed using Google Maps satellite and street view images. Final models were developed by combining predictions from LUR and CNN models. Historical land use/traffic data were used to project estimates back in time.

RESULTS: Our monitoring campaign included 700 hours of monitoring along 2,700 kilometers of roadways. Median observed UFP PNC and BC concentrations were 15,191 particles/cm3 (IQR = 13,614) and 1104 µg/m3 (IQR = 1015) respectively. Final models explained the majority of spatial variations in UFP PNC, UFP size, and BC across both cities. Model performance in independent test sets was: Montreal UFP PNC R2 = 0.64, Toronto UFP PNC R2 = 0.73, Montreal UFP size R2 = 0.52, Toronto UFP size R2 = 0.60, Montreal BC concentration R2 = 0.67, and Toronto BC concentration R2 = 0.70.

CONCLUSIONS: New models are available for ambient UFP PNC, UFP size, and BC concentrations in Montreal and Toronto, Canada. These models explain the majority of spatial variations in these pollutants and will be applied in new epidemiological studies examining associations between ambient UFPs and BC and nonaccidental and cause-specific mortality in Canada's two largest cities.
Research described in this article was conducted under contract to the Health Effects Institute (HEI), an organization jointly funded by the United States Environmental Protection Agency (EPA) (Assistance Award No. CR-83998101) and certain motor vehicle and engine manufacturers. The contents of this article do not necessarily reflect the views of HEI, or its sponsors, nor do they necessarily reflect the views and policies of the EPA or motor vehicle and engine manufacturers.

P-0100 Expression of aflatoxin genes in fungal isolates from vehicle air filters

Małgorzata Gołofit-Szymczak[1], Angelina Wójcik-Fatla[2], Rafał Górny[1], Agata Stobnicka-Kupiec[1]
[1]Central Institute for Labour Protection - National Research Institute, Warsaw, Poland, [2]Institute of Rural Health, Lublin, Poland

BACKGROUND AND AIM: In car air conditioning systems (filters, hoses and fittings), there are favorable conditions for the growth of fungi with infectious and toxic properties. The present study was conducted to detect aflD, aflO, aflS and aflR as four important genes contributing to aflatoxin B1 production cycle in Aspergillus species isolated from the automotive filter nonwovens.

METHODS: Sampling of used filter from the truck cab air conditioning system were carried out in “winter” and “summer” measurement seasons. The presence of gene fragments responsible for the production of selected aflatoxins in the obtained isolates from fungal cultures was confirmed using the polymerase chain reaction (PCR). The reaction utilized the pairs of primers complementary to fragments of structural (aflD and aflO) and regulatory (aflS and aflR) genes involved in the biosynthesis of aflatoxin B1. Detection of the amplification products was performed on 1.5% agarose gels.

RESULTS: The PCR amplification of selected genes for the detection of aflatoxigenic Aspergillus species showed the presence of specific PCR products of aflS, aflD and aflO genes in 6 out of 20 filter samples (30%). The regulatory gene aflR was not detected in any of the tested filter samples. Statistical analysis showed that the type of air-conditioning system and the measurement season had no effect on the amplification of the genes in the tested filter samples.

CONCLUSIONS: The molecular detection of aflatoxin biosynthesis genes (i.e. aflS, aflD, aflR and aflO) could be considered as a quick method for the detection of aflatoxigenic Aspergillus. The presence of these genes in the studied material indicates the presence of toxic fungi in the automobile AC system.

KEYWORDS: Aflatoxin, Aspergillus, PCR, automobile AC system, filters

P-0112 Effects of vitamin D on association between air pollution and mental health in Korean adults: Results from the Korea National Health and Nutrition Examination Survey (KNHANES)

Hyoseon Kim[1], Juyeon Hwang[2], Hyejin Lee[2], Seyoung Kim[1], Byungmi Kim[1,3], Ph.D Hyun-Jin Kim[2,3]
[1]Division of Cancer Prevention, National Cancer Control Institute, National Cancer Center, Goyang-si, Republic of Korea, [2]Cancer Big Data Center, National Cancer Control Institute, National Cancer Center, Goyang-si, Republic of Korea, [3]Department of Cancer Control and Population Health, Graduate School of Cancer Science and Policy, National Cancer Center, Goyang-si, Republic of Korea

BACKGROUND AND AIM: Evidence suggests that low individual vitamin D levels enhance adverse effects associated with air pollution on mental health conditions. However, these associations remain unclear. The aim of this study was to identify associations between ambient air pollution exposure, mental health, and serum vitamin D status in the general population of South Korea.

METHODS: We included national representative data for 29,373 adults in the final analysis. We measured serum 25-hydroxyvitamin D concentrations to assess vitamin D status for each participant. We assessed mental health factors (e.g., perceived stress, depressive symptoms, and suicidal ideation), and analyzed associations between these factors and individuals' annual average exposures to air pollutants, including particulate matter with an aerodynamic diameter ≤10 μm (PM10), nitrogen dioxide, sulfur dioxide, and carbon monoxide.

RESULTS: Using an adjusted model, we found PM10 affected major mental health outcomes, such as perceived stress (odds ratio [OR]=1.04; 95% confidence interval [CI]=1.00–1.09), depression symptoms (OR=1.12; 95% CI=1.06–1.18), and suicidal ideation (OR=1.11; 95% CI=1.05–1.17). Effects of the pollutants NO2 and CO were significant only in the group with perceived stress and depressive symptoms. PM10 and NO2 exposures were significantly associated with increased odds of adverse mental health outcomes in participants with vitamin D deficiency.

CONCLUSIONS: The study results suggested that high levels of vitamin D attenuated associations between air pollution and adverse mental health outcomes in adults, including perceived stress, suicidal ideation, and depression symptoms.

KEYWORDS: air pollution; vitamin D status; perceived stress, depressive symptoms, suicidal ideation

P-0120 Europe-wide air pollution modelling from 2000 to 2019 using geographically weighted regression

Youchen Shen[1], Kees de Hoogh[2,3], Oliver Schmitz[4], Nick Clinton[5], Karin Tuxen-Bettman[5], Jørgen Brandt[6], Jesper H. Christensen[6], Lise M. Frohn[6], Camilla Geels[6], Derek Karssenberg[4], Roel Vermeulen[1], Gerard Hoek[1,7]
[1]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, [2]Swiss Tropical and Public Health Institute, Basel, Switzerland, [3]University of Basel, Basel, Switzerland, [4]Department of Physical Geography, Faculty of Geosciences, Utrecht University, Utrecht, the Netherlands, [5]Google, Inc, Mountain View, California, USA, [6]Department of Environmental Science, Aarhus University, Roskilde, Denmark, [7]Julius Centre for Health Sciences and Primary Care, University Medical Centre, Utrecht University, Utrecht, the Netherlands

BACKGROUND AND AIM: Land-use regression (LUR) empirically relates air pollution concentrations to predictors such as traffic data, population, and land use data. Previously used regression methods in Europe wide models assumed spatially-fixed linear relationships between predictors and air pollution concentrations. Thus, to include spatial heterogeneity in relationships, we used geographically weighted regression (GWR) and the machine learning method Random Forest (RF), with the aim to further improve the accuracy of air pollution exposure estimates.

METHODS: We built separate LUR models for each year from 2000 to 2019 for NO2, O3, PM2.5 and PM10 using annual average concentrations from routine monitoring stations across Europe. The potential predictors included satellite retrievals, chemical transport model estimates and land-use variables. Supervised linear regression (SLR) was first used to select predictors, and then GWR estimated the potentially spatially-varying regression coefficients. We evaluated the model performance using five-fold cross-validation (CV) for each year and compared GWR with SLR and RF.

RESULTS: GWR explained measured concentrations generally well, with annual CV-R2 values of 0.62-0.67, 0.43-0.66, 0.48-0.71, 0.69-0.82, for NO2, O3, PM10, and PM2.5 respectively. GWR improved the R2 values compared to SLR by 4-7%, 7-15%, 7-14%, 0-6% and compared to RF by 1-4%, 0-10%, 0-11%, 7-19%, for NO2, O3, PM10, and PM2.5 respectively. Predictors selected and the spatially-varying coefficient values varied between years.

CONCLUSIONS: Including spatial heterogeneity using geographically weighted regression improved European air pollution LUR models. These models allow time-varying exposure-risk models.

KEYWORDS: Geographically weighted regression, spatial heterogeneity, land-use regression, air pollution, supervised linear regression, random forests

P-0137 Association of PM 2.5 components with the incidence of end-stage kidney disease in two large European cohorts

Gudrun Weinmayr[1], Matteo Renzi[2], Andrea Jaensch[1], Claudia Marino[2], Pietro Manuel Ferraro[3], Emanuel Zitt[4,5], Kees de Hoogh[6,7], Massimo Stafoggia[2], Gerard Hoek[8], Gabriele Nagel[1,4], Giulia Cesaroni[2]

[1]Ulm University, Ulm, Germany, [2]Department of Epidemiology, Lazio Region Health Service / ASL Roma 1, Rome, Italy, [3]Università Cattolica del Sacro Cuore, Rome, Italy, [4]Agency for Social and Preventive Medicine (aks), Bregenz, Austria, [5]Department of Internal Medicine 3, LKH Feldkirch, Feldkirch, Austria, [6]Swiss Tropical and Public Health Institute, Basel, Switzerland, [7]University of Basel, Basel, Switzerland, [8]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, the Netherlands

BACKGROUND AND AIM: End-stage kidney disease (ESKD) poses a high burden on patients and the health system. The very few studies on air pollution and ESKD have shown associations with $PM_{2.5}$, but no study so far has investigated which of the components may be most relevant. We investigate the association of long-term exposure to $PM_{2.5}$ elements with ESKD incidence in two large population-based European cohorts.

METHODS: Individuals in the Rome Longitudinal Study (RoLS) and the Vorarlberg Health Monitoring and Prevention Program (VHM&PP) were followed up with Dialysis and Transplant Registries from 1985 to 2019 and 2011 to 2019, respectively.
Long-term exposures to eight $PM_{2.5}$ components (copper, iron, potassium, nickel, sulfur, silicon, vanadium, and zinc) at residence were estimated with Europe-wide hybrid land use regression models at 100x100m scale.
Hazard ratios (HR) were determined from Cox-proportional hazard models with age as time axis and adjusted for individual and neighbourhood confounders.
RESULTS: RoLS contributed 3,231 cases from 1,939,461 individuals (mean age 52.4 years; crude incidence rate (CIR) 0.22 per 1000 person years) and VHM&PP 501 cases from 136,823 individuals (mean age 42.1years; CIR 0.14).
In RoLS, elements associated with ESKD were potassium (HR 1.25 [1.05,1.48]) and sulphur (HR 1.10 [0.97,1.25]) for an increase of 50 and 200 ng/m³, respectively, whereas in VHM&PP, risk of ESKD was associated with copper (HR 1.20 [0.97, 1.47]) and iron (1.30 [0.98, 1.74]) for 5 and 100 ng/m³, respectively .
CONCLUSION: Air pollution indicative for biomass burning (potassium) and long-range transport (sulphur) in Rome, and indicators of traffic-related air pollution (iron and copper) in Vorarlberg were associated with an increased risk of ESKD.

P-0138 Association between ambient air pollutants and influenza – A systematic review and meta-analysis

Regina Pickford[1], Margarethe Woeckel[1], Alexandra Schneider[1], Annette Peters[1,2,3]
[1]Helmholtz Munich, Neuherberg, Germany, [2]Institute for Medical Information Processing, Biometry and Epidemiology, Medical Faculty, Ludwig-Maximilians-Universität, Munich, Germany, [3]Department of Environmental Health, Harvard T. H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: There is emerging evidence that ambient air pollution exposure is not linked solely to chronic diseases but might also impact incidence and mortality of infectious diseases. The aim of this systematic review and meta-analysis was to examine the association between exposure to ambient air pollutants and risk of influenza/influenza like illness (ILI) and associated infection, morbidity and mortality.

METHODS: We conducted a systematic literature search and subsequently performed a random-effects meta-analysis using the Knapp-Hartung method with a restricted maximum likelihood (REML) estimator if at least four studies with similar outcome and exposure were available. We converted the estimates for each outcome into standardized increments for a 10 µg/m³ increase in air pollutant. Heterogeneity was assessed using I^2 and Cochranes Q. The study was registered at PROSPERO (CRD42020199906). An update including literature up to February 2022 is currently being prepared.

RESULTS: The literature search from 01.01.1980 to 27.10.2020 yielded 233 studies from PubMed and Web of Science and one study from the preprint server MedRxiv. In total, 10 articles were reviewed in-depth and risk of bias assessed.
For short-term studies, small positive associations were seen for a 10 µg/m³ increase in $PM_{2.5}$ for influenza incidence [relative risk: 1.02, 95%confidence interval: 1.01; 1.03]. The search yielded only two studies for hospital admission and no long-term studies or studies on mortality.

CONCLUSIONS: Our analysis indicates that ambient air pollution can exacerbate influenza infections. Lowering the current EU standards for $PM_{2.5}$ will reduce the adverse effects of ambient air pollution for chronic as well as infectious diseases. The results for influenza might also give some implications of possible associations for ambient air pollution with other respiratory virus diseases including SARS-CoV-2.

P-0148 Long-term exposure to air pollution and decreased renal function in older adults: A longitudinal cohort study

Heeseon Jang[1], Jaelim Cho[1], Changsoo Kim[1]
[1]*Department of Preventive Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea, Seoul, Republic of Korea*

BACKGROUND AND AIM: Epidemiological evidence suggests that ambient air pollution adversely affects renal health. However, previous studies on the association between air pollution and renal function impairment have reported mixed findings. Furthermore, most of the studies were cross-sectional. Therefore, we conducted a longitudinal study to investigate the relationship between long-term exposure to air pollution and changes in renal function in older adults.

METHODS: A total of 326 adults (aged ≥50 years) dwelling in four cities (Seoul, Incheon, and Wonju/Pyeongchang) in the Republic of Korea were included. They participated in baseline and follow-up surveys between 2014 and 2019. Long-term concentrations of particulate matter≤10μm in diameter (PM10), ≤2.5μm (PM2.5), and nitrogen dioxide (NO2) at each participant's residential address were estimated. The Modification of Diet in Renal Disease was employed to derive the estimated glomerular filtration rate (eGFR). We used linear mixed effect models to examine whether long-term exposure to air pollution were associated with changes in renal function markers, including eGFR, blood urea nitrogen (BUN), and uric acid (UA), while controlling for potential confounders.

RESULTS: The number of men was 155 (47.5%). The mean±standard deviation age was 65.2±4.4 years. A 10-ppb increment in NO2 significantly associated with decreased eGFR [β=−4.48mL/min/1.73m2, Standard error (SE)= 1.96, P=0.02] and increased BUN (β=1.15mg/dL, SE=0.53, P=0.03), but not with UA (β=0.14 mg/dL, SE=0.16, P=0.36). None of the association between PM10 or PM2.5 and all the renal function markers was statistically significant.

CONCLUSIONS: We found that long-term exposure to NO2 was associated with a decline in eGFR and a raised level of BUN among older adults. These findings suggest that NO2 exposure may contribute to renal function impairment.

P-0157 Impact of Do-It-Yourself and Commercial Air Cleaner Usage on Health and Residential PM2.5

Mallory Turner[1], Pradeep Prathibha[1], Amara Holder[2], Ana G. Rappold[2], Madison Kirshner[1], Beth Hassett-Sipple[2], Ann N. Chelminski[2]

[1]ORISE Fellow at the United States Environmental Protection Agency, USA, [2]United States Environmental Protection Agency, USA

BACKGROUND AND AIM: Wildfire smoke can threaten health, necessitating creating cleaner indoor air spaces. Commercially available portable air cleaners (PACs) mitigate smoke impacts indoors but can be expensive or inaccessible. Lower-cost Do-It-Yourself (DIY) PACs (furnace filter attached to box fan) offer an affordable alternative. However, evidence of their effectiveness in real-world settings is limited. This pilot study aimed to 1) evaluate the effect of DIY/commercial PAC usage on indoor PM2.5 and health outcomes during wildfire season among tribal community members in Hoopa, California and 2) assess barriers and facilitators to use of either intervention.

METHODS: During four one-to-two-week phases (baseline; DIY PAC usage ≥8 hours/day; commercial PAC usage ≥8 hours/day; and air sensor with visual display with optional PAC use), we monitored indoor and outdoor PM2.5 at participants' homes. We conducted phase-specific phone surveys about participants' health, behaviors, and perceptions. We analyzed indoor PM2.5 and health outcomes associated with PAC usage using mixed effects multivariate linear regression and tabulated behavioral responses.

RESULTS: DIY and commercial PAC usage was significantly associated with reduced infiltrated PM2.5 (n=6). High usage (≥30% of phase) of either PAC was significantly associated with improved health (measured as a composite score), relative to low usage (<10% of phase) (n=10). Noise was the primary barrier to DIY PAC use, while quiet operation and small size of commercial PACs facilitated use. Nonetheless, eight of nine participants who preferred commercial PACs said they would use DIY PACs if the air were very smoky.

CONCLUSIONS: DIY and commercial PACs were associated with improved indoor PM2.5 and health, but the loudness of DIY PACs hindered use. State, local, and tribal organizations should consider these conclusions in tailoring messaging and allocating resources in preparation for wildfire seasons. Disclaimer: Does not reflect EPA views or policy.

P-0180 Short-term effects of carbonaceous particles on mortality: A time-series study in London

Rachael Piper[1], Dimitris Evangelopoulos[1,2], Anja Tremper[2], Gary Fuller, David Green[1,2], Klea Katsouyanni[1,3]
[1]NIHR HPRU in Environmental Exposures and Health, Imperial College London, London, UK, [2] Environmental Research Group, MRC Centre for Environment and Health, Imperial College London, London, UK, [3]Department of Hygiene, Epidemiology and Medical Statistics, National and Kapodistrian University of Athens, Athens, Greece

BACKGROUND AND AIM: Exposure to ambient particulate matter (PM) has been identified as a major global health concern. Recent studies have suggested that it is the carbonaceous constituents of PM that pose the greatest health risks. Using time-series methods, we investigated the associations between short-term exposure to carbonaceous particles and mortality in London.

METHODS: Daily counts of natural, cardiovascular, and respiratory deaths were obtained for London between 2010 and 2019. for the same period, daily concentrations of various carbonaceous species [organic (OC), elemental (EC), black (BC), wood-burning (WC), and total carbon (TC)] were averaged across two centrally located monitoring sites: Marylebone Road (roadside) and North Kensington (background). Generalised additive models (GAM) were used to estimate percentage changes in risks of mortality associated with interquartile range (IQR) increases in particle concentrations, at different lags (single-day lag0 to lag6 and cumulative lag03, lag06). Stratified analyses were conducted by age (0-64, 65+), season and site type.

RESULTS: For natural deaths, we observed positive associations for all particle species at lag 1, with significant increases in mortality of 0.52% (95% Confidence interval (CI): 0.18% to 0.86%) and 0.44% (95% CI: 0.03% to 0.85%) for WC and OC, respectively. We also observed positive associations for respiratory deaths, with strongest effects at exposure lag03 for WC (1.73% (95% CI: 0.05% to 2.93%), TC (1.30% (95% CI: −0.46% to 3.08), and OC (1.28% (95% CI: −0.11% to 2.68). In contrast, associations with cardiovascular deaths were generally null. Results remained consistent after adjustment for PM mass.

CONCLUSIONS: Our preliminary results suggest that carbonaceous particles are associated with increased risks of both natural and respiratory mortality in London. These findings contribute to the growing understanding of the differential health effects of PM constituents that is crucial for the development of targeted polices.

P-0212 Partitioning personal measurements into personal exposure to pollution from indoor and outdoor sources in London inhabitants - An analysis within the MELONS* project

Hanbin Zhang[1,2,3], Dimitris Evangelopoulos[1,2,3], Klea Katsouyanni[1,3,4], Heather Walton[1,3], Benjamin Barratt[1,3]
[1]Environmental Research Group, School of Public Health, Imperial College London, London, UK, [2]MRC Centre for Environment and Health, Imperial College London, London, UK, [3]NIHR HPRU in Environmental Exposures and Health, Imperial College London, London, UK, [4]Department of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

BACKGROUND AND AIM. Air pollution, particularly particles, from indoor and outdoor sources originate from different activities, have different toxicities, may have different health effects and need to be addressed by separate interventions. for epidemiological studies, personal exposure to pollution from outdoor sources was proposed as true exposure often approximated by modelled estimates. This study aimed to derive partitioned personal exposure to pollution from indoor and outdoor sources from four diverse study populations gathering 13,871 participant-day personal measurements of exposure using wearables in London.

METHODS: A mixed approach, based on personal measurement frequency, fixed radius, clustering and reverse geocoding, was applied to tag one-minute personal measurements into personal microenvironments. Home addresses were paired with local ambient data to facilitate calculation of infiltration efficiencies. Then personal measurements were partitioned into personal exposure to pollution from indoor and outdoor sources at one-minute resolution for each participant.

RESULTS: COPD patients, compared to school children, had higher mean PM2.5 pollution from indoor sources (COPD: 6.9 ± 37.2, children: 4.1 ± 42.8 μg/m3), but similar pollution from outdoor sources (COPD: 5.1 ± 12.8, children: 5.3 ± 27.2 μg/m3). for black carbon, professional drivers, compared to healthy adults, had higher personal exposure to pollution from outdoor sources (drivers: 1.7 ± 4.3, healthy adults: 1.2 ± 2.5 μg/m3) and lower personal exposure to pollution from indoor sources (drivers: 0.3 ± 1.8, healthy adults: 0.8 ± 2.1 μg/m3).

CONCLUSIONS: By utilising GPS data, personal measurements from wearable monitors can be partitioned into personal exposure to pollution from indoor and outdoor sources to aid epidemiological studies and policy development. Our results, highlight that sources of pollution can be very different even though personal measurements of total exposure levels are similar. Further work is required to extrapolate results over longer time periods and larger populations.

BACKGROUND: Cooking with solid fuels such as wood and charcoal contributes to household air pollution and is associated with adverse birth outcomes. Cleaner fuel interventions may reduce HAP exposure sufficiently to prevent preterm birth (PTB, <37 weeks gestation). We assessed the effects of a randomized liquefied petroleum gas (LPG) stove and free fuel intervention on PTB and gestational duration (secondary outcomes of the trial), as well as associations with fine particulate matter (PM2.5), black carbon (BC), and carbon monoxide (CO) in the HAPIN trial conducted in Guatemala, India, Peru, and Rwanda.

METHODS: Pregnant women (18-35 years of age; gestation confirmed by ultrasound at 9-20 weeks) were randomly assigned to intervention arm (n=1,593) or control arm (n=1,607). We measured 24-hour personal exposure to PM2.5, BC, and CO at baseline, 18-24 weeks, and 32-36 weeks gestation. We used intent-to-treat approach to evaluate the intervention effect. We also assessed associations between measured pollution concentrations with PTB and gestational duration using linear and log-binomial regression models.

RESULTS: Intervention adherence was nearly exclusive; PM2.5, BC, and CO exposures were 66-80% lower post-randomization compared to control. The proportion of livebirths (n=3060) that were preterm was 5.9% (intervention arm) and 5.4% (control arm). Compared to the control arm, the relative risk of PTB among women randomized to the intervention was 1.09 (95% CI 0.82-1.46, p=0.56). The mean gestational duration was 39.3 weeks in both the intervention and control arm (adjusted mean difference 0.03 weeks, 95% CI -0.08-0.15, p=0.55). PM2.5, BC, and CO levels during pregnancy were not associated with PTB or gestational duration.

CONCLUSIONS: An LPG stove and fuel intervention did not reduce PTB risk or increase gestational duration in this study population, nor was measured personal pollution associated with either outcome.

P-0237 Air pollution impacts at very low levels: Shape of the concentration-mortality relationship in a large population-based Canadian cohort

Michael Brauer[1,9], Jeffrey Brook[2], Dan Crouse[3], Anders Erickson[1], Perry Hystad[4], Chi Li[5], Randall Martin[6], Jun Meng[5], Michael Tjepkema[7], Aaron van Donkelaar[6], Tanya Christidis[7], Lauren Pinault[7], Weiran Yuchi[1,7], Crystal Weagle[6], Scott Weichenthal[8], Richard Burnett[9]

[1]The University of British Columbia, Vancouver, Canada, [2]University of Toronto, Toronto, Canada, [3]Health Effects Institute, Boston, USA, [4]Oregon State University, Corvallis, USA, [5]Dalhousie University, Halifax, Canada, [6]Washington University St. Louis, St Louis, USA, [7]Statistics Canada, Ottawa, Canada, [8]McGill University, Montreal, Canada, [9]Institute for Health Metrics and Evaluation, University of Washington, Seattle, USA

BACKGROUND
Mortality is associated with long-term exposure to fine particulate matter, although the form of these associations remain poorly understood at lower concentrations. We applied novel 1 km satellite-derived estimates of PM2.5 exposure to a population-based cohort of 7.1 million Canadians.

METHODS: Cox proportional hazard ratios (HRs) were estimated for nonaccidental and cause-specific mortality and 10-year moving average exposure in models adjusted for a wide array of individual and contextual covariates. The shape of the concentration–response function was investigated using restricted cubic splines, threshold models and an extension of the Shape Constrained Health Impact Function (eSCHIF). Analyses examined sensitivity to co-pollutants, concentration thresholds and regional variation.

RESULTS: Each 10-µg/m3 increase in PM2.5 corresponded with a nonaccidental mortality HR of 1.084 (1.073 - 1.096). PM2.5 was associated mortality from ischemic heart disease, pneumonia, COPD, diabetes, and cerebrovascular disease, but not with heart failure, lung cancer, or kidney failure mortality. HR predictions steeply increased from the minimum concentration of 2.5 µg/m3 to 4.5 µg/m3, flattened from 4.5 µg/m3 to 8.0 µg/m3, then increased for concentrations above 8.0 µg/m3, a pattern also reflected in threshold and eSCHIF results. When restricting to those with exposures <10 µg/m3 shapes indicated positive associations for concentrations >9 µg/m3 with indications of adverse effects on mortality at concentrations as low as 2.5 µg/m3. In sensitivity analyses, PM2.5 - mortality associations were only observed in the highest tertile of oxidant gases with shapes varying across airsheds. These differences, were not related to variation in cohort composition or its access to healthcare, suggesting a role of spatially varying pollutant mixtures not sufficiently characterized by PM2.5 mass concentrations.

CONCLUSIONS: In a large Canadian cohort, associations were observed between exposure to PM2.5 with mortality at concentrations as low as 2.5 µg/m3, with no clear evidence of a threshold.

P-0239 Application of geostationary satellite and high-resolution meteorology data in estimating hourly PM2.5 levels during the Camp Fire episode in California

Bryan N. Vu[1,2], Jianzhao Bi[3], Wenhao Wang[2], Amy Huff[4], Shobha Kondragunta[5], Yang Liu[2]
[1]Harvard University, Boston, USA, [2]Emory University, Atlanta, USA, [3]University of Washington, Seattle, USA, [4]I.M. Systems Group, College Park, USA, [5]National Oceanic and Atmospheric Administration, Washington DC, USA

BACKGROUND: Wildland fire smoke contains large amounts of PM2.5 that can traverse tens to hundreds of kilometers, resulting in significant deterioration of air quality and excess mortality and morbidity in downwind regions. Estimating PM2.5 levels while considering the impact of wildfire smoke has been challenging due to the lack of ground monitoring coverage near the smoke plumes.
AIM: We aim to estimate total PM2.5 concentration during the Camp Fire episode, the deadliest wildland fire in California history.

METHODS: Our random forest (RF) model combines calibrated low-cost sensor data (PurpleAir) with regulatory monitor measurements (Air Quality System, AQS) to bolster ground observations, Geostationary Operational Environmental Satellite-16 (GOES-16)'s high temporal resolution to achieve hourly predictions, and oversampling techniques (Synthetic Minority Oversampling Technique, SMOTE) to reduce model underestimation at high PM2.5 levels. In addition, meteorological fields at 3 km resolution from the High-Resolution Rapid Refresh model and land use variables were also included in the model.

RESULTS: Our AQS-only model achieved an out of bag (OOB) R2 (RMSE) of 0.84 (12.00 μg/m3) and spatial and temporal cross-validation (CV) R2 (RMSE) of 0.74 (16.28 μg/m3) and 0.73 (16.58 μg/m3), respectively. Our AQS + Weighted PurpleAir Model achieved OOB R2 (RMSE) of 0.86 (9.52 μg/m3) and spatial and temporal CV R2 (RMSE) of 0.75 (14.93 μg/m3) and 0.79 (11.89 μg/m3), respectively. Our AQS + Weighted PurpleAir + SMOTE Model achieved OOB R2 (RMSE) of 0.92 (10.44 μg/m3) and spatial and temporal CV R2 (RMSE) of 0.84 (12.36 μg/m3) and 0.85 (14.88 μg/m3), respectively.

CONCLUSIONS: Hourly predictions from our model may aid in epidemiological investigations of intense and acute exposure to PM2.5 during the Camp Fire episode.

P-0240 Transportation-Related Emissions Surrogates Support Modeling of Oxides of Nitrogen Exposure

Nathan Pavlovic[1], Lianfa Li[2], Frederick Lurmann[1], Jun Wu[5], Beate Ritz[4], Rima Habre[2,3]
[1]Sonoma Technology, Inc, Petaluma, USA, [2]Spatial Sciences Institute, University of Southern California, Los Angeles, USA, [3]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, USA, [4]Departments of Epidemiology and Environmental Health, Fielding School of Public Health, University of California, Los Angeles, USA, [5]4Program in Public Health, Susan and Henry Samueli College of Health Sciences, University of California, Irvine, USA

BACKGROUND: Mobile sources such as traffic and airports contribute significantly to concentrations of nitrogen oxides (NOx) and nitrogen dioxide (NO2). Exposure to these pollutants in turn are associated with a range of negative health outcomes. Accurate, high resolution spatiotemporal models of NOx /NO2 are needed to support further epidemiological research. Traffic tailpipe emissions are especially elevated under high engine load (acceleration), and our earlier work shows accounting for airport emissions may decrease measurement error in our spatiotemporal NOx models. The goal of this work is to showcase improvements in accounting for these mobile sources more accurately and these features' importance in our spatiotemporal NOx models.

METHODS: We calculated airport-related NOx emissions by allocating airport-related NOx emissions from CARB's CEPAM emission inventory tool to each airport in California from 2004 through 2019. for 2020 and 2021, emissions were further scaled on a weekly basis to account for decreased flight volume during the COVID period. To account for on-road vehicle tailpipe emissions due to acceleration at intersections, we developed a dataset representing intersection density, broken into class by intersection type based on road class type and supported by GPS activity data. These variables were incorporated into spatiotemporal modeling of outdoor NOx/NO2 concentrations in California.

RESULTS: Airport emissions and intersection density were ranked highly by variable importance within the model. The transportation-related emissions surrogates improved the spatial representation of NOx/NO2 at fine scales, supporting accurate air quality exposure estimates.

CONCLUSIONS: Our findings demonstrate how improved measures of mobile source emissions (beyond distance to airports or roads) that capture gradients in emission patterns across spatial features (e.g. road class) can enhance spatiotemporal prediction performance of high resolution exposure models.

P-0242 Application of an ultra-low-cost passive sampler for light-absorbing carbon in India and Mongolia

Bujin Bekbulat[1], Pratyush Agrawal[2], Ryan Allen[3], Michael Baum[4], Buyantushig Boldbaatar[5], Lara P. Clark[1], Jargalsaikhan Galsuren[5], Perry Hystad[6], Meenakshi Kushwaha[2], Christian L'Orange[7], Sreekanth Vakacherla[8], John Volckens[7], Julian D. Marshall[1]

[1]Department of Civil and Environmental Engineering, University of Washington, Seattle, USA, [2]ILK Labs, Bengaluru, India, [3]Department of Health Sciences, Simon Fraser University, Burnaby, Canada, [4]Axon Engineering LLC, Bellevue, USA, [5]Department of Public Health, Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia, [6]Department of Public Health and Human Sciences, Oregon State University, Corvallis, USA, [7]Department of Mechanical Engineering, Colorado State University, Fort Collins, USA, [8]Center for Study of Science, Technology and Policy, Bengaluru, India

BACKGROUND: We previously developed and tested Washington Passive Samplers (WPS), an ultra-low-cost passive sampling method for long-term average level of light-absorbing carbon (LAC) air pollution. Briefly, we passively expose filter-paper in the WPS, and measure the before/after change in reflectance via analyzing filter images. Tests in a laboratory in Seattle and in polluted homes in Bangalore, India, (Clark et al., 2020) indicated robust reproducibility (duplicate samplers R2 = 0.98) but did not test accuracy.
AIM: to evaluate the WPS accuracy by co-locating the WPS with reference methods.

METHODS: We deployed three methods to each of 10 households in Ulaanbaatar, Mongolia, for multiple periods of 4 weeks each: one PurpleAir (PA; real-time PM2.5); two quartz filters using an ultrasonic personal aerosol sampler (UPAS; analysis: elemental carbon [EC]); and two WPS samplers (time-integrated LAC). Unadjusted LAC measurements are the change in pixel intensity [PI] per month (PI=65,535 would represent complete change from lightest (whitest) to darkest (blackest) colors).

RESULTS: Average indoor measurements were 180 µg/m3 PM2.5 (PA; uncalibrated), 14.1 µg /m3 BC (UPAS, EC), and 975 PI/month (WPS, LAC deposition rate). Calibrations the WPS to the UPAS results indicates that 1 µg of BC /m3 corresponds to 62 PI /month PM2.5, on average; if we predict BC concentrations from the passive LAC measurements, then the root-mean-square-error is 3.1 µg /m3 BC, or ~21% of the average BC concentration.
DISCUSSION: Prior research indicated high precision for the WPS; results here indicate reasonable accuracy (RMSE=21%). Compared to a conventional filter-and-pump, the WPS is substantially less expensive, easier to deploy, and offers time-integrated measurement.

P-0318 Relationship between cadmium exposure, triglyceride-glucose index and carotid artery atherosclerosis

Kwanghyun Kim[1,2], Dae Jung Kim[2], Kyoung Hwa Ha[2], Hyeon Chang Kim[1]
[1]Yonsei University College of Medicine, Seoul, Republic of Korea, [2]Ajou University School of Medicine, Suwon, Korea

INTRODUCTION: Cadmium exposure is suggested to be associated with cardiovascular and metabolic diseases. We investigated the association between cadmium and carotid artery atherosclerosis and the mediating effect of serum triglyceride and glucose level represented by triglyceride-glucose index (TyG index).

METHODS: Among Cardiovascular and Metabolic disease Etiology Research Center (CMERC) Cohort participants, participants who received serum heavy metal screening tests were selected (N=200). Patients with more than 3 standard deviation level of serum cadmium were excluded (N=1). TyG index was calculated as formula: ln [{fasting blood glucose (mg/dL) × triglyceride (mg/dL)}/2]. Carotid artery ultrasonography was conducted to test carotid artery atherosclerosis. Carotid artery plaque was considered present if the thickness is greater by 50% or more than the surrounding intima-media thickness or if its size was 1.5mm or more. We used linear regression to test the association between serum cadmium level and TyG index, and Poisson regression to test the association between serum cadmium level, TyG index and number of plaques. Mediation analyses was conducted to detect the mediating effect of TyG index.

RESULTS: Serum cadmium level was associated with TyG index (β=0.155, p-value=0.042). Both serum cadmium level(β=0.753, p-value=0.039) and TyG index(β=1.049, p=0.010) were associated with number of carotid artery plaques. Mediation analyses showed that TyG index significantly mediated the association between serum cadmium level and carotid artery plaque (direct effect: β=0.733, p-value=0.042; indirect effect: β=0.165, p-value=0.048).
CONCLUSION: Cadmium exposure increases the risk of carotid artery atherosclerosis. The assocaition is mediated by disturbance in serum triglyceride and glucose level.

P-0324 Prenatal Perfluorooctanoic Acid (PFOA) Exposure Significantly Decreases in utero Fetal Head Circumference and Biparietal Diameter Growth Among Women Reporting Higher Levels of Perceived Stress

Alicia Peterson[1], Sandrah Eckel[1], Rima Habre[1], Tingyu Yang[1], Dema Faham[1], Monica Amin[1], Brendan Grubbs[1], Shohreh Farzan[1], Kurunthachalam Kannan[2], Morgan Robinson[2], Deborah Lerner[3], Laila Al-Marayati[1], Daphne Walker[1], Edward Grant[1], Carrie Breton[1], Theresa Bastain[1]

[1]University of Southern California, Los Angeles, USA, [2]New York University, New York, USA, [3]Eisner Health, Los Angeles, USA

BACKGROUND AND AIM: Perfluoroalkyl Substances (PFAS) are ubiquitous synthetic chemicals with long half-lives and are known to cross the placenta during pregnancy. We examined the influence of maternal PFAS levels on in utero fetal growth trajectories and assessed whether maternal stress modified these associations.

METHODS: Blood serum concentrations of five PFAS (PFOS, PFHxS, PFNA, PFOA, PFDA) were measured in 335 prenatal specimens (mean gestational age (GA): 21±9 weeks) in the MADRES cohort. Fetal growth outcomes were abstracted from ultrasound medical records and head circumference (HC), abdominal circumference (AC), biparietal diameter (BPD), and femur length (FL) were also measured at the 3rd trimester study visit (N=833 scans, GA range 10-42 weeks, mean 2.4 scans/participant). Adjusted linear mixed models with a GA quadratic growth curve were used for each PFAS exposure and growth outcome. PFOS and PFHxS were modeled continuously (100% sample detection), while PFOA, PFNA, and PFDA were modeled categorically (57%-70% sample detection). Scores on the Perceived Stress Scale (PSS) measured in pregnancy were dichotomized at the median (<13 vs. ≥ 13) in stratified models.

RESULTS: Participants were on average 29±6 years old and predominately Hispanic (76%). Median serum concentrations of PFOS, PFHxS, PFNA, PFOA and PFDA were 1.34, 1.10, 0.07, 0.12, and 0.04 ng/mL, respectively. Participants with detected PFOA concentrations had fetuses with –2.5 mm (95% CI -4.2, -0.8) smaller HC and –0.7 mm (95% CI -1.3, -0.2) smaller BPD on average than those without detected PFOA concentrations. In models stratified by PSS level, the effects of PFOA on fetal growth parameters were stronger and only significant in participants with higher stress levels (HC: β= -3.5, 95% CI -5.8, -1.4; BPD: β = -0.8, 95% CI -1.6, -1.1).

CONCLUSIONS: Prenatal PFOA exposure adversely impacted fetal head biometric parameters in participants experiencing higher stress during pregnancy.

P-0329 Organophosphate Flame Retardant Exposures and Maternal Depression During Pregnancy in the Maternal and Developmental Risks from Environmental and Social Stressors (MADRES) Pregnancy Cohort

Ixel Hernandez-Castro[1], Sandrah P. Eckel[1], Max Aung[1], Tingyu Yang[1], Kurunthachalam Kannan[2], Morgan Robinson[2], Rima Habre[1], Shohreh F. Farzan[1], Genevieve Dunton[1], Brendan Grubbs[3], Laila Al-Marayati[3], Deborah Lerner[4], Isabel Lagomasino[5], Carrie V. Breton[1], Theresa M. Bastain[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [2]Department of Pediatrics, New York University School of Medicine, New York, USA, [3]Department of Obstetrics and Gynecology, Keck School of Medicine, University of Southern California, Los Angeles, USA, [4]Eisner Health, Los Angeles, USA, [5]Department of Psychiatry and the Behavioral Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Depression is a major contributor to pregnancy-related morbidity, and pregnancy is increasingly recognized as a vulnerable window for maternal health effects from environmental exposures. Organophosphate flame retardants (OPFRs) are a class of organic chemicals applied to various industrial and consumer products with hypothesized mental health impacts but limited epidemiological research. We evaluated the association between prenatal OPFR exposures and maternal depression during pregnancy in a predominantly low-income, Hispanic cohort.

METHODS: Third trimester bis(1,3-dichloro-2-propyl) phosphate (BDCIPP) and diphenyl phosphate (DPHP) urinary metabolite concentrations were measured in 422 participants (collection mean gestational age= 31.5±2.0 weeks) in the MADRES cohort. Detection frequencies were 94.6% for BDCIPP and 99.8% for DPHP. OPFR metabolites ≤LOD were imputed as LOD/√2, and concentrations were specific-gravity-adjusted and categorized into tertiles. Depression was assessed using the Center for Epidemiologic Studies-Depression (CES-D) scale administered at each trimester and participants were classified as depressed (N=137) or not depressed (N=285) if one or more CES-D scores met the suggested cutoff score for clinically significant depressive symptoms (≥16). We used Modified Log-Poisson regression to model the association between tertiles of prenatal BDCIPP and DPHP exposures and prenatal depression risk, adjusting for maternal age, pre-pregnancy BMI, season, gestational age at urine collection, race/ethnicity, income, and education.

RESULTS: Participants were 28.8±6.1 years old and predominately Hispanic (78.0%). BDCIPP and DPHP geometric means (ng/mL) for depressed versus not depressed participants were 1.26 and 1.04 versus 0.99 and 0.81. Relative to the lowest tertiles, participants with the highest tertile of BDCIPP exposure had 50% increased risk of maternal depression during pregnancy (95% CI:5%-115%) and 63% increased risk for the highest tertile of DPHP exposure (95% CI:17%-126%).

CONCLUSIONS: Higher OPFR metabolite levels were associated with increased prenatal maternal depression risk, stressing the importance of considering chemical exposure impacts on maternal depression.

KEYWORDS: Depression; OPFRs

P-0352 Exposure to Per- and polyfluoroalkyl substances is associated with altered pancreatic β-cell function

Jesse Goodrich[1], Emily Davidson*[2,3], Brittney Baumert[1], Ying Chen[2], Douglas Walker[4], Xiangping Lin[4], Xin Hu[5], Tanya Alderete[6], Zhanghua Chen[1], Damaskini Valvi[4], Zoe Fuentes[4], Sarah Rock[1], Kiros Berhane[7], Frank Gilliland[1], Dean Jones[5], Michael Goran[8], David Conti[1], Vasilis Vasiliou†[2], Leda Chatzi†[1]

*[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA; * These authors contributed equally to this work; † These authors contributed equally to this work, [2]Department of Environmental Health Sciences, Yale School of Public Health, Yale University, New Haven, USA, [3]Department of Cellular & Molecular Physiology, Yale School of Medicine, Yale University, New Haven, USA, [4]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [5]Clinical Biomarkers Laboratory, Division of Pulmonary, Allergy, Critical Care and Sleep Medicine, Emory University, Atlanta, USA, [6]Department of Integrative Physiology, University of Colorado Boulder, Boulder, USA, [7]Department of Biostatistics, Columbia University, New York, USA, [8]Department of Pediatrics, Children's Hospital Los Angeles, The Saban Research Institute, Los Angeles, USA*

BACKGROUND AND AIM: Epidemiological and experimental evidence suggests that exposure to per- and polyfluoroalkyl substances (PFAS) increases risk of type 2 diabetes (T2D). However, the mechanisms linking PFAS exposure and T2D risk remain unclear. We examined whether PFAS exposure alters insulin secretion in adolescents.

METHODS: Overweight/obese adolescents (n=124 female, n=167 males; baseline age: 11.3±1.7 years) from the Study of Latinos at Risk (SOLAR) underwent annual clinical visits. Acute insulin response to glucose (AIRg; indicates β-cell function) and disposition index (DI; indicates β-cell function relative to insulin sensitivity) were assessed via intravenous glucose tolerance tests (IVGTT). Associations of baseline PFAS and IVGTT outcomes were assessed using linear mixed models accounting for repeated measures across pubertal stages. To illustrate a functional relationship between PFAS exposure and insulin secretion in β-cells, results were compared to an in vitro model which examined the effects of physiologically-relevant (based on NHANES) PFAS exposure on glucose stimulated insulin secretion (GSIS) in rat insulinoma cells (INS-1).

RESULTS: In early puberty, high perfluorohexanesulfonic acid (PFHxS) levels (>50th percentile; >1.37 µg/L) was associated with 26% higher AIRg (p=0.01). Between early puberty and late puberty, girls with high PFHxS levels exhibited a 31% decrease in AIRg (p=0.004), but no change was observed in girls with low PFHxS (p=0.43). Changes in AIRg across puberty were not different between boys with high versus low PFHxS. No other associations between PFAS and AIRg or DI were observed. In the in vitro model, exposure to high PFHxS concentrations (10.8µg/L) resulted in 33% higher GSIS compared to low PFHxS concentrations (1.08µg/L; p=0.01). PFOS was not associated with altered GSIS.

CONCLUSIONS: PFHxS exposure in early puberty is associated with increased insulin secretion. Over time, this may lead to reduced β-cell function, especially in females, which could increase the risk of youth onset T2D.

KEYWORDS: Diabetes, PFAS, Insulin

P-0354 Associations of urinary metabolite concentrations of legacy phthalates and their replacements with body composition from mid-childhood to early adolescence

Lisa B. Rokoff[1], Shravanthi M. Seshasayee[1], Jenny L. Carwile[1], Sheryl L. Rifas-Shiman[2], Catherine M. Gordon[3], Russ Hauser[4], Tamarra James-Todd[4], Clifford J. Rosen[5], Emily Oken[2], Abby F. Fleisch[1,6]

[1]Center for Outcomes Research and Evaluation, Maine Medical Center Research Institute, Portland, ME, USA, [2]Division of Chronic Disease Research Across the Lifecourse, Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA, USA, [3]Department of Pediatrics, Texas Children's Hospital and Baylor College of Medicine, Houston, TX, USA, [4]Department of Environmental Health and Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, USA, [5]Maine Medical Center Research Institute, Scarborough, ME, USA, [6]Pediatric Endocrinology and Diabetes, Maine Medical Center, Portland, ME, USA

BACKGROUND AND AIM: Phthalates may adversely influence body composition by lowering anabolic hormones and activating peroxisome-proliferator activated receptor gamma. However, data are limited in adolescence when body mass distributions are rapidly changing and bone accrual is peaking. Also, the health impact of legacy phthalate replacements [e.g., di-2-ethylhexyl terephthalate (DEHTP)] has not been well studied.

METHODS: Among 578 children in the Project Viva cohort, we used linear regression to evaluate associations between urinary concentrations of 19 phthalate/replacement metabolites from mid-childhood (median: 7.6 years; 2007-2010) and change in dual-energy X-ray absorptiometry (DXA) measures of body composition between mid-childhood and early adolescence (median: 12.8 years). We used the two DXA measures to calculate longitudinal change in areal bone mineral density (aBMD) Z-score (i.e., bone accrual), lean mass, total fat mass, and truncal fat mass. To assess associations with the overall chemical mixture, we used quantile g-computation and Bayesian kernel machine regression. We adjusted for sociodemographics and tested for effect modification by sex.

RESULTS: Urinary concentrations were highest for mono-2-ethyl-5-carboxypentyl phthalate [median (IQR): 46.7 (69.1) ng/mL]. Metabolites of most replacement phthalates were detectable in a relatively small number of participants [e.g., 28% for mono-2-ethyl-5-hydrohexyl terephthalate (MEHHTP; metabolite of DEHTP)]. Detectable (versus non-detectable) MEHHTP was associated with less bone accrual in boys and marginally greater bone accrual in girls [change in aBMD Z-score (95% CI): -0.22 (-0.39, -0.05) in boys versus 0.17 (-0.005, 0.35) in girls; interaction p-value=0.01]. Other phthalate and replacement metabolites, and their mixtures, were not associated with longitudinal changes in body composition.

CONCLUSIONS: Boys with higher MEHHTP concentrations may have less bone accrual. Otherwise, there was limited evidence for adverse effects of mid-childhood phthalate/replacement exposure on body composition through early adolescence. As production of phthalate replacements such as DEHTP becomes more widespread, further investigation is warranted on the impact of early-life exposures.

P-0390 Associations between per- and polyfluoroalkyl substances and liver fibrosis and steatosis in U.S. adolescents and adults

Yu Zhang[1], Vicente Mustieles[2], Yi-Xin Wang[1], Yang Sun[1], Angela Slitt[3], Carmen Messerlian[1,4]
[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]University of Granada, Center for Biomedical Research (CIBM), Spain. Instituto de Investigación Biosanitaria Ibs GRANADA, Spain. Consortium for Biomedical Research in Epidemiology and Public Health (CIBERESP)., Spain, [3]University of Rhode Island, Kingston, USA, [4]Massachusetts General Hospital Fertility Center, Department of Obstetrics and Gynecology., Boston, USA

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) are associated with liver damage in experimental animals. This study aimed to examine associations between serum PFAS concentrations and liver fibrosis and steatosis in adolescents and adults from the general U.S. population.

METHODS: We included 288 adolescents (12-19 years) and 1391 adults (at or above 20 years) from the National Health and Nutrition Examination Survey (NHANES) 2017-2018 cycle. Serum concentrations of five prevalent PFAS compounds were examined, including perfluorooctane sulfonic acid (PFOS), perfluorooctanoic acid (PFOA), perfluorohexanesulphonic acid (PFHxS), perfluorononanoic acid (PFNA), and perfluorodecanoic acid (PFDeA). Liver fibrosis and hepatic steatosis were determined by ultrasound transient elastography. We used logistic regression and quantile g-computation to examine covariate-adjusted odds ratios (ORs) for cirrhosis and severe steatosis in relation to changes in individual PFAS concentrations and PFAS mixtures.

RESULTS: The prevalence of cirrhosis and severe steatosis were 1.4% and 16% in adolescents, and 2.6% and 35% in adults. Serum PFOS (OR: 3.91, 95% CI: 1.59, 9.63) and PFNA (OR: 5.28, 95% CI: 2.88, 9.67) were positively associated with cirrhosis in adolescents, though confidence intervals were wide due to the limited number of cases. All examined PFAS compounds showed imprecise positive relationships with severe steatosis in adolescents. Per quartile increase in the total PFAS mixture was associated with a 2.17 (95% CI: 0.92, 5.11) fold increase in the odds for severe steatosis in adolescents. No associations for PFAS and cirrhosis or severe steatosis were found in adults.

CONCLUSION

In this U.S. representative study, we found positive associations between some PFAS compounds as well as PFAS mixtures with cirrhosis and severe steatosis in adolescents. Findings support the potential liver toxicity of PFAS, especially in younger age groups. Larger prospective studies are needed to confirm these results.

P-0400 Control of prenatal exposures to mercury in Europe: harmonized communication of fish-consumption advice to pregnant women combined with human biomonitoring

Andromachi Katsonouri[1], Catherine Gabriel, Marta Esteban López, Þórhallur Ingi Halldórsson, Sónia Namorado, Janja Snoj Tratnik, Despina Giannadaki, Spyros Karakitsios, Elena Anastasi, Laura Rodriguez Martin, Milena Horvat, Achilleas Karakoltzidis, Noelia Domínguez Morueco, Chrysanthi Thoma, Ása Valgerður Eiríksdóttir, Ricardo Manuel Abreu de Assunção, Dimosthenis Sarigiannis

[1]*State General Laboratory, Ministry of Health, Cyprus, Nicosia, Cyprus*

BACKGROUND AND AIM: Mercury is a substance of high concern globally. It is biotransformed to methylmercury (MeHg), a potent developmental neurotoxicant bioaccumulating in aquatic food chains. Fish consumption during pregnancy can expose the fetus to mercury, but at the same time provides essential nutrients for optimal brain and eye development. The benefits can outweigh the risks if suitable dietary advice is followed. The harmonized European intervention study 'HBM4EU-MOM' combined fish consumption advice to pregnant women with human biomonitoring (HBM), to assess and control prenatal exposures to methylmercury.

METHODS: Harmonized tools for HBM and communication of dietary advice were developed and applied in five countries (Cyprus, Greece, Portugal, Spain, Iceland). 654 women, recruited during early pregnancy in 2021, provided hair samples for mercury biomonitoring and extensive information about their fish consumption practices and preferences. Targeted fish consumption advice was communicated to randomized 'intervention participants' of each national cohort and exposures were reassessed after ≥12 weeks.

RESULTS: at baseline, the cumulative geometric mean exposure (GM) was 0.59 µg/g, varied across countries from 1.56 µg/g to 0.31 µg/g and correlated with fish-consumption patterns. Around 12% of participants exceeded EFSA's health-based guidance value (HB-GV = 1.8 µg/g). at reassessment, the mean exposures in the highest exposed countries decreased significantly and the overall number of participants exceeding EFSA's HB-GV dropped to 7.5%.

CONCLUSIONS: European pregnant women may exceed current health-based guidance values for mercury exposure because of inappropriate fish consumption, which can be maintained below HB-GV through suitable consumption. HBM provides a way to evaluate the effectiveness of fish-consumption advice. Harmonized European mercury biomonitoring informs policies to protect human health in vulnerable populations.
HBM4EU-MOM was funded by the European Union's Horizon 2020 research and innovation programme (Grant No.733032).

P-0402 Allostatic Load as a Modifier of Associations Between Metals and Blood Pressure

Andrea Chiger[1], Jessie Buckley[1], Miranda Jones[1], Jordan Kuiper[1], Keeve Nachman[1]
[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, USA*

BACKGROUND AND AIM: Disadvantaged populations are often co-exposed to high levels of metals and psychological stressors. While limited research suggests that stress may increase susceptibility to lead cardiotoxicity, the influence of stress on other metals remains unexplored. We examined whether allostatic load (AL), a measure of chronic stress, modifies associations between metals (cadmium, mercury, arsenic, antimony, cesium, cobalt, molybdenum, thallium, tungsten, uranium, or lead) and blood pressure (BP).

METHODS: We analyzed cross-sectional data on 11 blood and urinary metal biomarkers and systolic and diastolic BP in 5,022 adults (20+ years) participating in NHANES 2003-2010 using linear regression models. We assessed whether associations were modified by AL using interaction terms and stratified analyses. Because there is no scientific consensus on how to measure AL, we compared four different approaches to dichotomize participants into high and low AL based on seven stress biomarkers. Final models for each metal were adjusted for age, sex, race/ethnicity, BMI, education level, serum cotinine, urinary creatinine (to account for urinary dilution), and other confounding metals (e.g., lead).

RESULTS: for diastolic BP, we observed no significant interactions between any metals and AL, but stratified analyses indicated that blood lead and urinary cobalt were significantly associated with higher BP in the high AL group only. These results were robust to the method used to define AL. for systolic BP, we observed the opposite trend: blood lead and urinary cobalt were associated with higher BP in the low AL group but not the high AL group, though results varied by AL definition.

CONCLUSIONS: AL may modify the association between certain metals and BP in adults. As results may differ by method used to define AL, future research should use multiple approaches to operationalize AL until consensus is reached on the most appropriate definition.

THEMATIC 18: Occupational Exposures and Health

P-1115 Cancer risks in the employees working at the Air Transportation Industries in the Republic of Korea

Kyung-eun Lee[1], Junhyeok Choi[1], Minjoo Yoon[1]
[1]*Occupational Safety and Health Research Institute, Korea Occupational Safety and Health Agency, Incheon, Republic of Korea*

OBJECTIVES: In this study the risk of cancer in the air transportation industries by their occupations considering known personal and lifestyle risk factors affecting the cancer risk using the air transportation industry cohort data and the National Health Insurance claims data.

METHODS: Standardized incidence ratios (SIRs) and Hazard ratios (HRs) for 24 cancers were calculated using the National Cancer Center's National Cancer Registration Statistics (1988-2017), Statistics Korea Cause of Death (1995-2017), and National Health Insurance Medical Examinations and Medical Examinations (2002-2017). The incidence rates were compared with the total workers enrolled in employment insurance during the same period. In the case of the air transport industries, the time when employment insurance started to be applied for the air transport business group after 1995 was considered as the start point of the tracking, and the final tracking ended on December 31, 2017.

RESULTS: The number of included workers was 72,045 in the air transportation industry group, and 8,094,552 in the control group. After adjusting lifestyles and economic factors, the HR for skin cancer in the female workers in the air transport industry was high as 1.94 (95% CI 1.09-3.44). In spite that the alcohol drinking was adjusted, the highest proportionate risks were still found in both male and female workers for oral cancer and nasopharyngeal cancer in the air transportation group. The HR of oral cancer and nasopharyngeal cancer was 1.47 (95% CI 1.10-1.96) in men and 2.10 (95% CI 1.12-3.94) in women, which was statistically significantly higher than that of the control group.

CONCLUSIONS: Further studies are required to assess the assessing whether the increased risks of cancers were due to work or other factors in a group of air transport industry workers.

KEYWORDS: Hazard ratio, Air transportation industries, Occupational cancer

P-1143 Environmental pollution from nephrite jade mines and lung cancer risk in a nearby community: An age-period-cohort analysis and joinpoint regression analysis in Fengtian, Taiwan

Hsiao-yu Yang[1], Sugio Furuya[2], Naoki Toyama[3]
[1]National Taiwan University, Taipei, Taiwan, [2]Japan Occupational Safety and Health Research Center, Tokyo, Japan, [3]Tokyo Occupational Safety and Health Center, Tokyo, Japan

BACKGROUND AND AIM: Nephrite is a nonasbestiform asbestos mineral comprised of microcrystalline tremolite and/or actinolite. Fengtian is a small village in Taiwan located near asbestos and nephrite mines. The objective of this study was to investigate the effects of age, period, and birth cohort on lung cancer incidence in the surrounding communities.

METHODS: We tracked the incidence rate of lung cancer (ICD-9 code 162: cancers of the trachea, bronchus, or lung) from 1980 to 2019, with data from the Taiwan Cancer Registry. We then calculated age-standardized incidence rates (ASIRs) for lung cancer based on the world standard population in 2000. Joinpoint regression was used to evaluate the trend change, and age-period-cohort models were used to investigate the effects of age, period, and birth cohort on lung cancer incidence.

RESULTS: From 1980 to 2019, there were 278 newly reported lung cancer cases, for a crude incidence rate of 60.7 cases per 100,000 person-years. The ASIR of lung cancer exhibited a significant increase from 1980 to 2010 (APC = 6.8%, 95% CI: 4.0–9.7%, $P < 0.01$) and then declined. The risk of lung cancer in the population peaked 40 years after nephrite mining commenced. The population born between during the mass production of asbestos and nephrite had an increased risk of developing lung cancer. The lung cancer risk in the community decreased 30 years after the cessation of nephrite mining.

CONCLUSIONS: Nephrite mining may increase the risk of lung cancer in nearby communities. Appropriate medical monitoring is warranted for individuals with similar exposures.

P-1165 Lung cancer and radon: Pooled analysis of uranium miners hired in 1960 or later

David Richardson[1], Estelle Rage[2], Paul Demers[3], Minh Do[3], Nora Fenske[4], Veronika Deffner[4], Michaela Kreuzer[4], Jonathan Samet[5], Stephen Bertke[6], Kaitlin Kelly-Reif[6], Mary Schubauer-Berigan[6,7], Ladislav Tomasek[8], Lydia Zablotska[9], Charles Wiggins[10,11], Dominique Laurier[2]

[1]University of California, Irvine, Irvine, USA, [2]Institute for Radiological Protection and Nuclear Safety (IRSN), Fontenay-aux-Roses, France, [3]Occupational Cancer Research Centre, Toronto, Canada, [4]Federal Office for Radiation Protection (BfS), Munich (Neuherberg), Germany, [5]Colorado School of Public Health, Aurora, USA, [6]National Institute for Occupational Safety and Health, Cincinnati, USA, [7]International Agency for Research on Cancer, Lyon, France, [8]National Radiation Protection Institute, Prague, Czech Republic, [9]University of California, San Francisco, San Francisco, USA, [10]University of New Mexico, Albuquerque, USA, [11]New Mexico Tumor Registry, Albuquerque, USA

BACKGROUND

Despite reductions in exposure for workers and the general public, radon remains a leading cause of lung cancer. Prior studies of underground miners depended heavily upon information on deaths among miners employed in the early years of mine operations when exposures were high and tended to be poorly estimated. To strengthen the basis for radiation protection, we report on follow-up of workers employed in later periods of mine operations for whom we have more accurate exposure information and for whom exposures tended to be accrued at intensities that are more comparable to contemporary settings.

METHODS: We conducted a pooled analysis of cohort studies of lung cancer mortality among 57,873 male uranium miners in Canada, Czech Republic, France, Germany, and the United States, who were first employed in 1960 or later (thereby excluding miners employed during the periods of highest exposure and focusing on miners who tend to have higher quality assessments of radon progeny exposures). We derived estimates of excess relative rate per 100 working level months (ERR/100 WLM) for mortality from lung cancer.

RESULTS: The analysis included 1.9 million person-years of observation and 1217 deaths due to lung cancer. The relative rate of lung cancer increased in a linear fashion with cumulative exposure to radon progeny (ERR/100 WLM=1.33; 95% CI: 0.89, 1.88). The association was modified by attained age, age at exposure, and annual exposure rate; for attained ages <55 years, the ERR/100 WLM was 8.38 (95% CI: 3.30, 18.99) among miners who were exposed at ages >=35 years and at annual exposure rates <0.5 working levels. This association decreased with older attained ages, younger ages at exposure, and higher exposure rates.

CONCLUSIONS: Estimates of association between radon progeny exposure and lung cancer mortality among relatively contemporary miners are coherent with estimates used to inform current protection guidelines.

P-1175 Establishing heat stress indicators for work in a warming world: multi-country field evaluation and consensus recommendations

BACKGROUND AND AIM: One third of the world labour force is frequently exposed to high heat stress at work, leading to significant health and labour implications. In a series of studies, we identified and validated the available thermal stress indicators (TSIs) for their capacity to protect individuals who work in the heat.

METHODS: We conducted a systematic review to identify all TSIs and provide reliable information regarding their use. Then, we identified the criteria to consider when adopting a TSI and we weighed their relative importance using a Delphi exercise with 20 experts from 12 countries. Finally, we conducted field experiments across nine countries (372 workers during 893 full work shifts) to evaluate the efficacy of the meteorology-based TSIs for protecting individuals working in the heat.

RESULTS: Our search identified 340 instruments and indicators developed between 200 BC and 2019 AD. of these, 187 can be mathematically calculated utilizing only meteorological data. of these meteorology-based TSIs, 127 were developed for people who are physically active, and 61 of those are eligible for use in occupational settings. Two Delphi iterations were adequate to reach consensus within the expert panel (Cronbach's α=0.86) for 17 criteria with varying weights to be considered when adopting a TSI. These criteria considered physiological parameters such as core/skin/mean body temperature, heart rate, and hydration status, as well as practicality, cost effectiveness, and health guidance issues. In the third study, when evaluated against the 17 Delphi criteria, the 61 meteorology-based TSIs for occupational settings scored from 4.7 to 55.4%. The indoor (55.4%) and outdoor (55.1%) Wet-Bulb Globe Temperature and the Universal Thermal Climate Index (51.7%) scored higher compared to other TSIs (4.7-42.0%).

CONCLUSIONS: We found that three TSIs are more efficacious and should be adopted to support evidence-based decision making and protect individuals who work in the heat.

THEMATIC 21: Water Quality

P-1245 Seasonal Changes in Physicochemical, Chemical and Bacteriological Parameters of Gomti River in Bangladesh

Farzana Yasmin[1], Tania Hossain[2], Saif Shahrukh[3], Mohammad Enayet Hossain[4], Gazi Nurun Nahar Sultana[5]
[1]School of Environmental Sciences, University of Guelph, Canada, [2]Centre for Advanced Research in Sciences, University of Dhaka, Bangladesh, [3]Department of Soil, Water and Environment, University of Dhaka, Bangladesh, [4]Department of Soil, Water and Environment, University of Dhaka, Bangladesh, [5]Centre for Advanced Research in Sciences, University of Dhaka, Bangladesh

BACKGROUND AND AIM: This study was undertaken to investigate the current pollution status of the Gomti river in Bangladesh by collecting water samples from twenty sites along the 120 km stretch of the Gomti river in the rainy season (June 2019) and dry season (January 2020).

METHODS: The collected samples were examined for their physicochemical parameters (pH, electrical conductivity (EC), total dissolved solids (TDS), total organic carbon (TOC), and
turbidity), chemical parameters (the concentrations of six heavy metals, namely chromium (Cr), copper (Cu), iron (Fe), nickel (Ni), lead (Pb), and zinc (Zn)), and bacteriological parameters (aerobic heterotrophic bacteria and total coliforms) in order to assess the suitability of the river water for various purposes.

RESULTS: The heavy metal concentrations of the Gomti river were compared with that of other national and international rivers and it was apparent that Fe, Ni, and Zn may potentially pose adverse effects on the aquatic ecosystems of the Gomti river. A significant ($p<0.05$) positive correlation was found between Cu and Zn indicating that water pollution by these two metals may have originated from common anthropogenic sources. The present study revealed for the first time that the river Gomti was considerably polluted with bacterial populations. The presence of Shigella spp., Salmonella spp., and Escherichia coli in the bacterial isolates is certainly a major water quality concern. Aerobic heterotrophic bacteria and total coliform counts were found to be 0.45×10^2 to 1.84×10^4 CFU/mL and 0.05×10^2 to 7.32×10^3 CFU/mL, respectively, which were above the permissible limits of WHO and are deemed unfit for drinking and domestic purposes, and for fish culture.

CONCLUSIONS: From this study, the priority pollutants of concern in the Gomti river water are Fe, Ni, Zn, aerobic heterotrophic bacteria, and total coliforms.

KEYWORDS: Water pollution, Heavy metals, Total coliform, Gomti river

P-1246 Polymers of micro- and nanoplastics in household tap water of Barcelona

Albert Vega-Herrera[5], Marta Llorca[5], Xavier Borrell-Diaz[5], Paula E Redondo-Hasselerharm[1,2,3], Esteban Abad[5], Cristina Villanueva[1,2,3,4], Marinella Farre[5]

[1]ISGlobal, Barcelona Institute for Global Health, Barcelona, Spain, [2]IMIM (Hospital del Mar Medical Research Institute), Barcelona, Spain, [3]Pompeu Fabra University (UPF), Barcelona, Spain, [4]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [5]IDAEA-CSIC, Barcelona, Spain, [6]IMDEA, Madrid, Spain

BACKGROUND AND AIM. Microplastics are emerging persistent pollutants present in drinking water. Previous studies evaluate 100-5 m particles, although smaller sizes are more biologically relevant and evidence suggest higher occurrence levels at the lowest range. However, analytical challenges to determine smaller particles result in limited population-based studies. We describe the concentrations of microplastics in the public drinking water network of Barcelona, Spain, through a novel workflow to quantify polymers of micro-and nanoplastics(MNPLs) in 0.7-20 m range.

METHODS: We conducted a cross-sectional study including 42 households(one per postal code), with home visits to collect tap water samples(5L). We conducted water fractionated filtration followed by toluene ultrasonic-assisted extraction and size-exclusion chromatography, using an advanced polymer chromatography column coupled to high-resolution mass spectrometry with atmospheric pressure photoionization source with negative and positive ionization conditions (HPLC(APC)-APPI(±)-HRMS) and normal phase chromatography HILIC LUNA® column and electrospray ionisation source in positive and negative mode (HPLC(HILIC)-ESI(±)-HRMS). Polymers were identified based on monomer characterisation through Kendrick Mass Defect analysis, plus confirmation and quantification using standards. A principal component analysis(PCA) was conducted to assess differences between the two areas supplied by different drinking water treatment plants. Analysis of bottled water samples are ongoing.

RESULTS: Polyethylene (PE), polypropylene (PP), polyisoprene (PI), polybutadiene (PBD), polystyrene (PS), polyamide (PA), and polydimethylsiloxanes (PDMS) were identified. PE, PP, and PA were the most highly detected polymers, and PI and PBD were found at the highest concentrations (9 and 1.9 µg/L, respectively). PCA showed no significant differences between the drinking water suppliers.

CONCLUSIONS: Citizens in Barcelona are exposed to MNPLs through drinking water, at variable concentrations depending on the polymer. The analytical method allows to analyse a smaller fraction compared to previous studies. Epidemiological research is needed to evaluate associated health risks

KEYWORDS: Drinking water, microplastics, nanoplastics, exposure, tap water, laboratory analysis, high-resolution mass spectrometry

P-1256 Abundance, Types, and Polymer Composition of Microplastics Present in a Coastal Region of Cox's Bazar, Bangladesh

Anika Nawar Ishika[1], Mahfuza Mirza Sadia[1], Rabeya Miazi[1], Farzana Yasmin[2], Saif Shahrukh[3], Gazi Nurun Nahar Sultana[2], Mohammad Enayet Hossain[1]

[1]Department of Soil, Water and Environment, University of Dhaka, Dhaka, Bangladesh, [2]Centre for Advanced Research in Sciences, University of Dhaka, Dhaka, Bangladesh, [3]Bangladesh Council of Scientific and Industrial Research, Dhaka, Bangladesh

BACKGROUND AND AIM: In Bangladesh, microplastics (MPs) in different forms (e.g., microbeads) are being released continually into the encompassing water bodies and wastelands in and around Dhaka, Chittagong, and Sylhet. These microplastics eventually find their way to the Bay of Bengal and affect the marine lives there. To date, data pertaining to microplastic pollution in the terrestrial and aquatic systems is still limited in Bangladesh. Therefore, the study was undertaken to determine microplastic abundance, types, and polymer composition in seawater and beach sediment.

METHODS: Eighteen surficial sediment samples and twelve seawater samples were collected from three beach points (Laboni, Sugandha, and Kolatoli) of the world's longest sea beach, Cox's Bazar, Bangladesh. The samples were processed and then examined under a stereomicroscope and scanning electron microscope. The microplastic was further analyzed for the identification of polymers using the attenuated total reflection Fourier transform infrared spectroscopy (ATR-FTIR).

RESULTS: This study provided the first quantification and characterization of MPs in the sediments and water of the world's longest sea beach. The study revealed a moderate abundance (368.68 ± 10.65 items/kg) and (210.12 ± 6.23 items/m3) of MPs in beach sediment and seawater, respectively. The identified MPs were mostly colorful (57%), and polyethylene (PE) (41%) and polyvinyl chloride (PVC) (29%) polymers were found to dominate the collected samples. The observed MPs were classified into three size ranges. The majority of the MPs (59%) measured were 1–5 mm in size, followed by 0.5–1 mm (27%) and <0.5 mm (14%).

CONCLUSIONS: This study gives insights into beach MPs pollution on the Bangladesh coast. This data can be used as baseline data for the management of this beach. Further research on the more precise identification of smaller microplastics present in marine biota using the Micro-FTIR Spectroscopy is warranted.

KEYWORDS: Microplastics, Marine Pollution, ATR-FTIR, Polyethylene, Polyvinyl chloride

P-0247 Long-term Exposure to Walkable Residential Neighborhoods Reduces the Risk of Obesity-related Cancer in Women

Sandra India-Aldana[1], Andrew Rundle, James Quinn, Tess Clendenen, Yelena Afanasyeva, Karen Koenig, Mengling Liu, Kathryn Neckerman, Lorna Thorpe, Anne Zeleniuch-Jacquotte, Yu Chen
[1]*NYU School of Medicine, New York, USA*

BACKGROUND AND AIM: Living in neighborhoods with higher levels of walkability has been associated with a reduced risk of obesity and higher levels of physical activity. Obesity has been linked to increased risk of 13 cancers in women. However, long-term prospective studies of neighborhood walkability (NW) and risk for obesity-related cancer are scarce. In this prospective study, we evaluated the association between average NW and risk of cancer.

METHODS: In the New York University Women's Health Study (NYUWHS), a prospective cohort with 14,274 women recruited between 1985 and 1991 in New York City and followed over nearly three decades, we geocoded residential addresses for each participant throughout follow-up. We calculated an average annual measure of neighborhood walkability across years of follow-up using data on population density and accessibility to destinations associated with geocoded residential addresses. We employed Cox proportional hazards models to assess the association between average NW and risk of overall and site-specific obesity-related cancers over a period of nearly three decades.

RESULTS: Residing in neighborhoods with a higher walkability level was associated with a reduced risk of overall and site-specific obesity-related cancers. The hazards ratio (95% CIs) associated with a standard deviation increase in average annual neighborhood walkability was 0.88 (0.85-0.93) for overall obesity-related cancer, 0.89 (0.84-0.95) for postmenopausal breast cancer, 0.82 (0.68-0.99) for ovarian cancer, 0.87 (0.76-0.99) for endometrial cancer, and 0.68 (0.49-0.94) for multiple myeloma, adjusting for potential confounders at both the individual and neighborhood level. The association between NW and risk of overall obesity-related cancer was stronger among women living in neighborhoods with higher levels of poverty compared to women living in areas with lower poverty levels (p-value, interaction=0.006).

CONCLUSIONS: Our study highlights a potential protective role of NW in preventing obesity-related cancers in women.

KEYWORDS: Neighborhood walkability, urban health, women's health, obesity-related cancer.

P-0268 Association between woodsmoke and respiratory health: A Dutch panel study

Frederique Froeling[1], Jie Chen[1], Gerard Hoek[1], Kees Meliefste[1], Marieke Oldenwening[1], Miriam Gerlofs[2], Jos van Triel[2], Amber Woutersen[2], Dave de Jonge[3], Paula Bronsveld[4], Danielle van Dinther[4], Marcus Blom[4], CHARRED Citizen Scientists[1], Roel Vermeulen[1]

[1]Universiteit Utrecht, Utrecht, Netherlands, [2]RIVM, Bilthoven, Netherlands, [3]GGD Amsterdam, Amsterdam, Netherlands, [4]TNO, Petten, Netherlands

BACKGROUND AND AIM: In the Netherlands household fireplaces are responsible for burning about 1 billion kilograms of wood per year, emitting a significant amount of woodsmoke. Little is known about the respiratory health effects associated with the level of woodsmoke exposure present in the Netherlands. Thus, our aim was to investigate the short-term changes in lung function, respiratory symptoms and medication use associated with short-term changes in woodsmoke exposures in citizens with and without COPD/asthma. The study was co-created with citizens.

METHODS: We conducted a panel study with repeated observations in 46 adults (11 asthma/COPD) between February and May 2021 in four Dutch cities. Participants were asked to document symptoms and medication use in a daily diary and conduct daily home spirometry measurements in the morning and evening. Woodsmoke exposure was characterized by measuring various exposures at central sites in each study location set-up specifically for the study, and individual woodsmoke perception (smell) recorded in the daily diaries. The association between woodsmoke and health was analyzed using linear and logistic regression, adjusting for time-varying confounders and repeated observations.

RESULTS: We found significant positive associations between the specific wood smoke marker levoglucosan and shortness of breath during rest (OR 1.15 (95%CI 1.01, 1.32) per IQR increment for previous day exposure) and extra medication use (OR 1.19 (95%CI 1.07, 1.33) per IQR increment for current day exposure). We found weak associations between woodsmoke and nasal symptoms, and no consistent association with either morning or evening lung function measurements. The associations with levoglucosan remained after the inclusion of generic PM2.5 as a co-pollutant in the statistical models.
CONCLUSION: People experienced more shortness of breath at rest, nasal symptoms and used more medication on days with higher levels of outdoor woodsmoke exposure.

KEYWORDS: Woodsmoke, Levoglucosan, Respiratory health, Panel study.

P-0282 The relation of residential greenness with fetal growth and the role of air pollution in Eastern Massachusetts, USA

Michael Leung[1], Hari Iyer[2], Anna M Modest[3,4], Michele R Hacker[1,3,4], Blair J Wylie[3,4], Yaguang Wei[1], Joel Schwartz[1], Brent A Coull[1], Marc G Weisskopf[1], Francine Laden[1,4,5], Stefania Papatheodorou[1]
[1]Harvard TH Chan School of Public Health, Boston, USA, [2]Dana-Farber Cancer Institute, Boston, USA, [3]Beth Israel Deaconess Medical Center, Boston, USA, [4]Harvard Medical School, Boston, USA, [5]Brigham and Women's Hospital, Boston, USA

BACKGROUND AND AIM: There is growing evidence that green spaces may be beneficial for health. However, the effects on pregnant individuals and fetuses, including the underlying mechanisms, have been underexplored. We examined the association between neighborhood greenness and fetal growth, and the role of air pollution in these relationships (interaction and mediation) in a Massachusetts-based cohort.

METHODS: Our study consisted of 9,446 pregnancies that delivered at Beth Israel Deaconess Medical Center, Massachusetts in 2011-2016. Neighborhood greenness was estimated using normalized difference vegetation index (NDVI) with 270 m resolution. Fetal growth parameters included birth weight (BW), and ultrasound measures of biparietal diameter (BPD), head circumference (HC), femur length, and abdominal circumference (AC). Ultrasound parameters were classified into three distinct gestational periods: 16-23 weeks, 24-31 weeks, and 32+ weeks. We used distributed lag models to estimate the time-varying association between monthly NDVI and fetal growth. All models were adjusted for sociodemographic characteristics, and time trends. for models in which we identified an association, we tested for potential interaction with particulate matter ≤2.5 µm (PM2.5) and nitrogen dioxide (NO2) —predicted from well-validated ensemble models— and assessed for mediation by these pollutants.

RESULTS: We found that higher NDVI was positively associated with BPD, HC, AC, and BW. for example, a 0.1 NDVI increase sustained up until week 32 was associated with a higher mean AC z-score of 0.03 (95% CI: 0.01, 0.06), and a higher mean BW z-score of 0.02 (95% CI: 0.01, 0.03). We found no evidence for interaction or mediation by air pollution.

CONCLUSIONS: Residential greenness was associated with larger fetal growth measures. Our effect decomposition suggests that the association of greenness with fetal growth is independent from associations with local air pollution.

KEYWORDS: greenness, air pollution, fetal growth, ultrasound, pregnancy, interaction, mediation

P-0295 Road traffic noise and incidence of primary hypertension: a prospective analysis in UK Biobank

Jing Huang[1,2], Teng Yang[2], John Gulliver[3,4], Anna L Hansell[3,4], Mohammadhossein Mamouei[1], Yutong Samuel Cai[3,4], Kazem Rahimi[1]

[1]Deep Medicine, Nuffield Department of Women's and Reproductive Health, University of Oxford, Oxford, UK, [2]Department of Occupational and Environmental Health Sciences, School of Public Health, Peking University, Beijing, China, [3]Centre for Environmental Health and Sustainability, University of Leicester, Leicester, UK, [4]National Institute for Health Research Health Protection Research Unit in Environmental Exposures and Health at the University of Leicester, UK

BACKGROUND AND AIM The quality of evidence regarding the associations between road traffic noise and hypertension is low due to the limitations of cross-sectional study design, with the role of air pollution remains to be further clarified. To evaluate associations of long-term road traffic noise and air pollution exposure with incident primary hypertension, we conducted a prospective population-based analysis in UK Biobank.

METHODS: Road traffic noise was estimated at baseline residential address using the Common Noise Assessment Method model. Incident primary hypertension (ICD 10: I10) was ascertained through linkage with medical records for ~250 000 participants. Cox proportional hazard models were used to estimate hazard ratios (HRs) for association between road traffic noise and incident primary hypertension, adjusting for covariates determined via directed acyclic graph.

RESULTS: During a median of 8.1 years follow up, 21 185 incident primary hypertension cases were ascertained. The HR for a 10 dB[A] increase in mean weighted average 24-h road traffic noise level (Lden) exposure was 1.08 [95% confidence interval (CI) 1.02, 1.14]. A dose-response relationship was found, with HRs of 1.14 (95% CI: 1.04, 1.26) for Lden > 65dB[A] vs. ≤ 55dB[A] (P trend <0.05), and HRs of 1.15 (95% CI: 1.04, 1.26) for night-time road traffic noise (Lnight)>55 dB[A] vs. ≤ 45dB[A] (P trend <0.05). The associations were all robust to adjustment for fine particulate matter (PM2.5) and nitrogen dioxide (NO2). Furthermore, the highest incident hypertension risk was seen in the group who were exposed to the highest level of both road traffic noise and air pollution.

CONCLUSIONS:Long-term exposure to road traffic noise was associated with increased incidence of primary hypertension, and the effect estimates were greater in those with higher air pollution exposure.

KEYWORDS: road traffic noise; air pollution; primary hypertension; prospective analysis

P-0298 Association between greenspace exposure and different domains of cognitive function in the French CONSTANCES cohort

Ana Ramos[1,3,4], Mohammad Javad Zare Sakhvidi[2], Antoine Lafontaine[1], Payam Dadvand[3,4,5], Kees de Hoogh[6,7], Emeline Lequy[8], Noémie Letellier[9], Marion Mortamais[10], Anna Ozguler[8], Danielle Vienneau[6,7], Marcel Goldberg[8], Marie Zins[8], Claudine Berr[10,11], Bénédicte Jacquemin[1]

[1]Univ Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) – UMR_S, Rennes, France, [2]Department of Occupational Health, School of Public Health, Yazd Shahid Sadoughi University of Medical Sciences, Yazd, Iran, [3]ISGlobal, Barcelona, Spain, [4]Universitat Pompeu Fabra (UPF), Barcelona, Spain, Barcelona, Spain, [5]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [6]SwissTropical and Public Health Institute, Allschwil, Switzerland, [7]University of Basel, Basel, Switzerland, [8]Université de Paris, Unité UMS 011 "Cohortes en Population" INSERM, Université Paris Saclay, UVSQ, Paris, France, [9]Herbert Wertheim School of Public Health and Human Longevity Science & Scripps Institution of Oceanography, UC San Diego, La Jolla, USA, [10]Université de Montpellier, INM, Institute of Neurosciences of Montpellier, Inserm U1298, F34091, Montpellier, France, [11]Memory Research and Resources Centre, Department of Neurology, Montpellier University Hospital Gui de Chauliac, Montpellier, France

BACKGROUND AND AIM: Greenspace has been suggested to be associated with better cognitive function in adults. We assessed the association between residential surrounding greenspace and different domains of cognition in the French CONSTANCES cohort.

METHODS: We included 76,482 participants aged 45 and older, who performed tests at enrollment (2012-2019) on three cognitive domains: episodic memory (fast free and cued recall), language skills (semantic and lexical fluency), and executive functions (digit-symbol substitution, trail making test part A and B [TMT-A and TMT-B]), and a global cognitive score (a composite of these six tests). Residential surrounding greenspace was quantified using satellite-based Normalized Difference Vegetation Index (NDVI) at 300m buffer around the participant's home in the enrollment year. We modeled the cross-sectional associations for urban, suburban, isolated cities, rural, and Paris separately, using multiple linear regressions on standardized outcomes (TMT-A and TMT-B were log-transformed) adjusted for age, sex, education, recruitment center, neighborhood deprivation, and air pollution.

RESULTS: The participants were 57.6±7.2 years old, 54.9% women, and 49.7% with university education. Average NDVI at 300m buffer (IQR: 0.26) was 0.58±0.14, 0.67±0.12, 0.71±0.11, 0.81±0.08, and 0.35±0.09 for urban, suburban, isolated cities, rural, and Paris respectively. We found significant beneficial association between residential surrounding greenspace and semantic fluency at urban, suburban, isolated cities, and rural areas (ß=0.048 [95% CI: 0.018, 0.079], 0.068 [0.037, 0.098], 0.105 [0.033, 0.177], 0.096 [0.033, 0.158] respectively). We also observed similar beneficial associations for executive functions in urban and suburban areas. No associations with greenspace were found for episodic memory, lexical fluency, and global cognitive score in most communes of residence.

CONCLUSION

Exposure to greenspace could be beneficial for cognition, especially semantic and executive functions, in adults. Urban and suburban residents probably gain more cognitive benefits from greenspace.

P-0301 Validation and Improvement of the Dutch Obesogenic Built Environment Characteristics Index

Thao Minh Lam[1,2,3], Haykanush Ohanyan[1,2,3,4], Nicolette Roelina den Braver[1,2,3], Ilonca Vaartjes[5], Derek Karssenberg[6], Alfred J Wagtendonk[1,2,3], Joline WJ Beulens[1,2,3,5], Jeroen Lakerveld[1,2,3]

[1]Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Epidemiology and Data Science, Amsterdam, Netherlands, [2]Amsterdam Public Health, Health Behaviours and Chronic Diseases, Amsterdam, Netherlands, [3]Upstream Team, Amsterdam UMC, VU University Amsterdam, Amsterdam, Netherlands, [4]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, [5]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands, [6]Department of Physical Geography, Faculty of Geosciences, Utrecht University, Utrecht, Netherlands

BACKGROUND AND AIM

Neighbourhood characteristics can influence physical activity and dietary behaviours, and therefore impact body weight. Characterizing neighbourhoods in terms of their 'obesogenicity' has useful applications in research and policymaking. Our study aimed to (1) develop a basic Obesogenic Built environment CharacterisTics (OBCT) index quantifying obesogenicity of all neighbourhoods in the Netherlands and (2) examine the associations between the index and overweight in a large population survey.

METHODS: The basic OBCT index consists of 20 equally-weighted components from both the food (densities of five food outlet types and an overall healthiness score) and physical activity environments (walkability, drivability, bikeability and sports facilities). We linked the index to residential addresses of 258,552 adult participants (>18 years old) of the Dutch Health Monitor, a nationwide cross-sectional survey in 2016; and analyzed the index by logistic regression against odds of overweight (BMI>25.0kg/m²), adjusting for individual demographic characteristics. Effect modification by age, sex and urbanicity was examined.

RESULTS: The OBCT index ranged from 0 (leptogenic) to 100 (obesogenic) across all Dutch neighbourhoods (mean=55.7, SD=10.5 for surveyed individuals). Mean BMI was 26.0 (SD=4.26) kg/m² with an oversampling of older adults >65 years old (n=131,296). The odds ratio (OR) of overweight per 10% increase in obesogenicity was 1.01 (95%CI:1.00-1.01) in a fully adjusted model, which was significantly higher for older adults (OR: 1.02, 95%CI:1.01-1.03) compared to those <65 years old (OR:1.00, 95%CI:0.99 -1.01). Associations were also significantly stronger for rural (OR:1.04, 95%CI:1.02-1.05) compared to urban residents (OR:1.00, 95%CI:0.98-1.01) but not for sex.

CONCLUSION

The basic OBCT index had limited association with BMI outcomes. As improvement, individual components of the index will be reweighted using four data-driven

METHODS: logistic regression, supervised principle component, random forest, and data envelopment analysis. Results of these modified weights in terms of predictive power for the resulting indices will be presented.

P-0304 Modeling MODIS LST at European scale

Alonso Bussalleu[1], Kees de Hoogh[1], Gerard Hoek[3], Itai Kloog[2]
[1]Swiss Tph, Basel, Switzerland, [2]Department of Geography and Environmental Development, Ben-Gurion University of the Negev, Beer Sheva, Israel, [3]Departement Population Health Sciences, Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, Netherlands

BACKGROUND
To harmonize exposure assessment of temperature in multi-cohort studies, models require to cover large temporal and geographical extends at high resolution. The daily 1km Land Surface Temperature (LST) product from MODIS instrument is an important satellite predictor in ambient temperature models. However, LST products present an uneven data distribution due to cloud and snow cover. Interpolating LST "gaps" can become computationally expensive and require performance indicators to evaluate spatial and temporal stability and overfitting. Traditional (global) performance indicators might not be sensitive to changes in performance resulting from local data density and autocorrelation structures.
This study aims (1) to evaluate different model configurations to understand how LST spatial and temporal data density patterns affect model performance at global and local levels, and (2) to identify the most stable models.

METHODS: We aggregated observations into 100km² spatial blocks, trained random forest models and evaluated performance through 5-fold block cross-validation. We tested different model configurations based on the number of predictor variables (latitude, longitude, elevation, date, NDVI & climatic variables), the model's temporal extent and the number of sampled instances per block for Europe.
RESULTS: Adding predictor variables and increasing the temporal extent dramatically increased time, but not performance. Sampling 25% of the maximum amount of observations per block show the largest drops in RMSE, while keeping the computational times low. We showed some evidence of overfitting when training large extents and sample sizes due to limited representativeness at blocks with less instances. Our best model showed a CV-RMSE of 2.4 Kelvin with 90% of mean RMSE at the block level below 0.93 Kelvin.
CONCLUSIONS: Using a block sampling approach can balance sample size, thus limiting overfitting and computational time.

KEYWORDS: Europe wide, temperature modelling, block cross-validation, Land surface temperature

P-0316 Improved Hyperlocal Air Quality Mapping: Can Traditional Deterministic Modelling Leverage Mobile Monitoring via Hybrid Modelling Approaches?

Jibran Khan[1,2], Jules Kerckhoffs[3], Zhendong Yuan[3], Thomas Ellermann[1], Matthias Ketzel[1,4], Steen Solvang Jensen[1], Roel Vermeulen[3,5], Gerard Hoek[3], Kees Meliefste[3], Ole Hertel[6]

[1]Department of Environmental Science, Aarhus University, Roskilde, Denmark, [2]Danish Big Data Centre for Environment and Health (BERTHA), Aarhus University, Roskilde, Denmark, [3]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, the Netherlands, [4]Global Centre for Clean Air Research (GCARE), University of Surrey, Guildford, UK, [5]Julius Centre for Health Sciences and Primary Care, University Medical Centre, University of Utrecht, the Netherlands, [6]Department of Ecoscience, Aarhus University, Roskilde, Denmark,

BACKGROUND AND AIM: Recent advances in mobile monitoring offer excellent opportunities to explore the hyperlocal variation of ambient air pollution. One example is Google Street View (GSV) car equipped with high-quality instruments. Here, some challenges are translating on-road pollution levels to the building façades and the scalability of such mapping at large spatial scales, e.g. national scale. Since "traditional" deterministic modelling has been a reliable method for pollution assessment and mapping, this talk aims to explore whether deterministic modelling, via hybrid modelling, can help address the challenges mentioned above and leverage mobile monitoring for improved pollution mapping.

METHODS: Three GSV cars measured hyperlocal levels of nitrogen dioxide (NO2), black carbon (BC) and Ultrafine particles (UFP) on all streets of Amsterdam (N = 46664) and Copenhagen (N = 28499) from October 2018 to March 2020. The measurements were corrected and, among others, compared with pollution estimates from national prediction models, the Danish DEHM-UBM-AirGIS, and the Dutch NSL (National Collaborative Air Quality Programme). Further, model estimates are incorporated with GSV measurements to test and apply hybrid modelling approaches using statistical (e.g. kriging) and machine learning techniques.

RESULTS: Overall, Amsterdam's measured pollution levels were relatively higher (e.g. median NO2 = 24 µg/m3) than in Copenhagen (median NO2 = 13 µg/m3). In addition, GSV NO2 measurements correlated moderately (Spearman's r = 0.50) (N = 7004) with the NSL estimates in Amsterdam, whereas in Copenhagen, the Spearman's correlation (r) was in the range 0.45 – 0.67 (N = 97 and 58234).

CONCLUSIONS: High-quality mobile monitoring offers a great way to study the hyperlocal variation of air pollution. Since the modelled vs measured correlation was moderate to slightly high, combining both datasets may better predict external data. The presentation will reflect on hybrid model development.

KEYWORDS: Mobile measurements, Google Street View, deterministic modelling, AirGIS, hybrid model

THEMATIC 07: Climate change and Health

P-0554 The prospective effects of Climate change on Neglected Tropical Diseases in the Eastern Mediterranean region: A review

Ahmed Al-Delaimy[1]
[1]*University of Anbar, Medical College, Baghdad, Iraq*

BACKGROUND AND AIM: An increase in the annual daily temperature is documented and predicted to occur in the coming decades. Climate change has a direct effect and adverse impact on human health, as well as on multiple ecosystems and their species. The purpose of this paper is to review the effect of climate change on neglected tropical diseases including leishmaniasis, schistosomiasis, and lymphatic filariasis in the Eastern Mediterranean Region (EMR).

METHODS: A list of engine web searches was done; 280 full-text records were assessed for eligibility. Only 48 original records were included within the final selection for the review study.

RESULTS: Most research results show an alteration of neglected diseases related to climate change influencing specifically the Eastern Mediterranean Region, in addition to the expectation of more effects at the level of vectors and reservoir whether its vector transmission route or its egg hatching and replication or even the survival of adult worms in the coming years. at the same time, not all articles related to the region interpret the direct or indirect effect of climate variations on these specific diseases.
CONCLUSION: Although few studies were found describing some of climate change effects on neglected tropical diseases in the region, still, the region lacks research funding, technical, and mathematical model expertise regarding the direct effect of climate change on the ecosystems of these neglected tropical diseases

KEYWORDS: climate change, neglected tropical diseases, Eastern Mediterranean region

P-0577 Short-term effects of air temperature on mortality in the Norwegian CONOR cohort – results of the EXHAUSTION project

Shilpa Rao-Skirbekk[1], Siqi Zhang[2], Terese Bekkevold[1], Alfonso Diz-Lois Palomares[1], Alexandra Schneider[2], Per Schwarze[1]

[1]Norwegian Institute of Public Health, Oslo, Norway, [2]Helmholtz Zentrum München – German Research Center for Environmental Health, Germany

BACKGROUND AND AIM: Short-term health effects of air temperature have been extensively investigated at the population level. However, such effects have rarely been assessed using individual-level data. This time-stratified case-crossover study examined short-term associations of air temperature with cause-specific mortality and potential effect modification by individual characteristics in the Cohort of Norway (CONOR) cohort.

METHODS: CONOR recruited ~173,000 participants from 1994 to 2003. Participants' vital status and cause of death were collected from the Cause of Death Registry of Norway. Daily mean air temperatures estimated by a spatial-temporal model were assigned to participants' residences. We applied conditional logistic regression models with the distributed lag non-linear model approach to assess cold and heat effects on cause-specific mortality up to a lag of 10 days. Effect modification was examined by an interaction term between air temperature and potential modifiers.

RESULTS: We identified 40,040 cases of natural-cause deaths through December 31, 2018, including 14,457 deaths from cardiovascular diseases and 3,699 deaths from respiratory diseases. The mean air temperature during the study period was 5.0 °C (SD: 7.5 °C). We observed an increased risk of natural-cause mortality (OR: 1.12, 95% CI: 0.99, 1.27) for a decrease in temperature from the 25th (0 °C) to the 1st (-13.3 °C) percentile. This was accompanied by a trend for increased risks of cardiopulmonary, cardiovascular, ischemic heart disease, and cerebrovascular mortality associated with decreasing air temperature. The cold effect on natural-cause mortality was more pronounced among participants who were female, had lower socioeconomic status, lived in sparsely populated areas, and had no history of CVD. We did not find adverse heat effects on mortality.

CONCLUSIONS: We find evidence for adverse short-term cold effects on mortality at the individual level in Norway and identify the sub-populations that are potentially most vulnerable.

KEYWORDS: Air temperature, mortality, cardiovascular, respiratory, susceptibility

P-0580 Ambient heat and emergency department visits for mental health in Canada: assessing temporal variations by greenspace, urbanicity and socioeconomic status

Eric Lavigne[1], Alana Maltby[2], Ana Maria Vicedo Cabrera[3], Kate Weinberger[4], Piotr Wilk[2]
[1]Health Canada, Ottawa, Canada, [2]Department of Epidemiology and Biostatistics, Schulich School of Medicine and Dentistry, Western University, London, Canada, [3]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, [4]School of Population and Public Health, University of British Columbia, Vancouver, Canada

BACKGROUND AND AIM: Although previous research has suggested that greenspace might attenuate health risks associated with ambient heat, there is limited research on mental health disorders. Thus, we evaluated the effect modification of greenspace on heat-related mental health emergency department (ED) visits and whether these effects changed over time.

METHODS: We conducted a case-crossover study for mental health-related ED visits in Canada between 2004 and 2021 during warm-season months (May to August). ED visits for all Canadians living in 111 health regions were included. Daily average temperature as well as greenspace exposure, estimated by the Normalized Difference Vegetation Index (NDVI), were assigned to individuals at their residential location. Extreme heat was defined as the 95th percentile of the health region-specific warm-season temperature distribution. Conditional logistic regression was used to estimate associations between heat and mental health-related ED visits.

RESULTS: A total of 10,638,372 ED visits for any mental health condition were included. Days of extreme heat were associated with an increased risk of ED visits for any mental health condition (OR = 1.07; 95% CI: 1.05-1.09). In the earlier part of the study period (2004–2009), the associations between ambient heat and mental health ED visits were stronger among individuals exposed to the lowest quartile of NDVI exposure (OR = 1.20; 95% CI: 1.15-1.25), compared to individuals in the highest quartile of NDVI (OR = 1.01; 95% CI: 0.96-1.07). This difference, however, accentuated in the later part of the study (2016-2021) with the ORs for regions in the lowest quartile of NDVI increasing to 1.29 (95% CI: 1.25-1.34) and remaining stable for regions in the highest quartile. Effects appeared strongest in the most deprived socioeconomic areas.

CONCLUSIONS: Potential health benefits of greenspaces should be considered in mitigation strategies regarding the impacts of climate change on mental health ED visits.

P-0590 Association between high temperature and hospital admissions for kidney diseases: a nationwide study

Elisa Gallo[1], Hicham Achebak[2], Cristina O'Callaghan-Gordo[2,3,4,5], Oriana Ramírez-Rubio[2,6], Joan Ballester[2], Xavier Basagaña[2]

[1]Unit of Biostatistics, Epidemiology and Public Health, Depanrtment of Cardiac, Thoracic, Vascular Sciences and Public Health, Uiversity of Padova, Padova, Italy, [2]Institute for Global Health, Barcelona, Spain, [3]Universitat Pompeu Fabra, Barcelona, Spain, [4]CIBER Epidemiología y Salud Pública, Madrid, Spain, [5]Universitat Oberta de Catalunya, Barcelona, Spain, [6]Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: High temperatures have a known impact on human morbidity and mortality.
Few small time series studies have documented associations between acute kidney injury (AKI) and temperature. Studies conducted on agricultural workers found an association between AKI and chronic kidney disease (CKD) of unknown origin. The association between temperature and kidney diseases was less investigated on the general population and on a large scale. The aim of this study is to evaluate the effect of temperature on kidney diseases hospital admissions in Spain.

METHODS: Data on daily hospital admission for AKI and CKD were retrospectively collected from 2004 to 2019 in Spain. A Conditional Poisson regression combined with Distributed Lag Non-Linear Models was applied to evaluate the overall cumulative effect of maximum temperature among the 7 days preceding the admission. Models were adjusted for humidity and national holidays, and analyses were also stratified by age and sex.

RESULTS: Overall, 244,348 and 39,448 admissions for AKI and CKD were registered, respectively. We observed a J-shaped curve for the association between AKI and temperature with a minimum morbidity temperature of 7°C. The overall cumulative relative risk (RR) at the 99th percentile versus the minimum morbidity temperature percentile was 1.46(95%CI:1.37-1.55). The impact of high temperature remained strong also in the analyses stratified by age and sex with the highest risk observed in the young (<65years) population (RR:1.59; 95%CI:1.43-1.75). Concerning CKD, results were not clear and varied by age and sex. An increased risk of being admitted for CKD in association with high temperature was observed among young males.

CONCLUSIONS: High temperatures increased the risk of AKI hospital admissions in the general population, whereas less evidences were found for CKD. Dehydration and hyperthermia caused by high temperatures may stress renal function leading to kidney injury.

P-0599 Describing cumulative exposure related to heat stress in France to support adaptation

Lucie Adelaide[1,2], Ian Hough[2,3], Emie Seyve[2], Itai Kloog[3], Mathilde Pascal[1], Johanna Lepeule[2]
[1]Santé publique France, 94415 Saint-Maurice Cedex, France, [2]Univ. Grenoble Alpes, Inserm, CNRS, IAB, 38700 La Tronche, France, [3]Department of Geography and Environmental Development, Ben-Gurion University of the Negev, Be'er Sheva, Israel

BACKGROUND AND AIM: Differential exposure to multiple environmental factors and social deprivation can enhance health vulnerabilities and thus limit the exposed population's capacity to adapt to climate change. We aimed to identify hotspots of cumulative exposure to urban heat island, air pollution, deficit of green spaces and social deprivation in continental France and to describe their evolution between 2000 and 2018.

METHODS: Daily gridded exposure to minimum, mean and maximum temperature and mean PM2.5, PM10 and NO2, were estimated based on validated exposure models with high spatial resolution (200m to 1km). Winter and summer mean NDVI (Normalized Difference Vegetation Index) was estimated using Landsat satellite images with a 30m spatial resolution. Over-exposure to temperature, air pollution and deficit of green spaces was assessed by defining thresholds for each indicator that are based on potential underlying health risks. WHO air quality guidelines were used to define over-exposure to air pollution. for temperature and green spaces, reference values were defined for each department by type of climate and urbanization rate. The frequencies of exceedance days for mean temperatures, PM10, PM2.5 and NO2 concentrations over a year were calculated and combined altogether with a deficit of green spaces indicator. The differential exposure to environmental hotspots related to social deprivation, assessed through European Deprivation Index (EDI) and French Deprivation Index (FDep), was studied by using distributions comparison methods.
CONCLUSION
This study will provide the first picture of fine scale exposure to heat stress and its co-exposures at a national scale. This work could be used to study the combined effect of temperature, air pollution, greenspace and social deprivation on health outcomes.

KEYWORDS: Social deprivation; environmental burden; spatial inequality; cumulative environmental exposures

P-0604 Extreme temperatures and cause-specific mortality in a temperate climate zone: a case-crossover study in Central Mexico

Ivan Gutierrez-Avila[1], Just A. C.[1]
[1]*Icahn School of Medicine at Mount Sinai, New York City, USA*

BACKGROUND AND AIM. The association between exposure to extreme temperatures with non-external mortality has been well documented in high-income regions. However, fewer studies have investigated this association with cause-specific mortality, especially in temperate climate zones. Understanding the link between extreme temperature and cause-specific mortality can inform targeted mitigation strategies.

METHODS: We conducted a time-stratified case-crossover study, including ~1.5 million ICD-10 coded deaths, to estimate the risk of cause-specific mortality associated with daily mean temperature (Tmean), in the Mexico City Metropolitan Area, 2004-2019. Tmean and $PM_{2.5}$ predictions came from our 1x1km satellite-based models for the region. We fit conditional logistic regressions with distributed lag non-linear Tmean terms exploring up to 21 days of lagged effects of Tmean on mortality. We estimate mortality risks for extreme-heat (99th Tmean-percentile), and extreme-cold (1st Tmean percentile) compared to the minimum mortality temperatures (MMT) stratified for age group, sex, or cause-specific mortality.

RESULTS: MMTs varied by age group, sex, and cause of death [MMT=11.2°C (3rd Tmean percentile) for suicides to MMT=21.3°C (98th Tmean percentile) for renal failure]. Overall, single-lag effects from extreme-heat peaked at lags 0-2, and remained positive one week after exposure. for extreme-cold, the strongest positive single-lag effects started at lag 2. Extreme-heat (cumulative $lag_{0\text{-}6}$) exhibited the strongest associations with suicides (OR=1.46, 95%CI: 1.16-1.90), ischemic stroke (OR=1.40, 95%CI: 1.14-1.71), chronic respiratory disease (OR=1.12, 95%CI: 1.03-1.22), pulmonary heart disease (OR=1.12, 95%CI: 0.86-1.44) and ischemic heart disease (OR=1.08, 95%CI: 1.04-1.12). Extreme-cold related mortality (cumulative $lags_{0\text{-}21}$) was stronger for extrapyramidal disorders, hypertensive disease, chronic respiratory disease, ischemic and hemorrhagic stroke.
CONCLUSION. Our results suggest that preventing temperature-related mortality in moderate climate zones should consider varying susceptibility for underlying health conditions.

P-0611 Climate change and cardiovascular disease mortality: exploring the association in Puducherry, India

Shreya Shrikhande[1,2,7], Hugo Pedder[3], Martin Roosli[1,2], Mohamed Aqiel Dalvie[4], Lakshmanasamy Ravivarman[5], Antonio Gasparrini[6], Juerg Utzinger[1,2], Gueladio Cisse[1,2]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]University of Basel, Basel, Switzerland, [3]Population Health Sciences, University of Bristol, Bristol, UK, [4]Centre for Environmental and Occupational Health Research, School of Public Health and Family Medicine, University of Cape Town, Cape Town, South Africa, [5]State Surveillance Officer, Department of Health and Family Welfare Services, Govt. of Puducherry, Puducherry, India, [6]Department of Public Health Environments and Society,Centre for Statistical Methodology, London School of Hygiene and Tropical Medicine, London, UK, [7]This project has received funding from the European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No 801076, through the SSPH+ Global Fellowship Programme in Public Health Sciences (GlobalP3HS) of the Swiss School of Public Health.,

BACKGROUND AND AIM: Climate change has far reaching consequences on all aspects of life, including health. Cardiovascular diseases (CVDs), the global leading cause of death, have also been found to be climate sensitive, mainly to temperature. However, the associations between CVDs and temperature are region-specific with relatively few studies on the topic from low-and-middle-income countries (LMICs). This study explores these associations in Puducherry, a coastal district in Eastern India.

METHODS: We analyzed the association between apparent temperature (Tapp) and CVD mortalities to estimate the burden of in-hospital CVD mortalities attributable to non-optimal temperatures between 2010-2020. We used a binomial regression model to analyze the temperature-mortality association along with a distributed lag non-linear model to capture the delayed and non-linear trends.

RESULTS: We found that the optimal temperature range for Puducherry is between 33^{o}C and 35^{o}C with respect to CVDs. Temperatures both above and below the optimal temperature range were associated with an increased risk of overall in-hospital CVD mortalities, resulting in a U-shaped association curve. Up to 20% of the CVD deaths could be attributable to non-optimal temperatures, with a slightly higher burden attributable to cold (11.2%) than heat (9.12%). We also found that males below 50 years of age were more vulnerable to colder temperatures while females above 50 years were more vulnerable to the heat. Mortality with cerebrovascular accidents was associated more with heat compared to cold, while ischemic heart diseases did not seem to be affected by temperature.

CONCLUSIONS: This study analyses the temperature-CVD mortality association for the first time in the Puducherry district. It also identified the age and gender differences in temperature attributable CVD mortalities, which can be socio-cultural. Further studies from India could identify the regional associations and enhance the development of regional and contextual climate-health action plans.

P-0698 Determinants of clean cooking fuels utilization in three peri-urban communities in Ghana: key lessons to inform national policy

Theresa Tawiah[1], Joseph Wilson[2], Sheila Abiemo[2], Stephaney Gyaase[1], Mathew Shupler[3], Rachel Anderson de Cuevas[3], Mieks Twumasi[1], Reginald Quansah[4], Elisa Puzzolo[3], Daniel Pope[3], Kwaku Poku Asante[1]

[1]Kintampo Health Research Centre, Research and Development Division of Ghana Health Service, Kintampo North Municipality, Bono East Region, Ghana, Kintampo, Ghana, [2]National Petroleum Authority, Ghana, Accra, Ghana, [3]Department of Public Health, Policy and Systems, University of Liverpool, Liverpool, UK, [4]University of Ghana, Accra, Ghana

Use of polluting fuels has negative effect on human health and the environment. Use of clean cooking fuels (liquefied petroleum gas (LPG) can address this burden but in Ghana adoption is low with accessibility, convenience and safety concerns being potential barriers to LPG use. In order to address these issues, the Ghanaian government launched a new LPG distribution model through cylinder recirculation in 2019 on a pilot basis

As part of the CLEAN-Air (Africa) project, we collaborated with National Petroleum Authority implementing the CRM to conduct face-to-face surveys of randomly selected households on household cooking fuels preferences and use in three peri-urban CRM pilot communities in Ghana. To analyse determinants of adoption and sustained use of LPG for cooking, individual, household and wider community characteristics were entered as covariates into logistic regression models as potential predictors.

A total of 5,008 respondents completed the questionnaires across the three communities (Obuasi; 1,987 (40.0%), Kwaebibirem; 1,731 (34.9%) and Hohoe; 1,248 (25.1%)). A total of 48.6% (Obuasi (50.1%); Kwaebibirem (44.4%); Hohoe (52.2%)) households reported currently using LPG as the main cooking fuel. Being head of the household, increased household size, home ownership, an indoor cooking area, increased educational status and an increased number of LPG burners were associated with household's choice of using LPG as a primary fuel. Households using an LPG stove with three or more-burners, were 68% [OR:1.68 (95%CI: 1.32, 2.14), 001] more likely to use LPG as a primary fuel than those using a single burner on top of the cylinder.

Given the importance of the CRM, understanding household level characteristics for adoption are important. Better education and awareness raising of benefits will be important in scaling adoption of LPG as a clean fuel for cooking at the household level.

KEYWORDS: clean cooking fuels, LPG, Cylinder Recirculation Model, primary fuel use

P-0687 Long-term exposure to PM2.5 and avoidable mortality in Colombia 2014-2019

Laura Andrea Rodriguez-Villamizar[1], Luis Carlos Belalcazar-Ceron Belalcazar-Ceron[2], Miss María Paula Castillo[2], Edwin Ricardo Sánchez[2], Victor Herrera[3], Dayana Milena Agudelo-Castañeda[4]
[1]Universidad Industrial de Santander (UIS), Bucaramanga, Colombia, [2]Universidad Nacional de Colombia, Bogotá, Colombia, [3]Universidad Autónoma de Bucaramanga, Bucaramanga, Colombia, [4]Universidad del Norte, Barranquilla, Colombia

OBJECTIVE: To compare estimates of surface PM2.5 concentrations in Colombia from 2014-2019 at municipality level derived from two global air quality models, as well as to quantify the avoidable deaths attributable to the long-term exposure to concentrations above the current PM2.5 annual mean national standard of 25 µg/m3 and projected standard of 15 µg/m3.

METHODS: We retrieved PM2.5 concentrations at the surface level from the ACAG and CAMSRA global air quality models for all 1,122 municipalities, and compare 28 of them with available concentrations from monitor stations. Annual mortality data 2014-2019 by municipality of residence and pooled effect measures for total, natural and specific causes of mortality were used to calculate the number of annual avoidable deaths and years of potential life lost.

RESULTS: Compared to surface data from 28 municipalities with monitoring stations in 2019, ACAG and CAMSRA models under or overestimated annual mean PM2.5 concentrations. Estimations from ACAG model had a mean bias 1,7 µg/m3 compared to a mean bias of 4,7 µg/m3 from CAMSRA model. Using ACAG model, estimations of total nationally attributable deaths to PM2.5 exposure over 25 and 15 µg/m3 were 142 and 34,341, respectively. Cardiopulmonary diseases accounted for most of the attributable deaths due to PM2.5 excess of exposure (38%). Estimates of YPLL due to all-cause mortality for exceeding the national standard of 25 µg/m3 were 2,381 years.

CONCLUSIONS: Comparison of two global air quality models for estimating surface PM2.5 concentrations during 2014-2019 at municipality scale in Colombia showed important differences. Avoidable deaths estimations represent the total number of deaths that could be avoided if the current and projected national standard for PM2.5 annual mean have been met, and show the health-benefit of the implementation of more restrictive air quality standards.

P-0694 Long-term ambient air pollution exposure and tuberculosis notification rates during 2005–2017 in Ningxia Hui Autonomous Region, China

Igor Popovic[2], Ricardo Soares Magalhães[2], Shu Kun Yang[3], Yu Rong Yang[3], Erjia Ge[4], Xiaolin Wei, Guy Marks[5], Luke Knibbs[1]

[1]The University of Sydney, Sydney, Australia, [2]The University of Queensland, Brisbane, Australia, [3]Ningxia Medical University, Yinchuan, China, [4]University of Toronto, Toronto, Canada, [5]University of New South Wales, Sydney, Australia

BACKGROUND AND AIM: Pulmonary tuberculosis (TB) is a persistent public health concern, with 1.3 million attributable deaths and 10 million new cases recorded annually worldwide. Low- and middle-income countries account for the greatest proportion of TB cases globally (>95%), where some of the highest levels of air pollution occur. Epidemiological studies of an association, however, have been limited in number. We conducted a small-area study in Ningxia, a low socioeconomic and high TB-burden area in rural China, using TB-registry data (2005 – 2017).

METHODS: We used TB registry data to determine if annual average concentrations of remote-sensing based estimates of ambient air pollution (particulate matter <2.5 µm; [PM2.5], nitrogen dioxide [NO2] ozone [O3]) were associated with township-level (n=358) TB notification rates. Pollutant effects on age-standardised TB-notification rates (as Incidence Rate Ratios [IRR]) at township-level were estimated using Generalised Estimating Equations.

RESULTS: Median concentrations of PM2.5, NO2, and O3 were 42 µg/m3 (IQR: 10 µg/m3), 15 ppb (IQR: 4 ppb) and 56 ppb (IQR: 1 ppb), respectively. In single pollutant models adjusted for socio-economic covariates, an interquartile range (IQR) increase (10 µg/m3) in PM2.5 was significantly associated with an increase in TB notification incidence rates (IRR: 1.35; 95% CI: 1.27–1.41). Comparable effects were observed per IQR (4 ppb) increase in NO2 (IRR: 1.23; 95% CI: 1.19–1.28). Ground-level ozone was not associated with TB-notification rate in any models. The observed effects remained consistent in multi-pollutant models, and when adjusted for indicators of household crowding, solid fuel use and remoteness.

CONCLUSIONS: These findings may suggest that improving air quality may have population-level health benefits in socio-economically disadvantaged, TB-endemic settings.

KEYWORDS: Tuberculosis, TB, respiratory disease, China, outdoor air pollution

P-0697 Effects of Environmental Pollution from Illegal Mining Activities on Community Health: A community-based study in Kenyasi, Ahafo Region

Prince Adoma[1]
[1]*University of Education, Winneba, Winneba, Ghana*

BACKGROUND AND AIM: Mining is the backbone of many economies in developing countries, however, its activities, no matter the scale, are disruptive to community health as a result of environmental pollution. The extent of environment pollution caused by mining activities is mainly due to illegal mining practices. The study aimed to determine perceived effects of environmental pollution from illegal mining activities on community health in Kenyasi, Ahafo Region.

METHODS: A community-based cross-sectional study was conducted between September to November, 2021. A multi-stage sampling technique was used to sample 410 community member resident in Kenyasi and data collected using a questionnaire. Data was analyzed using SPSS version 25. Frequencies, percentages, correlation and multiple linear regression tools were utilized at 0.05 confidence level.

RESULTS: Out of the 410 participants recruited for the study, 62.7% were males and a mean age of 34 years. Results from the study indicated that most of the participants (81.7%) think illegal mining causes environment pollution which has bad effect on community health. Correlation analysis indicated a positive relationship between environmental pollution from illegal mining and community health. Consequently, land pollution from illegal mining contributed the highest with coefficient of determination R2 = 0.35. The linear regression analysis showed that illegal mining activities were good predictors of the environmental conditions [F (3, 117) = 12.390 and p = 0.000], with surface mining being the best predictor. About 53.9% of the residents in the Kenyasi recommended building health facility was the best way of improving community health conditions in Kenyasi.
CONCLUSION
Illegal mining is a resource to every community; however, its activities are conducted with total disregard to community health. Therefore, government should strengthen the enforcement of environmental and safety laws to mitigate against harmful effect of environmental pollution.

KEYWORDS: Illegal mining, environmental pollution, community health, Kenyasi

P-0700 Main and added effects of heatwaves on hospitalizations for Mental and Behavioral Disorders in a tropical megacity of Vietnam

Tran Ngoc Dang[1], Nguyen Thi Tuong Vy[1], Do Thi Hoai Thuong[1], Dung Phung[2], Do Van Dung[1], Pham Le An[1]
[1]University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh City, Vietnam, [2]Centre for Environment and Population Health, School of Medicine, Griffith University, Brisbane, Australia, [3]Family Medicine Center, University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh, Vietnam,

BACKGROUND AND AIM: Vietnam is highly vulnerable to climate change-related extreme weather events such as heatwaves. This study assesses the association between heatwaves and hospitalizations due to mental and behavioral disorders (MBDs) in Ho Chi Minh City (HCMC).

METHODS: We collected daily MBD hospital admissions data at the HCMC Mental Health Hospital from 2017 to 2019. Heatwaves effects were characterized into the main effect (i.e., the intensity of temperature during heatwaves) and the added effect (i.e, the duration of heatwaves). Time series Poisson regression coupled with a distributed lag linear model (DLM) was used to quantify the 14-day lags effect of heatwaves. Confounders including long-term trend, seasonality, days of the week, holidays, relative humidity were included in the model.

RESULTS: Heatwaves increased all-cause MBD hospitalization by 62% (95%Cl, 36%–93%) for the main effect, and by 8% (95% Cl, -3%–19%) for the added effect. Noticeably, the group aged 18 to 60 years old was affected by the main effect of the heatwave, while the group aged 61 years and older was affected by the added effect of the heatwave. The effects of heatwaves differed among groups of MBD hospitalizations. The mental and behavioral disorder group due to psychoactive substance use was significantly affected by the main effect of heatwaves (RR:2.21; 95%Cl:1.55–3.15). The group of schizophrenia, schizotypal and delusional disorders were highly vulnerable towards both the main and the added effect of heatwaves with RR=1.50 (95%CI, 1.20–1.86) and RR = 1.14 (95%CI, 1.01–1.30), respectively.

CONCLUSIONS: These results aroused the need for adequate heat warning and adaptation programs when temperatures are not too high but prolonged, particularly with the elderly

P-0704 Geospatial modelling of road-traffic noise levels and frequency and the attributable burden of annoyance and sleep disturbance in Accra, Ghana

Sierra Clark[1], Abosede Sarah Alli[2], Majid Ezzati[1], Michael Brauer[3], Mireille Toledano[1], James Bennett[1], James Nimo[4], Josephine Bedford Moses[4], Solomon Baah[4], Allison Hughes[4], Ricky Nathvani[1], Jill Baumgartner[7], Samuel Agyei-Mensah[5], George Owusu[6], Raphael Arku[2]

[1]Department of Epidemiology and Biostatistics, Imperial College London, London, UK, [2]Department of Environmental Health Sciences, University of Massachusetts-Amherst, Amherst, USA, [3]School of Population and Public Health, The University of British Columbia, Vancouver, Canada, [4]Department of Physics, University of Ghana, Accra, Ghana, [5]Department of Geography and Resource Development, University of Ghana, Accra, Ghana, [6]Institute of Statistical, Social & Economic Research, University of Ghana, Accra, Ghana, [7]Institute for Health and Social Policy, McGill University, Montreal, Canada

BACKGROUND AND AIM: Limited city-wide data on environmental noise and sources in rapidly growing sub-Saharan African (SSA) cities constitutes a major barrier for investigating health impacts as well as environmental policy making. In a first of its kind study in SSA, we modelled and predicted noise levels and road-traffic-specific sounds in Accra, Ghana, and estimated the attributable burden of being highly annoyed and sleep disturbed in high-spatial resolution.

METHODS: From 2019-2020, we collected measurements of sound levels and audio recordings along the roadside in a large-scale campaign. The audio was processed with a deep learning acoustic classifier to identify the frequency of road-traffic sounds. We combined the acoustic data with geospatial predictors in land use regression models (mixed models/random forest) to predict noise levels (Lden, Lnight) and the frequency of road-traffic-specific sounds across the city. Finally, by combining population exposures to predicted Lden and Lnight with literature informed exposure-response relationships and disability weights, we estimated the attributable burden of being highly annoyed and sleep disturbed in aggregate and by census enumeration area (median size: 0.03km2).

RESULTS: Predicted road-traffic sounds were prevalent throughout the day (median: 81% of the time present) and nighttime (median: 62%) in Accra. Furthermore, 99% of the population in lived in census enumeration areas where average Lden and Lnight surpassed WHO guidelines for road-traffic noise (Lden <53; Lnight <45). Noise exposures in Accra translated into 21% and 7% of the population highly annoyed and sleep disturbed, with significant variation across areas, and a combined 10,761 Disability Adjusted Life Years lost.

CONCLUSIONS: In an area of the world where noise research is severely lacking, this work can support epidemiological studies, burden of disease assessments, and the development of policies and interventions that address noise exposure within Accra.

KEYWORDS: Noise, Africa, health burden, land-use-regression, audio processing, road-traffic noise

P-0729 Use of insecticide-treated nets and other household insecticides for preventing malaria in six-year-old children in Benin, sub-Saharan Africa

Florence Bodeau-Livinec[1,2], Kieran Kleman[2], Roméo Zoumenou[3], Manfred Accrombessi[4,6], Nadine Fiévet[3], Armel Djenontin[5], Achille Massougbodji[6], Philippe Glorennec[2]

[1]Ecole Des Hautes Etudes En Santé Publique, Rennes, France, [2]Univ Rennes, EHESP, Inserm, Irset (Institut de recherche en santé, environnement et travail) - UMR_S 1085, Rennes, France, [3]Institut de Recherche pour le Développement, Paris, France, [4]London School of Hygiene and Tropical Medicine (LSHTM), Faculty of Infectious Tropical Disease, Department of Control Diseases, London, UK, [5]Centre de Recherche Entomologique de Cotonou (CREC)/Centre de Recherche pour la lutte contre les Maladies Infectieuses Tropicales (CReMIT), Université d'Abomey-Calavi (UAC), Cotonou, Benin, [6]Institut de Recherche Clinique du Benin (IRCB), Abomey-Calavi, Benin

BACKGROUND AND AIM: In addition to early diagnosis and treatment of malaria, the cornerstone of malaria control lies in the use of insecticides such as long-lasting insecticidal treated nets (LLITNs), household spraying, mosquito coils or sprays. However, the quantification of other household insecticides use, including coils and sprays, was less assessed so far. The main insecticide used for LLITN, coils and sprays is pyrethroid. The objectives of the study were to describe the LLITN and other household insecticides used for preventing malaria and to determine factors associated with these different uses.

METHODS: Data were collected on 567 mothers from a birth cohort in the district of Allada, a semi-urban area in Benin. Mothers were interviewed using a standardized questionnaire when their offspring were 6 years of age. Associations between LLITNs, other household insecticide use, sociodemographic and environmental factors, were assessed using multiple logistic regression.

RESULTS: Eighty percent of mothers declared that their six-year-old child slept under a LLITN the night before the visit. Approximatively 23% and 7% of households used coils and sprays at home, respectively. When using coils, 62% of families were using them at least once a week. Being a girl, living with the father, having a high number of siblings at home, rainy season and non-use of coils at home were significantly associated with LLITN use. Use of coils was associated with non-LLITN use, having moved since child's birth and absence of stove in the house.

CONCLUSION

Children at six years of age were frequently sleeping under LLITN. However, a considerable proportion of them was sleeping in proximity to coils, but not under LLITN. These coils have no proven efficacy in the reduction of malaria vectors so far and may potentially expose children to pyrethroids.

THEMATIC 10: Environmental Equity

P-0755 Investigation on sociodemographic and health inequity of greenspace using different greenspace indicators in 3 US urban communities

Seulkee Heo[1], Michelle L. Bell[1]
[1]*School of the Environment, Yale University, New Haven, USA*

BACKGROUND AND AIM: Study results are inconclusive regarding how greenspace exposure differs by sociodemographic status potentially due to lack of consideration of varying dimensions of greenspace. We investigated the inequity of greenspace and its health effects by sociodemographic status comparing various greenspace metrics.

METHODS: We used five metrics: vegetation levels measured by Enhanced Vegetation Index (EVI), percent greenspace, percent tree cover, percent tree cover along walkable roads, and percent people living <500m of a park entrance (park accessibility). We used data for 2008–2013 in Census block groups in 3 US regions: New Haven, Connecticut; Baltimore, Maryland; Durham, North Carolina. We examined associations between each greenspace metric and indicators of income, education, linguistic isolation, race/ethnicity, and age. Logistic regressions examined associations between these greenspace metrics and age-standardized mortality controlling for sociodemographic indicators.

RESULTS: The region with the highest greenspace differed across metrics. Average percent greenspace was highest in Durham and lowest in Baltimore. Average percent people living <500m of a park entrance and percent tree cover along walkable roads were highest in New Haven. An interquartile range (64.7%) increase in people of color was associated with a 6.2% (95%CI: 3.1–9.3) increase in park accessibility, whereas it was associated with 0.03–7.3% decreases in other greenspace metrics. A 15.5% increase in the lower-education population was associated with a 2.1% increase (95%CI: -0.3%–4.6%) in park accessibility but decreases with other greenspace metrics (0.02–5.0%). The odds ratios of having an all-cause standardized mortality rate ≥75th percentile were inversely associated with all greenspace metrics except for park accessibility (OR=1.40, 95% CI: 0.52–3.75).

CONCLUSIONS: Environmental justice concerns and health benefits of greenspace can differ by form of greenspace and socioeconomic status within communities. Comparisons of greenspace between different greenspace metrics should be incorporated in decision-making.

KEYWORDS:
Environmental justice, greenspace, health inequity.

P-0758 Temperature and cardiovascular hospitalization in persons with and without disabilities: Invisible population in climate change discourse

Sera Kim[1], Jong-Tae Lee[1,2]
[1]Interdisciplinary Program in Precision Public Health, Department of Public Health Sciences, Graduate School of Korea University, Seoul, Republic of Korea, [2]School of Health Policy and Management, College of Health Sciences, Korea University, Seoul, Republic of Korea

BACKGROUND AND AIM: The adverse health effects of non-optimal temperatures are disproportionately distributed in the population due to differential susceptibility and adaptive capacity to heat and cold. Although persons with disabilities (PwD) can be one of the susceptible populations, they have been neglected in the climate change discourse. This study aimed to investigate the association of ambient temperature with cardiovascular hospitalization in persons with and without disabilities.

METHODS: This study used the National Health Insurance Service-National Sample Cohort established by South Korea. Using nationwide data from 2003 to 2013, we conducted a space-time-stratified case-crossover study using a conditional Poisson regression with a distributed lag nonlinear model to investigate the association between daily mean temperature and cardiovascular hospitalization. The extreme and moderate heat (99th and 95th temperature percentile, respectively) and cold (1st and 5th temperature percentile, respectively) effects on hospitalization over ten days were estimated using the minimum hospitalization temperature (MHT) as a reference. All analyses were conducted separately by the existence of a disability.

RESULTS: A J-shaped association between temperature and cardiovascular hospitalization was found with the MHT at 22.2°C and 15.9°C in persons with and without disabilities, respectively. In persons without disabilities, the effects of hot temperatures were acute and lasted several days, while the effects of cold temperatures appeared after 2-3 days. In PwD, the effects of hot temperatures lasted up to 10 days, while the effects of cold temperatures appeared immediately with the following deficit in hospitalizations. The cumulative cold effects over ten days were higher in PwD than their non-disabled counterparts, although the cumulative heat effects did not show a significant difference.

CONCLUSIONS: PwD were more susceptible to cold-related hospitalizations compared to their non-disabled counterpart. Precision adaptation strategies to heat and cold that considers susceptibility in PwD are needed.

P-0760 Historic redlining and the siting of oil and gas wells in the United States

David Gonzalez[1], Anthony Nardone[2], Andrew Nguyen[1], Rachel Morello-Frosch[1], Joan Casey[3]
[1]University of California, Berkeley, Berkeley, USA, [2]University of California, San Francisco, San Franisco, USA, [3]Columbia University, New York, USA

BACKGROUND AND AIM. The presence of active or inactive (i.e., postproduction) oil and gas wells in neighborhoods contributes to ongoing pollution. Racially discriminatory neighborhood security maps developed by the U.S. federal Home Owners Loan Corporation (HOLC) in the 1930s may contribute to environmental exposure disparities. Our aim was to determine whether receiving worse HOLC grades was associated with exposure to more oil and gas wells.

METHODS: We assessed exposure to oil and gas wells among HOLC-graded neighborhoods in 33 U.S. cities from 13 states where urban oil and gas wells were drilled and operated. Among the 17 cities for which 1940 census data were available, we used propensity score restriction and matching to compare well exposure neighborhoods that were similar on observed 1940 sociodemographic characteristics but that received different grades.

RESULTS: Across all included cities, redlined D-graded neighborhoods had 12.2 ± 27.2 wells km-2, nearly twice the density in neighborhoods graded A (6.8 ± 8.9 wells km-2). In propensity score restricted and matched analyses, redlined neighborhoods had 2.0 (1.3, 2.7) more wells than comparable neighborhoods with a better grade.

CONCLUSIONS: Our study adds to the evidence that structural racism in U.S. federal policy is associated with the disproportionate siting of oil and gas wells in marginalized neighborhoods.

KEYWORDS: Oil and gas, environmental justice, structural racism, health disparities

P-0766 Environmental Exposures in a Cohort of Swedish Women – Are there Inequalities by Socioeconomic Status?

Lara Stucki[1], Staffan Betnér[1,2], Mare Lõhmus[1,2], Jenny Selander[1], Agneta Åkesson[1], Charlotta Eriksson[1,2]
[1]Karolinska Institutet, Stockholm, Sweden, [2]Center for Occupational and Environmental Medicine, Region Stockholm, Stockholm, Sweden

BACKGROUND AND AIM: Recent reviews provide evidence for inequalities in environmental exposures between and within European populations. The aim of this study is to explore differences in exposure to air pollution, road-traffic noise, and greenness by multiple socio-economic determinants in a female cohort in Sweden.

METHODS: 20,407 women born in 1914-48 residing in Uppsala County, Sweden, were followed from 1997 until migration, death, or end of follow-up in 2017. We combined survey data, time-varying register data, and spatial-temporal modelled air pollutants ($PM_{2.5}$, PM_{10}, NO_2), road-traffic noise (Lden), and greenness (NDVI) at the residences. We descriptively assessed exposures over time and by categories of socio-economic variables, including age, civil status, employment status, education, individual, household, and area-based income, and municipality type. We applied linear regressions estimated with generalized estimating equations to assess differences in environmental exposures by socio-economic levels.

RESULTS: at baseline (1997), the average age of 19,953 women with complete data was 61.9 years, 50% were still employed and 56% lived in urban areas. Compared with the baseline population, 67.8% (n=12,682) remained at the end of follow-up (2017). Over the 20-y follow-up, the average exposure to $PM_{2.5}$, PM_{10}, and NO_2 declined significantly, however, levels of road-traffic noise and greenness were stable. Small but statistically significant differences in exposures were found across socio-economic levels. Suggested predictors of high exposure to air pollution, noise, and low greenness (only PM_{10} changes compared to references and 95%-CI in $\mu g/m^3$ shown) include high age (0.09 [0.05; 0.13]), being unmarried (0.09 [0.01; 0.17]), divorced/widowed (0.09 [0.05; 0.12]), or retired (0.03 [0.01; 0.05]), having high education (0.07 [0.004; 0.14]), high individual income (0.03 [0.003; 0.05]), but low area-based income (0.26 [0.20; 0.31]).
CONCLUSION: This study provides evidence of a complex interplay between environmental exposure and levels of socio-economic determinants.

KEYWORDS: Air pollution, road-traffic noise, greenness, socio-economy, inequality

P-0767 Sociodemographic Determinants of PFAS Contamination in United States Community Water Supplies: An Analysis of Sampling Data from 11 States

Jahred Liddie[1], Laurel Schaider[2], Elsie Sunderland[3]
[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Silent Spring Institute, Newton, USA, [3]Harvard John A. Paulson School of Engineering and Applied Sciences, Cambridge, USA

BACKGROUND AND AIM: Many studies show marginalized communities are disproportionately exposed to air pollution. However, relatively few studies have considered water quality disparities, including exposures to per- and polyfluoroalkyl substances (PFAS). We evaluated whether Community Water Systems (CWS) serving greater proportions of minority and low-income individuals had higher likelihoods of detecting PFAS and exceeding Maximum Contaminant Levels (MCL) using recent statewide drinking water monitoring data.

METHODS: We compiled drinking water PFAS concentration data from 11 states with statewide monitoring data and ancillary data on sociodemographics, CWS characteristics, active PFAS treatment, and PFAS sources. We examined associations between PFAS concentrations in drinking water and sociodemographics at various spatial units for 4,698 CWS (serving 62.2 million people) using multivariate logistic regressions.

RESULTS: CWS serving 20.8 million people (33%) had detectable concentrations (>5 ng/L) of at least one of five PFAS and those serving 16 million people (26%) exceeded the lowest state-level MCL for several PFAS. CWS with detectable PFAS levels and MCL exceedances served greater proportions of Hispanic and Black residents than those with PFAS levels below detection and without exceedances. at the county-level, a percentage point increase in the proportion of Hispanic residents served by a CWS was associated with a 4-6% increase in the odds of detecting PFAS. Results for state-level relationships were more mixed, although CWS in five of the 11 states had increased odds of detecting several PFAS for CWS serving counties with greater proportions of Hispanic residents.

CONCLUSIONS: Our findings suggest that CWS serving some communities with greater proportions of Hispanic and non-Hispanic Black residents have increased likelihood of detecting PFAS, including detection at levels above regulatory thresholds. These disparities are concerning and warrant consideration when planning remediation strategies and treatment for sites contaminated with PFAS.

P-0777 Fine particulate matter component air pollution in American Indian vs. Non-American Indian communities

Maggie Li[1], Jada Brooks[2], Markus Hilpert[1], Jeff Goldsmith[3], Steven Chillrud[4], Tauqeer Ali[5], Lyle Best[6], Joseph Yracheta[6], Jason Umans[7,8], Aaron van Donkelaar[9], Randall Martin[9], Ana Navas-Acien[1], Marianthi-Anna Kioumourtzoglou[1]

[1]Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [2]University of North Carolina School of Nursing, Chapel Hill, USA, [3]Columbia University Department of Biostatistics, New York, USA, [4]Lamont-Doherty Earth Observatory of Columbia University, New York, USA, [5]Department of Biostatistics and Epidemiology, College of Public Health, University of Oklahoma Health Sciences Center, Oklahoma City, USA, [6]Missouri Breaks Industries Research, Inc., Eagle Butte, USA, [7]MedStar Health Research Institute, Hyattsville, USA, [8]Georgetown/Howard Universities Center for Clinical and Translational Sciences, Washington DC, USA, [9]Department of Energy, Environmental and Chemical Engineering, Washington University, St. Louis, USA

BACKGROUND AND AIM: Exposure to fine particulate matter ($PM_{2.5}$) increases risk of numerous adverse health outcomes, with varying component-specific estimated effects. Prior work examining total $PM_{2.5}$ in primarily American Indian- (AI-) populated areas shows disparate trends over time compared to the rest of the US, with higher concentrations in more recent years. We compared trends in concentrations of six $PM_{2.5}$ components in American Indian (AI-) vs. non-AI-populated counties over time (2000 – 2017) in the contiguous US.

METHODS: Using a multi-criteria approach to classify counties as AI- or non-AI-populated, we ran component-specific linear mixed models to estimate differences in county-wide annual concentrations of sulfate, ammonium, nitrate, organic matter, black carbon, and soil from well-validated prediction models in AI- vs. non-AI-populated counties, adjusting for population density and median household income. We estimated whether trends in AI- vs. non-AI-populated counties varied over time using interaction terms with calendar year.

RESULTS: Our final analysis included 3,109 counties, of which 199 were classified as AI-populated (6.4%). On average, there was no difference in BC concentrations by AI-populated county type. Adjusted concentrations of all five other $PM_{2.5}$ components in AI-populated counties were significantly lower than in non-AI-populated counties. However, component-specific trends varied over time; sulfate and ammonium levels were significantly lower in AI- vs. non-AI-populated counties in 2000 but higher after 2011, nitrate levels were consistently lower in AI- counties, and black carbon, organic matter and soil levels showed inconsistent differences in AI- vs. non-AI-populated counties.

CONCLUSIONS: This study highlights how differences in time trends of certain components by AI-populated county type, namely sulfate and ammonium, are driving steeper declines in total $PM_{2.5}$ in non-AI vs. AI-populated counties, providing potential directives for air pollution regulations of key emissions sources on tribal and AI-populated lands.

P-0785 Modification by Multiple Social Stressors in Air Pollution-CVD Associations

Jane Clougherty[1], Jamie Humphrey[2], Ellen Kinnee[3]
[1]Drexel University Dornsife School of Public Health, Philadelphia, USA, [2]RTI International, Research Triangle Park, USA, [3]University of Pittsburgh University Center on Social and Urban Research (UCSUR), Pittsburgh, USA

BACKGROUND AND AIM: Susceptibility to urban air pollution is shown to vary by chronic psychosocial stressors (e.g., poverty, violence), though it remains unclear whether a confluence of multiple stressors may compound susceptibility, or confound observed modification by any one stressor.

METHODS: We examined modification by multiple community stressors on relationships between spatio-temporal pollutant exposures and risk of cardiovascular (CVD) event in New York City, using conditional logistic regression in a case-crossover design. We used exhaustive data on all inpatient (admitted) CVD events presenting at NYC emergency departments from 2005-2011 (n = 837,523), fine-scale spatial maps for PM2.5, NO2, SO2, and O3 from NYC Community Air Survey, and daily EPA pollution and NOAA weather data.
A range of stressor indicators were drawn from Census and administrative databases, examined against focus group and survey data to confirm relevance to residents' stress experience. Due to concern about stressors clustering by race and ethnicity (i.e., non-random assignment into tracts), we adjusted year-round models (NO2 and PM2.5) for modification by tract composition.

RESULTS: Testing stressors individually, we found significant associations between NO2 and CVD risk only in the highest quintile for violent crime, felony assault, poverty, or socioeconomic deprivation (SDI). Associations in all other quintiles were non-significant, as were associations for all other pollutants.
In models including separate interaction terms for violent crime and SDI, NO2 was associated with significant increases in CVD risk in all quintiles. Associations for NO2 modestly increased across quintiles of increasing violence, but not SDI.

CONCLUSIONS: Observed patterns of modification differed substantially when including multiple stressor modifiers, increasing observed NO2-CVD associations overall. These results suggest a need to capture community stress experience more holistically, to reduce confounding across stressors which may dampen observed pollutant-health associations and modification.

P-0796 Management of the Afghan Refugee Resettlement Crisis and Integration Challenges to Public Health

Absaar Ateeq[1], David Goldsmith[1]
[1]*George Washington University, Washington, USA*

BACKGROUND
After the peak of conflict in Afghanistan in 2021, 2.2 million Afghan refugees were left seeking asylum. The US welcomed 76,000 Afghan refugees and this brings challenges including resettlement issues, integration and access to public benefits to alleviate personal and mental health concerns. This article aims to study the benefits and challenges that refugees present when resettling into the US.

METHODS: The authors reviewed published health studies on Afghan refugees. They have engaged with non-profit organizations like the International Rescue Committee that are leading efforts to alleviate the challenges of US refugees. The authors communicated directly with refugees to understand their challenges. The primary issues include resettlement during a housing crisis in the US, access to healthcare, language barriers, job opportunities, and focusing on the integration challenges that come with moving to a foreign land.

RESULTS: The refugee crisis has collided with US housing shortage making it difficult and expensive to provide housing for unemployed refugees, leaving many in hotels for long periods of time. Refugee access to healthcare is difficult because of lack of coverage coupled with the fear of reaching out layered on concerns over costs, communication and cultural barriers, and transportation. Although the US provides a system to gain permanent legal residency and citizenship through the Special Immigrant Visa (SIV), the process is backlogged, and thus Afghan social integration is hampered.
CONCLUSION
There is a lack of federal involvement in the Afghan refugee crisis which has placed an overwhelming burden on local governments and non-profit organizations. We suggest forming a taskforce to study refugee challenges and how to overcome those hurdles. These challenges will have a lasting impact on these refugees, and if they are not resolved there will be serious consequences impacting them from a health and wellness standpoint.

P-0797 Per− and polyfluoroalkyl substances and psychosocial stressors have a joint effect on adverse pregnancy outcomes in the Atlanta African American Maternal-Child cohort

Stephanie Eick[1], Dana Barr[1], Patricia Brennan[2], Kaitlin Taibl[1], Youran Tan[1], Parinya Panuwet[1], Volha Yakimavets[1], P. Barry Ryan[1], Donghai Liang[1], Anne Dunlop[3]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Department of Psychology, Emory University, Atlanta, USA, [3]Department of Gynecology and Obstetrics, School of Medicine, Emory University, Atlanta, USA

BACKGROUND: African Americans (AAs) consistently experience high rates of adverse pregnancy outcomes relative to whites. Differential in utero exposure to environmental chemicals and psychosocial stressors may explain some of the observed health disparities, as exposures to per− and polyfluoroalkyl substances (PFAS) and experiences of discrimination have been linked to adverse birth outcomes, including preterm birth and fetal growth restriction. Few studies have examined chemicals and non-chemical stressors together as an exposure mixture, which may better reflect real-life exposure patterns. We adapted methods designed for the analysis of exposure mixtures to examine joint effects of PFAS and psychosocial stress on birth outcomes among AAs.

METHODS: Participants were a subset of the Atlanta African American Maternal-Child cohort for whom first trimester serum and questionnaire measures were available. Four PFAS (PFOA, PFOS, PFNA, PFHxS) were measured in 1st trimester serum samples and were natural log transformed for analysis. Validated questionnaires were administered during the first trimester and were used to assess psychosocial stress (perceived stress, depression, anxiety, gendered racial stress). Quantile g-computation and Bayesian kernel machine regression (BKMR) were used to estimate the joint effects between PFAS and psychosocial stressors on gestational age at delivery and birthweight for gestational age z-scores (N=348).

RESULTS: In quantile g-computation models, a simultaneous one quartile increase in all PFAS, perceived stress, depression, anxiety, and gendered racial stress was associated with a reduction in birthweight z-scores (mean change per quartile increase = -0.24, 95% confidence interval= -0.43, -0.06). BKMR similarly showed that increasing all exposures in the mixture was associated with a modest decrease in birthweight z-scores, but not a reduced length of gestation.

CONCLUSIONS: Using methods designed for analyzing exposure mixtures, we found that a simultaneous increase in in utero PFAS and psychosocial stressors was associated with reduced fetal growth.

KEYWORDS: stress, pregnancy, mixture, PFAS

P-0804 Exposomic Analysis of Organic Pollutants in Seminal Plasma and Male Reproductive Parameters

Haotian Wu[1], Vrinda Kalia[1], Katherine E. Manz[2], Lawrence Chillrud[1], Nathalie Hoffmann Dishon[3,4], Raoul Orvieto[3,4], Adva Aizer[3,4], Hagai Levine[5], Marianthi-Anna Kioumourtzoglou[1], Kurt D. Pennell[2], Ronit Machtinger[3,4], Andrea A Baccarelli[1]

[1]Columbia University Mailman School of Public Health, New York, USA, [2]School of Engineering, Brown University, Providence, USA, [3]Infertility and IVF Unit, Department of Obstetrics and Gynecology, Chaim Sheba Medical Center, Ramat Gan, Israel, [4]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [5]Hebrew University-Hadassah, Jerusalem, Israel

Previous studies of environmental exposures and male reproductive health have typically examined limited sets of exposures in the urine, which may not accurately capture the chemical burden in relevant tissues and do not consider a large range of concurrent exposures. Here, we used a combined targeted and untargeted exposome approach to identify novel associations of environmental pollutants found in seminal plasma, as individual metabolites and co-exposure patterns, with male reproductive parameters.

Semen samples were collected from male partners from 100 heterosexual couples undergoing assisted reproductive treatment in Tel Aviv after 2-7 day abstinence. Semen parameters were assessed for sperm concentration, percent motility, and total motile sperm. Using a novel QuEChERS (quick, easy, cheap, efficient, rugged, and safe) extraction method, 118 targeted and 2005 untargeted organic pollutant exposures were measured from seminal plasma using gas chromatography. We used linear regression, principal component pursuit (PCP), and Bayesian Kernel Machine Regression (BKMR) to estimate the associations of organic pollutants with semen parameters.

Using an exposome-wide association approach, we found that etriadizole, a common pesticide, was negatively associated with total motile sperm ($p<0.001$), concentration ($p=0.002$), and percent motility ($p=0.04$). Using PCP, a machine learning pattern recognition approach, we derived a low-rank matrix with one major principal component. This principal component was primarily loaded by one phthalate (diethyl phthalate) and three PAHs (anthracene, pyrene, phenanthrene) and was associated with lower total sperm ($p=0.03$) and percent motility ($p=0.05$). BKMR results confirmed that as an overall mixture, these four pollutants were negatively associated with percent motility, although anthracene was not important to the mixture effect.

Seminal plasma levels of etridiazole, diethyl phthalate, and polycyclic aromatic hydrocarbons (PAHs) are negatively associated with semen parameters. Future exposomic investigations using seminal plasma are warranted.

KEYWORDS: exposomics; exposome; seminal plasma; reproduction; reproductive health; semen; sperm; pesticide, etridiazole, phthalates, PAH

P-0813 A multi-environmental media approach to explore the association between metal exposure and the ability to identify smells among school-age children residing in Northern Italy

Stefano Renzetti[1], Christoph van Thriel[2], Roberto G Lucchini[1,3], Donald R Smith[4], Marco Peli[1], Laura Borgese[1], Paola Cirelli[1], Alessandra Patrono[1], Giuseppa Cagna[1], Stefania Idili[1], Elisa Ongaro[1], Stefano Calza[1], Matteo Rota[1], Robert O Wright[5], Birgit Claus Henn[6], Megan K Horton[5], Donatella Placidi[1]

[1]Università degli Studi di Brescia, Bergamo, Italy, [2]Leibniz Research Centre for Working Environment and Human Factors (IfADo), Dortmund, Germany, [3]Florida International University, Miami, USA, [4]University of California, Santa Cruz, Santa Cruz, USA, [5]Icahn School of Medicine at Mount Sinai, New York, USA, [6]Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: Inhalation of airborne particles can lead to olfactory dysfunction. We aimed to test the association between the exposure to a mixture of 12 metals measured in three environmental media and olfactory function among children and adolescents residing at different distances from ferromanganese alloy plants in the province of Brescia, Italy.

METHODS: We enrolled 130 children between 6 and 13 years old (51.5% females) residing in Valcamonica and Bagnolo Mella, respectively. The Burghart “Sniffin` Sticks” test was used to investigate olfactory performance in identifying smells. Metal concentrations in soil, indoor, and outdoor deposited dust samples from the subjects’ households were analyzed with a portable X-ray fluorescence instrument. A Multi Environmental Media (MEM) Weighted Quantile Sum (WQS) regression for count data was applied to test for the association between the exposure to metals and child olfactory function. All models were adjusted by age, sex, socio-economic status, area of residence, intelligence quotient, BMI and passive smoking.

RESULTS: The metal mixture was negatively associated with the identification score (□=-0.229; 95%CI -0.439, -0.018). Cadmium (17.0%), iron (13.0%), lead (11.5%) and arsenic (8.5%) provided the strongest contribution to the association. Indoor dust resulted as the environmental media with the strongest contribution to the association with olfactory function for most of the elements considered in the mixture.

CONCLUSIONS: We identified metal concentrations in indoor dust as a risk factor for olfactory dysfunction in children and adolescents residing close to ferroalloy plants. Indoor pollution can be improved through public health interventions; moreover, the identification of the factors that can deteriorate olfactory functions can also prevent neurodegenerative disease.

KEYWORDS: Environmental exposure; olfactory function; metal exposure; soil; outdoor dust; indoor dust.

THEMATIC 14: Health Impact Assessment, Risk communication and Participatory Epidemiology

P-0904 Seasonal and spatial patterns of mortality and socio-economic characteristics associated with exposure to air pollution and a lack of green areas

Bram Vandeninden[1,2], Catherine Bouland[1], Eva De Clercq[2], Christel Faes[3]
[1]Université Libre De Bruxelles, Brussels, Belgium, [2]Sciensano, Brussels, Belgium, [3]Hasselt University, Hasselt, Belgium

BACKGROUND AND AIM. Air pollution and lack of green spaces can be important burdens to health, contributing to considerable levels of mortality and morbidity. The objective of this study was to quantify – at a high spatial resolution (the statistical sector level in Belgium)- associated mortality estimates and socio-economic inequalities.

METHODS: We combined high-resolution (10x10 metre) annual and seasonal modelled data on air pollution (NO2, PM2.5, BC, O3) and NDVI-data (as a proxy for green space availability) with relative risk estimates from published meta-reviews on the relation between total mortality, cause-specific mortality and exposure to those environmental stressors. We calculated annual and seasonal population attributable fraction (PAF), being the percentage of the total mortality that can be explained by exposure to air pollution and lack of green space.

RESULTS: More than 10% of all annual deaths are associated with air pollution in Belgium with strong spatial and seasonal variations. for nitrogen dioxide, double the amount of deaths occurring in the winter compared to summer and in terms of spatial patterns, the population attributable fraction ranges from < 5% in some statistical sectors to >20% in other statistical sectors. for green spaces, we examined that, in some areas with very limited presence of green spaces, up to 20% of mortality could be prevented if those areas were as green as the greenest areas in Belgium. Socio-economic inequalities are significantly associated with the seasonal and spatial patterns of mortality related to air pollution and a lack of green areas.

CONCLUSIONS: A lack of green spaces and air pollution are causing considerable amounts of mortality. There are strong spatial and temporal variations in the amount of attributable mortality. at the same time, socio-economic inequalities are strongly associated with increased attributable mortality.

KEYWORDS: Health impact assessment, air pollution, green spaces, socio-economic characteristics, environmental equity.

P-0925 Lanthanum, cerium and praseodymium in urban topsoils, an emerging health concern?

Antonio Peña-Fernández[1], Manuel Higueras[2], Carmen Lobo-Bedmar[3]
[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, UK, [2]Scientific Computation & Technological Innovation Center (SCoTIC), Universidad de La Rioja, Logroño, Spain, [3]Departamento de Investigación Agroambiental. IMIDRA. Finca el Encín, Crta. Madrid-Barcelona Km, 38.2, Alcalá de Henares, Spain

BACKGROUND AND AIM: Rare earth elements (REEs) are contaminants of emerging concern. Lanthanum (La), cerium (Ce) and praseodymium (Pr) were monitored in the environment of Alcalá de Henares, one of the biggest cities in the Community of Madrid (Spain), to characterise their risks for the population.

METHODS: Ninety-four topsoil samples were collected in July 2017: urban (66), industrial (24) and city centre public garden (4). REEs were analysed by ICP-MS after acid digestion in a microwave system.

RESULTS: REEs were detected in all samples and presented identical distribution, i.e. higher and significantly higher concentrations in the garden and industrial areas, respectively, compared to the urban area. This distribution would be logical due to their anthropic uses in fertilisers (e.g., higher concentrations of REEs has been detected in fertilisers used in Spain), as additives in ceramics/glass (Alcalá had important ceramic fabrication) and electronic/industrial uses (e.g. in alloys, catalytic converters, phosphors). Our results might suggest a low anthropic input in urban topsoils in Alcalá, as the ranges (mg/kg) of La (2.13-36.01 vs. 1.10-143), Ce (4.03-72.87 vs. 2.45-267) and Pr (0.55-8.84 vs. 0.29-31.6) found were lower than their baseline concentrations reported in topsoils in Europe. Levels were also lower than the averages reported in Spanish soils as reference (17.92 vs. 33; 36.57 vs. 63; 4.51 vs. 7.7; respectively), suggesting low contamination. Provisional reference doses for La and Pr were used to characterise non-carcinogenic risks for ingestion/dermal contact, which were lower than the threshold.

CONCLUSIONS: There is no potential risk of toxic pathology resulting from the ingestion/dermal contact of La and Pr in soils and resuspended soils for the different areas monitored in Alcalá. However, efforts should be initiated to determine the toxic effects of REEs, especially Ce owing to its high presence, for a better characterisation of the risks to these emerging contaminants.

P-0929 Dwelling mouldy area size and current asthma in adults from the French CONSTANCES cohort

Tajidine Tsiavia[1], Emilie Fréalle[2], Valérie Bex[3], Orianne Dumas[1], Marcel Goldberg[4], Nicole Le Moual[1], Marine Savouré[1,5], Raphaëlle Varraso[1], Marie Zins[4], Bénédicte Leynaert[1], Laurent Orsi[1,6], Rachel Nadif[1,6]

[1]Université Paris-Saclay, UVSQ, Univ. Paris-Sud, Inserm, Équipe d'Épidémiologie respiratoire intégrative, CESP, villejuif, France, [2]CHU Lille, Institut Pasteur de Lille, ULR 4483-IMPacts de l'Environnement Chimique sur la Santé (IMPECS), Univ. Lille, Lille, France, [3]Service parisien de santé environnementale, Paris, France, [4]Université Paris-Saclay, UVSQ, Inserm, Cohortes Epidémiologiques en population, Villejuif, Paris, [5]Agence de l'environnement et de la Maîtrise de l'Energie, Angers, France, [6]Co-last authors,

BACKGROUND AND AIM: Mould presence is a key determinant of poor indoor air quality. Data on mouldy contamination and its effects on respiratory health from nationwide population-based studies are scarce. We studied the associations between visible mould, including for the first time their area size, and current asthma in adults from the population-based cohort Constances.

METHODS: Participants responded to 2019 self-questionnaire on mould exposure. Reports of visible mould (yes/no), and of mouldy area, i.e., maximum area size in bathroom, kitchen, or main living quarter (living room, bedroom), expressed as: 0m², spots, <0.2m², [0.2m²-1m²[, [1m²-3m²] or >3m²) were studied. Between 2019-2021, participants had one medical exam including a self-questionnaire on respiratory health. Current asthma was defined among ever-asthmatics by self-report of asthma attacks, symptoms or treatments in the last 12 months. Logistic models adjusted for age, sex, smoking and occupant-surface ratio were performed.

RESULTS: Visible moulds were reported by 21.2% of the 21,390 adults included in the analyses (mean age: 48 years, 51.4% women, 31.8% living in flats, 7.7% current asthma). Mouldy area of spots, <0.2m², [0.2m²-1m²[, [1m²-3m²] or >3m² were reported by 12.9%, 6.0%, 1.4% 0.6%, and 0.3% of the participants, respectively. Report of visible moulds was associated with current asthma (adjusted(a)OR[95%CI]=1.25[1.11-1.41], this association being more marked 1) when restricting to the main living quarter: aOR=1.43[1.20-1.69], or 2) for those living in flats as compared to those living in houses: aOR=1.44[1.19-1.75]. The likelihood of current asthma increased with increasing mouldy area (from spots to >3m², 0m² as reference): aOR=1.21[1.05-1.39], 1.36[1.12-1.65], 1.09[0.73-1.63], 1.60[0.93-2.74], 1.42[0.62-3.25] (pTrend=0.0004).

CONCLUSIONS: More than 20% of participants reported visible mould in a population-based cohort in France in 2019. Visible mould and mouldy area size were associated with an increased risk of current asthma in adults, highlighting the need for prevention measures.

KEYWORDS: Asthma, mould exposure, indoor air

P-0945 Occupational exposure to benzene and risk of non-Hodgkin lymphoma in Shanghai: an extended follow-up of two population-based prospective cohorts of Chinese women and men

Nathaniel Rothman[1], Bryan Bassig[1], Xiao-Ou Shu[2], Melissa Friesen[1], Roel Vermeulen[3], Mark Purdue[1], Bu-Tian Ji[1], Gong Yang[2], Jason Wong[1], Wei Hu[1], Yu-Tang Gao[4], Wei Zheng[2], Qing Lan[1]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, USA, [2]Division of Epidemiology, Department of Medicine, Vanderbilt Epidemiology Center, Vanderbilt-Ingram Cancer Center, Vanderbilt University School of Medicine, Nashville, U.S.A., [3]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands, [4]Dept. of Epidemiology, Shanghai Cancer Institute/Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China

BACKGROUND AND AIM: The carcinogenicity of benzene, a ubiquitous environmental chemical causally associated with acute myeloid leukemia, was reevaluated by the International Agency for Research on Cancer in 2017, with the Working Group reaffirming positive yet still inconclusive associations with non-Hodgkin lymphoma (NHL). To extend our previous observation of a significant exposure-response for cumulative occupational benzene exposure and NHL risk among Chinese women in a population-based prospective cohort in Shanghai, we conducted additional follow-up of this cohort and pooled the data with a similarly designed population-based cohort of men in Shanghai.

METHODS: Benzene exposure status and cumulative exposure estimates were derived for 134,449 participants in the pooled analysis using a previously developed exposure assessment framework that combined ordinal job-exposure matrix intensity ratings with quantitative benzene exposure measurements from an inspection database of Shanghai factories. Associations between benzene exposure metrics and total NHL (n = 363 cases including multiple myeloma (MM)) were assessed using Cox proportional hazard models.

RESULTS: Ever occupational exposure to benzene in the pooled population was significantly associated with increased NHL risk (HR=1.5, 95%CI=1.2-2.0), and significant exposure-response relationships were observed for increasing duration (ptrend=0.003) and cumulative exposure (ptrend=0.003). The associations with ever exposure, duration, and cumulative exposure were similar for NHL with and without MM in the case definition, including lifetime cumulative exposures in the highest quartile (HR=1.6, 95%CI=1.1-2-4 with MM included; HR=1.7, 95%CI=1.1-2.7 with MM excluded). No significant heterogeneity in the associations by study/sex was observed. An elevated risk of chronic lymphocytic leukemia was also suggested in the pooled analyses (HR for ever vs. never exposure=2.3, 95%CI=0.9-5.6).

CONCLUSIONS: These observations provide additional data to support and extend the most recent IARC reevaluation of benzene carcinogenicity and suggest that benzene is a lymphomagen and are consistent with substantial mechanistic data.

P-0948 Estimating the health burden of ambient fine particulate matter in Korea

SHIJIN KIM[1], Hyun-joo Bae[2], YURA LIM[3]
[1]Korea Environment Institute, Sejong, Republic of Korea, [2]Korea Environment Institute, Sejong, Republic of Korea, [3]Seoul National University, Seoul, Republic of Korea

Korea has been making efforts to reduce the PM2.5 concentration through policy intervention but the PM2.5 level still belongs to a lower group among OECD countries. The aim of this study is to thus to evaluate the cases of premature deaths due to PM2.5 levels in Korea using AirQ+ model. We also examined the effect of reducing the burden of disease according to the current level of PM2.5 and future reduction targets in Korea.

The burden of disease analysis of PM2.5 was based on cases of premature death of chronic obstructive pulmonary disease (COPD), stroke, ischemic heart disease (IHD), acute lower respiratory disease (ALRI), and lung cancer (LC). for the scenario, the current PM2.5 conc. of 25 $\mu g/m^3$, and the future reduction targets of 17 $\mu g/m^3$ and 15 $\mu g/m^3$ were applied. Also, Statistics Korea's population and baseline mortality data by disease were used.

The premature deaths of the five diseases due to the current and future PM2.5 scenarios in Korea were calculated as 12826, 12808, and 13223, respectively. The increase of premature deaths cases due to aging in the future population offset the effect of improving PM2.5, and thus the actual number of deaths did not decrease. However, the contribution rates of PM2.5 to the premature death cases decreased to 15.8%, 12.2%, and 11% as the concentration improved. In particular, the concentration rate of PM2.5 in ALRI, COPD, and LC decreased by more than 5%.

In conclusion, it could be more effective to estimate the contribution rate rather than the absolute death case for the health improvement effect due to the reduction of PM2.5 in the case of countries where aging is expected in the future. In addition, this study showed that the reduction of PM2.5 in Korea was slightly more effective in reducing premature death of respiratory disease than cardiovascular disease.

P-0966 DNA methylation and aeroallergen sensitization – The chicken or the egg?

Anna Kilanowski[1,2,3,4], Sarina Abrishamcar[3], Dakotah Feil[3], Elisabeth Thiering[1,4], Melanie Waldenberger[1,5], Annette Peters[1,6], Marie Standl[1,7], Anke Hüls[3,8]

[1]Institute for Epidemiology, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany, [2]Institute for Medical Information Processing, Biometry, and Epidemiology; Pettenkofer School of Public Health, LMU Munich, Munich, Germany, [3]Department of Epidemiology, Rollins School of Public Health, Emory University, Atlanta, USA, [4]Division of Metabolic and Nutritional Medicine, von Hauner Children's Hospital, University of Munich Medical Center, Munich, Germany, [5]Research Unit Molecular Epidemiology, Helmholtz Zentrum München - German Research Center for Environmental Health, Neuherberg, Germany, [6]Chair of Epidemiology, Ludwig-Maximilians University, Munich, Germany, [7]German Center for Lung Research (DZL), Giessen, Germany, [8]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA

BACKGROUND AND AIM: DNA methylation (DNAm) is considered a plausible pathway through which genetic and environmental factors may influence the development of allergies. However, causality has to be determined as it is unknown whether DNAm is rather the cause or consequence of allergic sensitization.
Here, we investigated the direction of the observed associations between well-known environmental and genetic determinants of allergy, DNAm, and aeroallergen sensitization using a combination of high-dimensional and causal mediation analyses.

METHODS: Using prospectively collected data from the German LISA birth cohort from two time windows (6&10 years: N=234; 10&15 years: N=167), we tested whether DNAm is the cause or the consequence of aeroallergen sensitization (specific immunoglobulin E>0.35kU/l) by conducting mediation analyses for both directions of effect using prenatal smoking, family history of allergies, and a polygenic risk score (PRS) for any allergic disease as exposure variables. We evaluated individual CpG sites (EPIC BeadChip) and allergy-related methylation risk scores (MRS) as potential mediators in the mediation analyses. We applied various high-dimensional mediation approaches (HIMA, DACT, gHMA) and validated results using causal mediation analysis.

RESULTS: We identified five CpGs using HIMA and DACT as mediators of sensitization with significant ($p<0.05$) indirect effects in the causal mediation analysis (smoking: 2 CpGs, family history: 1, PRS: 2). The effect of family history on allergy-related MRS was significantly mediated by aeroallergen sensitization (proportions mediated: 36% to 51%), suggesting changes in DNAm occurred prior sensitization.

CONCLUSIONS: The results indicate that DNAm may be a cause or consequence of aeroallergen sensitization depending on genomic location. Allergy-related MRS, identified as a potential cause of sensitization, can be used as a cross-sectional biomarker of disease. Differential DNAm in individual CpGs, identified as mediators of the development of sensitization, could be used as clinical predictors of disease development.

P-0967 Contribution of gut bacteria to arsenic metabolism in the first year of life in a prospective birth cohort

Hannah E. Laue[1], Yuka Moroishi[1], Juliette C. Madan[1,2], Margaret R. Karagas[1]
[1]Geisel School of Medicine at Dartmouth College, Lebanon, USA, [2]Departments of Pediatrics and Psychiatry, Children's Hospital at Dartmouth, Lebanon, USA

BACKGROUND AND AIM: Gut bacteria are at the interface of environmental exposures and human systems, and may aid host metabolism and excretion of toxic chemicals. We investigated whether arsenic metabolism by gut bacteria is related to arsenic exposure and metabolism.

METHODS: In the New Hampshire Birth Cohort Study, urine and stool samples were obtained at six weeks (n=186) and one year (n=190) of age. Inorganic arsenic (iAs), monomethylarsonic acid (MMA), dimethylarsinic acid (DMA), and arsenobetaine (AsB) were quantified in infant urine samples using high-performance liquid chromatography with inductively coupled plasma mass spectrometry. Total arsenic exposure (tAs) was summarized as Σ(iAs, MMA, DMA) and log10-transformed. Fecal DNA underwent metagenomic sequencing and the relative abundance of bacterial gene pathways were grouped as KEGG Orthologies (KOs) using BioBakery algorithms. In the first set of models, arsenic-related KOs with >80% detection were log10-transformed and modeled continuously using linear regression, those with <10% were not evaluated and those with 10-80% detection were analyzed dichotomously (detect/non-detect) using logistic regression. Models adjusted for age at sample collection and child's sex. Effect modification by delivery mode was assessed in stratified models. In the second set of models, the association between the relative abundance/detection of the KOs and arsenic speciation (%iAs, %MMA, %DMA) was assessed with linear regression.

RESULTS: tAs was associated with the increased relative abundance/detection odds of several arsenic-related KOs, including K16509, an arsenate reductase transcriptional regulator, with stronger associations among six-week-olds than one-year-olds. K16509 was also associated with increased %MMA and %DMA at six weeks and one year, suggesting it contributes to host metabolism. Notably, many associations were stronger among Caesarean-delivered than vaginally-delivered infants, suggesting vertical transfer of arsenic-related genes.

CONCLUSIONS: Our findings suggest that the infant gut microbiome may be responsive to arsenic exposure and may aid host metabolism and excretion.

KEYWORDS: arsenic, microbiome

P-0976 Prenatal polycyclic aromatic hydrocarbon (PAH) exposure in relation to placental corticotropin releasing hormone (pCRH) in a sociodemographically diverse U.S. cohort

Emily Barrett[1], Tomomi Workman[3], Marnie Hazlehurst[3], Sophie Kauderer[4], Christine Loftus[3], Kurunthachalam Kannan[5], Alicia Smith[6], Roger Smith[7], Kaja LeWinn[8], Sheela Sathyanarayana[3], Catherine Karr[3], Nicole Bush[8]
[1]Rutgers School of Public Health, Piscataway, USA, [2]Environmental and Occupational Health Sciences Institute, Piscataway, USA, [3]University of Washington, Seattle, USA, [4]Robert Wood Johnson Medical School, Piscataway, USA, [5]New York University School of Medicine, New York, USA, [6]Emory University, Atlanta, USA, [7]University of Newcastle, Newcastle, Australia, [8]University of California- San Francisco, San Francisco, USA

BACKGROUND AND AIM: Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous endocrine-disrupting combustion by-products that have been linked to preterm birth. One possible mechanism underlying this association is disruption of placental corticotropin releasing hormone (pCRH), a key hormone implicated in parturition. Extending prior research identifying pCRH as a potential target of endocrine disruption, here we examine maternal urinary PAHs in relation to pCRH in the sociodemographically diverse CANDLE cohort, part of the ECHO-PATHWAYS Consortium.

METHODS: In a subset of 810 pregnant CANDLE participants, we measured urinary mono-hydroxylated PAH metabolites in Trimester 2 (T2) and serum pCRH in T2 and Trimester 3 (T3). Associations between individual log-transformed PAHs and log(pCRH) (at each timepoint as well as the change over time) were estimated using linear regression models. Minimally adjusted models included gestational age and specific gravity, while fully adjusted models also included sociodemographic characteristics. We additionally evaluated effect modification by factors including pregnancy complications and fetal sex.

RESULTS: Participants were 62% Black, 32% White, and mean age 26.8±5.6 years. In minimally adjusted models, most PAH metabolites were inversely associated with pCRH concentrations. for instance, 1-hydroxypyrene was associated with lower T2 (β=-0.10, 95%CI: -0.16, -0.03) and T3 (β=-0.08, 95%CI: -0.15, -0.003) log(pCRH). After adjustment for sociodemographic factors, however, results were attenuated for all PAHs, including associations between 1-hydroxypyrene and log(pCRH) at T2 (β=-0.01, 95%CI: -0.07, 0.06) and T3 (β=0.01, 95%CI: -0.07, 0.08). There was no evidence of effect modification by any factors considered.

CONCLUSIONS: In the only epidemiological study of PAHs and pCRH to date, we observed little evidence of association after adjustment for covariates. PAHs may nevertheless affect timing of birth through other mechanisms, such as inflammatory or oxidative stress pathways.

P-0995 Maternal DNA Methylation Signatures of Arsenic Exposure is Associated with Adult Offspring Insulin Resistance in the Strong Heart Study

Christian Dye[1], Arce Domingo-Relloso, Naomi Tinkelman[1], Miranda Spratlen[1], Anne Bozack[2], Maria Tellez-Plaza[3], Maria Grau-Perez[1], Walter Goessler[4], Jean MacCluer[5], Karin Haack[5], Jason Umans[6], Shelley Cole[5], Andrea Baccarelli[1], Ana Navas-Acien[1]

[1]Mailman School of Public Health, Columbia University, New York, USA, [2]University of California, Berkeley, Berkeley, USA, [3]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, USA, [4]University of Graz, Graz, Austria, [5]Texas Biomedical Research Institute, San Antonio, USA, [6]Georgetown University, Washington, DC, United State of America

BACKGROUND AND AIM: Exposure to low-to-moderate arsenic levels has been associated with type 2 diabetes (T2D) and other chronic diseases in American Indian communities. Prenatal exposure to arsenic may increase the risk for T2D in adulthood, however, detection of long-term disease risk due to arsenic exposure has yet to be realized. We hypothesized that a molecular biosignature of arsenic exposure in mothers can be used to evaluate risk for T2D-related outcomes in offspring into adulthood.

METHODS: We evaluated the association of maternal DNA methylation with incident T2D and T2D-related variables (fasting glucose, homeostatic model assessment of insulin resistance (HOMA2-IR)) in adult offspring. for DNA methylation, we used 20 differentially methylated cytosine-guanine dinucleotides (CpG) associated with urinary total arsenic in the Strong Heart Study.

RESULTS: 6 CpGs were associated with HOMA2-IR in a fully adjusted model that included offspring adiposity measurements; a similar model that included maternal adiposity measurements showed 3 CpGs associated with HOMA2-IR, 2 that overlapped the offspring adiposity model. Using the 6 HOMA2-IR-associated CpGs, 3 associated with offspring fasting glucose in unadjusted models, although none remained significantly associated in adjusted models. Finally, the adjusted odds ratio of incident T2D was positively associated with maternal DNA methylation at one HOMA2-IR associated CpG, cg12116137. Our results indicated offspring adiposity had the largest effect on effect estimates between unadjusted and fully models, suggesting offspring adiposity as potentially mediating the relationship between maternal DNA methylation and offspring metabolic health.

CONCLUSIONS: We identified several arsenic exposure-associated CpGs in mothers that were associated with HOMA2-IR, and one CpG of which also associated with incident T2D, in offspring. Our findings support a role for epigenetic biosignatures of maternal arsenic exposure as a potential biomarker for evaluating risk of T2D-related outcomes in offspring later in life.

P-0996 Establishing a method to isolate blood-borne extracellular vesicles derived from microglia: a critical biomarker source for environmental exposure-linked neurotoxicity

Tanya Butt[1], Roheeni Saxena[1], Cherine Jaafar[1,2], Lina Marcinczyk[1], Mohammad Alayyoub[1], Eva Tipps[1], Diane B. Re[1]
[1]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA, [2]Paris Saclay University, Paris, France

BACKGROUND AND AIM: Extracellular vesicles (EVs) are membrane-bound nanostructures, whose contents are increasingly recognized for their potential as biomarkers and mediators of environmental exposures. The function of EVs as intercellular communicators further suggests their involvement in disease mechanisms. Microglial cells, critical for brain homeostasis, appear to be instrumental in the neurotoxic effects of aerosolized pollutants. Particulate matter (PM) exposure was shown to activate microglial cells and stimulate EV release in experimental models. To better elucidate potential mechanisms underlying air pollution-induced brain pathophysiology, we aimed to develop the first method to isolate microglial-derived EVs from human plasma samples. We compared the efficiency of two microglial-specific cell surface markers and evaluated protein enrichment to determine microglial origin.

METHODS: We isolated microglial-EVs using a direct immunoprecipitation (IP) protocol, which we previously optimized for astroglial-EVs, with antibodies against homeostatic, microglia-specific markers for the purinergic receptor P2Y12 and cell-surface protein TMEM119. Starting with 0.5mL of plasma, we incubated samples in different concentrations of primary antibody solution. We utilized nanotracking particle analysis (NTA) and transmission electron microscopy (TEM) to characterize EVs, and enzyme-linked immunoassays (ELISAs) to evaluate concentrations of different neuronal, glial, microglial, as well as EV and non-EV associated protein markers.

RESULTS: Preliminary ELISA results showed greater concentrations of the pan-EV marker syntenin-1 in microglial EVs isolated using P2Y12 compared to TMEM119. Additional ELISA data for P2Y12 microglial-derived EVs showed little enrichment of neuronal and astrocytic protein markers for neurofilament light chain (NEFL), glial fibrillary acidic protein (GFAP), and glutamine synthetase (GLUL), compared to microglial protein markers of P2Y12. NTA results of EVs isolated using P2Y12 showed 1.73x107 particles/mL, with an approximate size of 187.45nm (SD: 20.16nm).

CONCLUSIONS: Preliminary results suggest that an IP using microglial antibodies specific to P2Y12 may be a feasible, lower-cost technique for isolating microglial derived EVs.

P-0997 Epigenetic Modulations with BPA and PFOA Exposure Prior to Pubertal Onset in Growing Up Female

Cecily Fassler, Frank Biro[2], Changchun Xie[1], Ricky Yuet-Kin Leung[3], Shuk-Mei Ho[3], Susan Pinney[1]
[1]University of Cincinnati College of Medicine, Cincinnati, USA, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, USA, [3]University of Arkansas Medical Sciences, Little Rock, USA

BACKGROUND AND AIM: Changes in the degree of DNA methylation in peripheral blood may occur with exposure to an environmental chemical. Examining the differential methylation status by exposure to BPA or PFOA will begin to address the interaction between the epigenome and environmental exposures. Our aim was to identify CpG sites of increased or decreased DNA methylation, which may provide clues to the mechanism whereby the exposure causes a change in pubertal development.

METHODS: 108 girls of the Cincinnati BCERP puberty study cohort with banked blood samples obtained prior to thelarche (when the girl was observed to be in Tanner breast stage 2 (-18 or -24 months) were selected for this discovery study. Eligibility requirements included consistent breast staging (no regression to breast stage 1 after being observed in breast stage 2) and the thelarche-first pubertal maturation pathway. Genome-wide methylation was measured using the Illumina 850K methylation bead chip assay. Serum perfluorooctanoic acid and urinary bisphenol-A were measured at CDC. Association analyses, without the Y chromosome probes and using a paired t-test with a false discovery rate (FDR) control at 0.05 were conducted on the methylation array data.

RESULTS: Median urinary BPA and serum PFOA were 1.7ng/ml and 7.55 ng/mL Linear regression models were used to test the main effect of BPA or PFOA on percent methylation adjusting for race. After adjusting for multiple testing, no significant association existed between urinary BPA and degree of methylation at any site. for serum PFOA, we identified 20 CpG sites with FDR<0.05. The CpG site with smallest P-value was cg18323749.
CONCLUSION: PFOA exposure prior to puberty may result in changes in the degree of DNA methylation at certain CpG sites, which may result in changes in gene expression and consequently changes in pubertal development.

KEYWORDS: PFOA, BPA, DNA methylation, puberty

DAY 1 (Monday, September 19)

THEMATIC 01: Advances in Epidemiology and Statistical

P-0001 A Machine Learning Exposure Response Analysis of the effect of PM2.5 on Myocardial Infarctions Using Regression Adjustment Causal Modeling

Joel Schwartz[1], Mahdieh Danesh Yazdi[1], Yaguang Wei[1]
[1]*Harvard School of Public Health, Boston, USA*

BACKGROUND AND AIM: The association of short-term exposure to PM2.5 with myocardial infarctions is well established and recent studies provide evidence for long-term exposure as well. Few have used causal modeling approaches to examine the concentration-response association.
METHOD: Using the U.S. Medicare cohort between 2000 and 2016 we stratified PM2.5 exposure into deciles. Within each decile, we fit a gradient boosting algorithm predicting the risk of MI based on multiple SES variables, smoking rate, mean BMI, access to care variables, race/ethnicity and exposure to NO2 and O3, and calendar year. We then applied those 10 models to the entire cohort, to predict the counterfactual risk of MI had everyone been exposed to each decile. We bootstrapped the process 200 times to obtain confidence intervals.

RESULTS: We find a significant association with no evidence of a threshold down to 5 μg/m3. Each 1 μg/m3 increase in PM2.5 increased the MI rate by 0.148 cases per 1000 per year (95% CI 0.139, 0.156).

CONCLUSIONS: Annual PM2.5 exposure increases the risk of Myocardial Infarctions in the Elderly.

KEYWORDS: Causal, Machine Learning, PM2.5, Heart Attacks

P-0002 Effect of pesticides exposure on oxidative stress and epigenetic changes biomarkers in Czech adults and children from the CELSPAC-SPECIMEn cohort

Tomáš Janoš[1], Ilse Ottenbros[2,3], Jelle Vlaanderen[2], Lucie Bláhová[1], Petr Šenk[1], Libor Šulc[1], Pavel Čupr[1]
[1]RECETOX, Faculty of Science, Masaryk University, Brno, Czechia, [2]IRAS, Utrecht University, Utrecht, Netherlands, [3]National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands

BACKGROUND AND AIM: Pesticides exposure occurs through diet and environmental application readily in both agricultural and urban settings. While pesticides exposure has been associated with many health effects, the question of the adverse outcome pathways is still not clearly answered. Among various molecular mechanisms linked to pesticide-induced chronic diseases, DNA damage due to oxidative stress and their role in epigenetics seems to be of great importance. Thus, we have explored the associations between pesticide metabolites and biomarkers of oxidative stress and epigenetic changes in urine samples from Czech adults and children population during two seasons.

METHODS: A total of 440 adult-child pairs urine samples were collected during winter and summer season of 2019-2020. Twelve current-use pesticides or their metabolites were measured in urine as well as 8-hydroxydeoxyguanosine and five methylated DNA bases as biomarkers of oxidative stress and epigenetic changes, respectively. To examine the associations, linear mixed effect models accounting for intraindividual and intrahousehold correlations were utilized. We have applied false discovery rate procedure (FDR) to account for multiplicity and have adjusted for several potential confounding variables.

RESULTS: In fully adjusted single exposure models, pyrethroids, chlorpyrifos and tebuconazole metabolites were associated with changes in both oxidative stress and epigenetic biomarkers. In the final fully adjusted multiple exposure model, the greatest effect estimate was observed for chlorpyrifos metabolite which interquartile range change was associated with 15.1 % increase (FDR adjusted 95% confidence interval = 1.16, 31.0) in 5-methyl cytosine biomarker concentration.

CONCLUSIONS: Our findings showed some significant associations between urinary metabolites of current-use pesticides and oxidative stress biomarker and methylated DNA bases measured in human urine of general population. These findings suggest potential use of oxidative stress and epigenetic changes biomarkers in future epidemiological studies linking exposure to pesticides and health outcomes.

KEYWORDS: pesticides exposure, chlorpyrifos, oxidative stress, epigenetic, DNA methylation

P-0004 Adjustment for Unmeasured Spatial Confounding in Settings of Continuous Exposure Conditional on the Binary Exposure Status: Conditional Generalized Propensity Score-Based Spatial Matching

Honghyok Kim[1], Michelle Bell[1]
[1]*Yale University School of The Environment, New Haven, USA*

BACKGROUND AND AIM: Generalized propensity score (GPS) is used to estimate causal effects of continuous treatments/exposures. The valid estimation relies on the assumption of no unmeasured confounding. Many environmental, demographic, built-environmental, behavioral, and health data can exhibit spatial patterns, raising concerns of unmeasured spatial confounding. Furthermore, researchers are often confronted with settings where continuous exposure is conditional on binary exposure status (e.g., level of a contaminant (continuous) within a specified radius from residence (binary)). Both binary and continuous exposures can commonly exhibit spatial patterns, such that unmeasured spatial confounding in both dimensions may be concerning. We developed a novel GPS matching method for such settings, called conditional GPS (CGPS)-based spatial matching (CGPSsm).

METHODS: CGPSsm estimates the average treatment effect in the treated. CGPSsm matches exposed observational units (e.g., exposed participants) to unexposed units by their spatial proximity and GPS integrated with spatial information. GPS is estimated by separately estimating PS for the binary status (exposed vs. unexposed) and CGPS on the binary status. Spatial regression and machine learning can be leveraged to estimate GPS. A motivating example is to investigate the association between refineries with high petroleum production and refining (PPR) and stroke prevalence in the southeastern USA.

RESULTS: CGPSsm maintains the salient benefits of propensity score matching and spatial analysis: straightforward assessments of covariate balance and adjustment for unmeasured spatial confounding. Statistical simulations showed that CGPSsm can adjust for unmeasured spatial confounding. Using our example, we found positive association between PPR and stroke prevalence.

CONCLUSIONS: CGPSsm has potential in epidemiological studies where exposure has both binary and continuous attributes and unmeasured spatial confounding may be of concern (e.g., accessibility to emergency services, exposure to nearby environmental factors, and surrounding built environments). Our R package, CGPSspatialmatch, is publicly available.

P-0005 Counternull sets in randomized experiments

Marie-Abele Bind[1], Donald Rubin
[1]*Massachusetts General Hospital, Boston, USA*

Consider a statistical analysis for a randomized experiment that draws inferences based on hypothesis testing. In such settings, the plausibility of a null hypothesis is often examined using a p-value associated with a test statistic. In controlled experiments such as the ones that Bob conducts, Fisher-exact p-values are available and should be used to help evaluate results rather than the more commonly reported asymptotic p-values associated with common statistical tests (e.g., t-tests). Low p-value typically indicates some evidence against the null hypothesis, and when p-values are large, no definite statistical conclusions should be drawn! To avoid misinterpretations when testing a null hypothesis, we will present the “counternull value”, which was first defined by Rosenthal and Rubin (1994) and illustrate these concepts using some of Bob's chamber experiments.

P-0008 Performance of Competing Methods for Quantile Regression with Count Data: A Simulation Study with Applications for Environmental Epidemiology

Josh Alampi[1], Bruce Lanphear[1,2], Lawrence McCandless[1]
[1]Simon Fraser University, Burnaby, Canada, [2]Child and Family Research Institute, BC Children's Hospital Research Institute, Vancouver, Canada

BACKGROUND AND AIM: Quantile regression is a useful tool in health research, but count data, which are common in environmental epidemiology, are incompatible with frequentist quantile regression. Using Bayesian methods and applying dithering (also known as jittering) to frequentist methods are possible workarounds, but the optimal strategy is unclear. We compared the performance of all available methods for quantile regression on count data, including 11 dithered frequentist methods and two undithered Bayesian methods. We also assessed whether dithering was associated with a loss of performance.

METHODS: We conducted Monte Carlo simulation studies to estimate the empirical coverage probabilities, bias, variability of point estimates, and interval widths of all methods. We simulated various scenarios (smaller sample sizes, heteroscedasticity, lognormal covariates, skewed error distributions) that might occur in the field of environmental epidemiology.

RESULTS: Point estimates from Bayesian quantile regression were the slightly less variable, and may be slightly less biased in certain circumstances. The adjusted Bayesian ("bnid") method had good empirical coverage probabilities, while the xy-bootstrap and rank-based methods had nearly perfect coverage. In contrast, the unadjusted Bayesian ("biid") method had poor coverage. Finally, the adjusted Bayesian ("bnid") and rank-based methods had the most variable interval widths. Dithering did not diminish performance.
CONCLUSION: We recommend the xy-bootstrap with dithering for conducting quantile regression with count data; xy-boostrapping had the best performance and it is easily implemented. We also found that dithering is a valid technique and endorse its use for count data, although it is unnecessary for continuous data.

P-0009 Time series clustering using self-organizing maps to identify longitudinal pollutant exposure profiles

Erika Garcia[1], Brittney Marian[1], Kenan Li[2], Yue Zhang[3,4,5], Edward B Rappaport[1], William S Linn[1], Frank D Gilliland[1], Sandrah P Eckel[1]

[1]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, USA, [2]Spatial Sciences Institute, University of Southern California, Los Angeles, USA, [3]Department of Internal Medicine, University of Utah, Salt Lake City, USA, [4]Department of Family and Preventive Medicine, Salt Lake City, USA, [5]Veteran Affairs Salt Lake City Health Care System, Salt Lake City, USA

BACKGROUND AND AIM: Metrics for assessment of air pollutant exposures are often reduced to summaries of time-series data. These overlook detailed patterns of high-resolution diurnal data, possibly obscuring important features of exposure for health response. We use a novel methodology featuring self-organizing maps (SOMs) to perform time-series classification to identify distinct diurnal patterns of air ambient pollution in Southern California.

METHODS: SOMs are an unsupervised learning process for multi-dimensional data reduction with the ability to discern distinct temporal patterns, particularly at high temporal resolution. We implemented a two-stage approach using: 1) SOM with dynamic time warping to perform dimensionality reduction and feature extraction, and 2) partitioning around medoids (PAM), a time-series clustering method, to identify clusters of characteristic diurnal profiles. PAM is advantageous because expository cluster time-series come from existing data rather than generating new time-series that may average cluster members and be sensitive to outliers. Hourly monitoring data for particulate matter <2.5µm and <10µm, nitrogen dioxide, and ozone were obtained from the USEPA's Air Data website for 2006 through 2010 in 6 coastal and 2 populous inland counties of Southern California.

RESULTS: Using SOMs, we identified 100 diurnal patterns characteristic of Southern California for each air pollutant that emphasized peaks and plateaus of different magnitude, length, and time of occurrence. for each pollutant, the 100 patterns were partitioned into 8 clusters. Using chi-squared tests, the 8 diurnal patterns were found to statistically significantly vary by season ($p<0.001$) and day of week ($p<0.001$) for all pollutants. We also observed differences in diurnal patterns by geography, including coastal versus inland.

CONCLUSIONS: Temporally resolved exposure profiles of potential health significance determined through SOMs (with PAM) demonstrate utility as a novel alternative to prevailing pollutant exposure summaries. This methodology is being extended to a multipollutant framework.

KEYWORDS: time-series, exposure, methods, clustering, air pollution

P-0010 Estimating high-dimensional heterogeneous treatment effects in the context of climate and health: a case study exploring the role of effect modification in the relationship between precipitation shocks and diarrheal illness

Michael Cheung, Anna Dimitrova[1], Tarik Benmarhnia
[1]*University of California, San Diego, La Jolla, USA*

Identifying heterogeneity of treatment or exposure effects among subgroups of a study population is important in public health to identify subgroups to target with priority. Previous approaches have relied on the estimation of the conditional average treatment effect, which requires effect modifiers to be specified a priori and for a limited number of potential effect modifiers. More recently, machine learning (ML) algorithms have been proposed for estimation of effect heterogeneity in observational studies, which allow for greater flexibility and accuracy in the identification of heterogeneous subgroups in high-dimensional settings. One advancement in this area is the Causal Rule Ensemble (CRE) method which identifies heterogeneous population subgroups with high statistical precision while also offering improved interpretability of results. In this study, we apply the CRE estimator to study modification in the effect of precipitation shocks on diarrheal illness among children under three years of age by a set of demographic and socio-economic covariates. for this purpose, we use a large dataset of 807,073 children from 56 low- to middle-income countries (LMICs) via the Demographic and Health Surveys in combination with high resolution precipitation data via the Climate Hazards Group InfraRed Precipitation with Station dataset. Precipitation shocks (both droughts and floods) have been linked to outbreaks of water-borne diseases, including diarrheal illnesses that are among the leading causes of child death in LMICs. Better understanding is needed of the factors that increase disease susceptibility of populations exposed to such climatic shocks. Our results show high degree of heterogeneity in the effect of droughts on infectious illness among multiple population subgroups. We demonstrate how innovative ML algorithms can be leveraged in climate and health research to optimize the benefits of public health policies.

P-0011 Bridging differences across cohorts in the relationship between prenatal secondhand smoke exposure and birth weight: Transportability of effect estimates in the ECHO consortium

Andreas Neophytou[1], Jenny Aalborg[2], Brianna Moore[2], Sheryl Magzamen[1], Dana Dabelea[2]
[1]Colorado State University, Fort Collins, USA, [2]University of Colorado Denver - Anschutz Medical Campus, Aurora, USA

BACKGROUND AND AIM: Transportability of effect estimates in epidemiology can potentially help investigators explain the differences in effect estimates for the same exposure-outcome relationships observed across different cohorts. In this study we aim to explain potential differences in the relationship between prenatal secondhand smoke exposure (SHS) and birth weight across different cohorts of the Environmental influences on Child Health Outcomes (ECHO) consortium that may be due to population differences in sociodemographic characteristics.

METHODS: We assessed transportability of effect estimates across 5 different cohorts in the ECHO consortium consisting of 6582 mother-offspring dyads. We first estimated individual cohort effects using Targeted Maximum Likelihood Estimation adjusting for several sociodemographic covariates. We then proceeded to estimate transported effects from one cohort to each of the remaining cohorts using a robust non-parametric estimation approach. We compared the transported effect estimates to the original effect estimates for these cohorts with any decrease in differences between cohort-specific estimates potentially attributable to different sociodemographic variable distributions.

RESULTS: Individual cohort effects associated with SHS exposure varied across the 5 cohorts with a range of strongly suggestive results for harmful effects of exposure (149.0 gram decrease in birthweight (95% confidence interval (CI): -254.4, -43.5), to results on the protective side of the null albeit with very wide confidence intervals. Transported effect estimates partially explained differences in 3 out of the 4 cohort pairs, explaining 7% to 97% of the differences in the effect point estimates.
CONCLUSION: Differences in sociodemographic characteristics across different populations may partially explain differences observed in the relationship between prenatal SHS exposure and birth weight across cohorts in the ECHO consortium. This framework could have broader implications in in multi-cohort consortiums by aiding in the comparability of cross-cohort results.

P-0012 Does trajectory of ambient air pollutant (PM2.5, NO2) exposure influence cognitive function? A co-pollutant examination using sequence analysis

Kristina Dang[1], Jennifer Weuve[2], Maria Glymour[1], Kevin Lane[2], Michael Brauer[3], Mary Haan[1], Isabel Allen[1], Anusha Vable[1]

[1]University of California San Francisco, San Francisco, USA, [2]Boston University, Boston, USA, [3]University of British Columbia, Vancouver, Canada

Historical pattern of longitudinal changes in air pollution exposure may be relevant to cognitive risk in older adulthood. We used sequence analysis to characterize 10-year trajectories of PM2.5 and NO2 exposure and evaluate their association with cognition in a US-representative sample of 8,245 adults 65+ years old.

The CACES database provided census tract mean annual PM2.5 and NO2 (trichotomized at 2010 25th and 75th percentiles [7.9 µg/m3; 10.8µg/m3 and 4.8 ppb; 10.8 ppb respectively]) from 2000-2010. Sequences of PM2.5 and NO2 were evaluated using the Halpin optimal matching algorithm. We linked exposure trajectory group to residential census tract (N=3,559) of each participant of NHATS. Participants underwent cognitive assessments annually; their episodic memory score in a given year was the mean of their immediate and delayed word recall scores, standardized to NHATS 2011 baseline mean and sd. We used linear mixed models to estimate the association of air pollution trajectory with memory, adjusted for age, gender, education, race/ethnicity, smoking status, neighborhood SES, and census division.

Over 10 years, we observed 1,208 unique air pollution trajectories, which were clustered into 7 groups based on similarity. In general, participants occupying the higher exposure clusters had lower memory scores (e.g. high NO2 and PM2.5 until 2008, followed by medium level exposure by 2010 = -0.19; 95%CI: -0.29, -0.09).
Through this novel application of sequence analysis, we identified 7 distinct air pollution trajectories. We found that participants' historical pattern of air pollution exposure differentially predicted memory level such that, despite more recent lower exposures, higher exposures in the more distant past were associated with the greatest memory deficit . Our findings provide further support that use of more expansive air pollution exposure histories may offer more comprehensive discovery of air pollution's adverse cognitive effects in older adulthood.

P-0013 Is cadmium a risk factor for breast cancer – results from a Mendelian randomization analysis

Eva Andersson[1,2], Malte Sandsveden[3], Niklas Forsgard[4], Gerd Sallsten[1], Jonas Manjer[5], Gunnar Engström[5], Lars Barregard[1]

[1]School of Public Health and Community Medicine, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, [2]Occupational and Environmental Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden, [3]Department of Surgery, Skane University Hospital Malmo, Lund University, Malmo, Sweden, [4]Department of Clinical Chemistry, Sahlgrenska University Hospital, Gothenburg, Sweden, [5]Department of Clinical Science in Malmo, Lund University, Malmo, Sweden

BACKGROUND AND AIM: Previous research have indicated cadmium as a possible risk factor for breast cancer, as cadmium has estrogen-like properties. Using observational data for environmental risk assessment, however, there is always risk for confounding, due to e.g. unbalanced data. The aim of this study is to use previously identified single nucleotide polymorphisms (SNP:s) as instrumental variables for cadmium exposure, to investigate the association with breast cancer risk using data from a Swedish cohort study.

METHODS: A previous genome-wide association study, performed in the Swedish Malmo Diet and Cancer cardiovascular sub cohort, showed a significant association between erythrocyte cadmium and two SNP:s among never-smoking women (Borné, Hum Mol Genet 2016). A breast cancer case-control study nested in the same Malmo cohort, showed an increased risk at high blood cadmium levels (Andersson, Can Epi Biom Prev 2021). A single sample mendelian randomization was performed using the inverse-variance weighting method with robust regression in the MendelianRandomization package in R.

RESULTS: The mean age at baseline among 1332 women (current, former and never smokers) was 57.0 (range 45-73) and the median blood cadmium level was 0.28 µg/L (p5=0.11, p95=1.72). for the rs12681420 SNP, the allele distribution was 29, 50 and 21 % (AA, GA, GG) and for rs17574271 it was 82, 17 and 1% (TT, CT, CC). Preliminary results, using an additive allele model, indicated an odds ratio, for breast cancer, of 1.21 per each doubling of blood cadmium levels (95% CI 0.59-2.49).

CONCLUSIONS: Preliminary results suggested a possible risk increase in breast cancer associated with cadmium, although the estimate was not precise. for never smokers in Sweden, the exposure is mainly through food (e.g. cereals, potatoes, vegetables) and preventive measures against cadmium pollution are warranted.

P-0014 Using triangulation to assess confounding by co-exposures to multiple per- and polyfluoroalkyl substances (PFAS)

Elizabeth Radke[1]
[1]*U.S. Environmental Protection Agency, Center for Public Health and Environmental Assessment, Washington, USA*

BACKGROUND AND AIM: Evaluation of health effects of highly correlated chemicals like per- and polyfluoroalkyl substances (PFAS) is complicated by the potential for confounding. We used a triangulation approach to determine the likelihood that observed associations could be explained by confounding across PFAS.

METHODS: As part of a systematic review of the hepatic effects of perfluorooctanoic acid (PFOA), we considered the sources and direction of bias in studies with varying exposure scenarios. In addition, we examined PFAS correlations and multipollutant modeling results within and across studies.

RESULTS: Twenty-five studies reported on the association between PFOA exposure and hepatic effects. Fourteen were in the general population using biomarkers in blood, in which individuals are exposed to a mixture of PFAS and it can be challenging to disentangle individual effects. Eight studies were in workers exposed to PFOA via inhalation and two were in communities with significant PFOA drinking water contamination. In these studies, PFOA exposure is predominant so there is less confounding by other PFAS but there may be potential for selection bias (e.g., healthy worker effect in occupational studies and heightened awareness of PFAS exposure and toxicity in contamination communities) and other confounding (occupational). for all exposure scenarios, the majority of studies reported associations between PFOA exposure and increased alanine aminotransferase in blood.

CONCLUSIONS: Consistency in the direction of association combined with differences in the sources of bias across studies with different exposure sources reduces the likelihood that the observed effects can be fully explained by confounding across PFAS.

Chan School of Public Health, Boston, USA, Boston, USA, [6]Population Health Research Institute, St George's, University of London, London, UK, London, UK, [7]School of Public Health, Department of Epidemiology and Biostatistics, Imperial College, London, UK, London, UK, [8]Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, the Netherlands., Utrecht, Netherlands

BACKGROUND AND AIM: Exposure Measurement error (ME) in air pollution leads to imprecise and biased health effects estimates, while its impact when multiple exposures are considered presents additional challenges. Within the EXPANSE project where multiple exposures are investigated we assessed the application of regression calibration (RC) as an approach to correct effect estimates in multi-exposure Cox models.

METHODS: We simulated data informed by the Cardiovascular Effects of Air Pollution and Noise in Stockholm cohort in order to investigate multiple exposures effects on cardiovascular mortality applying Cox regression models. PM2.5, NO2 and road traffic noise were considered as ME-prone exposures. We simulated the “true” exposure levels for each exposure by subtracting ME from surrogate measures under two different scenarios derived from the exposure assessment methods. The observed correlations between the three exposures ranged from 0.3 to 0.7. We simulated survival data for cardiovascular mortality based on the “true” effect estimates of the multi adjusted exposures under two scenarios. The average surrogate and RC-corrected effect estimates across 1000 repetitions were assessed. Estimates are reported as Hazard Ratios (HR) for 1-unit increase in respective exposures.

RESULTS: Prevailing classical-type error was defined for noise, while Berkson-type error for PM2.5 and NO2. Under the scenario with average performing exposure assessment (R2: 0.39-0.66), the surrogate estimates underestimated all associations and the RC correction slightly reduced the bias, except for PM2.5. Under the scenario of better exposure assessment (R2:0.68-0.77), the surrogate exposures underestimated the PM2.5 and noise effect while the RC correction reduced bias for all exposures (HR PM2.5: True 1.000 vs. RC 1.000; HR NO2: True 0.998 vs. RC 1.000; HR Noise: True 1.004 vs. RC 1.004).

CONCLUSIONS: RC performed well in both scenarios and reduced the bias of most effect estimates in multi-exposure Cox models.

P-0016 Exploiting dose-response trends in registry-based studies for regulatory risk assessment: arsenic in drinking water and congenital heart disease

Christian Ritz[1]
[1]*National Institute of Public Health, Copenhagen K, Denmark*

BACKGROUND AND AIM: Regulatory risk assessment of toxic compounds is commonly based on dose-response data that are obtained from planned, small-scale dose-response toxicity experiments involving test organisms, which can range from cellular material to higher order plants and animals (e.g., common duckweed and daphnia). Subsequently, results are translated to a human health setting through appropriate scaling factors. Recently, a large-scale registry-based study provided evidence that the risk of congenital heart disease in offspring was associated with maternal exposure to arsenic in drinking water through an increasing concentration-response relationship. The aim is to adapt risk assessment concepts from standard toxicity experiments to registry-based studies.

METHODS: Benchmark concentration/dose analysis involves fitting a regression model to the intake-outcome data. Based on the model fit, inverse regression allows deriving intake concentrations corresponding to specified levels of excess risk above the background level in a unexposed scenario. These estimates are called benchmark concentrations (BMC's). Often the lower limits of the corresponding confidence interval (BMCL's) are used as the point of departure for subsequent risk assessment. The concentration-response trend previously seen in the incidence in congenital heart disease as arsenic concentrations increased was re-visited to estimate benchmark concentrations corresponding to an excess risk in incidence of 1 and 2 per 1000 births. A log-logistic concentration-response Poisson model was fitted and BMCL's obtained through inverting the estimated s-shaped curve.

RESULTS: for an excess risk of 1 and 2 more cases of congenital heart disease per 1000 births, the estimated BMCL's were found to be 0.95 and 1.13 µg/L, respectively. These thresholds are smaller than several recommended maximum intake levels.

CONCLUSIONS: The window of harmless exposure to arsenic is seemingly very narrow. Moreover, it has been demonstrated that registry-based studies may also be used for regulatory risk assessment.

P-0017 Bias amplification and variance inflation in distributed lag models using low spatial resolution data

Michael Leung[1], Sebastian T Rowland[2], Brent A Coull[1], Anna M Modest[3,4], Michele R Hacker[1,3,4], Joel Schwartz[1], Marianthi-Anna Kioumourtzoglou[2], Marc Weisskopf[1], Ander Wilson[5]

[1]Harvard TH Chan School of Public Health, Boston, USA, [2]Columbia University Mailman School of Public Health, New York, USA, [3]Beth Israel Deaconess Medical Center, Boston, USA, [4]Harvard Medical School, Boston, USA, [5]Colorado State University, Fort Collins, USA

BACKGROUND AND AIM: Distributed lag models (DLMs) are often used to estimate lagged associations and identify critical exposure windows. Here, we focus on two perils that can occur when fitting DLMs to low-spatial-resolution exposure data: 1) bias amplification in the presence of residual confounding by time trends, and 2) variance inflation that arises from concurvity between a distributed lag function and a secular function of time.

METHODS: We demonstrate these issues using the example of NO2 and birth weight through a simulation study and in a real-data analysis. We first estimate the NO2–birth weight lag-response function using DLMs in a Massachusetts-based cohort. Then, using the lag–response relationships estimated from the real data, we illustrate using simulations that bias amplification and variance inflation can manifest under certain combinations of spatial resolution, DLM estimation approach, and time trend adjustment method.

RESULTS: Our simulations showed that when using high-spatial-resolution exposure (1-km resolution), any time trend adjustment method produced low bias and nominal coverage for the distributed lag estimator. When using low-spatial-resolution exposures (county-level or no resolution), bias due to time trends was amplified for all adjustment methods. Variance inflation was higher in low-spatial-resolution DLMs when using a long-term spline to adjust for time trends due to concurvity between a distributed lag function and secular function of time. NO2-birth weight analyses in the Massachusetts-based cohort showed that associations were negative for exposures experienced in gestational weeks 15-30 when using 1-km-resolution DLMs; however, associations were null and positive for DLMs with county-level and no-spatial-resolution exposures, respectively, which is likely due to bias amplification.

CONCLUSIONS: DLM analyses should jointly consider the spatial resolution of exposure data and the parameterizations of the time trend adjustment and lag constraints.

BACKGROUND AND AIM: Multi-pollutant studies based on linear regression with independent priors for metal effects can lead to identifiability problems due to correlated metals. In addition, metal exposures may be lower than limit of detection (LOD) of the measurement technique, forcing those observations to be discarded or imputed, often by partial fixed values. The aim of this talk is to propose a Bayesian model that makes practical imputations of metal exposures below the LOD and mitigates collinearity, by applying it to longitudinally assess the association between multiple metals exposure and blood pressure (BP).

METHODS: Metal exposures below LOD are predicted by a multivariate normal with a Gaussian process-based mean function, and the LOD is set as the upper bound of prediction. Furthermore, a multivariate prior distribution is defined for metal regression coefficients. This methodology is implemented in a multi-output longitudinal model based on mixed-effects linear regression to assess associations between multiple metals (18 metals measured in urine) and BP among 617 children from the Spanish INMA cohort measured at 4, 7 and 9 years of age.

RESULTS: Complete predictive posterior distributions upper bounded by the LOD are obtained for each one of the observations below LOD. By defining a multivariate prior for regression coefficients improves inference on the posterior with nearly collinear predictor metals. Regarding the application, the most significant single metal effects on BP are: Mg and As, associated with higher BP, and Cu and Mo, associated with lower BP, in both systolic and diastolic BP.

CONCLUSIONS: Full posterior distributions of metals below the LOD are used for inference, as opposed to point estimates or fixed imputations that can have excessive influence on the model. The use of linear effects is more effective to capture subtle associations as those between metals and BP.

P-0025 The Long-term Effect of Fine Dust Concentration on Exacerbation of Environmental Diseases for Vulnerable and Susceptible Individuals in South Korea : The Necessity of Personalized Standards on Air Quality Index

Youhyun Park[1,2], Se Hwa Hong[1,2], Dae Ryong Kang[2,3], Yong Whi Jeong[1], Sung Hwa Kim[1]

[1]Department of Biostatistics, Graduate School,Yonsei University, Seodaemun-gu, Republic of Korea, [2]Institute of National Health Big Data Clinical Research, Wonju College of Medicine, Yonsei University, Wonju, Republic of Korea, [3]Department of Precision Medicine & Biostatistics, Yonsei University, Wonju College of Medicine, Wonju, Republic of Korea

Indoor and outdoor air pollutants have been known to effect health through many studies. WHO has identified the levels of air quality necessary to protect public health worldwide. Many countries also announce standards suitable for each country. In Korea, the appropriate concentration standard of PM10 is less than 50 $\mu g/m^3$ per year. However, there are still few studies confirming whether these air quality standards are valid for vulnerable and susceptible individuals.

This study aimed to investigate the association between the occurrence of worsening environmental diseases according to PM10 concentration.

The study used nationwide population data from the Korea National Health Insurance Service and AirKorea data, which summarized the concentration of air pollutants. From 2015 to 2019, subjects newly diagnosed with environmental disease were followed up for period of 1 month and 12 months before acute exacerbation of environmental diseases occurred. Hazard ratios(HRs) was estimated through cox proportional-hazard model.

For 1 month, compared with the lowest level of PM10 (Quartile 1), the risk of exacerbation of most environmental diseases significantly increased in the highest quartile level (Quartile 4) (COPD: HR 1.85, 95% Confidence Interval (CI) 1.57-2.18/ Asthma: HR 1.79, 95% CI 1.62-1.97/ Arrhythmias: HR 1.20, 95% CI 0.83-1.75/ Stroke: HR 1.42, 95% CI 1.20-1.68). Exposure for 12 months was not statistically significant. When a stratified analysis of 12 months exposure was performed by age group, the cut-off value of the pm10 concentration, which is likely to COPD be exacerbated upon exposure, was 49 in children (HR 0.947, 95%CI 0.847-1.058) and 45 in the elderly (HR 1.045, 95%CI 1.031-1.058).

In Korea, fine dust concentration standards were valid not only for the general public but also for vulnerable and sensitive individuals. However, the cut-off value of PM10 was different depending on their characteristics. These results suggest the necessity for concentration standards reflecting individual characteristics.

P-0027 Spatially Stratified Controls: A simulation study of pre-term births

Ian Tang[1], Scott Bartell[1], Verónica Vieira[1]
[1]*University of California, Irvine, Irvine, USA*

BACKGROUND AND AIM: A simple random sample (SRS) of non-cases often selects the majority of controls from metropolitan areas and may not be an ideal approach for a spatial study. Unmatched spatially stratified random selection (SSRS) may be a useful alternative to sample a geographically balanced selection of controls from the population, facilitated by the MapGAM package.

METHODS: We divided the study area into non-overlapping spatial strata and then randomly selected controls from among the non-cases within each stratum. Inverse-probability weights were calculated to account for non-random sampling. To illustrate this approach in a spatial case-control study, we conducted simulations using generalized additive models to analyze the association between location and preterm birth in Massachusetts, and compared results for models with SSRS or SRS controls to the model with all non-cases. We selected 1-3 controls per stratum to observe if efficiency increased, and compared mean squared error (MSE), bias, relative efficiency, and map areas with significantly different risks across models.

RESULTS: We analyzed 4389 preterm births in models with approximately 8778 controls using SSRS and SRS to select from among 64,785 non-cases. Adjusted SSRS models had lower average MSE (range: 0.0042-0.0047) and higher relative efficiency (range: 76-79%) across simulations compared to SRS models (MSE/ relative efficiency ranges: 0.0067-0.0073; 71%). In addition, SSRS provided better estimates along the map edge. All SRS and SSRS models detected areas of high risk, but SSRS model results were more consistent across simulations and some were able to identify areas of statistically significant low risk SRS models did not.

CONCLUSIONS: The SSRS approach improved study efficiency by selecting controls geographically distributed across the study area, particularly in low population density areas and map edges, compared to the SRS approach. This method should be considered when sampling controls for spatial studies.

P-0032 Exploring the role of humidity on heat-health impacts using a risk assessment framework

Sidharth Sivaraj[1,2], Ana Maria Vicedo-Cabrera[1,2], Samuel Lüthi[3]

[1]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, [2]Oeschger Centre for Climate Change Research, University of Bern, Bern, Switzerland, [3]Weather and Climate Risks Group, ETH Zürich, Zürich, Switzerland

While physiological models showed that high humidity leads to stronger heat-stress, findings from epidemiological studies remain inconclusive. We aim to explore the role of humidity on heat-health impacts with a new analytical framework combining epidemiological modelling techniques with existing methods in hazard-risk assessments. This approach characterises events based on the severity of health impacts and allows assessing the role that humidity played in extreme events.

For illustrative purposes, we used temperature-mortality series in Zurich (Switzerland, May-September, 1989-2018). Using the state-of-the-art epidemiological models, we derived the temperature-mortality association and corresponding daily heat-related deaths using (1) daily mean temperature as exposure (adjusted for partial pressure humidity, PPH), and (2) daily wet-bulb temperature (combining temperature and humidity), in separate models. Events (four-day windows) were ordered based on the cumulative heat deaths and then characterized by the return period (i.e., inverse of the probability of occurrence of events equal to or severe than corresponding event in terms of impact). We then compared the impact estimates and return-periods across models and assessed whether high-impact events are also high-humid events (PPH > 95thpercentile).

Using mean-temperature as exposure, 3 out of the 11 events of high impact severity (i.e., with a return period above once-in-100 events) were also high-humid events. for wet-bulb, this ratio was 6 out of 11. Estimates from wet-bulb temperature in extremes returned higher heat-mortality for events with same return period compared to mean-temperature based estimates.

Based on our preliminary findings, high humidity seems to exacerbate heat-health impacts, but it may not be the only factor driving elevated heat stress. Further analyses will be conducted across other locations with different heat,humidity conditions. This framework could provide valuable insights into the role of humidity in heat-stress mortality, and other complex research questions in environmental epidemiology.

P-0033 How well can we estimate causal effects with exposome data in the absence of strong a-prior hypotheses?

Salome Kakhaia[1], Roel Vermeulen[1,2], Lützen Portengen[2], René Eijkemans[1]
[1]University Medical Center Utrecht, Utrecht University, Utrecht, The Netherlands, [2]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands

BACKGROUND AND AIM: Linking multi-exposure data to exposome-related disease risks is one of the major goals of environmental epidemiology and, when successful, may lead to improved disease prediction and prevention, thereby reducing morbidity, mortality, and healthcare costs. However, epidemiological and statistical analysis of exposome data is extremely challenging due to its high-dimensionality, often skewed exposure and outcome distributions, strong correlations between (subsets of)exposures, and complex causal structures including possible non-linear exposure-response relations and age/time-varying interactions. We aim to build an efficient high-dimensional causal inference framework, to evaluate environmental mixture effects and the contribution of individual components to disease-risks.

METHODS: State-of-art methods of causal inference and data integration will be applied to a large prospective cohort of UK-Biobank with high-dimensional exposure and OMICs data to identify causal factors related to cardiometabolic and pulmonary health. Environmental exposures, social and behavioral factors affect the complex set of biomarkers at the internal exposome level, inferring the development of the health outcome. Thus, OMICs features are considered as potential mediators in causal pathways relating exposures to health outcomes, which may result in the identification of potential intervention targets.

RESULTS: We present a critical review of existing methods with illustrative examples and argue their strengths/limitations, especially regarding the peculiarities of multi-layered exposome data. We discuss the separate challenges of identifying important exposures and obtaining unbiased, precise causal effect estimates in the absence of strong a-priori hypotheses and the presence of strong (multi)collinearity.

CONCLUSIONS: Highly challenging causal effect estimation for exposome data is unlikely to succeed with current approaches and limited data from single studies. To achieve a comprehensive causal inference framework, it will be necessary for exposome researchers to collaborate even more intensively and for existing statistical methods to be developed further to tackle the complexity of real-world applications.

P-0034 Principal Component Pursuit for Source Apportionment from Block Missing Data: An Application to NYC PM2.5 Data

Lawrence Chillrud[1], Jingkai Yan[2], John Wright[2], Jeff Goldsmith[3], Marianthi-Anna Kioumourtzoglou[1]
[1]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA, [2]Department of Electrical Engineering, Columbia University, New York, USA, [3]Department of Biostatistics, Mailman School of Public Health, Columbia University, New York, USA

BACKGROUND AND AIM: It is often of interest to identify sources of environmental exposures from imperfect data that suffer from block missingness, in which observations for multiple pollutants are missing across large portions of the study period.

METHODS: We adapted Principal Component Pursuit (PCP), a robust dimensionality reduction algorithm, to identify air pollution sources from incomplete data. PCP decomposes the pollutant matrix into consistent patterns while separately isolating unique or outlying pollution events. PCP handles structural missingness by reconstructing missing blocks using the information from observed blocks of the exposure matrix. We applied PCP to apportion 26 PM2.5 constituents to their sources in New York City, using data from three monitors (2001 – 2020). Two constituents, elemental (EC) and organic carbon (OC), were missing all measurements from 2001 to 2007, comprising 2.6% of the overall pollution matrix.

RESULTS: PCP reconstructed six years of EC and OC data consistent with existing literature, and identified five sources of PM2.5 pollution: crustal dust, road dust, salt, secondary/regional sulfate, and traffic, as well as three single-constituent components: arsenic, barium, and chromium. Traffic contributed most to total PM2.5 concentrations (20.2%) across the study period, peaking during the winter months and on weekdays. PCP also identified interpretable outlying pollution events, most notably spikes in potassium ion concentrations around each fourth of July.

CONCLUSIONS: PCP can serve as a useful and robust technique capable of handling data suffering from block missingness to identify exposure patterns and sparse events amenable to public health messaging and research.

P-0037 Generating daily high-resolution gridded meteorological datasets for New York State from 2017-2018 using two-stage downscaling model

Xinlei Deng[1], Howard Chang[2], Jerald Brotzge[3], Melissa Tracy[4], Xiaobo Romeiko[1], Shao Lin[1]

[1]Department of Environmental Health Sciences, State University of New York at Albany, Rensselaer, USA, [2]Department of Biostatistics and Bioinformatics, Rollins School of Public Health, Emory University, Atlanta, USA, [3]New York State Mesonet, State University of New York at Albany, Albany, USA, [4]Department of Epidemiology and Biostatistics, State University of New York at Albany, Rensselaer, USA

BACKGROUND AND AIM: Exposure misclassification in weather-related epidemiological studies is always a concern because there are a limited number of weather monitoring sites. This study aimed to build a high-resolution meteorological dataset using two-stage downscaling model and simulate exposures with a highly dense monitor system, New York State (NYS) Mesonet.

METHODS: High-resolution covariates for terrestrial characteristics, meteorological conditions, and temporal features were linked with NYS Mesonet data from 2017-2018, which contains 126 weather monitor stations (around 27 km x 27 km). These 126 weather stations were split into training set (116 stations) and testing set (10 stations). Machine learning models were used to generate initial meteorological simulations at the first stage. In the second stage, Bayesian spatial-temporal model was used to correct the spatial-correlation residuals from the first stage to get the final high-resolution gridded meteorological datasets (1 km x 1 km).

RESULTS: From 2017-2018, the optimal two-stage downscaling model on testing set had R2 = 0.992, RMSE = 0.996 °C, and MAE = 0.703 °C for temperature; R2 = 0.876, RMSE = 4.698 %, and MAE = 3.580 % for RH; R2 = 0.952, RMSE = 1.743 MJ/m2, and MAE = 1.261 MJ/m2 for SR; and R2 = 0.774, RMSE = 3.895 mm, and MAE = 1.603 mm for rainfall. The overall performance of the optimal two-stage downscaling model across training set and testing set had R2 = 0.999 for temperature, R2 = 0.978 for RH, R2 = 0.996 for SR, and R2 = 0.980 for rainfall.

CONCLUSIONS: This study proposed a two-stage downscaling model by combining machine learning models and Bayesian spatial-temporal models. We generated high-resolution gridded meteorological datasets (1 km x 1 km) which can be used by other researchers in environmental epidemiological studies to reduce exposure misclassification.

KEYWORDS: Meteorological exposure, exposure assessment, downscaling model, high resolution

THEMATIC 06: Children's environment and health

P-0411 Association of lifestyle factors with per- and polyfluoroalkyl substance (PFAS) concentrations in breast milk of Korean mothers

Ju Hee Kim[1], Na Lae Moon[1], Jae-Won Lee[2], Qaim Mehdi[2], Hyo-Bang Moon[2]
[1]College of Nursing Science, Kyung Hee University, Korea, Seoul, Seoul, Republic of Korea, [2]Department of Marine Science and Convergence Technology, Hanyang University, Ansan, Republic of Korea

BACKGROUND: Per- and polyfluoroalkyl substances (PFAS) is a group of synthetic chemicals used frequently in our daily life and has high stability in the environment and human body. The aim of our study is to measure the concentrations of per- and polyfluoroalkyl substance (PFAS) in breast milk of Korean mothers and find out the associations with the life-style factors.
Objective: The study population was made up of 207 primipara mothers who had one infant and enrolled in nationwide breastfeeding clinic from July 2 to September 9, 2018 in Korea.

METHODS: We analysed 14 PFAS and it includes 4 Perfluoroalkyl sulfonic acids (PFBA, PFHxS, PFOS and PFDS) and 10 Perfluoroalkyl carboxylic acids (PFPeA, PFHxA, PFHpA, PFOA, PFNA, PFDA, PFUnDA, PFDoDA, PFTrDA, PFTeDA). A questionnaire covering demographic features, obstetrical, life-style, and neonatal information was given to mothers.

RESULTS: PFOS and PFOA were detected 100% of breast milk samples followed by PFHxS (87.4%), PFNA (87%), and PFHxA (72.9%). The median concentrations were 0.05 ng/mL, 0.1 ng/mL, 0.031 ng/mL, 0.007 ng/mL, 0.033 ng/mL for PFOS, PFOA, PFHxS, PFNA, PFHxA respectively. There was 178% of increase of PFOA concentrations between 2007 and 2018. We also found that PFAS levels in Korean mothers' breast milk were higher than those in other countries. In the bivariate association test, the factors associated with the PFAS concentrations were body mass index, area, neonatal age, fish consumption, frequency of Ice-cream and canned food intake. In the multiple regression model, fish consumption had significant effect on the PFOS levels in breast milk (B=0.88 p=0.033).

CONCLUSIONS: As the PFAS has a high stability in the environment and hard to break down naturally, it is important to pay attention how it enters in our body and how can we reduce it to protect our family.

P-0413 Building Characteristics and Bioaerosols' Size Distribution as Predictors of Respiratory morbidities among Elementary School Pupils in Nigeria

Oyewale Mayowa Morakinyo[1], Godson Rowland Ana[1]
[1]*University of Ibadan, Ibadan, Nigeria, Ibadan, Nigeria*

BACKGROUND AND AIM: Bioaerosols are among pollutants that impair indoor air quality in schools where children spend long hours daily. Knowledge of bioaerosols' sizes is essential for the identification of associated risks in Nigeria. This study investigated school building characteristics, bioaerosols' size distribution and associated respiratory morbidities among elementary school pupils.

METHODS: In nine randomly selected schools, indoor air sampling was conducted in occupied and unoccupied classrooms. Airborne Bacterial Respirable Fraction (BRF) and Fungal Respirable Fraction (FRF) of aerodynamic diameter of 1.1–4.7 µm which corresponds to regions between the human primary bronchus and the alveolar duct were sampled using a six-stage cascade impactor. Building risk score was estimated and categorised as high (0-39) and low (40-56) using a validated walk-through checklist. A standardised questionnaire was adapted to elicit information from 554 randomly selected pupils on respiratory morbidities. Data were analysed using Mann-Whitney U, Spearman's rank correlation and multivariate logistic regression model at α0.05.

RESULTS: Median BRF and FRF were significantly higher when classrooms were occupied (3906 and 230 cfu/m3) than unoccupied (2800 and 214 cfu/m3), respectively. About 67.5% of the total bacterial and 77.8% fungal aerosols were respirable fractions. Building risk score was inversely correlated with BRF ($p<0.001$) and FRF ($p<0.001$). Exposure to high BRF and FRF was significantly associated with current rhinitis (aOR = 1.78, 95%CI: 1.11–2.85 and aOR = 1.83, 95%CI: 1.14–2.93) and current wheeze (aOR = 2.77, 95%CI: 1.73–4.43 and aOR = 1.88, 95%CI: 1.18–3.00), respectively.

CONCLUSIONS: Exposure to high levels of BRF and FRF was associated with respiratory health outcomes. Provision of new sustainable buildings is key to dipping the levels of indoor bioaerosols fractions and consequently, reduction in the prevalence of associated respiratory morbidities.

KEYWORDS: Indoor air quality, Microbial aerosols, Aerosol size distribution

P-0416 Environmental noise effect on 11 year old children sleep quality: a DAG model

Ane Arregi[1,2], Nerea Lertxundi[1,2,3], Gonzalo García-Baquero[2,3], Asier Anabitarte[2,4], Alba Jimeno-Romero[4], Oscar Vegas[1,2], Jesús Ibarluzea[1,2,3,5], Aitana Lertxundi[2,3,4]

[1]Faculty of Psychology, University of The Basque Country, San Sebatian, Spain, [2]Biodonostia Health Research Institute, Group of Environmental Epidemiology and Child Development, San Sebastian, Spain, [3]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Madrid, Spain, [4]Department of Preventive Medicine and Public Health, Faculty of Medicine, University of the Basque Country, Leioa, Spain, [5]Health Department of Basque Government, Sub-directorate of Public Health of Gipuzkoa, San Sebastian, Spain

BACKGROUND AND AIM: Environmental noise is considered the second environmental risk factor in Europe. Most of the noise effects in the adult population are associated with sleep quality, but there is little evidence about how environmental noise can affect children´s health and sleep and literature is inconclusive. It is thought that noise effects in health derives from the same mechanism as in adults; noise exposure creates a stress response, stimulating endocrine system and autonomic nervous system. Therefore, the goals of the study are: the description of environmental noise exposition in 11-year-old children from a cohort from northern Spain and the creation of a DAG model to test the unbiased effect of noise exposition on children´s sleep quality

METHODS: Data from 377 children participating in the Gipuzkoa cohort from the INMA project in the 11 year follow-up phase was used. Environmental noise exposition at children´s home, and both subjective and objective sleep quality were measured. Other variables were also assessed. Analyse was based on DAG model, that allows to identify a minimal sufficient adjustment set of variables to test the unbiased direct and total effect of environmental noise on sleep quality.

RESULTS: Children are exposed in media an exposition of 53,7dB during the evening and 46,73dB during the night. 60% of children are exposed to a day-evening-night environmental noise exposure above 55dB Lden. Clear sociodemographic differences were not observed. A suitable causal model to explain the unbiased effect of environmental noise on sleep quality has been created. No evidence was found that environmental noise has a significant effect on any sleep outcome.

CONCLUSIONS: Our study observed environmental noise exposition is very high. However, no effect on sleep quality was observed. for better understanding, further research is needed including a bigger sample and other sleep quality markers.

KEYWORDS: Environmental Noise, Sleep quality, stress

P-0417 Birth Cohort of Environmental Exposure and Childhood Development - PIPA Project – Rio de Janeiro, Brazil

Carmen Fróes Asmus[1], Nataly Damasceno[1], Volney Camara[1]
[1]*Federal University of Rio De Janeiro, Rio De Janeiro, Brazil*

BACKGROUND AND AIM: As a developing country, Brazil presents a wide range of environmental risks that may constitute hazards to child health. Currently, the Brazilian population faces environmental risks concerning both domiciliary and community scenarios. According to the Brazilian Institute of Geography and Statistics, over 80% of the Brazilian population lives in urban areas. The industrial development process in the country was accelerated and disorganized, comprising human migratory movements to large metropolitan areas, leading to urban clusters near industrial areas.

METHODS: The "PIPA project" is a prospective maternal-infant health study hosted in the city of Rio de Janeiro and designed to investigate childhood development alterations associated with multiple exposures to urban environmental pollutants from pregnancy until the age of 4. The project was initiated in June 2021, and the study population comprises all children born at the UFRJ Maternity University until June 2022 (12 months).

RESULTS: To date, 734 pregnant women have enrolled in the project, with 605 births. Maternal blood (n = 639) and urine (n = 595) were collected between the 32nd and 38th weeks of pregnancy. Newborn umbilical cord blood (n = 564) samples were collected at birth. Prematurity was observed in 14% and low weight in 6% of births. Returned for follow-up 214 3-month babies with 210 newborn urine samples and 169 maternal milk samples collected. Lead, mercury and arsenic concentrations were detected in 99,7%, 92,5% and 60,4% of 361 umbilical cord blood samples, respectively, with geometric means of 0,92 µdL (Pb), 0,75 µL (Hg) and 0,27 µL (As). In the 3-months babies following, 8,7% presented high and 1,7% low weight gain, according to the IMC Z score.

CONCLUSIONS: These results indicate the need to monitor maternal-child environmental pollutant exposure and correspondent investigation of its toxic effects on child health.

KEYWORDS: environmental pollutants; maternal-child health.

P-0418 Child Health Cohort Study. “Bruminha project”

Carmen Fróes Asmus[1], Aline Spindola[1], Ana Paula Natividade[2], Renam Duarte[1], Michelle Costa[1], Volney Camara[1]
[1]Federal University of Rio De Janeiro, Rio De Janeiro, Brazil, [2]Oswaldo Cruz Foundation _ Fiocruz, Rio de Janeiro, Brazil

BACKGROUND AND AIM: In Brazil, mining activities are one of the economic pillars of the country and the hundreds of municipalities. Mining disasters, their socio-environmental and health effects are part of the externalized environment, and their social costs are left to local territories and their inhabitants. In many situations, the exposed population has a low income and precarious access to drinking water and basic sanitation services, also suffering from any infectious or chronic diseases and nutritional deficits. Concerning child populations, exposure to any pollutant may lead to additional risk factors, worsening their vulnerability.

METHODS: The Bruminha project is a prospective cohort study established after the breakdown of a mining tailings dam in the city of Brumadinho, Brazil, in January 2019. This project investigates metal concentrations and their effects on the growth and immunological, neurodevelopmental, and respiratory health of children aged 0 to 4 years old living in the surrounding area of the disaster.

RESULTS: The cohort had begun in July 2021. Were examined 217 children, and 186 urine samples were collected. Arsenic and lead in urine samples were above the reference limits in 43% (80) and 13% (24) of the evaluated children. Underground water consumption was observed in 40% (83) of the study population. Fail in neuropsicomotor development was observed in 38% (82) of children after Denver Developmental Screening Test II (DDST-II) application. Fail in the DDST-II test was not associated with metal exposure but 66% (54) of children in the fail group lived in the communities directly affected by the impact of the mud of metals residue. Around 10% of children presented overweight.

CONCLUSIONS: The examined children live in a social-environmental vulnerability condition. These first results indicate the need to monitor pollutants exposure and investigate their toxic effects on these children´s health.

KEYWORDS: mining disasters; metals exposure; child health.

P-0419 Prenatal Exposure to Metals and Neurodevelopment in Infants at Six Months: Rio Birth Cohort Study of Environmental Exposure and Childhood Development (PIPA Project)

Monica Seefelder De Assis Araujo[1], Nataly Damasceno de Figueiredo, Carmen Ildes Rodrigues Froes-Asmus
[1]*Federal University of Rio De Janeiro, Rio de Janeiro, Brazil*

Intrauterine and early childhood metal exposure can affect neurodevelopment. Metal exposure in urban areas can occur through the air, water, and food routes. The literature reports an association between metal exposure during pregnancy and early childhood and impaired cognitive function in children. The city of Rio de Janeiro is the second more populous of Brazil and the sixth most populous in the American continent. The Rio Birth Cohort Study of Environmental Exposure and Childhood Development (PIPA Project) is the first cohort in Rio de Janeiro to assess pollutants in umbilical cord blood and investigate the relationship with childhood neurodevelopment, among other outcomes. The PIPA Project is a prospective birth cohort study based in Rio de Janeiro, Brazil, whose pilot study was carried out between October 2017 and August 2018. Arsenic, cadmium, lead, and mercury concentrations were determined in maternal (n = 49) and umbilical cord blood (n = 46). The Denver Developmental Screening Test II (DDST-II) was applied in 50 six-month-old infants. Metals were detected in 100% of the mother and newborn samples above the limits of detection. Maternal blood lead concentrations were higher in premature newborns (GM: 5.72 µg/dL; p = 0.05). One-third of the infants (n = 17–35.4%) exhibited at least one fail in the neurodevelopment evaluation (fail group). Maternal blood arsenic concentrations were significantly (p = 0.03) higher in the “fail group” (GM: 11.85 µg/L) compared to infants who did not fail (not fail group) (GM: 8.47 µg/L). Maternal and umbilical cord blood arsenic concentrations were higher in all DDST-II domains in the “fail group”, albeit non-statistically significant, showing a tendency for the gross motor domain and maternal blood (p = 0.07). These findings indicate the need to further investigate the toxic effects of prenatal exposure to metals on infant neurodevelopment.

KEYWORDS: prenatal exposures; metals; neurodevelopment.

P-0420 Identifying critical windows of perinatal lead exposure for serum antibody levels following childhood vaccination

Elena Colicino[1], Lucia Gerbi[1], Christine Austin[1], Nicolo Foppa Pedretti[1], Maria J Rosa[1], Nia McRae, Sally A. Quataert[2], Marina Oktapodas Feiler[3], Kelly Thevenet-Morrison[2], Martha M. Tellez-Rojo[4], Hector Lamadrid-Figueroa[4], Manish Arora[1], Robert O Wright[1], Todd A. Jusko[2]

[1]Icahn School of Medicine, New York, USA, [2]University of Rochester School of Medicine and Dentistry, Rochester, USA, [3]College of Public Health, Temple University, Philadelphia, USA, [4]National Institute of Public Health, Cuernavaca, Mexico

BACKGROUND AND AIM: Many aspects of child health depend on the proper development of the immune system during pre- and early post-natal periods. Mounting evidence suggests that early-life lead exposure may alter aspects of the immune response, including T-cell dependent antibody responses to childhood immunizations. However, no studies have identified critical windows of susceptibility to lead exposure.
We aim to identify critical time windows of lead exposure—measured weekly from 16 weeks before birth to 14 weeks after birth—that are associated with antibody responses to MMR (measles, mumps, and rubella) and DTP (diphtheria, tetanus, and pertussis) vaccinations measured at 5-years of age.

METHODS: Weekly pre- and post-natal dentine lead concentrations were measured in 302 children enrolled in the PROGRESS (Programming Research in Obesity, GRowth, Environment, and Social Stress) study in Mexico City. at age 5 years, serum anti-MMR and anti-DTP antibody levels were determined by a Luminex multiplexed-microbead array immunoassay. Time-varying associations between log2–transformed antibody levels and log2–transformed dentine lead concentrations were estimated by fitting distributive lag models. Models were adjusted for maternal age, education, parity, child sex, and child age. Sensitivity models also included maternal smoking, time since vaccination, and a lead exposure-sex interaction.

RESULTS: Higher lead levels in the first month postpartum were associated with lower anti-tetanus antibody levels at 5-years of age. Weekly coefficients indicated that, on average, a two-fold higher dentine lead concentration was associated with a 4% decrease in anti-tetanus antibody levels. A critical window of lead exposure was identified as one week before to one week after birth for anti-diphtheria antibody levels, although these associations were borderline significant. Sensitivity analyses indicated a lack of sex-specific differences, and observed associations were robust to alternative model specifications.

CONCLUSIONS: Early-life lead exposure may program immune dysregulation that manifests in later childhood.

KEYWORDS: child immune system, dentine lead levels

P-0421 Effects of air pollution exposure predicting sleep efficiency in children modified by exposure to violence, 4-7 years, in the PROGRESS birth cohort

Terry Thompson[1]
[1]*Icahn School of Medicine at Mount Sinai, New York City, USA*

BACKGROUND: Studies suggest that expose to both air pollution and violence may alter development trajectory, as it may disrupt the HPA-axis which plays an important role in how the human body reacts to environmental stressors affecting sleep. We propose that prenatal air pollution exposure may interact with violence to affect the efficiency of sleep, therefore, modified by exposure to violence.

METHODS: We studied 412 children enrolled in Programming Research in Obesity, GRowth, Environment and Social Stressors (PROGRESS), a birth cohort study in Mexico City. We used a spatio-temporal model to estimate individual daily prenatal PM2.5 exposure at each participant's residential address. We assessed the sleep efficiency (defined with time awake divided by time in bed) of all kids at age 4-7 years with assigned accelerometer worn during sleep, and recorded sleep patterns for a week to examine the association between PM2.5 exposure and sleep efficiency.

RESULTS: Participants are mostly low SES families (54.6%) with slightly lower proportion of low maternal education (42.1%) and are racial/ethnicity uniformed. Sleep efficiencies are normally distributed and ranging from 63.5 to 91.8. at age 4, children who were exposed to low-to-mid violence are more likely to have their sleep efficiency disrupted by prenatal PM2.5 exposure (ETV at 10%tile, β=-0.26, CI:-1.19,0.68; However, at age 6, we found that PM2.5 reduced sleep efficiency at even lower levels, (ETV at 10%tile, β=-0.26, CI:-1.05,0.54; peak PM effect at ETV at 36%tile, β=-0.71, CI:-1.5,0.09; ETV at 90%tile, β=0.28, CI:-1,1.55;).
CONCLUSION: As the literature expands on sleep and sleep disparities, the sparseness of studies on children's sleep highlights a research void that if addressed could mitigate the adverse impact of child sleep disparities on long term health.

KEYWORDS: environmental stressors, violence, sleep health, disparities, exposure

P-0423 Pre and postnatal exposure to mercury and sexual development in 9-year-old children in Spain: The role of brain-derived neurotrophic factor

Blanca Sarzo[1,2], Raquel Soler-Blasco[3,4], Maria-Jose Lopez-Espinosa[1,3,4], Manuel Lozano[1,3], Gabriel Riutort-Mayol[5], Andrea Beneito[3], Mario Murcia[3,6], Gorka Iriarte[7], Ferran Ballester[1,3,4], Sabrina Llop[3,4]

[1]Universidad de Valencia, Valencia, Spain, [2]University of Edinburgh, Edinburgh, Scotland, [3]Epidemiology and Environmental Health Joint Research Unit, FISABIO-Universidad Jaume I-Universidad de Valencia, Valencia, Spain, [4]CIBERESP, Madrid, Spain, [5]FISABIO Public Health, Valencia, Spain, [6]Conselleria de Sanitat, Generalitat Valenciana, Valencia, Spain, [7]aboratorio de Salud Pública, Alava, Spain

BACKGROUND: Early exposure to the mercury has been related to endocrine disruption. Steroid hormones play a crucial role in neural cell migration, differentiation, as well as protecting against several neurotoxic compounds. Some studies have reported interactions between steroid hormones and the brain-derived neurotrophic factor (BDNF), a polypeptide known to play an important role in the survival, differentiation and outgrowth of neurons. We investigate the relation between mercury exposure and children's sexual development, and we evaluate the possible influence of different BDNF polymorphisms on this relation.

METHODS: Our study sample comprised 412 9-year-old children (49.5% of females) participating in the INMA (Environment and Childhood) Valencia cohort (2004–2015, East of Spain). Total mercury (THg) concentrations were measured at birth (cord blood) and at 4 and 9 years of age (hair). Sexual development was assessed by levels of sex steroid hormones (estradiol and testosterone) in saliva and the Tanner Stages of development (categorized as 1: pre-puberty and >1: puberty). Covariates were collected through questionnaires during pregnancy and childhood. Polymorphisms in the BDNF gene were genotyped in cord blood DNA. Multivariate linear and logistic regression analyses were performed between mercury levels and children's sexual development by sex and including the effect modifier variables of genetic polymorphisms.

RESULTS: We found some evidence of inverse associations between 9 year-old THg (geometric mean=0.8 and 1.0 µg/g for boys and girls, respectively) and testosterone levels (β[95%CI]=-0.16[-0.33,0.001], and -0.20[-0.42,0.03], for boys and girls, respectively). Additionally, we found that prenatal THg was negatively associated with puberty onset in boys. Finally, we found significant genetic interactions for some single nucleotide polymorphisms in the BDNF gene.
In conclusion, pre and postnatal exposure to THg seems to affect children's sexual development and BDNF may play a role in this association, but further research would be needed.

KEYWORDS: mercury, sexual development, birth cohort

P-0424 Short-term nitrogen dioxide exposure and asthma emergency hospital admissions in children: a case-crossover study in England

Weiyi Wang[1], John Gulliver[2], Sean Beevers[1], Anna Freni Sterrantino[3], Richard Atkinson[4], Daniela Fecht[1]
[1]MRC Centre for Environment and Health, School of Public Health, Imperial College London, London, UK, [2]Centre for Environmental Health and Sustainability, George Davies Centre, University of Leicester, Leicester, UK, [3]The Alan Turing Institute, London, UK, [4]Population Health Research Institute and MRC-PHE Centre for Environment and Health, St George's, University of London, London, UK

BACKGROUND AND AIM: Most studies on the acute health effects of air pollution rely on temporally resolved exposure information, potentially ignoring the high spatial variability of pollutants such as nitrogen dioxide (NO_2). Our study aims to examine associations of short-term NO_2 exposure with the risk of asthma-related emergency hospital admission in children in England, using spatio-temporal (ST) highly resolved air pollution data.

METHODS: We conducted a time-stratified case-crossover study including 111,766 asthma emergency hospital admissions in children (aged 0-14 years) during 2011-2015. Daily NO_2 levels were predicted at the patients' place of residence using ST models by combining land use data and chemical transport model estimates. Conditional logistic regression models were used to obtain odds ratios (OR) and confidence intervals (CI), adjusting for temperature, relative humidity, bank holidays and influenzas. Effect modification of risk by age, sex, season, income deprivation index and region were explored.

RESULTS: for a 10 $\mu g/m^3$ increase of NO_2 exposure, a positive association was observed in children aged 0-14 years, between emergency admission for asthma and NO_2 concentrations with a 5-day moving average (mean lag0-4) (OR 1.082, 95% CI 1.064-1.100). The associations were higher for males (OR 1.095, 95% CI 1.072-1.119) than females (OR 1.059, 95% CI 1.030-1.089), but results were similar for different age groups. We found evidence of effect modification by season with the strongest effect for the cold season (OR 1.101, 95% CI 1.079-1.123). Small differences in estimates were found by income deprivation and region, most of these were statistically significant.

CONCLUSIONS: Our study provides evidence that some sub-populations are more susceptible to the effects of ambient NO_2 and are of higher risk of asthma-related hospital admissions, which has implications for air quality regulatory standards and policymaking.

KEYWORDS: nitrogen dioxide, asthma, children, emergency hospital admissions, case-crossover, effect modifiers

P-0425 Pediatric Anxiety and Daily Fine Particulate Matter: A Longitudinal Study

Andrew Vancil[1], Jeffrey Strawn[2,1], Erika Rasnick[1], Amir Levine[3,4], Heidi Schroeder[2], Ashley Specht[2], Ashley Turner[1], Patrick Ryan[1,5], Cole Brokamp[1,5]

[1]Cincinnati Children's Hospital Medical Center, Division of Biostatistics & Epidemiology, Cincinnati, USA, [2]University of Cincinnati, Anxiety Disorders Research Program, Department of Psychiatry & Behavioral Neuroscience, Cincinnati, USA, [3]Department of Psychiatry, College of Physicians and Surgeons, Columbia University, New York, USA, [4]Division of Child and Adolescent Psychiatry, New York State Psychiatric Institute, New York, USA, [5]University of Cincinnati, College of Medicine, Department of Pediatrics, Cincinnait, USA

BACKGROUND & AIM: Ambient fine particulate matter with an aerodynamic diameter of less than 2.5 μm (PM2.5) is a potential contributor to the morbidity of anxiety disorders in children and adolescents. Recent PM2.5 has been associated with increased anxiety symptom severity and frequency in cohort studies, but daily PM2.5 has not been studied outside of emergency department utilization data, nor in a longitudinal study design. We sought to determine the association between daily ambient PM2.5 concentrations and repeated measures of anxiety symptom severity in a cohort of adolescents with untreated, moderate to severe anxiety.

METHODS: Anxiety symptom severity was measured weekly for up to 8 weeks in 23 non-medicated adolescents with moderate to severe generalized anxiety disorder by using a clinician-administered instrument (Pediatric Anxiety Rating Scale, PARS). PM2.5 was assessed based on the date and residential address using a previously validated spatiotemporal exposure prediction model. We used a distributed lag nonlinear model with fixed effects for study participant and controlled for confounding by air temperature, relative humidity, and day of the year.

RESULTS: An increase in PM2.5 concentration from the 25th percentile to the median (5.93 μg/m3 versus 7.96 μg/m3) was significantly associated with increased PARS scores two (0.57, 95% CI: 0.06, 1.07), three (0.82, 95% CI: 0.18, 1.45), and four (0.62, 95% CI: 0.11, 1.14) days later. We found evidence of a supralinear dose-response curve, with increases at lower concentrations being associated with larger changes in PARS scores compared to similar increases at higher concentrations.
CONCLUSION: Fine particulate matter may be a novel, modifiable exposure that could inform population level interventions to decrease psychiatric morbidity.

KEYWORDS: Particulate matter 2.5, General Anxiety Disorder, Pediatric Anxiety Rating Scale, distributed lag nonlinear model, environmental exposure, pediatrics

P-0429 Early-Life Stages Human Health Risk Assessment of toxic and essential metals in Rice and Rice-Based Baby Foods

Mom Tatah Mentan[1], Syprose Nyachoti[1], Tewodros Godebo[1]
[1]*Tulane University, New Orleans, USA*

BACKGROUND AND AIM: Dietary exposure to heavy metals in Rice and Rice Based foods can have deleterious effects including lung and kidney cancer, Keratosis and Diabetes. Early-life exposure to these toxicants from consuming these foods is a growing area of research that requires further study. This research utilizes a probabilistic analysis to examine the likelihood of adverse health effects from early life consumption of rice and rice-based foods.

METHODS: Thirty-three rice and rice-based foods for infants and toddlers were purchased via an online market based survey. These samples were subsequently acid digested and underwent Inductively Coupled Plasma Mass Spectrometry Analysis. The elements of interests were Arsenic (As), Cadmium (Cd), Lead (Pb) and Selenium (Se). These metals were then used to conduct a probabilistic risk analysis including a Hazard quotient (HQ), margin of exposure (MOE) and lifetime cancer risk (LCR) calculation, principal component analysis (PCA). Also, we generated descriptive and inferential statistics.

RESULTS: As and Se had the highest mean concentrations 111 + 67.1, 72 + 58.5 respectively. Significant differences were found between Cd and Hg metal concentrations for samples cultivated in USA versus Internationally $p < 0.05$. for PCA, three pc scores were selected for a total variance of 59.8%. As was highly negatively correlated with PC3, meanwhile Se and Cd were negatively correlated with PC2 and PC1. HQ calculations were indicative of a negligible risk. Both MOE and LCR analysis indicate risk of genotoxic and carcinogenic outcomes.

CONCLUSIONS: Overall, findings indicated that mean exposure to As above the FDA's recommended safe level. PCA also showed that these metals likely came from varying anthropogenic sources. Risk analysis highlighted increased risks of genotoxicity and carcinogenicity.

KEYWORDS: Arsenic, Cadmium, Lead, Baby food

P-0430 Educational intervention in rural schoolchildren exposed to pesticides: a qualitative analysis of their experiences and testimonies

María Teresa Muñoz-Quezada[1], Boris Lucero[1]
[1]*Universidad Católica del Maule, Talca, Chile*

BACKGROUND: Organophosphate pesticides (OP) are frequently used in agriculture and are toxic to humans. In Chile, OP metabolites were detected in the urine of rural schoolchildren. Although there are studies examining the effect of educational interventions on risk perception and urine metabolites in students exposed to pesticides, there are no qualitative data available.
OBJECTIVE: The aim of this study was to conduct a qualitative analysis of the pictorial and narrative experiences of two Chilean rural educational communities that participated in a pesticide exposure intervention.

METHODS: The intervention lasted four weeks and involved 48 schoolchildren and their parents over a two-year period (2016-2017). The experience's systematization was investigated qualitatively using pictorial compositions and oral testimonies from participants during and after the intervention.

RESULTS: Both parents and children show an increased knowledge of the environmental concerns associated with pesticide exposure and its consequences on health, occupational conflicts, and cohabitation with neighbors who use these agrochemicals. Certain individuals experience cognitive dissonance when they apply pesticides due to their toxicity. Children have a discourse that is risk-averse, concerned with the common good, and prioritizes the pursuit of justice, solidarity, and accountability; nonetheless, they are dependent on the actions of adults. The parents believe the children's demands are reasonable, but they express frustration over the lack of monitoring and the difficulties in filing complaints due to a lack of knowledge about the procedures, a lack of connectivity, or fear of disagreement with those who use pesticides.

CONCLUSIONS: It is critical that interventions are centered on the direct experiences of rural schoolchildren and their families, while remaining true to scientific content and grounded in local knowledge and culture, and that they contribute significantly to the community's search for solutions and actions in the face of environmental conflict.

KEYWORDS: Pesticides, schoolchildren, qualitative analysis.

P-0431 Exploring blue spaces' effects on childhood leukaemia inci-dence: A population-based case-control study in Spain

Carlos Ojeda Sánchez[1], Javier García-Pérez[1,5], Diana Gómez-Barroso[1,5], Alejandro Domínguez-Castillo[1], Elena Pardo Romaguera[3], Adela Cañete[3], Juan Antonio Ortega-García[4], Rebeca Ramis[1,5]

[1]Carlos III Institute of Health (ISCIII), Madrid, Spain, [2]Albacete University Hospital, Albacete, Spain, [3]Spanish Registry of Childhood Tumours (RETI-SEHOP), University of Valencia, Valencia, Spain, [4]Pediatric Environmental Health Speciality Unit, IMIB-Arrixaca, Clinical University Hospital Virgen de la Arrixaca, Murcia, Spain, [5]CIBER Epidemiología y Salud Pública - CIBERESP, Madrid, Spain

BACKGROUND AND AIM: Blue spaces have been a key part of human evolution, providing resources and helping economies develop. To date, no studies have been carried out to explore how they may be linked to paediatric oncological diseases. The aim of this study was to explore the possible relationship of residential proximity to natural and urban blue spaces on childhood leukaemia.

METHODS: A population-based case control study were conducted in four regions of Spain across the period 2000-2018. 936 incident cases and 5,616 controls were included, individually matched by sex, year-of-birth and place-of-residence. An exposure proxy with four distances (250m, 500m, 750m and 1 km) to blue spaces was built using the geographical coordinates of the participants' home residences. Odds ratios (ORs) and 95% confidence intervals (95%CIs), blue space exposure were calculated for overall childhood leukaemia, and the acute lymphoblastic (ALL) and acute myeloblastic leukaemia (AML) subtypes, with adjustment for socio-demographic and environmental covariates.

RESULTS: A decrease in overall childhood leukaemia and ALL-subtype incidence was found as we came nearer to children's places of residence, showing, for the study as a whole, a reduced incidence at 250m (odds ratio (OR)=0.77; 95%CI=0.60-0.97), 500m (OR=0.78; 95%CI=0.65-0.93), 750m (OR=0.80; 95%CI=0.69-0.93) and 1000m (OR=0.84; 95%CI=0.72-0.97). AML model results showed an increasing incidence at closest to subjects' homes (OR at 250m = 1.06; 95%CI=0.63-1.71).

CONCLUSIONS: Our results suggest a possible association between lower childhood-leukaemia incidence and blue-space proximity. This study is a first approach to blue spaces' possible effects on childhood leukaemia incidence; consequently, it is necessary to continue studying these spaces – while taking into account more individualized data and other possible environmental risk factors.

KEYWORDS: urban blue spaces; environmental factors; childhood cancer; childhood leukaemia; incidence; spatial epidemiology.

P-0432 Prenatal exposure effects to environmental pollutants on birth weight and weight gain during the first six months of life

Ana Natividade[1], Nataly Damasceno[2], Carmen Froes[3]
[1]Fiocruz, Rio de Janeiro, Brazil, [2]UFRJ, RIO DE JANEIRO, Brazil, [3]UFRJ, RIO DE JANEIRO, Brasil

The intrauterine period and first months after birth are critical concerning pollutant exposure, as the fetus and infant are especially vulnerable to developmental disrupting pollutants during these timeframes. Environmental pollutants can cross the placental barrier and affect intrauterine growth and development, which can lead to birth weight effects, as well as changes that may only manifest in adulthood. Birth weight and growth and development assessments are important child health indicators. This study evaluated the relationship between biological sample pollutant concentrations and birth weight and weight gain in the first six months of life.

Data from the PIPA-UFRJ Project pilot study were used, evaluating metal (lead, mercury, cadmium, arsenic), organochlorine (4'4DDE), and perfluoroalkyl substances (PFOS) concentrations in umbilical cord blood and pyrethroids (3BPA) in the urine of pregnant women, as well as birth weight and weight gain at 6 months in 125 and 58 children, respectively, born at the UFRJ Maternity School from October/2017 to August/2018.

Prenatal DDE exposure was associated with weight gain (Z score >2) at six months of age OR= 6,0 (CI 95% 1,03 – 34,90). Mean arsenic concentrations were also significantly higher in children with high weight gain at six months of age (p=0,046). Mean birth weight was lower in female newborns exposed to 3BPA (p=0,081), and weight gain at six months of age was moderately and inversely correlated with 3BPA (p=0,096), although not significant.

The PIPA-UFRJ Project pilot study was the first in Brazil to evaluate umbilical cord blood environmental pollutants in relation to birth weight and weight gain at 6 months. These results are in agreement with other findings in the literature and indicate the need for further studies to investigate the relationship between prenatal environmental pollutant exposure and weight gain in the Brazilian child population.

KEYWORDS: Prenatal Exposure; Environmental Pollutants; Birth Weight; Weight gain

P-0433 Exposure to ambient ultrafine particles and allergic sensitization in children up to 16 years

Femke Bouma[1], Gerard Hoek[1], Gerard Koppelman[2,3], Judith Vonk[3,4], Jules Kerckhoffs[1], Roel Vermeulen[1,5], Ulrike Gehring[1]

[1]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, [2]Department of Pediatric Pulmonology, Beatrix Children's Hospital, University Medical Center Groningen, Groningen, Netherlands, [3]Groningen Research Institute for Asthma and COPD, University of Groningen, Groningen, Netherlands, [4]Department of Epidemiology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [5]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands

BACKGROUND AND AIM: Few epidemiological studies so far have investigated the role of long-term exposure to ultrafine particles (UFP) in allergy development. The purpose of this study was to assess the association between UFP exposure and allergic sensitization to inhalant and food allergens in children up to 16 years old in the Netherlands.

METHODS: 2295 participants of the prospective PIAMA birth cohort with specific IgE measurements to common inhalant and food allergens at ages 4, 8 or 12 or to common inhalant allergens at age 16 were included in the study. Annual average UFP concentrations were estimated for the home addresses at birth and at the time of the IgE measurements using land-use regression models. Generalized estimating equations were used for the assessment of overall and age-specific associations between UFP exposure and allergic sensitization. Additionally, single- and two-pollutant models with NO2, PM2.5, PM2.5 absorbance and PM10 were assessed.

RESULTS: We found no significant associations between UFP exposure and allergic sensitization to inhalant and food allergens (OR (95% CI) ranging from 1.02 (0.95 – 1.10) to 1.05 (0.98 – 1.12), per IQR increment). In contrast, NO2, PM2.5, PM2.5 absorbance and PM10 showed significant associations with sensitization to food allergens (OR (95% CI) ranging from 1.09 (1.00–1.20) to 1.23 (1.06–1.43) per IQR increment) but not with sensitization to inhalant allergens (OR (95% CI) ranging from 0.98 (0.90-1.07) to 1.08 (0.93-1.25) per IQR increment). for NO2, PM2.5 and PM2.5 absorbance, the associations with sensitization to food allergens persisted in two-pollutant models with UFP.
CONCLUSION: This study found no association between annual average exposure to UFP and allergic sensitization in children up to 16 years of age. NO2, PM2.5, PM2.5 absorbance and PM10 were associated with sensitization to food allergens.

KEYWORDS: ultrafine particles, IgE sensitization, inhalant and food allergens, children, air pollution, allergy

P-0434 Exposure to endocrine-disrupting chemical mixture and IQ at 4-6 years of age: in Mother and Children's Environmental Health study (MOCEH study)

Dajeong Ham[1], Mina Ha[2], Hyesook Park[3], Yun-Chul Hong[4], Yangho Kim[5], Eunhee Ha[6], Sanghyuk Bae[1]

[1]Department of Preventive Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea, [2]Department of Preventive Medicine, College of Medicine, Dankook University, Seoul, Republic of Korea, [3]Department of Preventive Medicine, College of Medicine, Graduate Program in System Health Science and Engineering, Ewha Womans University, Seoul, Republic of Korea, [4]Department of Preventive Medicine, College of Medicine, Seoul National University, Seoul, Republic of Korea, [5]Department of Occupational and Environmental Medicine, University of Ulsan College of Medicine, Seoul, Republic of Korea, [6]Department of Occupational and Environmental Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea

BACKGROUND AND AIM: Early childhood is important for neurodevelopment and exposure to endocrine disruptors such as bisphenol-A and phthalate in this period may cause neurodevelopmental disorders such as autism spectrum disorder, attention deficit hyperactivity disorder and developmental delay. The present study aimed to examine the association between exposure to endocrine-disrupting chemical mixture in early childhood and IQ at 4-6 years of age.

METHODS: Mother and Children's Environmental Health study (MOCEH study) is a prospective Korean birth cohort study. We used the urinary concentrations of metabolites of endocrine-disrupting chemicals (Bisphenol-A, Mono-(2-ethyl-5-oxohexyl) phthalate, Mono-(2-ethyl-5-hydroxyhxyl) phthalate, Mono-(2-ethyl-5-buyl) phthalate) measured at the age of 24 and 36 months. We measured the children's IQ with Korean Wechsler Intelligence Test at the age between 4 through 6 years. After adjusting for the potential confounders, multivariate linear regression was conducted to examine the association between the endocrine-disrupting metabolic substances eack and the IQ of the children. Bayesian kernel machine regression analysis was used to assess the association between exposure to endocrine-disrupting chemical mixtures and IQ(n = 164).

RESULTS: All endocrine-disrupting chemicals measured at both 24 and 36 months were significantly associated with decreased IQ. Mono-(2-ethyl-5-buyl) phthalate measured at 36 months showed the greatest magnitude of association (β = -0.026, 95% confidence interval: -0.049, -0.003). The exposure to mixture of all chemicals was associated with lower IQ. Among the four chemicals and two periods, Mono-(2-ethyl-5-buyl) phthalate exposure at 36 months was identified as the most critical factor associated with IQ scores.

CONCLUSIONS: We observed that exposure to endocrine-disrupting chemical mixture was negatively associated with children's IQ.

P-0435 Exposure to greenspace and bluespace in relation to cognitive functioning in children and adolescents - A systematic review

Dorota Buczyłowska[1], Tianyu Zhao[2], Nitika Singh[1], Anna Jurczak[1], Agnieszka Siry[1], Iana Markevych[1]
[1]*Institute of Psychology, Jagiellonian University, Kraków, Poland,* [2]*Institute and Clinic for Occupational, Social and Environmental Medicine, LMU University Hospital Munich, Munich, Germany*

BACKGROUND AND AIM: The field of green- and bluespace research including studies in relation to cognitive functioning is rapidly growing. Thus, there is a strong need to systematically review the existing studies. Several systematic reviews have been already published on this topic but none of them is specific to cognitive outcomes in children of the entire age range. Moreover, only few of them examined the effects of bluespace in addition to greenspace. Also, previous reviews were focused either only on observational studies or on experimental studies. Our systematic review focuses on cognition in relation to green- and bluespace in children and adolescents between birth and 18 years old and captures both observational and experimental studies.
METHODS: We followed the Preferred Reporting Items for Systematic Review and Meta-analysis (PRISMA) guidelines. Searches were conducted in two databases – PubMed and PsychInfo. Free-text terms related to outcome, exposure, and population as well as MeSH terms for outcome and population were used. Further, the reference lists of publications identified as eligible for full-text review were "snowball" searched to detect additional studies.
RESULTS: Records identified from PubMed (n=2030) and PsycINFO (n=1168) were deduplicated and screened. 22 publications were selected. 13 additional publications were identified through „snowball" search. The extration of data revealed heterogeneity among studies. Methodological flaws and differences between studies should be considered. First, various methods of exposure and outcome assessment were used. Second, risk of bias assessment revealed inappriopriate use of statistical methods including the confounding and modifying variables, and mediating methods, exclusion data from analysis and selective reporting of outcomes, and inappriopriate assessment of cognition.
CONCLUSIONS: Improvement regading the methodological quality of future studies is required: expertise from several domains such as environmental epidemiology, statistics, and psychology should be involved in conducting future studies.

KEYWORDS: green space, blue space, cognitive development

P-0436 Unconventional oil and gas exposure and risk of childhood leukemia in Pennsylvania

Cassandra Clark[1], Nicholaus Johnson[1,2], Mario Soriano[3], Joshua Warren[4], Keli Sorrentino[2], Nina Kadan-Lottick[5], James Saiers[3], Xiaomei Ma[6], Nicole Deziel[1,2]

[1]Yale School of Public Health, Department of Environmental Health Sciences, New Haven, USA, [2]Yale Center for Perinatal, Pediatric, and Environmental Epidemiology, New Haven, USA, [3]Yale School of the Environment, New Haven, USA, [4]Yale School of Public Health, Department of Biostatistics, New Haven, USA, [5]Georgetown Lombardi Comprehensive Cancer Center, Washington D.C., USA, [6]Yale School of Public Health, Department of Chronic Disease Epidemiology, New Haven, USA

BACKGROUND/AIM: Unconventional oil and gas development (UOGD), commonly known as "fracking," is a rapidly expanding industry that releases chemicals that have been linked to cancer and childhood leukemia. Despite high community concern, studies of childhood cancer are sparse. We evaluated potential associations between residential proximity to UOGD and risk of acute lymphoblastic leukemia (ALL), the most common form of childhood leukemia, in a large regional sample using UOGD-specific metrics, including a novel metric representing the water pathway.

METHODS: We conducted a registry-based case-control study of 405 children aged 2-7 years diagnosed with ALL in Pennsylvania between 2009-2017, and 2,080 controls matched on birth year. We used adjusted logistic regression to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for the association between residential proximity to UOGD (including a new water-specific proximity metric) and ALL in two exposure windows: a primary window (three months pre-conception to one year prior to diagnosis/reference date) and a perinatal window (three months pre-conception–birth).

RESULTS: Children with at least one UOG well within 2 km of their birth residence during the primary window had 1.98 times the odds of developing ALL versus those with no UOG wells (95% CI: 1.06-3.69). Children with at least one versus no UOG wells within 2 km during the perinatal window had 2.80 times the odds of developing ALL (95% CI: 1.11-7.05). These relationships were slightly attenuated after adjusting for maternal race and socio-economic status (OR: 1.74 [95% CI: 0.93-3.27], OR: 2.35 [95% CI: 0.93-5.95], respectively). Analyses based on the water-specific metric yielded similar findings.

CONCLUSIONS: Our large regional study including a novel water-specific metric found UOGD to be a risk factor for childhood ALL. This work adds to mounting evidence of UOGD's impacts on children's health, supporting the need to limit UOGD near residences.

KEYWORDS: Childhood leukemia, unconventional oil/gas

P-0437 Early-life exposure to per- and polyfluoroalkyl substances and gut microbial composition

Hannah E. Laue[1], Yuka Moroishi[1], Thomas J. Palys[1], Brock C. Christensen[1], Rachel Criswell[2], Emily R. Baker[3], Margaret R. Karagas[1], Juliette C. Madan[1,4], Megan Romano[1]

[1]Department of Epidemiology, Geisel School of Medicine at Dartmouth College, Lebanon, USA, [2]MaineGeneral Medical Center, Augusta, USA, [3]Department of Obstetrics and Gynecology, Dartmouth Hitchcock Medical Center, Lebanon, USA, [4]Departments of Pediatrics and Psychiatry, Children's Hospital at Dartmouth, Lebanon, USA

BACKGROUND AND AIM: Human milk is an under-appreciated source of toxic exposures, including immunomodulatory per- and polyfluoroalkyl substances (PFAS), for breastfed infants. The immune-related effects of PFAS may, in part, be due to alterations of the microbiome. We aimed to identify changes in the infant gut microbiome related to milk PFAS exposure.

METHODS: In the New Hampshire Birth Cohort Study, PFAS were quantified in human milk samples from ~six weeks postpartum using solid-phase extraction coupled to high-performance liquid chromatography-isotope dilution tandem mass spectrometry. A molar sum (ΣPFAS) was calculated. Caregivers collected infant stool samples at six weeks (n=116) and/or one year postpartum (n=119). Stool DNA was extracted and underwent metagenomic sequencing. We profiled bacterial species and KEGG Orthologies (KOs) using BioBakery pipelines. Diversity was quantified with the Shannon Index. We estimated the association of PFAS with alpha diversity and relative abundances of species and KOs with linear regression. Single- and multi-pollutant models adjusted for confounders and predictors of the microbiome, with missing covariate data imputed. Each outcome timepoint was considered separately and analyses at six weeks were restricted to infants who were exclusively fed human milk (n=90).

RESULTS: Perfluorooctanesulfonic acid (PFOS) and perfluorooctanoic acid (PFOA) were detected in 94% and 83% of milk samples, respectively. PFOS was associated with increased Shannon Index at six weeks [β=0.24 per PFOS doubling, (95%CI: 0.03, 0.45), p=0.03]. Estimates were stronger in multi-pollutant than single-pollutant models, and among complete cases. ΣPFAS was associated with one-year-old Bacteroides vulgatus relative abundance [(β=-2.48 % per doubling (-3.77, -1.18), FDR q=0.05]. No other associations were observed.

CONCLUSIONS: PFAS may increase diversity of the infant gut microbiome and alter the relative abundance of cardiometabolically-active bacteria. Additional analyses may highlight susceptible populations and identify related health outcomes.

KEYWORDS: per- and polyfluoroalkyl substances, microbiome, human milk

P-0438 Investigation of the relationship between multiple environmental exposures and pediatric obesity in a national cross-sectional study of Canadian children

Rose Dugandzic[1], Yamei Yu[1], Sabit Cakmak[1], Eric Lavigne[1,2], Sebastian Srugo[4], Justin Lang[3,4], Paul Villeneuve[3], Tyler Pollock[1], Errol Thomson[1,2], Miranda MacPherson[1], Robert Dales[1,2,5]

[1]Health Canada, Ottawa, Canada, [2]University of Ottawa, Ottawa, Canada, [3]Carleton University, Ottawa, Canada, [4]Public Health Agency of Canada, Ottawa, [5]The Ottawa Hospital, Ottawa, Canada

BACKGROUND AND AIM: Pediatric obesity rates in Canada have nearly tripled in the last 30 years, leading to increased rates of morbidity. While environmental exposures are suspected to be obesogenic, data are lacking and mostly employ a single-exposure approach. We aimed to evaluate the potential associations between multiple environmental factors and pediatric obesity.

METHODS: We used nationally-representative biomonitoring and health data for children aged 3-11 from the cross-sectional Canadian Health Measures Survey. Chemicals of interest, monitored in blood or urine, were polyaromatic hydrocarbons (PAH), bisphenol A (BPA), parabens, perfluorinated compounds, phthalates and metals. Obesity was characterized by WHO sex-specific body mass index (BMI) for age z-scores. Central obesity was defined using international waist circumference percentile cutoffs. Using generalized additive models, we examined the impact of multiple environmental characteristics, including proximity to greenspace, fine particulate matter (PM 2.5), nighttime light brightness and walkability (active living environment), on associations between single-chemical exposures and obesity. Using quantile-based G computational analysis, we quantified the combined effects of chemicals captured in all cycles, where feasible. Models were adjusted for confounders identified in a directed acyclic graph. Results are adjusted odd ratios with 95% confidence intervals (95% CI).

RESULTS: Overall, 9,147 children were included. In single-exposure models, several PAH compounds, BPA, cadmium and total phthalates were linked to increased obesity and central obesity. Per interquartile range increase in total PAHs, risks of obesity and central obesity were elevated to 1.09 (95%CI 1.01, 1.18) and 1.14 (95%CI 1.01, 1.30), respectively. In combined-effects models for PAHs and BPA, risks of obesity and central obesity were strengthened to 1.46 (95%CI 1.20, 1.78) and 1.29 (95%CI 1.10, 1.56), respectively.

CONCLUSIONS: Our findings support the role of early chemical exposure in pediatric obesity, particularly PAHs. The combined effects of chemicals strengthened the observed associations.

KEYWORDS: Pediatric; Chemicals; Obesity; Public Health; Environment

P-0446 Associations between prenatal and early-life air pollution exposure and lung function in young children: exploring influential windows of exposure on lung development

Andreas Neophytou[1], Liza Lutzker[2], Kristen Fedak[1], Elizabeth Noth[2], Stephanie Holm[2], Sadie Costello[2], Ellen Eisen[2], Tim Tyner[5], Fred Lurmann[3], Katharine Hammond[2], John Balmes[2,4]

[1]Colorado State University, Fort Collins, Co, USA, [2]University of California, Berkeley, USA, [3]Sonoma Technology, Petaluma, USA, [4]University of California, San Francisco, USA, [5]University of California, San Francisco-Fresno, Central California Asthma Collaborative, Fresno, USA

BACKGROUND AND AIM: Evidence in the literature suggests that air pollution exposures experienced prenatally and early in life can be detrimental to normal lung development, however potentially more influential windows during development are not fully understood. We evaluate air pollution exposures during the prenatal and early-life period in association with lung function at ages 7-9, in an effort to identify potentially influential windows of exposure for lung development.

METHODS: Our study population consisted of 222 children aged 7-9, from the Fresno-Clovis metro area in California with spirometry data collected between May 2015 and May 2017. We used distributed-lag non-linear models to flexibly model the exposure-lag-response for monthly average exposure to fine particulate matter (PM2.5) and ozone (O3) during the prenatal months and first three years of life in association with forced vital capacity (FVC), and forced expiratory volume in the first second (FEV1), adjusted for covariates.

RESULTS: PM2.5 exposure during the period spanning pregnancy and the first 3-years of life was associated with lower FVC and FEV-1. Specifically, an increase from the 5th percentile of the observed monthly average exposure (7.55 µg/m3) to the median observed exposure (12.69 µg/m3) was associated with 0.42 L lower FVC (95% confidence interval (CI): -0.81, -0.03) and 0.38 L lower FEV1 (95% CI: -0.74, -0.01). The shape of the lag-response indicated that the second half of pregnancy may be a more influential window of exposure. Associations for ozone were not as strong and typically CIs included the null.

CONCLUSION: Our findings indicate that prenatal and early-life exposures to PM2.5 are associated with decreased lung function later in childhood. Exposures during the latter months of pregnancy may be especially influential.

KEYWORDS: air pollution, lung development, distributed-lag models, exposure windows

P-0447 Seasonal attack patterns in childhood atopic dermatitis are related to different environmental factors

Yi-Sheng Yang[1,2], Chi-Hsien Chen[1,3], Bing-Yu Chen[3], Ching-Chun Huang[1,3], Yue Leon Guo[1,2,3,4]
[1]Department of Environmental and Occupational Medicine, National Taiwan University Hospital, Taipei, Taiwan,, [2]Institute of Environmental and Occupational Health Sciences, National Taiwan University College of Public Health, Taipei, Taiwan,, [3]Department of Environmental and Occupational Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan,, [4]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli, Taiwan,

BACKGROUND AND AIM: Atopic dermatitis (AD) is a prevalent childhood condition involving many people. The attack pattern has been quite diverse. Few studies have classified AD children into subgroups according to seasonal attack pattern. This study explores the methods to group AD children into seasonal attack patterns, and examines hereditary and environmental factors on each subgroup in children with AD.
METHODS: In Taiwanese children from one elementary and one middle schools in each of the 22 cities/counties, allergic status, hereditary and living environmental factors were surveyed in 2016, as well as air pollutants by air monitoring stations. Among those with current AD, principal component analyses on weighted moving average of monthly attack score was applied to categorize AD attack subtypes. Generalized Estimating Equation was used to study the effects of environmental exposure on each AD attack subgroups.
RESULTS: A total of 11,585 children were surveyed, and 17.6% of children reportedly had AD attack in the past 1 year. Among them, four attack patterns were identified: spring, summer/fall, winter and perennial. Parental atopic diseases and higher education, and molds in residence are important factors for AD. Among seasonal attack patterns, lower temperature, higher humidity, and PM2.5 were related to spring-attack; higher temperature to summer-fall-attack; lower humidity to winter-attack; and traffic-related air pollutants to perennial-attack AD.
CONCLUSIONS: Distinguished attack patterns are identified in children with current AD. Depending on individual attack subtypes, environmental factors can be different.

KEYWORDS: seasonal attack pattern; atopic dermatitis; environmental factors; GEE

P-0453 Prenatal exposure to persistent organic pollutants and early child growth: a pooled analysis in two Belgian birth campaigns

Anran Cai[1,2], Lützen Portengen[1], Eva Govarts[2], Laura Rodriguez Martin[2], Greet Schoeters[3], Juliette Legler[1], Roel Vermeulen[1,4], Virissa Lenters[4], Sylvie Remy[2], on behalf of the GOLIATH Consortium

[1]Institute for Risk Assessment Sciences, Department of Population Health Sciences, Utrecht University, Utrecht, The Netherlands, [2]VITO Health, Flemish Institute for Technological Research (VITO), Mol, Belgium, [3]Department of Biomedical Sciences, University of Antwerp, Antwerp, Belgium, [4]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, The Netherlands

BACKGROUND AND AIM: Children are born with a burden of persistent organic pollutants (POPs) which have endocrine-disrupting properties and may contribute to the rise in childhood obesity. The current evidence is equivocal, partly because many studies are cross-sectional or prospective studies addressing the effects at one time point during childhood. We aimed to assess the associations between prenatal POP exposures and growth during infancy and across early childhood.

METHODS: We used data from two campaigns of a Belgian cohort with five organochlorine [(dichlorodiphenyldichloroethylene (p,p'-DDE), hexachlorobenzene (HCB), polychlorinated biphenyls (PCB138, -150, -180)] (n=1397) and two perfluoroalkyl substances [perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS)] (n=343) measured in cord blood. We assessed infant growth, defined as body mass index (BMI) z-score change between birth and 2 years, and early childhood growth, characterized as BMI trajectory from birth to 8 years. In addition to a single-pollutant approach (linear regression), we applied a multi-pollutant approach (penalized elastic net regression with stability selection) to evaluate the associations with 2-year infant growth, controlling for covariates and co-exposures. Associations with 8-year early childhood growth were evaluated by assessing alterations in growth trajectories using single-pollutant covariate-adjusted linear mixed models with natural cubic splines.

RESULTS: Prenatal exposure to PCB-153 and -180 was significantly associated with increased infant growth in single-pollutant models (β=0.002, 95%CI: 0.000-0.005 per ng/g lipid and β=0.004, 95%CI: 0.001-0.008 per ng/g lipid, respectively). Both were also selected in elastic net models, although with modest precision. We found no clear associations between any of the exposures and growth trajectories (p-value>0.05 for the interaction of single exposure and child age).

CONCLUSIONS: These results suggest that prenatal exposure to two PCB congeners may be associated with increased infant growth in the first two years, with little evidence of more persistent effects.

KEYWORDS: Prenatal exposures, POPs, Early childhood, Growth

P-0455 Ambient ozone exposure and bone turnover markers in children: Results from the GINIplus and LISA birth cohorts

Tianyu Zhao[1,2,3], Iana Markevych[4], Marie Standl[3], Zhonglin Lyu[5], Tamara Schikowski[6], Dietrich Berdel[7], Sibylle Koletzko[8,9], Andrea von Berg[7], Joachim Heinrich[1,2,10]

[1]Institute and Clinic for Occupational, Social and Environmental Medicine, University Hospital, LMU Munich, Munich, Germany, [2]Comprehensive Pneumology Center Munich (CPC-M), German Center for Lung Research (DZL), Munich, Germany, [3]Institute of Epidemiology, Helmholtz Zentrum München - German Research Center for Environmental Health, Neuherberg, Germany, [4]Institute of Psychology, Jagiellonian University, Krakow, Poland, [5]Department of Hematology, The Second Medical Center & National Clinical Research Center for Geriatric Diseases, Chinese PLA General Hospital, Beijing, China, [6]IUF-Leibniz Research Institute for Environmental Medicine, Düsseldorf, Germany, [7]Research Institute, Department of Pediatrics, Marien-Hospital Wesel, Wesel, Germany, [8]Department of Pediatrics, von Hauner Children's Hospital Munich, University Hospital, LMU Munich, Munich, Germany, [9]Department of Pediatrics, Gastroenterology and Nutrition, School of Medicine Collegium Medicum University of Warmia and Mazury, Olsztyn, Poland, [10]Allergy and Lung Health Unit, Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia

BACKGROUND: Multiple environmental factors can regulate bone metabolism, and it is hypothesized that air pollution may be adversely involved in this regulation. However, only a few studies considered bone turnover markers (BTMs) - sensitive and specific markers of bone metabolism - as outcomes, and no study explored the exposure to ambient ozone. We aimed to analyze associations between long-term exposure to ozone and concentrations of two BTMs, osteocalcin and β-isomer of C-terminal telopeptide of type I collagen (CTx), among 10-year-old children.

METHODS: Cross-sectional analyses were based on 1848 children from the Munich and Wesel centers of the GINIplus and LISA German birth cohorts. Serum osteocalcin and CTx concentrations were measured. We estimated ozone exposures by optimal interpolation and assigned them to home addresses. Nitrogen dioxide and particulate matter with an aerodynamic diameter < 10 µm were assessed by land use regression models. We adjusted linear regression models for covariates and co-pollutants, and the analyses were further stratified by area.

RESULTS: The mean concentrations were 93.09 ng/mL and 663.66 ng/L for osteocalcin and CTx, respectively. In general, higher levels of ambient ozone exposure were associated with lower concentrations of BTMs in both areas. The number of days per year with a maximum 8-hour average concentration exceeding 120 µg/m³ showed consistent results across different models. Specifically, models adjusted for co-pollutants illustrated that the beta estimates and 95% confidence intervals on osteocalcin and CTx were -2.51 (-3.78, -1.14) and -44.53 (-57.12, -31.93), respectively, for an increase of 10 days.

CONCLUSIONS: Long-term exposure to ambient ozone was associated with decreased concentrations of BTMs in German children. Unless other prospective studies confirm our results, the adverse effects of exposure to ozone on bone development in children should be interpreted with caution.

P-0457 Prenatal manganese and working memory in school-aged children in Mexico City: A multi-media biomarker approach

Jamil Lane[1], Shelley H. Liu[2], Lourdes Schnaas[3], Sandra Martinez-Medina[3], Martha M. Téllez-Rojo[4], Paul C. Curtin[1], Chitra J. Amarasiriwardena[1], Robert O. Wright[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Department of Population Health Science, Icahn School of Medicine at Mount Sinai, New York, USA, [3]National Institute of Perinatology, Mexico City, Mexico, [4]Center for Nutrition and Health Research, National Institute of Public Health, Cuernavaca, Mexico

BACKGROUND/AIM: Mn is a nutrient, and over/underexposure may be linked to poorer development, but little work has addressed executive functioning, including working memory (WM). We used the multi-media biomarker (MMB) approach to assess prenatal blood and urine levels as predictors of WM in children.

METHODS: Leveraging the PROGRESS birth cohort in Mexico City, children (N = 572) ages 6–8 completed the CANTAB Spatial Working Memory (SWM) task. We used between errors (incorrectly returning to a previously selected empty box) and strategy (whether children begin new searches randomly or in a pattern) as primary outcomes. Blood and urinary Mn levels were collected from mothers in the 2nd and 3rd trimesters. Multiple regression models estimated the association between Mn biomarkers at each trimester with SWM. We categorized Mn exposure as low (1st quintile of Mn concentrations), moderate (2nd–4th quintiles), and high (5th quintile) levels. We used weighted quantile sum regression to estimate the MMB integrated effect of combined Mn biomarkers on the SWM measures. Models were adjusted for maternal age, education, socioeconomic status, and child's gender and age at CANTAB assessment.

RESULTS: Low blood Mn in the 3rd trimester was associated with higher between error scores, indicating poorer WM (B = 3.24, 95% CI: 0.11, 6.36) using moderate blood Mn as the reference group, but was not with the strategy scores. The integrated Mn MMB was inversely associated with WM performance (B = -2.19, 95% CI: -3.51, -0.09). In the 2nd and 3rd trimesters, urinary Mn contributed the most prominent weight to the MMB effect (40.4% and 40.1% contributions, respectively).
CONCLUSION: Lower prenatal blood Mn and combined blood and urine Mn were associated with poorer WM performance in school-age children. Given that Mn is a nutrient, this analysis suggests that maternal Mn deficiency may affect WM.

P-0458 Maternal urinary phthalate metabolites during pregnancy and thyroid function: The MAKE Study

Byungmi Kim[1,5], Seyoung Kim[1], Eun Kyo Park[2], Jeoung A Kwon[3], Eun Young Park[1], Bomi Park[4], Bohyeoun Park[1]
[1]National Cancer Control Institute, National Cancer Center, Goyang-si, Republic of Korea, [2]Department of Occupational and Environmental Medicine, Ewha Medical Research Institute, Seoul, Republic of Korea, [3]Institute of Health Services Research, Yonsei University, Seoul, Republic of Korea, [4]Department of Preventive Medicine, College of Medicine, Chung-Ang University, Seoul, Republic of Korea, [5]Department of Cancer Control and Population Health,National Cancer Center Graduate School, Republic of Korea

BACKGROUND AND AIM: Phthalates, endocrine-disrupting chemicals that are commonly found in consumer products, may adversely affect thyroid hormones, but findings from prior epidemiologic studies have been inconsistent. In a prospective cohort study, we investigated whether maternal urinary phthalate metabolite concentrations and phthalate mixtures measured during pregnancy were associated with thyroid hormones among pregnant women.

METHODS: We measured five phthalate metabolites [monoethyl phthalate (MEP), mono-n-butyl phthalate, mono-isobutyl phthalate, monobenzyl phthalate (MBzP), and four monoesthers of di(2-ethylhexyl) phthalate] in urine collected at pregnant women in MAKE Study. Thyroid stimulating hormone (TSH) and free and total thyroxine and triiodothyronine were measured in maternal serum (n = 215). We used multivariable linear regression to assess associations between individual urinary phthalate metabolites and concentrations of maternal thyroid hormones. We used weighted quantile sum regression (WQS) to create a phthalate index describing combined concentrations of phthalate metabolites and to investigate associations of the phthalate index with individual thyroid hormones.

RESULTS: The geometric mean urinary concentrations of specific gravity adjusted MEPm MBzP and MECCP were 2.1, 0.2, and 0.1 μg/L, respectively. The phthalate index was had a significantly positive effect on the maternal serum TSH (WQS beta = 0.13; p = 0.02). However, no significant association was found with both maternal serum TT3 (WQS beta = -0.23; 0.89) or and TT4 (WQS beta = -0.02; p=0.83)

CONCLUSIONS: Our results suggest that co-exposure to multiple phthalates was positively associated with TSH in pregnant women in this birth cohort. These findings highlight the need to study chemical mixtures in environmental epidemiology.

KEYWORDS: Phthalates; Pregnancy; Thyroid hormones; Weighted quantile sum regression.

P-0459 Exposure to mixtures of phenols, phthalate metabolites, parabens, and pesticide and BMI and lipid profiles in adolescents age 12-18 po

Bohyun Park[1], Byungmi Kim[1], Chung Ho Kim[1], Seyoung Kim[1], Bomi Park[2]
[1]National Cancer Control Institute, National Cancer Center, Goyang, Republic of Korea, [2]Department of Preventive Medicine, College of Medicine, Chung-Ang University, Seoul, Republic of Korea

BACKGROUND AND AIM: Endocrine disrupting chemicals (EDCs) interfere endocrine system and lead to the imbalance in the regulation of lipid metabolism and body weight. Some recent studies suggest that EDCs may increase the risk for obesity or dyslipidemia, but most previous studies have evaluated the health effects of individual EDCs in isolation. We evaluated the association of combined exposure of EDCs with body mass index (BMI) and lipid profiles in a representative sample of a general population from Korea.

METHODS: Urinary concentrations of exposures including three phenols (bisphenol A, bisphenol F, bisphenol S), eight phthalate metabolites (mono- (2-ethyl-5-hydroxyhexyl) phthalate, mono-(2-ethyl-5-oxohexyl) phthalate, mono-n-butyl phthalate, monobenzyl phthalate, mono-(2-ethyl-5-carboxypentayl) phthalate, mono-(carboxyoctyl) phthalate, mono-(carboxynonyl) phthalate, mono(3-carboxylpropyl) phthalate), three parabens (methyl paraben, ethyl paraben, propyl paraben), and pyrethroid pesticides metabolite (3-phenoxybenzoic acid) and outcomes of interest including BMI, triglycerides (TG), total cholesterol, and high-density lipoprotein cholesterol (HDL-c) were measured in 891 adolescents. Age, sex, monthly household income, mother's education level, frequency of fast-food, physical activity, smoking status, and alcohol consumption were adjusted. The association was examined using Bayesian Kernel Machine Regression (BKMR), and the analyses were stratified by sex to assess the potential effect modification.

RESULTS: BMI, TG to HDL-c ratio (TG/HDL), and total cholesterol to HDL ratio (TC/HDL) showed significant increasing trends when all the chemicals were at different levels from 25th percentile to 75th percentile, although the confidence intervals were wide. and the overall effects were more significant among males compared to female. for BMI, parabens showed the highest group posterior inclusion probability (PIP). On the other hand, for TG/HDL and TC/HDL, phthalate metabolites showed the highest group PIP.

CONCLUSIONS: Our findings suggest that higher exposure to EDCs mixture is associated with higher BMI, TG/HDL, TC/HDL, particularly in male adolescents.

P-0460 The association between exposure to mixture of phenols, phthalate metabolites, and persistent organic pollutants with insulin resistance in children

Bomi Park[1], Chung Ho Kim[2], Hye Ah Lee[3], Hae Soon Kim[4], Young Sun Hong[5], Hyesook Park[6]
[1]Department of Preventive Medicine, College of Medicine, Chung-Ang University, Seoul, Republic of Korea, [2]National Cancer Control Institute, National Cancer Center, Goyang, Republic of Korea, [3]Clinical Trial Center, Mokdong Hospital, Ewha Womans University, Seoul, Republic of Korea, [4]Department of Pediatrics, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [5]Department of Internal Medicine, College of Medicine, Ewha Womans University, Republic of Korea, [6]Department of Preventive Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea

BACKGROUND AND AIM: Endocrine disrupting chemicals (EDCs) exposure has been suggested to play an important role in increasing insulin resistance. However, there has been limited epidemiologic evidence, particularly in children, and most previous studies focused on the effect of individual chemical. Given that we are exposed to various EDCs simultaneously, we aim to study the overall effects of EDCs mixture on insulin resistance.

METHODS: Children from the Ewha Birth and Growth Cohort Study who underwent follow-up examinations at 7-9 and 13-15 years of age was analyzed. We included chemicals with detection rates greater than 50%. Urinary bisphenol A (BPA), 9 urinary phthalate metabolites, and 14 serum persistent organic pollutants (POPs) measured at 7-9 years of age were included in the analysis. Fasting insulin was measured at 7-9 and 13-15 years of age. Homeostatic model assessment of insulin resistance (HOMA-IR) and homeostatic model assessment of beta-cell function (HOMA-β) were measured at 7-9 years of age. Age, sex, monthly household income, mother's education level, and frequency of soda consumption and fast-food consumption were adjusted. A total of 89 to 158 children, depending on outcome variables, with complete data were analyzed. We used Bayesian Kernel Machine Regression (BKMR) to evaluate the joint effects of multiple chemical exposures on insulin resistance.

RESULTS: We found significant positive associations between the chemical mixtures at 7-9 years of age with insulin, HOMA-IR, and HOMA- β at 7-9 years of age and insulin at 13-15 years of age. and the increasing trend was shown more significantly among females compared to male. Phthalates showed the highest group posterior inclusion probability for all outcomes.

CONCLUSIONS: Our results indicated that mixtures of BPA, phthalate metabolites, and POPs may increase the insulin resistance and the effects persist for years.

KEYWORDS: phenol, phthalate, POPs, mixture, BKMR, insulin resistance, children

P-0462 Maternal and child exposure to organophosphate ester mixtures and child neurobehavior

Zana Percy[1], Aimin Chen[2], Heidi Sucharew[1,3], Joseph Braun[4], Weili Yang[1], Ann Vuong[5], Bruce Lanphear[6], Kim Cecil[3], Yingying Xu[3], Kimberly Yolton[1,3]

[1]University of Cincinnati, Cincinnati, USA, [2]University of Pennsylvania, Philadelphia, USA, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, USA, [4]Brown University, Providence, USA, [5]University of Nevada Las Vegas, Las Vegas, USA, [6]Simon Fraser University, Burnaby, Canada

Organophosphate esters (OPEs) are a class of chemicals used mainly as flame retardants and plasticizers, but growing experimental evidence of their neurotoxicity has raised concerns of potential effects in humans. We aim to study whether exposure to OPE mixtures in early life is associated with child behavior.

We quantified urinary concentrations of three OPE metabolites, bis-2-chloroethyl phosphate (BCEP), bis(1,3-dichloro-2-propyl) phosphate (BDCIPP), and diphenyl phosphate (DPHP), at prenatal (16 and 26 weeks of gestation and birth) and postnatal time points (ages 1, 2, 3, and 5 years) in the Health Outcomes and Measures of the Environment Study, a longitudinal pregnancy and birth cohort in Cincinnati, Ohio, USA. Using latent variable analysis and quantile g-computation, we investigated associations between mixtures of the three urinary OPE metabolites and child behaviors at ages 3 and 8 years, as measured by the Behavioral Assessment System for Children, Second Edition.

In the latent variable analysis, higher log-OPE exposure at 16 weeks was associated with fewer externalizing problem behaviors (ß = -5.74; 95% CI = -11.24, -0.24) and fewer overall behavioral problems at age 3 years (ß = -5.26; 95% CI = -10.33, -0.19), whereas higher exposure at birth was associated with poorer overall behavioral problems at age 3 years (ß = 2.87; 95% CI = 0.13, 5.61). OPE exposures at 16 weeks, 26 weeks, and birth were not associated with child behavior at age 8. Higher log-OPE exposure at age 3 was associated with fewer externalizing behaviors at age 8 years (ß = -2.62; 95% CI = -5.13, -0.12). The quantile g-computation estimates, albeit null, had directions largely consistent with the latent variable analysis results.

Pre- and postnatal urinary OPE metabolite mixtures were associated with child behaviors at 3 and 8 years, but we did not identify a consistent pattern.

KEYWORDS: Organophosphate esters; children; neurobehavior; cohort; mixtures

P-0463 Children's exposure and risks to the rare earth elements of gadolinium and yttrium in Alcalá de Henares (Spain).

Antonio Peña-Fernández[1], Manuel Higueras[2], María Carmen Lobo-Bedmar[3]
[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, UK, [2]Scientific Computation & Technological Innovation Center (SCoTIC), Universidad de La Rioja, Logroño, Spain, [3]Departamento de Investigación Agroambiental. IMIDRA. Finca el Encín, Crta. Madrid-Barcelona Km, 38.2, Alcalá de Henares, Spain

BACKGROUND AND AIM: Widespread applications of rare earth elements (REEs) has increased their environmental presence, facilitating accumulation in humans. The aim was to determine the environmental presence, exposure and risks of gadolinium (Gd) and yttrium (Y) in topsoils in children living in Alcalá de Henares (Spain).

METHODS: Scalp-hair was collected from 120 children (6 to 9-years-old; 70 girls) born and residing in Alcalá. Gd and Y were analysed by ICP-MS after appropriate removal of exogenous contamination using Triton X-100/bath sonication. Additionally, Gd was monitored in 66 topsoil samples randomly sampled from different urban parks across the city in 2017, meanwhile Y was analysed in 97 topsoil samples collected in a previous study in 2001 in the same parks. Data was processed using statistical methods applied to censored data available in the 'NADA' statistical package.

RESULTS: The limits of detection in hair (µg/g) and soils (mg/kg), respectively, were: Gd (0.000386; 0.0007), Y (0.0056; 0.033). Although both REEs were detected in all the topsoil samples, only Gd was detected in the hair samples, 80.5% of samples. Median and range for Gd in scalp hair in µg/g was 0.00067 (0.000388-0.002), which were lower to those found in Chinese children environmentally exposed to REEs. Concentrations in topsoils in mg/kg were: Gd 2.902 (0.348-4.951), Y 4.982 (1.294-12.526). Provisional reference dose for Y was used to characterise non-carcinogenic risks for ingestion/dermal contact, which were lower than the unit (threshold).

CONCLUSIONS: Our results suggest minimal environmental exposure to both REEs, as human hair has been proposed as an effective biomonitoring tissue to identify individuals who have been chronically exposed to Gd and Y. Further monitoring studies should be performed to rule out the risks from exposure to both REEs in topsoils, particularly for Y, due to the time differences in which samples were collected.

P-0464 Monitoring lanthanum and praseodymium in Spanish children's hair

Antonio Peña-Fernández[1], María Carmen Lobo-Bedmar[2], Manuel Higueras[3]
[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, UK, [2]Departamento de Investigación Agroambiental. IMIDRA. Finca el Encín, Crta. Madrid-Barcelona Km, 38.2, Alcalá de Henares, Spain, [3]Scientific Computation & Technological Innovation Center (SCoTIC), Universidad de La Rioja, Logroño, Spain

BACKGROUND AND AIM: Children may be threatened by emerging contaminants such as lanthanides. The aim was to identify whether children living in Alcalá de Henares (Madrid Region, Spain), are exposed to lanthanum (La) and praseodymium (Pr).

METHODS: Lanthanides were analysed in scalp-hair from 120 children (6 to 9-years-old; 70 girls) by ICP-MS. Data was processed in the 'NADA' statistical package.

RESULTS: Pr was detected in most of the samples (82.4%; LoD=0.0005 μg/g), meanwhile La was detected in 63.2% (LoD=0.0055 μg/g), which may suggest a general exposure for both elements, as they were poorly detected in scalp hair from other population groups from the Madrid Region. Alcalá had important industries dedicated to manufacturing glass and ceramics, important sources for both lanthanides that might explain our results. The concentrations found (median and interquartile range; μg/g): La 0.0071 (<0.0055, 0.0114) and Pr 0.0014 (0.0007, 0.0021), were lower than those reported in populations living in contaminated areas. Although both lanthanides did not show sex dependency, Pr showed statistical significance according to zones of residency (p=0.008), possibly due to its uses. Thus, mean Pr level was higher in children's hair living in the area close to the glass/ceramics fabrics than those living in areas with higher densities of green spaces (0.00203 vs. 0.00132 μg/g).

CONCLUSIONS: Exposure to La and Pr would not represent a risk for Alcalá's children, as their levels were within the same order of magnitude as those reported in hair from healthy French children. Although a general exposure was observed, more studies are needed as beryllium, an important element also linked with glass/ceramics industries, was not detected in these samples in a previous study. A better understanding of the exposure to these lanthanides is required, as recent reports have observed that exposure to Pr could contribute to pathogenesis of pediatric cancer.

P-0465 Associations of Maternal Urinary Arsenic Concentrations during Pregnancy with Infant and Child Mental, Psychomotor, and Cognitive Development: The HOME Study

Antonio José Signes Pastor[1], Megan E. Romano, Brian Jackson, Joseph M. Braun, Kimberly Yolton, Aimin Chen, Bruce Lanphear, Margaret R. Karagas

[1]Department of Epidemiology, Geisel School of Medicine, Dartmouth College, NH, USA.,, [2]Unidad de Epidemiología de la Nutrición. Universidad Miguel Hernández, Alicante, Spain. CIBER de Epidemiología y Salud Pública (CIBERESP), Instituto de Salud Carlos III (ISCIII), Madrid, Spain. Instituto de Investigación Sanitaria y Biomédica de Alicante (ISABIAL), Spain,

BACKGROUND AND AIM: Arsenic exposure during pregnancy may increase the risk for intellectual deficits in children, but limited data exists from prospective epidemiologic studies, particularly at low arsenic exposure levels. We investigated the association between prenatal urinary arsenic concentrations and childhood cognitive abilities in the Health Outcomes and Measures of the Environment (HOME) Study.

METHODS: We used anion exchange chromatography coupled with inductively coupled plasma mass spectrometry detection to measure arsenic species content in pregnant women's urine. The summation of inorganic arsenic (iAs), monomethylarsonic acid (MMA), and dimethylarsinic acid (DMA) refers to ∑As. We longitudinally assessed children's cognitive function (n = 260) longitudinally at 1, 2, and 3 years using Bayley Scales of Infant and Toddler Development, at 5 years using Wechsler Preschool and Primary Scale of Intelligence, and at 8 years using Wechsler Intelligence Scale for Children.

RESULTS: We observed a modest decrease in mental development index and full-scale intelligence quotient at ages 3 and 5 years with each doubling of ∑As (median and IQR of 3.63 and 2.40-5.86 µg/L) with estimated score (ß) differences and 95% confidence interval (CI) of -1.8 from -4.1 to 0.5 and -2.5 from -5.1 to 0.0, respectively. This trend was stronger among children whose mothers had lower iAs methylation capacity and low urinary arsebonetaine concentrations.

CONCLUSIONS: Our findings suggest that exposure levels relevant to the general US population may adversely affect children's cognitive abilities.

KEYWORDS: arsenic; neurodevelopment; cognitive; Bayley Scale of Infant Development; Wechsler Preschool and Primary Scale of Intelligence; in utero exposure; Mental development index; Full scale intelligence quotient.

P-0466 Ultraviolet radiation exposure in children, behavioral factors associated with measured doses and seasonality

Ben Spycher[1], Jessica E Laine[1], Cristophe L Folly[1], Eleftheria Michalopoulou[1], Astrid Coste[2]
[1]University of Bern, Bern, Switzerland, [2]Center Léon Bérard, Département Prévention Cancer Environnement, Lyon, France

BACKGROUND AND AIM: Ultraviolet radiation (UVR) exposure is associated with both positive and adverse health, such as beneficial aspects of vitamin D and skin cancer, respectively. Childhood is a time of great variability for sun behaviours and increased sensitivity to UVR. However, the relationship between one's received exposure and the level of ambient UVR is modified by activities. There is a need to document UVR exposure in relation to concurrent activities and sun protection behaviour for children and adolescents. While several studies have measured UVR exposure in children there has been no study conducted in Switzerland, where skin cancer incidence is one of the highest in Europe.
METHODS: UVR was measured in children aged 4-17 years (n=120) over 5 consecutive days using dosimeters worn on the chest. The dosimeter included an acceleration sensor, to identify periods during which it was worn. During measurement of UVR parents recorded children's activities in activity diaries. Measurements were related to reported activities and mean exposure (and spread) was assessed by activity type and season.
RESULTS: 4'058 hours of exposure measurements was assessed. The measured mean cumulative daily exposure was 0.46 standard erythmal dose (SED) per participant. The largest contribution to the total cumulative dose came from activities that involved playing outdoors (83.4 SED), followed by walking (32.6 SED), and hiking (25.7 SED), which had the highest mean exposures. The mean exposures were higher during midday hours and at higher altitudes; however, did not evidently vary by season during the measurement period.

CONCLUSIONS: Children's UVR in Switzerland varies considerably by activity and whereabouts, and is highest during midday and early afternoon hours, with only modest variation between seasons. While measured UVR intensities are similar for different outdoor activities, the largest contribution to received doses comes from playing outdoors.

P-0467 Gestational exposure to phthalates and phthalate replacements in relation to neurodevelopmental delays in early childhood

Seonyoung Park[1], Emily Zimmerman[2], Gredia Huerta-Montanez[3], Zaira Rosario[3], Carmen Vélez Vega[4], Akram Alshawabkeh[3], José Cordero[5], John Meeker[1], Deborah Watkins[1]

[1]Department of Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, USA, [2]Department of Communication Sciences and Disorders, Northeastern University, Boston, USA, [3]Department of Civil and Environmental Engineering, Northeastern University, Boston, USA, [4]University of Puerto Rico Graduate School of Public Health, UPR Medical Sciences Campus, San Juan, [5]Department of Epidemiology, University of Georgia, Athens, USA

BACKGROUND AND AIM: Phthalates are endocrine-disrupting chemicals that have been linked to changes in child neurodevelopment. However, sex-specificity has been reported inconsistently, and little is known about the impact of recent phthalate replacement chemicals. We aimed to examine the associations between prenatal exposure to phthalates/phthalate replacements and neurodevelopment, and the sex-specificity of such relationships.

METHODS: Our analysis included mother-child pairs (N=274) from the PROTECT birth cohort in Puerto Rico. Phthalate metabolites were measured in maternal urine collected up to three times during pregnancy. Neurodevelopment was measured at 6, 12, and 24 months of age using the Battelle Developmental Inventory-2nd edition (BDI), which provides scores for adaptive, personal-social, communication, motor, and cognitive domains. Multivariable linear regression was used to examine associations between the geometric mean of individual phthalate metabolite concentrations across pregnancy and BDI scores, adjusting for maternal age, maternal education, child age, and specific gravity. Differences by sex were assessed with sex*exposure interaction terms and stratified models.

RESULTS: Cognitive domain scores were associated with mono-carboxy-isooctyl phthalate (MCOP) at all assessment ages, and all five domains were associated with mono-carboxy-isooctyl phthalate (MCOP), mono-3-carboxypropyl phthalate (MCPP), and mono-oxononyl phthalate (MONP) at age 24 months. Sex-specificity existed for all timepoints (p-interaction<0.2), in general, showing stronger associations among boys. for example, metabolites of a recent phthalate replacement, di-2-ethylhexyl terephthalate (DEHTP), were differentially associated with Adaptive scores (boys β=-6.38, 95%CI:-12.36,-0.41 vs. girls β=-0.72, 95%CI:-4.31,2.86), and Cognitive scores (boys β=-4.88, 95%CI:-8.78,-0.99 vs. girls β=-1.56, 95%CI:-3.34,0.22) at 6 months, and with Motor scores (boys β=-4.32, 95%CI:-7.24,-1.41 vs. girls β=0.71, 95%CI:-2.38,3.44) at 24 months.

CONCLUSIONS: Gestational exposure to phthalates and phthalate replacements was associated with neurodevelopmental delay across multiple domains, with differences by sex and child age. Further research pertaining to neurodevelopmental delay throughout childhood and sex dimorphism over time is needed.

KEYWORDS: phthalates, phthalate replacements, neurodevelopment, sex-specificity

P-0468 Associations of a metal mixture with neuromotor function in a cross-sectional study of Italian adolescents

Alexa Friedman[1], Samantha Schildroth[1], Victoria Fruh[1], Roberto G Lucchini[2,3,4], Donald Smith[5], Robert Wright[4], Megan Horton[4], Donatella Placidi[3], Maxine Krengel[6], Yorghos Tripodis[7], Roberta F. White[1,6], Birgit Claus Henn[1]
[1]Department of Environmental Health, Boston University School of Public Health, Boston, USA, [2]Department of Environmental Health Sciences, Florida International University, Miami, USA, [3]Department of Medical and Surgical Specialties, Radiological Sciences, and Public Health, Brescia, Italy, [4]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [5]Department of Microbiology and Environmental Toxicology, Santa Cruz, USA, [6]Department of Neurology, Boston University School of Medicine, Boston, USA, [7]Department of Biostatistics, Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: Motor function is critical for children's overall well-being but remains an understudied neurodevelopmental domain. Evidence supports links between exposure to individual metals and motor function, but no epidemiological study has examined the joint effects of metals.

METHODS: We estimated associations between an industrial metal mixture and multiple measures of motor function among 612 adolescents (10-14 years old; 49% female) within a cross-sectional study. Concentrations of blood lead and hair manganese, copper, and chromium were quantified using inductively coupled plasma mass spectrometry. Neuropsychologists administered three motor assessments: Pursuit Aiming (PA), Finger tapping (FT), and subtests from the Luria Nebraska (LN) battery. We quantified associations with 95% confidence intervals (CI) between motor function and the metal mixture using quantile g-computation (qgComp) and multivariable linear regression (MLR), adjusting for child age, sex, and socioeconomic status. We explored sex-specific associations in stratified models.

RESULTS: All metals had high detection frequency (>99%). The metal mixture was associated with worse scores on tests of fine motor function: a quartile increase in the mixture was associated with 2.7 fewer correct responses on the PA test (95% CI: -5.8, 0.4). This association was stronger among girls (β= -4.5, 95% CI: -8.8, -0.2) than boys (β= -1.9, 95% CI: -6.2, 2.3). Joint associations were null for the FT and LN tests. In MLRs, a 1-SD increase in hair Cu was associated with fewer total responses (β= -2.07, 95% CI: -5.4, 1.2); this association was stronger among boys (β =-6.9, 95%CI -11.9, -2.0) than girls (β=1.20, 95% CI: -3.3, 5.7).

CONCLUSIONS: Although most associations between metal mixtures and motor function were null, our findings suggest adverse effects of the mixture on visual-motor abilities. This work begins to fill a gap in understanding effects of environmental metals on motor function in children.

KEYWORDS: metals, mixtures, motor function, neurodevelopment

P-0469 Fetal exposure to cannabis, neonatal adiposity, and postnatal growth trajectories: The Healthy Start study

Brianna Moore[1,2], Katherine Sauder[2,3], Emily Hébert[4], Adrienne Hoyt[4], Erica Wymore[3], Allison Shapiro[5], Gregory Kinney[1], Dana Dabelea[1,2,3]

[1]Department of Epidemiology, Colorado School of Public Health, Aurora, USA, [2]Lifecourse Epidemiology of Adiposity and Diabetes (LEAD) Center, Colorado School of Public Health, Aurora, USA, [3]Department of Pediatrics, University of Colorado School of Medicine, Aurora CO, USA, Aurora, USA, [4]Department of Health Promotion and Behavioral Sciences, The University of Texas Health Science Center, Austin, USA, [5]Department of Psychiatry, School of Medicine, University of Colorado Anschutz Medical Campus, Aurora, USA

OBJECTIVE: Cannabis use during pregnancy is associated with lower birth weight and may influence postnatal growth. We estimated associations of fetal exposure to cannabis with neonatal adiposity and body mass index (BMI) z-score trajectories through age 3 years, as well as effect modification by breastfeeding.

METHODS: We leveraged a subsample of 130 mother-child pairs from a Colorado-based cohort. Twelve cannabinoids/metabolites (including delta 9-tetrahydrocannabinol [THC] and cannabidiol [CBD]) were measured in maternal urine collected at ~27 weeks gestation. Fetal exposure to cannabis was dichotomized as exposed (any cannabinoid≥limit of quantification) and not exposed (cannabinoids<limit of quantification). Generalized linear models estimated the associations between fetal exposure to cannabis with birth weight and neonatal adiposity (measured by air displacement plethysmography). A mixed-effects model estimated the association between fetal cannabis exposure and BMI z-score trajectories. Interaction by breastfeeding duration was assessed by including a product term (with fetal exposure to cannabis) in a mixed-effects model.

RESULTS: Fetal exposure to cannabis was associated with lower birth weight (-206g; 95% CI: -393, -18; p=0.03) and neonatal adiposity (-2.0%; 95% CI: -3.7, -0.02; p=0.03) followed by rapid postnatal growth through 3 years (0.37 increase in BMI z-score per square root year; 95% CI: 0.01, 0.60; p=0.02). Breastfeeding modified this association (p for interaction<0.01). Among cannabis-exposed offspring who were not breastfed, BMI z-scores were 0.42 lower at 6 months (95% CI: -1.15, 0.31) but 0.54 higher at 36 months (95% CI: -0.36, 1.44). Conversely, BMI z-scores were no different by fetal cannabis exposure among offspring who were breastfed for ~5 months.

CONCLUSIONS: Our data suggests that fetal exposure to cannabis alters fetal and postnatal growth, and that breastfeeding may stabilize over-compensatory growth among cannabis-exposed offspring. Although the impact of lactational exposure to cannabis requires further investigation, it remains important to caution against cannabis use during pregnancy and lactation.

P-0472 Association between Air Pollution, Stress, and Sleep Efficiency in 6 -7 year old Children living in East Harlem

Terry Thompson[1]
[1]*Icahn School of Medicine at Mount Sinai, New York City, USA*

Environmental toxicants, broadly defined to encompass chemical and non-chemical risk factors, present in the built environment, can adversely impact children's growth and development. Children are particularly vulnerable to environmental exposures because of the sensitive nature of children's neurodevelopment, a prenatal life stage marked by cell differentiation. A recent study by Bose et al., found an association between prenatal PM2.5 exposure and poorer sleep outcomes (i.e., sleep quantity and quality) in childhood. Yet, little is known about the relationship between air quality and sleep efficiency among children, within the larger context of household and psychosocial conditions. To address this knowledge gap, this pilot research study will examine potential relationships between indoor air quality and its effects on sleep patterns among twenty-five Hispanic children, 6-7 years old living in East Harlem, NY. Specific research aims are: 1) Convene and engage with the Community Advisory Board (CAB) quarterly to elicit meaningful input on pilot study design, implementation and dissemination of how air quality impacts child sleep in 6–7 year-old children in East Harlem. 2) Together with East Harlem families and MPH student researchers, we will quantify a). PM2.5 exposure using indoor air monitors, b). children's time spent sleeping, quantity of awakenings, and c). children's 24-hour activities wearing continuous wrist-worn actigraph watches over 7 days, to examine potential associations between air quality and sleep, and 3) The research team and the CAB will collaborate on the design, and implementation of a bi-lingual study questionnaire, to assess child caregivers' understanding of air pollution, sleep, and household environmental risk factors. A diary along with instructions will be given to all caregivers to write down how they interpret sleepiness and sleep quality in their own words. This will provide important information that can guide meaningful study report back to study participants.

P-0473 Life after discharge from Pediatric Intensive Care Units: Long-term effects of air pollution on re-hospitalization rates in fragile children

Elisa Gallo[1], Rosanna Comoretto[2], Dario Gregori[1], Andrea Wolfler[3], Angela Amigoni[4]
[1]Unit of Biostatistics, Epidemiology and Public Health, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, University of Padova, Padova, Italy, [2]Department of Public Health and Pediatrics, University of Torino, Torino, Italy, [3]Department of Anaesthesia, Gaslini Hospital, Genova, Italy, [4]Pediatric Intensive Care Unit, Department of Women's and Children's Health, University Hospital of Padova, Padova, Italy

BACKGROUND AND AIM: Air pollution is a known risk factor for cardiovascular, respiratory and neurological hospitalizations in the general population. Several studies assessed the effect of air pollution on subjects with specific pathologies, but only few of them focused on subjects with a previous hospitalization in Intensive Care Unit (ICU). The aim of this study is to evaluate the risk of re-hospitalization in children that were previously hospitalized in the Pediatric ICU (PICU).

METHODS: Children hospitalized in the PICU of Padova hospital (Italy) between 2013 and 2019 were selected from hospital discharged records. All subsequent hospitalizations for cardiovascular, respiratory or neurological diagnosis have been tracked until 2020.
To account for time-varying air pollution levels, a Cox model with the Andersen-Gill counting process adjusted for exposure and subject-related confounders was applied to evaluate the association between NO2, PM10 and PM2.5 and the risk of re-hospitalization within one and five years from the discharge. A ridge penalty was applied to face the collinearity among covariates.

RESULTS: Overall, 1204 children were admitted to the PICU of which 425 for cardiovascular, respiratory or neurological issues. The 77% was re-hospitalized during the first year after the PICU discharge. NO2 shows a non-linear impact on the risk of re-hospitalization with higher hazards at higher concentrations (HR1.44; 95%CI:1.06-1.94 for an IQR increase in NO2) that remains significant when including children re-hospitalized within 5 years (HR1.37; 95%CI:1.04-1.82). Interestingly, PM10 and PM2.5 have no effect on the risk of re-hospitalization.

CONCLUSIONS: The exposure of fragile children (those with a previous PICU admission) to high levels of NO2 could lead to severe outcome as re-hospitalization for several diseases. It is crucial to assess the association between these two events in order to adopt public health policies aimed at safeguarding this particularly fragile population.

KEYWORDS: children; air pollution; nitrogen dioxide;

P-0474 Comprehensive exploration of interactions between persistent organic pollutants and nutritional biomarkers on birth weight

German Cano-Sancho[1], Charline Warembourg[2,3,4,5], Mme Nuria Güil[2,3,4], Nikos Stratakis[2,3,4], Aitana Llertxundi[4,6,7], Amaia Irizar[4,6,7], Sabrina Llop[4,8,9], Maria-Jose Lopez-Espinosa[4,8,9], Xavier Basagaña[2,3,4], Juan Ramon González[2,3,4], Silvia Fernandez[2,3,4], Jean-Philippe Antignac[1], Martine Vrijheid[2,3,4], Maribel Casas[2,3,4]

[1]LABERCA, ONIRIS, INRAE, Nantes, France, [2]ISGlobal, Barcelona, Spain, [3]Pompeu Fabra University, Barcelona, Spain, [4]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Madrid, Spain, [5]Univ Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) - UMR_S 1085, Rennes, France, [6]Biodonostia, Unidad de Epidemiologia Ambiental y Desarrollo Infantil, San Sebastian, Spain, [7]Facultad de Medicina, UPV-EHU, Leioa, Spain, [8]Epidemiology and Environmental Health Joint Research Unit, Foundation for the Promotion of Health and Biomedical Research in the Valencian Region, FISABIO-Public Health, FISABIO–Universitat Jaume I–Universitat de València, Valencia, Spain, [9]Faculty of Nursing and Chiropody, University of Valencia, Valencia, Spain

BACKGROUND AND AIM: Pregnant women are exposed to complex chemical mixtures, either nutrients or environmental stressors, whose joint impacts on fetal growth has been scarcely explored. The main objective of this study was screening interactions between chemicals and nutrients to better characterize their joint associations with birth weight.

METHODS: We analysed data from the population-based INMA birth cohort, relying on blood biomarkers from the first trimester and weight at birth. The most representative biomarkers of organochlorine compounds (OCs) and perfluoroalkyl substances (PFAS) were included, as well as nutritional biomarkers for vitamins and carotenoids. A dataset with minimal imputation was established with complete data of OCs and PFAS, carotenoids and vitamins (n=810). The statistical framework included a screening phase to identify interactions using Gradient Boosting Regression and Glinternet. Identified interactions were further characterized using regression models.

RESULTS: The screening step revealed interactions between perfluorooctanesulfonic acid (PFOS) and carotenoids, but also with other chemicals like the pesticide dichlorodiphenyldichloroethylene (p,p'-DDE). The regression methods showed that at low levels of β-cryptoxanthin (tertile 1 and 2) the associations between PFOS and birth weight were clearly strengthened compared the flat slope of the highest tertile, yet the interaction was not statistically significant. Moreover, statistically significant interaction between PFOS and p,p'-DDE was confirmed: a log increase of PFOS, increased 131.0 g (95% confidence interval 18.4-243.6) of birth weight in the Tertile 1 of p,p'-DDE whereas a reduction of -59.6 g (95% confidence interval -155.9, 36.7) was found in the Tertile 3 of p,p'-DDE (p interaction= 0.01).

CONCLUSIONS: The results of this study support the presence of complex interactions between chemicals and nutrients during pregnancy and birth weight. These findings may help to better characterize the heterogeneous findings in the overall body of epidemiological evidence, yet further research is needed to confirm those findings.

P-0475 Early pregnancy phthalate and phthalate alternative metabolites in relation to fetal cardiac development

Danielle Stevens[1], Emma Rosen[1], Barrett Welch[1], Alexander Keil[2], Alfred Abuhamad[3], George Saade[4], Kelly Ferguson[1]

[1]Epidemiology Branch, National Institute of Environmental Health Sciences, Durham, USA, [2]Department of Epidemiology, University of North Carolina-Chapel Hill, Chapel Hill, USA, [3]Department of Obstetrics and Gynecology, Division of Maternal-Fetal Medicine, Eastern Virginia Medical School, Norfolk, USA, [4]Department of Obstetrics and Gynecology, University of Texas Medical Branch, Galvenston, USA

BACKGROUND AND AIM: Environmental exposures can impact organogenesis, contributing to adverse fetal cardiac development. Phthalate exposure contributes to fetal cardiac malformations in mice, but human studies have not been conducted. We sought to examine associations between biomarkers of exposure to phthalates and new alternative phthalates in early pregnancy and fetal cardiac development.

METHODS: Analyses were conducted among 260 singleton pregnancies in a prospective cohort. Twenty metabolites of phthalates and alternatives were assessed in up to two spot urine samples collected at 12- and 14-weeks gestation. Metabolite concentrations were corrected for urine dilution and averaged to provide a stable exposure estimate. Fetal cardiac outcomes (cardiothoracic area ratio, annulus displacement, fractional shortening, myocardial performance index, and the ratio of peak velocities in early and late diastole [E/A]) were assessed using M-Mode and Doppler conducted at 12-, 20-, and 32-weeks' gestation. Single- and multi-pollutant associations between metabolites and longitudinal fetal cardiac development were estimated using generalized estimating equations and quantile g-computation models, respectively. Models adjusted for maternal sociodemographics, smoking, and fetal sex.

RESULTS: Phthalate and alternative metabolites were highly detected (>90%). In single-pollutant models, all metabolites were inversely associated with the cardiothoracic area ratio. MiBP and MEP were inversely associated with the mitral E/A ratio (β: -0.02 [95% confidence interval: -0.03, 0.00] and -0.02 [-0.03, -0.01], respectively). In multi-pollutant models, a one-quartile increase in the exposure mixture was inversely associated with the cardiothoracic ratio (-0.69 [-1.22, -0.17]) and the mitral E/A ratio (-0.02 [-0.03, 0.00]).

CONCLUSIONS: Confirming findings in animal models, prenatal phthalate and phthalate alternative exposure was inversely associated with fetal cardiothoracic area and E/A ratios, indicating cardiac malformations, ventricular stiffness, and worse diastolic function. These developmental modifications manifest structural and functional cardiac adaptations, contributing to an elevated risk of cardiovascular disease.

KEYWORDS: pregnancy; cardiovascular disease; endocrine disrupting chemicals

P-0476 Environmental Noise Exposure During Pregnancy and Childhood and Embryonic and Fetal Growth: the Generation R Study

Naomi Graafland[1,2], Anke Posthummus[1], Esmée Essers[3,4,5,6], Albert Ambrós[3,4,6], Eric Steegers[1], Mònica Guxens[3,4,5,6]
[1]Obstetrics & Gynaecology, Generation R, Rotterdam, The Netherlands, [2]Generation R Study, Erasmus MC, Rotterdam, The Netherlands, [3]ISGlobal, Barcelona, Spain, [4]Universitat Pompeu Fabra, Barcelona, Spain, [5]Department of Child and Adolescent Psychiatry/Psychology, Erasmus MC, Rotterdam, The Netherlands, [6]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Instituto de Salud Carlos III, Madrid, Spain

BACKGROUND AND AIM: Noise exposure is considered a risk factor for adverse health outcomes. Literature has studies the association between noise exposure during pregnancy and adverse birth outcomes intensively, suggesting moderate to high quality evidence for an absence of association. However, few studies have explored the association with embryonic and fetal growth during pregnancy.

METHODS: We studied 7946 pregnant women from the Dutch Generation R Study. Average 24h noise exposure at the home address during pregnancy were estimated using EU maps from road traffic and total noise (road, aircraft, railway, industry). Embryonic and fetal growth parameters (crown-rump length, head circumference, femur length, estimated fetal weight) were measured by ultrasound at several points in pregnancy. Information on neonatal anthropometrics at birth (head circumference, length, weight) and adverse birth outcomes (preterm birth, low birthweight, small for gestational age) were retrieved from medical records. Linear mixed models were conducted to analyze the association between noise exposure and repeatedly measured fetal growth. Linear and logistic regression models were used to analyze the association between noise exposure and embryonic growth in the first trimester and birth outcomes.

RESULTS: Median total noise exposure levels were 55.3dB. Total noise exposure during pregnancy was associated with larger crown-rump length (0.04 SDS, 95%CI 0.00; 0.07), but not with repeatedly measured head circumference, length, and weight. Total noise exposure during pregnancy was not associated with neonatal anthropometrics at birth or adverse birth outcomes. Similar results were observed with road traffic noise exposure.

CONCLUSIONS: Noise exposure during pregnancy was associated with larger embryonic growth. We did not observe evidence of an association between noise exposure during pregnancy and fetal growth nor with birth outcomes. Additional research is warranted to confirm and elucidate the potential effects of noise exposure during pregnancy on altered embryonic growth.

KEYWORDS: environmental pollution, development, cohort study, pregnancy

P-0477 As safe as houses; the risk of childhood lead exposure from housing in England

Helen Crabbe[1], Neville Q Verlander[1], Neelam Iqbal[1], Rebecca Close[1], Geraldine White[1], Giovanni S Leonardi[1], Araceli Busby[1]
[1]*UK Health Security Agency, Didcot, UK*

BACKGROUND AND AIM: Exposure to lead can harm a child's health, including damage to the nervous system. Lead exposure in children is still a concern and cases require public health management to find the exposure source. Housing characteristics can indicate the presence of lead-contaminated paint and leaded water supply pipes. We aimed to explore the relationship between housing characteristics and elevated blood lead concentration (BLC) in children in England.

METHODS: We used a retrospective cohort design and included all cases of lead exposure in children reported to the UK Health Security Agency between 2014 and 2020 via surveillance. A case was a child aged under 16 years, resident in England, BLC of ≥0.48µmol/L and referred for public health management. We collected case demographic details and housing characteristics (age and type). We explored associations between elevated BLC and risk factors, using generalised linear mixed effects models and compared cases' housing type to that expected nationally.

RESULTS: 266 cases met the case definition. There was no difference in BLCs between genders, age groups, deprivation and housing type. After adjusting for reporting source, housing age and type, cases residing in housing built pre-1976 had a BLC of 0.32 (95%CI 0.02, 0.63) µmols/L higher than cases living in housing built after this time. Cases were 1.68 times more likely to be living in terraced housing than other children and less likely to live in apartments and detached properties.
CONCLUSION: This study suggests an association between housing characteristics and BLC in children. Housing age and type may act as a proxy for lead exposure risk through exposure to leaded paint, lead water pipes and lead contaminated dust from outdoor sources. Public health action should consider targeting families more at risk in older housing raising awareness of lead pipes and paint.

KEYWORDS: Lead, children, housing

P-0478 Description of childen's chemical exposome and possible determinants of exposure based on hair analysis

Alba Iglesias-González[1,2], Mylène Schweitzer[1], Paul Palazzi[1], Fengjiao Peng[1], Serge Haan[3], Elisabeth Letellier[3], Brice M. R. Appenzeller[1]

[1]Human Biomonitoring Research Unit, Department of Precision Health, Luxembourg Institute of Health, Strassen, Luxembourg, [2]University of Luxembourg, Esch-sur-Alzette, Luxembourg, [3]Molecular Disease Mechanisms Group, Department of Life Sciences and Medicine, Faculty of Science, Technology and Medicine, University of Luxembourg, Belvaux, Luxembourg

BACKGROUND AND AIM: Chemical exposure at young ages is associated with various diseases, and 25% of all deaths of children younger than 5 y/o are caused by exposure to unhealthy environment. Moreover, the specific physiology and behaviour of children, which differ significantly from adults, make them particularly vulnerable to chemical exposure. As a result, children exposure cannot be extrapolated from data obtained in adults and specific studies must be conducted on children. In the present study, hair samples were collected from 264 children inhabitants of Luxembourg aged below 13 y/o to investigate their chemical exposome and possible determinants of exposure.

METHODS: Each sample was analysed with a multi-residue method targeting 153 biomarkers, including 140 pesticides (persistent and non-persistent), 4 PCBs, 7 BDEs, and 2 bisphenols. Moreover, anthropometric parameters, information on diet, residence area and presence of pets at home were collected through self-reported questionnaires.

RESULTS: The number of compounds detected per sample ranged from 29 to 88 (median = 61). Twenty-three biomarkers were detected in ≥95% of the samples, including 13 in all samples (11 pesticides, BPA and BPS). Results showed higher exposure in younger children, and higher exposure to non-persistent pesticides in boys. Moreover, the results showed that diet (organic vs conventional), residence area, and living with pets at home are determinants of exposure.

CONCLUSIONS: The present study demonstrates that children are exposed simultaneously to multiple pollutants from different chemical classes, and confirms that hair is well adapted to investigate children exposure. The presence of many persistent organic pollutants (POPs) in most children, despite their young age, strongly suggests that exposure to POPs is still ongoing. The results obtained here set the basis for further investigations to better understand the determinants of exposure to pollutants in children.

P-0483 Indoor Air Quality in Classrooms Before and During the COVID-19 Pandemic: Lessons Learned from the Health Effects of Lebanese Schools Indoor Environment (HELSIE) Study Study

Myriam Mrad Nakhlé[1], Raymond EL Hajj, Maher Abboud, Emile Whaibeh, Hadiya Leya Affara, Elias Chalhoub, Wehbeh Farah

[1]*University of Balamand Faculty of Health Sciences, Beirut, Lebanon*

BACKGROUND AND AIM: COVID-19 interrupted the education of millions of children in the Eastern Mediterranean Region (EMR), including Lebanon, and, as educational institutions began to partially, gradually, and cautiously return to in-person learning, safety guidelines have underscored the importance of proper ventilation in response to the pandemic. Indoor Air Quality is critical for student populations because it is associated with growth disturbance, reduced attention, and increased absenteeism as well as diseases such as influenza, asthma, and other respiratory diseases. The aim of this study is to evaluate the COVID-19 safety guidelines adopted by Lebanese schools and their effects on IAQ by comparing air quality and health indicators measured before and during the COVID-19 pandemic.

METHODOLOGY:

Launched in 2019, before the COVID-19 pandemic, the HELSIE study measured carbon dioxide (CO2), particulate matter (PM2.5), Volatile Organic Compounds (VOCs), Nitrogen Dioxide (NO2) in indoor and outdoor microenvironments in 6 Lebanese schools. Questionnaire data were also collected from students, parents, and school staff. Upon the re-opening of schools in Lebanon, the project resumed to collect post-COVID-19 measurements of indoor and outdoor air quality indicators and to assess the adopted safety guidelines followed by the same schools.

FOCUS AND IMPLICATIONS:

Improving IAQ and ventilation systems is not only instrumental for COVID-19 safety but also to address the schools' preparedness to reduce the risks and adverse outcomes of seasonable infections and respiratory diseases. This study aims to guide the development of national and/or regional guidelines for classroom IAQ for the COVID-19 era and beyond.

Studies on the association between exposure to green spaces and child health have captured only a narrow range of outcomes. Here, we conducted an outcome-wide study on more than 90,000 mother-children's dyads from 11 European birth-cohort studies, to examine the association of residential availability (NDVI) and accessibility to green spaces (yes/no) in a 300 meters buffer during pregnancy and childhood with a range of outcomes. Fourteen outcomes in three areas of child health (respiratory health, obesity, neurodevelopment) will be included. The latest available measure of each outcome within the age band 3-12 years, was selected for each child. for postnatal period, green space exposures were calculated from birth up to the age before the outcome assessment. Using a federated-analysis tool (DataSHIELD), we fitted linear and logistic regression models in each cohort separately and then combined the results using random-effects meta-analysis. All the analyses were adjusted for child age (years) and sex, maternal education (low, medium, high), and area-level socioeconomic status (low/medium/high deprived). More than 70% of study participants lived close to green space during pregnancy and childhood period. Preliminary analyses on eight outcomes show no associations between availability of, or accessibility to, green spaces and respiratory (asthma diagnosis, forced expiration volume, and wheezing symptoms) and neurodevelopmental (gross and fine motor, internalization and externalization problems score tests, ADHD symptoms) outcomes. Further analyses will be presented on the full set of outcomes, including Body Mass Index, blood pressure, and general intelligence.

P-0485 Prenatal exposure to multiple persistent organic pollutants and adiposity markers and blood pressure in 12-year-old children

BACKGROUND: Several studies reported that prenatal exposure to some persistent organic pollutants (POPs) is associated with greater adiposity in childhood. Few studies have assessed whether this finding persists into adolescence and have considered exposure to POPs as a mixture. This study aims to assess the association between prenatal exposure to multiple POPs and adiposity markers and blood pressure in 12-year-old children.

METHODS: This study included 1658 mother-child pairs enrolled in the PELAGIE (France) and the INMA (Spain) mother-child cohorts. Three polychlorobiphenyls (PCB 138, 153 and 180, treated as a sum of PCBs) and three organochlorine pesticides (Dichlorodiphenyldichloroethylene [DDE], β-hexachlorocyclohexane [β-HCH], and hexachlorobenzene [HCB]) were assessed by biomarkers. Body mass index z-score (zBMI), abdominal obesity (waist-to-height ratio>0.5), percentage of fat mass, and blood pressure were measured around 12 years old. Single-exposure associations were studied using linear and logistic regressions and the POP mixture effect was evaluated using Quantile G-computation (qgComp) and Bayesian Kernel Machine Regression (BKMR). All models were adjusted for potential confounders and were performed for boys and girls together and separately.

RESULTS: Prenatal exposure to the POP mixture was associated with higher zBMI (beta [95% CI] of the qgComp = 0.15 [0.07; 0.24]) and percentage of fat mass (0.80 [0.28; 1.32]) at 12 years old. These mixture effects were also statistically significant using BKMR, and after stratification by sex. In overall, these associations were mainly driven by exposure to HCB and, to a lower extent, to β-HCH. Additionally, the single-exposure models showed an association between β-HCH and DDE with higher systolic blood pressure, especially in girls (beta [95% CI] of DDE for girls = 0.91 [0.06; 1.76], p sex-interaction=0.08).
CONCLUSION: This study suggests that prenatal exposure to POPs, especially to organochlorine pesticides, remains associated with adiposity markers until age 12.

KEYWORDS: Chemicals; Body mass index; Mixture; Birth cohort

P-0486 In utero exposure to tobacco smoke and reproductive health related markers in children: Evidence from the Rhea mother-child cohort, Crete, Greece

Vicky Bempi[1], Katerina Margetaki[1], Eleni Papadopoulou[2], Theano Roumeliotaki[1], Manolis Kogevinas[3], Leda Chatzi[4], Marina Vafeiadi[1]

[1]Department of Social Medicine, School of Medicine,University of Crete, Heraklion, Greece, [2]Division of Environmental Medicine, Norwegian Institute of Public Health, Oslo, Norway, [3]ISGlobal, Institute of Global Health, Barcelona, Spain, [4]Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Early fetal exposure to tobacco smoke has been associated with several adverse effects on offspring reproductive development possibly due to the suspected endocrine disrupting action of toxic compounds contained in cigarettes. We investigated the association of prenatal exposure to tobacco smoke with anogenital distance measures in young children and reproductive-related hormones in pre-adolescents from the Rhea birth cohort in Greece.

METHODS: Information regarding tobacco smoke exposure was obtained from maternal questionnaires throughout pregnancy. Anogenital distances - sexually dimorphic, longer in males than females- [(AGD; anus to upper penis), anoscrotal distance (ASD; anus to scrotum), anoclitoral (ACD; anus to clitoris) and anofourchetal distance (AFD; anus to fourchette)] were measured in 350 boys and 350 girls at the age of 2 years. at 10-11 years of age, we measured dehydroepiandrosterone sulfate (DHEA-S), luteinizing hormone (LH) and follicle-stimulating hormone (FSH) in 242 children (132 boys and 110 girls). Adjusted associations were obtained via multivariable regression analyses.

RESULTS: Maternal active smoking before and during pregnancy was associated with increased ACD in girls (adjusted β= 1.9 mm; 95% CI: 0.6, 3.3, β= 1.7 mm; 95% CI: 0.1, 3.3 respectively). Moreover, maternal exposure to passive smoking -via paternal active smoking- was associated with decreased LH in girls (adjusted β=-0.7 mUI/mL; 95% CI: -1.4, 0.0). In boys, maternal smoking in early pregnancy was associated with increased FSH (adjusted β= 0.5 mUI/mL; 95% CI: 0.1, 0.8) and the same association was observed for maternal smoking during any trimester of gestation(adjusted β= 0.4 mUI/mL; 95% CI: 0.1, 0.7).

CONCLUSIONS: In utero exposure to tobacco smoke was associated with increased anogenital distances in girls and altered hormonal levels in both sexes. Further research is needed to understand whether these findings may indicate long-term adverse effects on the reproductive health.

KEYWORDS: smoking during pregnancy, anogenital distance, reproductive hormones

P-0487 Prenatal air pollution exposure and childhood obesity: Effect modification by maternal fruits and vegetables intake

Katerina Margetaki[1], Eirini Michalaki[1], Theano Roumeliotaki[1], Vicky Bembi[1], Minas Iakovides[1], Euripides Stephanou[1], Manolis Kogevinas[2], Leda Chatzi[3], Marina Vafeiadi[1]
[1]University of Crete, Herakion, Greece, [2]ISGlobal, Barcelona, Spain, [3]University of Southern California, LA, USA

BACKGROUND & AIMS: Prenatal exposure to air pollution is associated with fetal growth but the relationship with postnatal growth and childhood obesity remains unknown. We examined the association of prenatal exposure to air pollution with growth and childhood obesity and evaluated the possible protective effect of the diet.

METHODS: We included 637 mother-child pairs from the Rhea birth-cohort in Crete, Greece. Fine particles (PM2.5 and PM10) during pregnancy were estimated using land-use regression models. We measured weight, height, and waist circumference at 4 and 6 years of age and body composition analysis was performed at 6 years using bioimpedance. Adjusted associations were obtained via multivariable regression. Interactions and stratified analyses were performed to evaluate the potential protective effect of nutrition.

RESULTS: Exposure to PM2.5 in utero (median (IQR): 14.4 (13.0, 15.4) µg/m3) was not associated with childhood obesity or abdominal obesity at 4 years of age. at 6 years of age, an IQR increase in prenatal PM2.5 was associated with increased risk of abdominal obesity (waist circumference > 90th percentile; RR 1.55, 95% CI: 1.01, 2.38). Moreover, in children whose mothers reported less than 5 servings of fruits and vegetables per day, an IQR increase in PM2.5 during pregnancy was associated with increased risk of obesity (RR 3.54, 95% CI: 2.18, 5.77) and increased risk of abdominal obesity (RR 3.69, 95% CI: 1.67, 8.15) at 6 years of age. Similar associations were observed between PM2.5 and body fat at 6 years as well as between PM10 (median (IQR): 35.5 (35.1, 37.2) µg/m3) and BMI, risk for obesity and abdominal obesity at 6 years.

CONCLUSIONS: Exposure to fine particulate matter during pregnancy was associated with higher risk of childhood obesity, while mothers' diet during pregnancy may protect against air-pollution related adverse effects.

KEYWORDS: Childhood obesity, particulate matter, air pollution, diet, interaction

P-0488 Prenatal exposure to mixtures of non-persistent endocrine disrupting chemicals and respiratory health in children from the Rhea birth cohort study, Greece

Theano Roumeliotaki[1], Antonis Myridakis[2], Katerina Margetaki[1], Euripides Stephanou[2], Manolis Kogevinas[3], Leda Chatzi[4], Marina Vafeiadi[1]

[1]Department of Social Medicine, School of Medicine, University of Crete, Greece, Heraklion, Greece, [2]Environmental Chemical Processes Laboratory (ECPL), Department of Chemistry, University of Crete, Heraklion, Greece, [3]ISGlobal, Barcelona, Spain, [4]Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Endocrine-disrupting chemicals (EDCs) are present in many consumer products and can affect the development and functions of the immune system. There is growing concern over the role of EDCs, including phthalates, bisphenol A (BPA) and parabens, on early life origins of respiratory diseases, however, results are inconsistent and most studies assessed one chemical at a time. We investigated whether prenatal phthalates, BPA and parabens are associated with childhood wheeze and asthma using a mixtures approach in the RHEA birth cohort in Greece.

METHODS: We quantified concentrations of seven phthalate metabolites, six parabens, and BPA in first trimester maternal urine. Information on wheezing and asthma up to 11 years was obtained from parent-completed questionnaires and lung function by spirometry. Multiple regression and quantile g-computation was used to assess the independent and joint associations between the EDCs and respiratory outcomes, respectively.

RESULTS: Prenatal exposure to monobenzyl-, mono(2-ethyl-5-hydroxyhexyl)-, and mono(2-ethyl-5-oxohexyl)-phthalates was associated with increased risk for early wheezing (≤4 years). Mono(2-ethyl-5-hydroxyhexyl) and mono-isobutyl phthalates were associated with higher FEV1 and FEV1/FVC ratio at 6 years, respectively. Methyl paraben was associated with increased risk for late wheezing (>4 years) and n-butyl paraben was associated with increased risk for current asthma at 6 years and ever asthma. Moreover, methyl and n-propyl parabens were associated with higher FEV1 at 6 years. We did not find any associations between prenatal BPA and any of the respiratory outcomes. In the mixture analysis, one quartile increase in phthalates was associated with higher FEV1 and in parabens with higher FEV1/FVC ratio at 6 years, respectively.

CONCLUSIONS: Our data indicate that prenatal exposures to phthalates, parabens and their mixtures may be associated with child respiratory health. Further research is needed to verify these findings and shed light on the molecular mechanisms.

KEYWORDS: prenatal, phthalates, parabens, mixtures

P-0489 Assessing the Effect of Heavy Metal Exposures on Pediatric Tuberculosis

Rehnuma Haque[1], Mohammad Jobayer Chisti[1], Mahbubur Rahman[1], Shariful Islam[1], Mohammad Moniruzzaman[2], Syed Moshfiqur Rahman[3], Rubhna Raqib[1]

[1]icddr,b: International Centre for Diarrhoeal Disease Research, Bangladesh, 68, Shaheed Tajuddin Ahmed Sarani, Mohakhali, Dhaka-1212, Bangladesh, [2]Bangladesh Council of Scientific and Industrial Research (BCSIR), Qudrat-E-Khuda Road, Dhaka 1205, Bangladesh, [3]Uppsala University, Akademiska sjukhuset, SE-75185 Uppsala, Sweden, Sweden

BACKGROUND AND AIM: Children are particularly vulnerable to environmental pollution due to their underdeveloped immune systems. Exposure to environmental pollutants such as heavy metals may alter the immune system, increasing human susceptibility to infectious diseases, particularly respiratory diseases including tuberculosis (TB). Our aims are a) test the hypothesis that exposure to heavy metals (e.g., As, Pb, Cd and Cr) is a risk factor for tuberculosis b) Quantify environmental sources.

METHODS: We hypothesize that children in urban Bangladesh are exposed to high concentrations of heavy metals, and these contribute to immune modulation and the occurrence of (precipitating) respiratory tract infections. Our ongoing study found Pb from recycling lead-acid batteries and the adulterated turmeric contribute to elevated blood lead levels; Cadmium (Cd) and Arsenic (As) also contributes to health disparities. This study will compare exposure to metals among children (1-15years) diagnosed with TB (cases) and matched healthy children (controls) in the Dhaka region. To measure exposure and infection status, we will analyze whole blood for metal level, immune assay and antibody markers. We will also conduct house dust sampling and questionnaire surveys to evaluate parental occupational exposures (including engagement in industrial and agricultural practices), household exposures (smoking and type of cooking fuel), and behaviors relevant to exposure. Based on the surveys and described samples, we will run a generalized /Bayesian additive model to estimate immune and antibody markers interlinked with the metal exposures.

RESULTS: Heavy metal pollution will be viewed as a sentinel indicator of predisposition, development, and severity of infectious disease outcomes. That are linked to TB are likely to also contribute to other infectious diseases such as pneumonia and bronchiolitis in children.

CONCLUSIONS: This research will uncover the interplay and potential causal pathway connecting environmental metals to tuberculosis and inform interventions to improve children's health.

P-0492 Prenatal and postnatal exposure to ambient air pollution and cognitive function in school-age children in France

Ariane Guilbert[1], Jonathan Y. Bernard[2], Hugo Peyre[3], Nathalie Costet[4], Ian Hough[1], Emie Seyve[1], Claire Philippat[1], Rémy Slama[1], Itai Kloog[5], Cécile Chevrier[4], Barbara Heude[2], Franck Ramus[3], Johanna Lepeule[1]
[1]Inserm - IAB, La Tronche, France, [2]Inserm - CRESS, Paris, France, [3]CNRS, Paris, France, [4]Inserm, Rennes, France, [5]Ben-Gurion University of the Negev, Be'er Sheva, Israël

BACKGROUND AND AIM: There is growing evidence that early life exposure to ambient air pollution may affect child cognitive development. However, combined effects of both prenatal and early postnatal exposure has rarely been investigated and critical periods of sensitivity are unknown. This study explored the temporal relationship between pre- and postnatal exposure to ambient air pollution and child cognitive abilities.

METHODS: Using validated spatiotemporally resolved exposure models, pre- and postnatal daily PM2.5, PM10 and NO2 concentrations at the mother's residence were estimated for 789 mother–child pairs from the French EDEN and PELAGIE cohorts. Scores representative of children General, Verbal and Non-Verbal abilities at 5-6 years were constructed based on subscale scores from the WPPSI-III, WISC-IV, NEPSY-II batteries, using confirmatory factor analysis. Associations of both prenatal (first 35 gestational weeks) and postnatal (60 months after birth) exposure to air pollutants with child cognition were explored using Distributed Lag Non-linear Model (DLNM) adjusted for confounders.

RESULTS: Increased exposure to PM2.5 in the third trimester of pregnancy was associated with better General and Verbal abilities. Exposure to higher NO2 levels in the first month of pregnancy and third trimester of pregnancy was related to improved Verbal abilities. During the postnatal period, increased exposure to PM2.5, PM10 and NO2 between 2-4 years was positively associated with General and/or Verbal abilities. Contrariwise, exposure to high PM2.5 or NO2 concentrations during the first year of life was associated with decreased General and/or Verbal abilities. No sex-specific association was observed after stratification of the analyses.

CONCLUSIONS: These results suggest better or poorer cognitive development associated with higher exposure to ambient air pollution in early life, depending on the exposure window. Further analyses will be conducted to assess the robustness of these results.

BACKGROUND AND AIM: Exposure to ambient air pollution may contribute to childhood obesity, but few large longitudinal studies have explored this. We aim to examine associations between exposure to pre-, early postnatal and childhood air pollution on offspring body-mass index (BMI) in key developmental periods using harmonized data from ten European birth cohorts.

METHODS: Ambient exposure to nitrogen dioxide (NO_2) and fine particulate matter ($PM_{2.5}$) was estimated at home addresses during pregnancy, the first year of life and the year before outcome measurement. We derived child age-and-sex standardized BMI in four age periods (infancy (0-2 years), early childhood (2-5 years), adiposity rebound (5-9 years), and later childhood (9-12 years)). Cohort specific estimates were calculated using confounder adjusted linear regressions, and meta-analysed afterward. The fraction of variance due to heterogeneity (I^2) was calculated. All analyses were conducted in DataSHIELD, a platform for non-disclosive federated analysis.

RESULTS: Meta-analysis results (N=29,535) showed no robust associations between air pollutants and BMI, and heterogeneity between cohorts was generally high (I^2>25). However, a tendency was observed for an association between higher prenatal $PM_{2.5}$ and NO_2 exposure and higher BMI at 0-2 years and 9-12 years respectively (e.g BMI_{0-2} beta for 10 µg/m³ increase in $PM_{2.5}$=0.03 (95%CI -0.02;0.09), I^2=0). Tendency for positive associations was also observed for some postnatal exposures, including $PM_{2.5}$ in the first year of life with BMI at 2-5 years (beta=0.06 (95%CI -0.03;0.14), I^2=0) and NO_2 in the year before outcome assessment with BMI at 5-9 years (beta=0.02 (95%CI -0.01;0.05), I^2=31).

CONCLUSIONS: In this large European meta-analysis there was little evidence for an association between prenatal or childhood exposure to ambient air pollution and childhood BMI, although considerable heterogeneity between study areas is noted.

P-0494 Ambient air pollution and inflammation-related proteins during early childhood

Shizhen He[1], Susanna Klevebro[2,3], Gabriel Baldanzi[1,4], Göran Pershagen[1,5], Björn Lundberg[2,3], Kristina Eneroth[6], Anna M Hedman[7], Ellika Andolf[8], Catarina Almqvist[7,9], Matteo Bottai[1], Erik Melén[2,3], Olena Gruzieva[1,5]

[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Department of Clinical Science and Education, Karolinska Institutet, Södersjukhuset, Stockholm, Sweden, [3]Sachs' Children and Youth Hospital, Södersjukhuset, Stockholm, Sweden, [4]Department of Medical Sciences, Molecular Epidemiology, Uppsala University, Uppsala, Sweden, [5]Centre for Occupational and Environmental Medicine, Region Stockholm, Stockholm, Sweden, [6]Environment and Health Administration, SLB-analys, Stockholm, Sweden, [7]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, [8]Department of Clinical Sciences, Karolinska Institutet, Danderyd Hospital, Stockholm, Sweden, [9]Pediatric Allergy and Pulmonology Unit at Astrid Lindgren Children's Hospital, Karolinska University Hospital, Stockholm, Sweden

BACKGROUND AND AIM: Experimental studies show that short-term exposure to air pollution may alter cytokine concentrations. There is, however, a lack of epidemiological studies evaluating the association between long-term air pollution exposure and inflammation-related proteins in young children. Our objective was to examine whether air pollution exposure is associated with inflammation-related proteins during the first 2 years of life.

METHODS: In a pooled analysis of two birth cohorts from Stockholm County (n=158), plasma levels of 92 systemic inflammation-related proteins were measured by Olink Proseek Multiplex Inflammation panel at 6 months, 1 year and 2 years of age. Time-weighted average exposure to particles with an aerodynamic diameter of <10 µm (PM_{10}), <2.5 µm ($PM_{2.5}$), and nitrogen dioxide (NO_2) at residential addresses from birth and onwards was estimated via validated dispersion models. Mixed effect model was applied to estimate the overall effect of preceding air pollution exposure on combined protein levels, "proteome" at respective ages, followed by protein-specific bootstrapped quantile regression analysis.

RESULTS: We identified significant association between overall proteome profile at the age of 6 months and PM_{10} exposure during the first 6 months of life (p=0.03), particularly among girls (p interaction with sex=0.03), whereas no associations were observed with $PM_{2.5}$ or NO_2. Subsequent protein-specific analyses revealed significant associations of PM_{10} exposure with an increase in IFN-gamma and IL-12B in boys, and a decrease in IL-8 in girls at different percentiles of proteins levels. Several inflammation-related proteins were also significantly associated with preceding $PM_{2.5}$ and NO_2 exposures, at ages 1 and 2 years, in a sex-specific manner.

CONCLUSIONS: Ambient air pollution exposure may influence inflammation-related protein levels already during early childhood. Our results also suggest age- and sex-specific differences in the impact of air pollution on children's inflammatory profiles.

P-0496 Individual and joint associations between prenatal polycyclic aromatic hydrocarbon exposure and asthma at age 8-10 in a multi-site longitudinal study

Allison Sherris[1], Christine Loftus[1], Adam Szpiro[1], Marnie Hazlehurst[1], Logan Dearborn[1], Margaret Adgent[2], Emily S. Barrett[3], Nicole R. Bush[4], Kurunthachalam Kannan[5], Ruby N.H. Nguyen[6], Yu Ni[1], Anne M. Riederer[1], Morgan Robinson[5], Sheela Sathyanarayana[1], Kecia Carroll[7], Paul Moore[2], Catherine J. Karr[1]

[1]University of Washington, Seattle, USA, [2]Vanderbilt University Medical Center, Nashville, USA, [3]Rutgers School of Public Health, New Brunswick, USA, [4]University of California San Francisco, San Francisco, USA, [5]New York University Grossman School of Medicine, New York, USA, [6]University of Minnesota School of Public Health, Minneapolis, USA, [7]Mount Sinai Icahn School of Medicine, New York, USA

BACKGROUND AND AIM: A few studies suggest prenatal exposure to polycyclic aromatic hydrocarbons (PAHs) influences wheezing or asthma in preschool-aged children. The hypothesized mechanisms for these associations include disruption to endocrine and immune function, oxidative stress, and inflammation. However, the impact of prenatal PAH exposure on asthma in population-based middle childhood remain unclear. We investigated these associations in the diverse participants of the ECHO PATHWAYS multi-cohort consortium.

METHODS: We included 1,015 mother-child dyads in the CANDLE and TIDES cohorts across five U.S. cities. Maternal mid-pregnancy urinary mono-hydroxylated metabolite concentrations (OH-PAH) were measured. Asthma was defined at age 8-10 years by caregiver report of physician diagnosis as well as current asthma medication use and/or recent wheezing. We used modified Poisson regression with robust standard errors to estimate relative risk of current asthma associated with seven individual OH-PAHs, adjusting for urine specific gravity, maternal and child characteristics, study site, prenatal and postnatal smoke exposure, and birth year and season. We used multiplicative interactions to evaluate effect modification by child sex, and we explored PAH mixture effects through Weighted Quantile Sum regression.

RESULTS: The prevalence of asthma was 10.5% (65% male). Overall, 47% of women were Black and 45% were White; 58% had graduated from college or technical school at enrollment. We did not find evidence of associations between individual OH-PAH concentrations or mixtures of OH-PAHs and child asthma at age 8-10. In males, we found a suggestion of a protective association between 1- and 2- hydroxynaphthalene and asthma, but the interaction term between child sex and all OH-PAH concentrations was not statistically significant.

CONCLUSIONS: In a large, multi-region U.S. cohort, we did not find evidence of an association between prenatal exposure to PAHs and child asthma at age 8-10, an age when asthma is more readily diagnosed.

P-0497 Parental arsenic exposure and DNA methylation in Bangladeshi infants with spina bifida

Gwen Tindula[1], Sudipta Kumer Mukherjee[2], Sheikh Muhammad Ekramullah[2], DM Arman[2], Joynul Islam[2], Bernardo Lemos[3], Liming Liang[3], David Christiani[3], Benjamin Warf[1], Maitreyi Mazumdar[1]
[1]Boston Children's Hospital, Boston, USA, [2]National Institute of Neurosciences and Hospital, Dhaka, Bangladesh, [3]Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Arsenic, a chemical naturally occurring in soil and drinking water, is a recognized human toxicant and has been linked to numerous adverse health outcomes. An emerging hypothesis linking arsenic to detrimental health involves the epigenome, the multitude of compounds that affect DNA transcription but do not alter the underlying DNA sequence. The objective of the current study was to investigate the relationship between parental arsenic exposure and DNA methylation in infants diagnosed with spina bifida in a case-control study in Bangladesh.

METHODS: We analyzed arsenic in maternal and paternal toenail samples using inductively coupled plasma mass spectrometry. Infant DNA methylation was measured in dural tissue, buccal swab, and whole blood samples using the Illumina Infinium MethylationEPIC BeadChip and we used M-values for analysis. A total of 28 children with spina bifida and their parents were included in the analysis.

RESULTS: After accounting for child sex, child age at sample collection, maternal serum folate levels, and surrogate variables, and after adjusting for multiple hypothesis testing, DNA methylation levels at cg24039697 (β=0.59, p=7.6E-9) were associated with paternal toenail arsenic levels (log_2-transformed) in the child dural tissue models. None of the sites in the maternal arsenic and child dural tissue analysis remained significant after accounting for multiple hypothesis testing. In the models including child whole blood or buccal swab DNA methylation, we did not observe any significantly differentially methylated CpG sites related to either paternal or maternal arsenic exposure following adjustment for multiple hypothesis testing.

CONCLUSIONS: The findings from this study provide novel insight into the role of environmental arsenic exposure in DNA methylation patterns in multiple tissues collected from children with neural tube defects. The study warrants replication in larger groups to validate findings and to inform targeted prevention strategies.

KEYWORDS: Arsenic, DNA methylation, Bangladesh, folate, spina bifida

P-0500 Associations of prenatal ambient air pollution exposures with asthma in middle childhood

Marnie Hazlehurst[1], Kecia N. Carroll[2], Paul E. Moore[3], Adam A. Szpiro[1], Christine T. Loftus[1], Yu Ni[1], Logan Dearborn[1], Margaret A. Adgent[3], Nicole R. Bush[4], Kaja Z. LeWinn[4], Sheela Sathyanarayana[1,5], Emily S. Barrett[6], Ruby H.N. Nguyen[7], Catherine J. Karr[1]

[1]University of Washington, Seattle, USA, [2]Icahn School of Medicine at Mount Sinai, New York, USA, [3]Vanderbilt University Medical Center, Nashville, USA, [4]University of California San Francisco, San Francisco, USA, [5]Seattle Children's Research Institute, Seattle, USA, [6]Rutgers School of Public Health, Piscataway, USA, [7]University of Minnesota, Minneapolis, USA

BACKGROUND AND AIM: Early life susceptibility to air pollutants may reflect unique vulnerabilities across the well-described phases of prenatal morphological lung development. We assessed associations between air pollution exposures in these periods and asthma among school-age children.

METHODS: Participants were drawn from full-term births in three prospective cohorts spanning six US metropolitan areas in the ECHO-PATHWAYS Consortium: CANDLE, TIDES, and GAPPS. Current asthma at age 8-10 was assessed by parent-report on the International Study of Allergies and Asthma survey and required asthma diagnosis and either asthma medication use or recent wheezing. Prenatal nitrogen dioxide (NO_2) and ozone (O_3) exposures were estimated using a national spatiotemporal model in the pseudoglandular (5-16 weeks), canalicular (16-24 weeks), saccular (24-36 weeks) and alveolar (36+ weeks) lung development phases. Modified Poisson regression models to estimate relative risk (RR) were adjusted for child, maternal, and socioeconomic factors. Effect modification was evaluated with interaction terms for maternal history of asthma and child sex.

RESULTS: In this sample (n=1214), 9.7% of children had current asthma. Among mothers, 18% reported a history of asthma. No statistically significant associations were observed between prenatal NO_2 or O_3 and child asthma. We found suggestive evidence of an adverse association with NO_2 in the saccular phase among those without maternal history of asthma (RR=1.31 per 5 ppb; 95% CI: 0.90-1.91) and possible reduced risk (RR=0.61; 95% CI: 0.35-1.07) among those with maternal history of asthma (p-interaction=0.02). No effect modification was observed by child sex.

CONCLUSIONS: We found a suggested adverse effect of maternal NO_2 exposure during mid to late pregnancy on asthma risk in middle childhood, but only for children without one marker of a familial predisposition (maternal asthma history). Further research to examine this potential critical window and discrepancies by genetic risk factors is needed.

KEYWORDS: air pollution, asthma, children's environmental health

P-0501 Association of maternal fluoride exposure during pregnancy with increased size at birth and the potential mediation effect by maternal thyroid hormones: the Swedish NICE birth cohort

Mariza Kampouri[1], Klara Gustin[1], Mia Stråvik[2], Malin Barman[1,2], Michael Levi[1], Vasiliki Daraki[3], Bo Jacobsson[4,5], Anna Sandin[6], Ann-Sofie Sandberg[2], Agnes Wold[7], Marie Vahter[1], Maria Kippler[1]

[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Food and Nutrition Science, Department of Biology and Biological Engineering, Chalmers University of Technology, Gothenburg, Sweden, [3]Department of Endocrinology, University Hospital of Heraklion, Heraklion, Greece, [4]Department of Obstetrics and Gynecology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [5]Institute of Clinical Sciences, Department of Obstetrics and Gynecology, Sahlgrenska University Hospital, Gothenburg, Sweden, [6]Department of Clinical Science, Pediatrics, Sunderby Research Unit, Umeå University, Umeå, Sweden, [7]Institute of Biomedicine, Department of Infectious Diseases, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

BACKGROUND AND AIM: Observational studies have indicated that maternal fluoride exposure during gestation may impair child neurodevelopment but a potential impact on birth outcomes is understudied. The aim of the study is to evaluate the impact of gestational fluoride exposure on birth outcomes and assess the potential mediating role of maternal thyroid hormones.

METHODS: We studied 583 mother-child pairs in the NICE cohort in northern Sweden, where drinking water fluoride varies considerably. Fluoride concentration was measured in urine at gestational week 29 using an ion selective electrode. Plasma levels of free and total thyroxine and triiodothyronine, and thyroid stimulating hormone at gestational week 29 were measured with electrochemiluminescence immunoassays. The infant's length, head circumference, weight, and gestational age at birth were extracted from hospital records.

RESULTS: Median maternal urinary fluoride concentration was 0.7 mg/L (5th-95th percentile 0.3-1.9 mg/L; specific gravity adjusted). In multivariable-adjusted regression models, every doubling of maternal urinary fluoride was associated with a mean increase in birth length by 0.4 cm (95%CI: 0.2, 0.6), head circumference by 0.18 cm (95%CI: 0.04, 0.31), and weight by 67 g (95%CI: 22, 112), as well as an increased odds of being born large for gestational age (OR=1.49, 95%CI: 1.11, 2.02). Every doubling of maternal urinary fluoride was also associated with a mean increase in the plasma tT3 level by 0.04 µmol/L (95%CI: 0.00, 0.09) but with no other marker of thyroid functioning. In mediation analysis, maternal tT3 levels explained only about 10% of the urinary fluoride-birth length/weight associations.

CONCLUSIONS: Gestational fluoride exposure was associated with increased size at birth and even increased odds of being born large for gestational age. The observed associations were not explained by maternal thyroid hormone levels.

KEYWORDS: urinary fluoride, pregnancy, birth length, head circumference at birth, birth weight, large for gestational age, thyroid hormones

P-0503 Association between short-term exposure to ambient air pollution and cognitive interference: evidence from the Environment and Development of Children cohort

Jiawei Zhang[1], Bung Nyun Kim[2], Yun Chul Hong[3,4,5], Choong Ho Shin[6], Young Ah Lee[7], Zorana Jovanovic Andersen[1], Johanna Inhyang Kim[6], Youn-Hee Lim[1]

[1]Section of Environmental Health, Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [2]Department of Psychiatry; Seoul National University College of Medicine, Seoul, Republic of Korea, [3]Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea, [4]Division of Public Health and Preventive Medicine, Seoul National University Hospital, Seoul, Republic of Korea, [5]Institute of Environmental Medicine, Seoul National University Medical Research Center, Seoul, Republic of Korea, [6]Department of Psychiatry, Hanyang University Medical Center, Seoul, Republic of Korea, [7]Department of Pediatrics, Seoul National University Children's Hospital, Seoul National University College of Medicine, Seoul, Republic of Korea

BACKGROUND AND AIM: Fine particulate matters with diameter < 2.5 and 10 μm (PM2.5 and PM10) have been linked to cognitive interference, but the evidence on gaseous pollutants, such as NO2, SO2, and CO is scarce. Besides, very few studies examined the short-term association between air pollution and cognitive interference. This study aimed to investigate the association of short-term air pollution exposure with cognitive interference.

METHODS: We conducted a repeated measurement study with 470 children in the Environment and Development of Children cohort. Cognitive interference was assessed when children were aged 6 and 8 years using the Stroop Color and Word Test. Air pollution levels (PM2.5, PM10, NO2, SO2, and CO) from the day to 2-week moving average prior to the test were linked to the children based on the residential district. We applied a mixed-effect linear model after controlling for maternal characteristics during the mid-pregnancy or at birth (maternal age, gestational age, parity, smoking before or during the pregnancy,) in addition to children's characteristics (sex, physical activities, and second-hand smoking) and spatial-temporal information (month of the test, residential region, temperature, and humidity).

RESULTS: An interquartile range increase in PM2.5 (11.4 μg/m3) on a week moving average was associated with 1.70 (95% confidence interval [CI]: 0.53, 2.87), 2.29 (95% CI: 1.12, 3.45) and 1.33 (95% CI: -0.05, 2.72) decreases in Stroop word, color, and color-word test scores, respectively. Similar associations were detected for PM10, NO2, SO2, and CO. The negative associations were greater for girls, preterm births, and children with vigorous physical activities.
CONCLUSION: Our study suggests that short-term air pollution exposure is associated with childhood cognitive interference. Further improvement in air quality may benefit the cognitive development of children.

P-0507 Adherence to Mediterranean diet and metal exposure during childhood in the INMA study

Leyre Notario[1], Raquel Soler, Gabriel Riutort, Jesús Ibarluzea, Loreto Santa-Marina, Martine Vrijheid, Jesús Vioque, Andrew Meharg, Manus Carey, Maribel Casas, Adonina Tardón, Ana Fernández Somoano, Antonio J Signes Pastor
[1]*Instituto de Investigación Sanitaria y Biomédica de Alicante. Universidad Miguel Hernández (ISABIAL-UMH)., Alicante, Spain*

BACKGROUND AND AIM: The Mediterranean diet (MD) has been shown to have beneficial effects in children. A greater adherence to this pattern has been associated with a lower risk of developing obesity, diabetes, and cardiovascular disease. Yet, the contribution of the MD to the ingestion of essential and non-essential elements during childhood is unknown. Here, it is investigated the association between children's adherence to the MD and exposure to essential and non-essential elements.
METHODS: Our study population of 714 children come from the INMA cohort study (INfancia y Medio Ambiente). Urinary concentrations of essential (Co, Cu, Zn, Se, and Mo) and non-essential (As, Pb and Cd) elements were measured as exposure biomarkers. Urinary arsenic speciation was also determined, and concentrations were adjusted for urine dilution. The MD dietary indexes rMED (relative Mediterranean Diet Score) and aMED (alternate Mediterranean Diet Score) were calculated based on the information gathered with a validated food frequency questionnaire (FFQ). The urine samples and data from FFQ were collected at 4 years of age.
RESULTS: The median urinary concentrations of Co, Cu, As, Se, Mo, Cd, Pb and Zn were 0.78, 7.64, 24.45, 23.07, 92.76, 0.08, 0.37 and 377.39 μg/L, respectively. Urinary arsenic species concentrations (median) included arsenobetaine (10.83 μg/L), monomethylarsonic acid (0.36 μg/L), dimethylarsinic acid (3.00 μg/L), and inorganic arsenic (1.17 μg/L). An increased adherence to MD was associated with higher Mo, As and lower Co concentrations. The non-toxic arsenobetaine was associated with fish consumption in both indexes, but vegetables consumption was related to the inorganic arsenic exposure only in aMED index.
CONCLUSIONS: These findings suggest that the level of adherence to the MD is associated with exposure to essential but also non-essential elements. Efforts should aim to reduce toxic dietary exposures while preserving beneficial nutrients in children's dietary patterns.

P-0508 Exposure to Pesticides and Respiratory Health Outcomes in Children Residing in Imperial Valley, CA

Yoshira Ornelas Van Horne[1], Shohreh F. Farzan[1], Elizabeth M. Kamai[1], Brandyn C. Ruiz[1], Jill E. Johnston[1]
[1]*Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA*

BACKGROUND AND AIM: Exposure to pesticides have been linked with adverse respiratory health outcomes such as lower lung function and greater wheezing. Pesticide use registries (PURs) have been used to estimate geospatially-based pesticide exposures throughout the life-course, but their usage in epidemiological studies remains underutilized. We aim to link data from a pesticide use registry in California with parent-reported respiratory health symptoms in predominantly Latino children enrolled in a longitudinal cross-sectional study in Imperial Valley, CA.

METHODS: We leveraged the Children's Assessing Imperial Valley Respiratory Health and the Environment cohort located in the highly burdened rural agricultural community of Imperial Valley near the US-Mexico border. We calculated the pounds of total pesticides applied within 400 meters of children's residential addresses for the years 2016-2018 and created three exposure categories (none, low, high), with the low and high exposure groups split at the median (47 kg). We used logistic regression to examine associations of pesticide exposures with respiratory symptoms, including wheezing and asthma medication usage, and controlled for language of survey completion, age, doctor-diagnosed asthma, and sex. All health variables were derived from the validated ISAAC questionnaire.

RESULTS: A total of 746 children were included in this analysis. 62% of children lived within 400m of at least one pesticide application within 12 months prior to survey administration. Compared to children with no pesticide exposure in the past 12 months, those with the highest level of pesticide exposure reported greater wheezing (OR=1.86, 95%CI 1.01, 3.45), and medication usage (OR=2.43, 95%CI 1.14, 5.35). There were no associations with coughing or bronchitic symptoms.

CONCLUSIONS: We observed associations of living near pesticide applications during the 12-months prior to survey administration with wheezing and asthma medication usage outcomes among children living in a highly agricultural rural county along the US-Mexico border.

KEYWORDS: pesticides, wheezing, children

P-0510 Prenatal exposure to traffic-related air pollution and childhood acute leukaemia in France - GEOCAP Birth 2010-2015

Stéphanie Goujon[1,2], Antoine Lafontaine[3], Bénédicte Jacquemin[3], Jacqueline Clavel[1,2]
[1]Inserm UMR 1153 (CRESS) - EPICEA Team, Villejuif, France, [2]Université Paris Cité, Paris, France, [3]Rennes University, EHESP, INSERM IRSET UMR S 1085, Rennes, France

BACKGROUND AND AIM: Acute leukemia (AL) affect approximately 500 children under 15 each year in France. Living near major roads and being exposed to traffic-related air pollutants are increasingly suggested as risk factors for childhood AL.
The present GIS-based registry-based case-control study investigates the hypothesis that prenatal exposures to traffic-related pollutants increase the risk of AL, using exposure at the residence at birth as a proxy of prenatal exposure.

METHODS: the study included all the AL cases born and diagnosed in France during 2010-2015 (n=728) and 11,908 controls representative of the French births during the same period.
Addresses of residence at birth were geocoded. Exposure indicators were the length of major roads within 150 m of the address, and the concentrations of NO2, fine particulate matter (PM2.5) and black carbon (BC) estimated by land use regression models.
Odds-ratios were estimated for several exposure categories and under the hypothesis of a log-linear increase in childhood AL risk with increasing level of exposure, using unconditionnal logistic regression models (all AL) and polytomic logistic models (AL subtypes). The analyses were also stratified according to the degree of urbanization of the municipality.

RESULTS: childhood AL was not associated with major road length. Overall, PM2.5 and BC concentrations were associated with an increased risk of childhood AL (OR=1.3 [1.2-1.4] and OR=1.1 [1.0-1.2] per inter-quartile range increase, respectively). However, no positive association was observed for BC when the effect of BC was isolated from that of total PM2.5. Stratifying by urbanization status did not change the results for PM2.5 but the associations were weaker for BC especially in most urban areas. Non-significant positive associations were observed for NO2.

CONCLUSIONS: our findings suggest a role of prenatal exposure to traffic-related air pollution in childhood AL.

KEYWORDS: Childhood leukemia; road traffic; air pollution; prenatal exposure

P-0512 Residential green space improves cognitive performances in primary schoolchildren independent of traffic-related air pollution exposure

Nelly Saenen[1], Tim Nawrot[1,2], Pauline Hautekiet[1,3], Congrong Wang[1], Harry Roels[4], Payam Dadvand[5,6,7], Michelle Plusquin[1], Esmée Bijnens[1,8]

[1]Hasselt University, Diepenbeek, Belgium, [2]KU Leuven, Leuven, Belgium, [3]Sciensano (Belgian Institute of Health), Brussels, Belgium, [4]Université catholique de Louvain, Brussels, Belgium, [5]ISGlobal, Barcelona, Spain, [6]Pompeu Fabra University, Barcelona, Spain, [7]Ciber on Epidemiology and Public Health (CIBERESP), Madrid, Spain, [8]Ghent University Hospital, Ghent, Belgium

BACKGROUND AND AIM: Cognitive performances of schoolchildren have been adversely associated with both recent and chronic exposure to ambient air pollution. In addition, growing evidence indicates that green space is associated with a wide range of health benefits. Therefore, we aimed to investigate if surrounding green space improves cognitive performance of children while taking into account air pollution exposure.

METHODS: Cognitive performance tests were administered repeatedly to a total of 307 primary schoolchildren aged 9-12y, living in Flanders, Belgium (2012-2014). These tests covered three cognitive domains: attention (Stroop, Continuous Performance Tests), short-term memory (Digit Span Forward and Backward Tests), and visual information processing speed (Digit-Symbol, Pattern Comparison Tests). High-resolution green space exposure was estimated within several radii around their current residence (50-2000 m). Furthermore, residential air pollution exposure (year before examination) was modelled using a spatial-temporal interpolation method.

RESULTS: An improvement of the children's attention was found with more residential green space exposure independent of traffic-related air pollution (NO_2 and distance to major roads). for an IQR increment (21%) of green space within 100 m of the residence, a significantly lower mean reaction time was observed for sustained (-9.21 msec, 95%CI: -16.0 to -2.4 msec, p=0.008) and selective attention (-62.55 msec, 95%CI: -112.6 to -12.5 msec, p=0.02). Moreover, residential green space exposure within a large radius (>1000 m) was significantly associated with a better performance in short-term memory and a higher visual information processing speed, taking into account traffic-related exposure. However, all associations were attenuated after taking into account long-term residential $PM_{2.5}$ exposure.

CONCLUSIONS: Our panel study showed that exposure to residential surrounding green space was associated with better cognitive performances. These findings support the necessity to build attractive green spaces in the residential environment to promote healthy cognitive development in children.

P-0513 Strengthening the global role of environmental epidemiology in the Respiratory Diseases Exploratory: Analysis of Age in the Diagnosis of Asthma in Brazil, 2019

Telma Cassia dos Santos Nery[1], Sonia Quezia G M Zago[2], Rafalea G Dantas[3], Felipe Fonseca Martins Costa[4], Rafael Stelmach[1]

[1]Divisao de Pneumologia InCor HC FMUSP, Sao Paulo, Brazil, [2]UNINOVE, Sao Paulo, Brazil, [3]UNIFESP, Sao Paulo, Brazil, [4]Faculty of Medicine of Americas, Sao Paulo, Brazil

Asthma is a recurrent inflammatory lung disease in which certain stimuli (factors triggers) inflame the airways and cause them to narrow temporarily, resulting in breathing difficulties. Can be develop at any age, begins most often in childhood, especially in the first five years of life. It is a chronic disease and should be routinely monitored. Affects more than six million children in the USA, where more than 8.5% of children in the USA were diagnosed with asthma, indicating a 100% increase in recent decades. the rate goes up to 25% to 40% among some urban child populations. Asthma is one of the main causes of hospitalization of children and is the main chronic clinical condition school absenteeism. Important to know when the diagnosis of asthma is being made in Brazil, aiming at preventive measures.

OBJECTIVE: to identify the age group in which it was performed. Asthma diagnosis by regions of Brazil in 2019.Descriptive study. An open database analysis of the National Health Survey (PNS) and the Brazilian Institute of Geography and Statistics (IBGE).108,525 households were visited and 94,114 interviews were carried out. Analyzed: Regions of Brazil,sex, race, color, household characteristics and age at diagnosis asthma doctor.

RESULTS: The mean age in Brazil was 15.5 years (95% confidence), and by regions: North(N):10.8;Northeast (NE): 14.4; Southeast (SE):14.8; South (S): 16.1; Midwest (CO): 15.5. The coefficients of the variations found were: Brazil - 2.8; N-8.0; NE -14.4; SE - 4.9; S-5.2; CO-6.4. There is one important variation in the age of asthma diagnosis in Brazil that deserves to be known and addressed. Research with open data from the Ministry of Health and IBGE can contribute to the discussion of preventive health measures considering the early diagnosis, treatment of asthma and environmental discussion.

P-0522 Factors effecting inflammatory-based diseases anxiety and atopy in Australian children

Nicholas Osborne[1,2,3], Diana Garcia-Sánchez[1], Nathalie Ang[1,4], Darsy Darssan[1]
[1]University of Queensland, Herston, Australia, [2]University of New South Wales, Kensington, Australia, [3]European Centre for Environment and Human Health, Truro, UK, [4]National University of Singapore, Singapore, Singapore

BACKGROUND AND AIM: New evidence is emerging that some mental health disease is related to inflammation. This could see individuals with multiple inflammatory diseases sharing pathological pathways. A variety of environmental factors will influence these relationships.

METHODS: We used the Longitudinal Study of Australian Children, a population representative survey of Australian children which has been running since 2003 and consists of nine waves of data with. 10000 participants. We analysed the remaining 3127 adolescents and 3037 young adults. A range of questionnaire data on risks and health have been used to identify health status and risk factors/confounders. Relationships were adjusted for a range of know potential confounders, including sex, BMI, socio-economic indexes for areas, latitude, state of residence and remoteness of the area.

RESULTS: Of the 4-5 year old 1.6% (95% CI 1.3-2.0 had both anxiety and asthma, of the 16-17 year old 6.8% (95% CI 5.5-8.5). In two sub-cohorts, anxiety was associated with asthma diagnosis (aOR 1.6, 95%CI 1.2, 2.0) and (aOR 1.5, 95%CI 1.2, 1.9). Presence of anxiety increased the risk of other atopic-related diseases eczema and food allergy. There was a trend for more atopic disease in southern regions compare to the northern cities.

CONCLUSIONS: There is a relationship between anxiety and atopy in this Australian cohort, which may be bi-directional. A common pathological pathway for both diseases groups is possible. Solar exposure in more northerly states may be related to better immune health.

KEYWORDS: Inflammation, allergy, anxiety, vitamin D, children

P-0525 Associations of prenatal exposure to outdoor PM2.5 and NO2 with childhood respiratory symptoms

Alan Ricardo Patlán-Hernández[1], Etienne Audureau[2], Johanna Lepeule[3], Mélanie Bertin[4], Ralph Epaud[5], Sophie Lanone[6], Charline Warembourg[1], Christine Monfort[1], Cécile Chevrier[1], Bénédicte Jacquemin[1]

BACKGROUND AND AIM: Prenatal and early life exposures to air pollution have been shown to play an important role in the development of childhood respiratory and allergic diseases. Nitrogen dioxide (NO2) has been associated with increased paediatric asthma incidence, while prenatal exposure to fine particulate matter (PM2.5) has chronic and adverse effects in lung development and respiratory health. The aim of the study was to assess the associations of prenatal exposure to air pollutants with the prevalence of respiratory symptoms, asthma, allergic rhinitis, and eczema in children.

METHODS: We selected 2150 children from the PELAGIE Cohort in Brittany, France, that were followed-up at 2, 6 and 12 years old. Parents reported children's respiratory health history, family lifestyle behaviours and children's immediate environment through standardized and validated questionnaires. Concentrations of PM2.5 and NO2 were modelled during the pregnancy at residential address. We used logistic regression models to assess the associations per one increase of an interquartile range (IQR), adjusted by sex, parents smoking during pregnancy, environmental tobacco smoke of children and children smoking (at 12).

RESULTS: Prenatal concentrations of NO2 were 20.04±6.33µg/m3 (IQR=2.48) and PM2.5 10.24±1.17µg/m3 (IQR=1.59). Prenatal exposure to higher NO2 concentrations was associated with increased odds of wheezing episodes at the age of 2 years [odds ratio (OR) = 1.26; 95% confidence interval (CI):1.00–2.61] and higher odds of suffering asthma at 12 years old [OR=1.33; 95%CI: 0.97–1.82]. Overall, higher exposure to NO2 and PM2.5 during the prenatal period showed associations with increased odds of sneezing, wheezing and asthma attacks during childhood; however, these associations were at the limit of statistical significance.
CONCLUSION:
Prenatal exposures to ambient PM2.5 and NO2 seem associated with higher risk of respiratory and allergic diseases in children even at relatively low levels of air pollution concentrations.

KEYWORDS: Air pollution, children health, allergic diseases, prenatal exposure.

P-0527 The NeuroTox study – Investigating in-utero exposures to environmental toxicants and neurodevelopment

Adriano Winterton[1], Gro Villanger[1], Stephanie Engel[2], Thea Skogheim[4], Amanda Ramos[2], Jake Thistle, Elizabeth Kamai[5], Cathrine Thomsen[3], Line Haug[3], Kjell Vegard Weyde[1], Guido Biele[1], Pål Surén[1], Heidi Aase[1]

[1]Department of Child Health and Development, Division of Mental and Physical Health, Norwegian Institute of Public Health, Oslo, Norway, [2]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, USA, [3]Department of Food Safety, Division of Climate and Environmental Health, Norwegian Institute of Public Health., Oslo, Norway, [4]Division for Health Services, Norwegian Institute of Public Health, Oslo, Norway, [5]Keck School of Medicine of the University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Chemical pollution is an increasing threat to child health worldwide and the impact of environmental toxicant on early brain development could contribute to the origins of neurodevelopmental disorders and cognitive impairments. The NeuroTox study has investigated prenatal exposure to environmental chemicals and child neurodevelopmental outcomes in the Norwegian Mother, Father and Child Cohort study (MoBa). We evaluate the relations between population levels of common environmental toxicants in pregnant women and child neurodevelopment across NeuroTox findings.

METHODS: Toxic metals, essential elements, and per- and polyfluoroalkyl substances (PFAS) were measured in the mother's blood, while phthalates and organophosphate esters (OPEs) were measured in urine of 3,500 mother–child pairs from the MoBa study during gestation. Relationships between toxicant levels and neurodevelopmental outcomes (Attention-Deficit/Hyperactivity Disorder [ADHD], Autism-spectrum disorders [ASD], and cognitive impairment) in children were assessed using multivariable-adjusted quartile or quintile, logistic, restricted-cubic-spline, and quantile-based-g-computation models controlling for maternal age, education, parity, smoking, seafood intake, and child sex.

RESULTS: Published findings from NeuroTox show that elevated maternal levels of phthalates and PFAS (e.g. perfluorooctanoic acid [PFOA] and perfluorooctane-sulfonic acid [PFOS]) were associated with lower cognitive functions in the child. Elevated maternal cadmium, lead, arsenic, PFOA, PFOS, manganese, and cobalt were associated with increased risk of ADHD and/or ASD, while elevated OPEs and phthalates with increased risk of ADHD. With PFOA, lead and manganese, both low and high levels were associated with an adverse effect in non-linear dose-response relationships.

CONCLUSIONS: These results suggest that population levels of these toxicants in pregnancy even in a high-income country (Norway) may adversely impact brain development by contributing to the risk of neurodevelopmental disorders and cognitive impairments. Planned developments will investigate how socioeconomic status modulates both the exposures and their downstream effects on brain development and child mental health.

KEYWORDS: PFAS, Neurodevelopment, OPEs, metals, Prenatal exposure

P-0529 Adverse Birth Outcomes Related to NO2 and PM Exposure: European Systematic Review and Meta-Analysis

Valentin Simoncic[1], Christophe Enaux[1], Severine Deguen[2], Wahida Kihal[1]
[1]Laboratoire Image Ville Environnement, Strasbourg, France, [2]Université de Bordeaux, Bordeaux, France

There is a growing number of international studies on the association between ambient air pollution and adverse pregnancy outcomes, and this systematic review and meta-analysis have been conducted focusing on European countries, to assess the crucial public health issue of this suspected association in this geographical area. A systematic literature search (based PRISMA guidelines) has been performed on all European epidemiological studies published up until 1 April 2020, on the association between maternal exposure during pregnancy to nitrogen dioxide (NO2) or particular matter (PM) and the risk of adverse birth outcomes, including low birth weight (LBW) and preterm birth (PTB). Fourteen articles were included in the systematic review and nine of them were included in the meta-analysis. Our meta-analysis was conducted for 2 combinations of NO2 exposure related to birth weight and PTB. Our systematic review revealed that the risk of LBW increases with the increase of air pollution exposure (including PM10, PM2.5, and NO2) during the whole pregnancy. Our meta-analysis found that birth weight decreases with NO2 increase (pooled beta = −13.63, 95% confidence interval (CI) (−28.03, 0.77)) and the risk of PTB increase for 10 µg/m3 increase in NO2 (pooled odds ratio (OR) = 1.07, 95% CI (0.90, 1.28)). However, the results were not statistically significant. Our findings support the main international results, suggesting that increased air pollution exposure during pregnancy might contribute to adverse birth outcomes, especially LBW. This body of evidence has limitations that impede the formulation of firm conclusions. Further studies, well-focused on European countries, are called to resolve the limitations which could affect the strength of association such as the exposure assessment, the critical windows of exposure during pregnancy, and the definition of adverse birth outcomes.

KEYWORDS: systematic review; meta-analysis; birth weight; low birth weight; preterm birth; exposure; air pollution; PM; NO2

P-0530 A study protocol to explore the social effects of environmental exposure and lifestyle behaviours on adverse pregnancy outcome: an overview of pregnant women cohort study

Valentin Simoncic[1], Mme Virginie Hamann[1,2], Mme Loriane Huber[2], Phillipe Deruelle[2], Nicolas Sananes[2], Christophe Enaux[1],Maxime Alter[3], Charles Schillinger[3], Severine Deguen[4], Wahida Kihal[1]

[1]Laboratoire Image Ville Environnement, Strasbourg, France, [2]Department of Obstetrics and Gynaecology, Strasbourg University Hospital, STRASBOURG, France, [3]ATMO Grand Est, STRASBOURG, France, [4]Université de Bordeaux, Bordeaux, France

A growing number of international studies have highlighted the adverse consequences of lived experience in the first 1000 days of early life on the probability of stillbirth, child mortality and healthy development during both childhood and adulthood. The lived experience of the foetus inside the womb and at the birth is strongly related to maternal health during pregnancy and mother's exposure to various environmental factors known as 'exposome'. The aim of our project is to explore the relationships between exposome characteristics and the health status of pregnant women and their newborns. Specifically, we study the relationships between the social inequality of adverse pregnancy outcomes and short-term exposure to atmospheric pollution, and pregnancy lifestyle.

METHODS: and analysis This is a cohort study of pregnant women, involving on university hospital across two sites in the Eurometropolis of Strasbourg. The researchers collect data on outcomes and individual characteristics from registries, clinical records data and questionnaires. Participants are being recruited from first trimester antenatal ultrasound examinations conducted on weekdays at both sites; each woman meeting our inclusion criteria enters the cohort at the end of the first trimester. Study participants receive three online questionnaires covering socio-demographic characteristics, travel behaviour patterns, and lifestyle. The level of personal exposure to air pollution is characterized using a dynamic spatio-temporal trajectory model that describes the main daily movements of pregnant women and the time spent in each place frequented. Univariate, multilevel and baysian model will be used to investigate the relationships between exposome characteristics and the health status of pregnant women and their new-borns.
Ethics and dissemination Research approved by the Commission de Protection des Personnes Ile de France VI on 9 December 2020 and the Agence Nationale de Sécurité du Médicament was informed of it on 15 December 2020.

KEYWORDS: urban exposome, pregnancy, new-born, socio-environmental approach

P-0531 Effect of toenail metal concentrations on thyroid function in Bangladeshi children

Maria Argos[1], Muhammad Kibriya[2], Farzana Jasmine[2], Brian Jackson[3], Mohammad Hasan Shahriar[2,4], Golam Sarwar[4], Habibul Ahsan[2]

[1]University of Illinois at Chicago, Chicago, USA, [2]University of Chicago, Chicago, USA, [3]Dartmouth College, Hanover, USA, [4]UChicago Research Bangladesh, Dhaka, Bangladesh

BACKGROUND AND AIM: The ubiquitous presence of toxic metal exposures in the environment is a global public health concern. Arsenic, cadmium, and mercury are commonly occurring toxic environmental metal exposures in the general population. These metal exposures appear among the top 20 of the Agency for Toxic Substances and Disease Registry Substance Priority List, prioritizing substances based on their frequency, toxicity, and potential for human exposure. The existing experimental literature supports the hypothesis that the disruption of hormone signaling by metals at key developmental time points might underlie health outcomes observed in childhood, adolescence, and adult life. While limited data exist in humans, experimental studies have observed correlations of metals with endocrine function. This study evaluates the associations between toenail metal concentrations and free thyroxine (T4) among 500 Bangladeshi children aged 5-7 years enrolled in the Bangladesh Environmental Research in Children's Health (BiRCH) cohort.

METHODS: We investigated the associations of toenail metal concentrations of arsenic, cadmium, and mercury with free T4 using linear regression models (single-metal and mutually-adjusted models), adjusted for a priori covariates. Additionally, Bayesian kernel machine regression (BKMR) was conducted as a secondary analysis to test the robustness of findings and potential exposure patterns.

RESULTS: Arsenic was positively associated with free T4 (Q4 versus Q1 b=0.10, 95% CI=0.03-0.17), and mercury was inversely associated with free T4 (Q4 versus Q1 b= -0.07, 95% CI=-0.14-0.002). No association was observed with cadmium. Secondary analyses examining metal mixtures yielded similar results.

CONCLUSIONS: Findings from linear regression modeling and secondary analyses using BKMR suggest thyroid function may serve as an important mechanism for arsenic and mercury toxicity. Future research is needed to evaluate the inter-related roles of metal exposures and thyroid function across the life course.

KEYWORDS: metals, thyroid, children's environmental health

P-0532 A 40-year follow-up study of liver cancer risk in Taiwan:An age-period-cohort analysis and joinpoint regression analysis

Hsiao-yu Yang[1], Shien-Chieh Chen[1], Wan-Chin Chen[1], Ya-Ting Chung[1]
[1]*National Taiwan University, Taipei, Taiwan*

OBJECTIVES:
Malignant neoplasm of liver and intrahepatic bile ducts is a leading cause of cancer-related mortality in Taiwan. The objective of this study was to investigate the effects of age, period, and birth cohort on liver and intrahepatic bile ducts cancer incidence in Taiwan.

METHODS: We tracked the incidence rate of malignant neoplasm of liver and intrahepatic bile ducts (ICD-10 code C22) from 1980 to 2019, with data from the Taiwan Cancer Registry. We then calculated age-standardized incidence rates (ASIRs) for liver and intrahepatic bile ducts cancer based on the world standard population in 2000. Joinpoint regression was used to evaluate the trend change, and age-period-cohort models were used to investigate the effects of age, period, and birth cohort on liver and intrahepatic bile ducts cancer incidence.

RESULTS: From 1980 to 2019, there were 278,363 newly reported cases of liver and intrahepatic bile ducts cancer, for a crude incidence rate of 32.17 cases per 100,000 person-years. The ASIR exhibited a significant increase from 1980 to 2000 (APC = 7.4%, 95% CI: 6.9–7.8%, P = <0.001), maintained at the plateau from 2000 to 2009, and then declined. The risk of liver and intrahepatic bile ducts cancer in the population peaked in 2005-2010. The population born between 1965 and 1975 had the highest risk of developing liver and intrahepatic bile ducts cancer compared to the other cohort. The cancer risk dropped after hepatitis B vaccination program since 1980s.

CONCLUSIONS: Hepatitis B vaccination program may decrease the risk of liver and intrahepatic bile ducts cancer in Taiwan. Appropriate vaccination program is advised for countries with similar exposures.

P-0535 Blood mercury levels of Brazilian preschool children and associated risk factors

Kelly Polido Kaneshiro Olympio[1], Fernanda Junqueira Salles[1], Elizeu Chiodi Pereira[1], João Paulo Goés Pereira[2], Marcelo de Oliveira Lima[2], Thais Karolina Lisboa Queiroz[2], Agnes Soares da Silva[3], Maria Regina Alves Cardoso[4]
[1]Environmental Health Department, School of Public Health - University of São Paulo, São Paulo, Brazil, [2]Evandro Chagas Institute, Belém, Brazil, [3]Communicable Diseases and Environmental Determinants of Health (CDE), Pan American Health Organization (PAHO/WHO), USA, [4]Epidemiology Department, School of Public Health - University of São Paulo, São Paulo, Brazil

BACKGROUND AND AIM: Environmental exposure to mercury in preschool children can increase their blood total mercury levels (BML) and impact their health. This study aimed to determine BML in preschool children from the most populous city of Brazil and investigate associated risk factors.

METHODS: Blood samples were collected from 2,436 children (1-5-year-old) attending 50 daycare centers (DCC) located in São Paulo, Brazil, in 2013. Parents or guardians answered questionnaires about sociodemographic information and potential risk factors. BML was determined by Cold Vapor Atomic Absorption Spectrophotometry (CV-AAS). BLM was dichotomized at a cut-off point of 2.77 μg L^{-1}, which represents the 75th percentile. Summary data and multiple logistic regression were performed ($p<0.05$).

RESULTS: The geometric mean for BML was 1.65 μg L^{-1} (95%CI: 1.60-1.70), the arithmetic mean was 2.15 μg L^{-1} (95%CI: 2.09-2.22), the 75th percentile was 2.77 μg L^{-1} (95%CI: 2.67-2.91) and the 95th percentile was 5.51 μg L^{-1} (95%CI: 5.18-5.92). The regression model was adjusted for vehicle flow in the DCC location (high/low), DCC geographic zone (northwest/south/east), fish intake in the last two days (yes/no), recent home renovation (yes/no), and parents living together (yes/no). DCCs located in the Northwest and East zone ($p<0.001$) and fish consumption in the last two days ($p=0.04$) were associated with high BML.

CONCLUSIONS: The Brazilian geometric mean for BLM in preschoolers was higher than the U.S. 95th percentile, which is five times lower than the 95th percentile determined in this study. The mercury exposure in preschool children was related to multiple risk factors, highlighting the need to identify and control hot spots in Sao Paulo, Brazil, where children can be exposed to elevated mercury levels. Formulation of public health policies to understand and eliminate mercury sources is crucial. Funded: Fapesp (2011/13076-0, 2011/23272-0, 2012/21840-4, 2018/18391-0, 2017/25424-9) and Capes.

KEYWORDS: Children; Mercury; Blood; Exposure

P-0539 Changes of heavy metals in Korean pregnant women and cord blood from 2006 to 2018 in MOCEH and KoCHENS

Kyoung Sook Jeong[1,2], Yangho Kim[3]
[1]Yonsei University, Wonju College of Medicine, Wonju, Republic of Korea, [2]Wonju Environmental Health Center, Wonju Severance Christian Hospital, Wonju, Republic of Korea, [3]Ulsan University Hospital, Ulsan, Republic of Korea

BACKGROUND AND AIM: Environmental pollutions affect the concentrations of heavy metals. Heavy metals affect the neurocognitive development of infants and children. Korean government and Koreans have tried to improve environmental pollutions. We investigated how much the concentration of heavy metals in maternal and umbilical cord blood changed over 10 years due to environmental pollution improvement.
METHODS: MOCEH (MOthers and Children Environmental Health) and KoCHENS (Korean Children Health and ENvironmental Study) are population-based birth cohort studies which was recruited in 2006 -2010 and 2015-2018, respectively. 1,696 and 4,299 mothers included in this study among 1,751 and 5,459 participants in MOCEH and KoCHENS. Lead (Pb), cadmium (Cd) and mercury (Hg) were measured in early and late pregnancy, and cord blood at birth. Food intakes, residential environments, and general characteristics were measured by questionnaire. All protocols were approved by the research ethics committee. SPSS 25.0 was used for statistical analyses.
RESULTS: Pb, Cd, and Hg concentrations were 52.3-55.5%, 33.8-45.1%, and 56.5-64.5% in KoCHENS compared to MOCEH. Pb decreased towards the end of pregnancy, Cd was highest in late pregnancy and lowest in cord blood, and Hg was highest in cord blood. The correlation coefficient was greater in KoCHENS than in MOCEH during pregnancy and delivery. Cd was not correlated with maternal and umbilical cord blood concentrations. Despite the approximately 37% decrease in Hg over 10 years, the ratio of Hg concentrations between cord blood and late gestation was greater in KoCHENS, with 1.65 and 1.83 in MOCEH and KoCHENS, respectively.

CONCLUSIONS: As the environment improved, maternal heavy metal concentrations decreased. However, the mother's heavy metals are still transmitted to the fetus, and the intensity is stronger, so continuous efforts are needed to reduce the level of heavy metal exposure.

P-0544 Tetrachloroethylene exposure and neurobehavioral performance among children living in a small community with multiple contamination sites

Sa Liu[1], Jung Hyun Lee[1], Marwan Alajlouni[1], Alaina Bryant[1], Brandon Tso[1], Thomas Wallace[2], Steven Koch[3], Mary Turyk[4], Brandon Boor[1], Antonios Tasoglou[5]

[1]Purdue University, West Lafayette, USA, [2]Martinsville Indiana Superfund Site Association, Martinsville, USA, [3]Indiana University, Indianapolis, USA, [4]University of Illinois at Chicago, Chicago, USA, [5]RJ Lee Group Inc., Monroeville, USA

BACKGROUND: Tetrachloroethylene (PCE) is a neurotoxicant based on evidence from high levels of occupational exposure among workers. Community PCE exposures potentially impact many people (often disadvantaged) living near contaminated sites, but have not been well studied.
AIM: To evaluate the association between PCE exposure and neurobehavioral performance among children living in a community that overlays multiple contamination sites with PCE being the primary contaminant.

METHODS: Participants are 6 - 11 years old children recruited in 2021–2022. PCE is measured in participants' exhaled breath. Past exposure is estimated based on residential history. Neurobehavioral performance is assessed using the Wide Range Achievement Test Fifth Edition (WRAT-5), the Behavior Assessment System for Children Third Edition (BASC-3), and NIH Toolbox cognitive measures. Children are classified as exposed or unexposed based on PCE concentration in their exhaled breath in this initial analysis. Multiple linear regression is used to examine the association of PCE exposure and outcome measures after adjusting for covariates.

RESULTS: Eighty-three participants have been recruited, with 64 and 39 having finished the outcome assessment and the first round of exhaled breath testing, respectively. The second round of breath testing will be conducted in May 2022. Twenty-seven percent of tested participants had detectable PCE concentrations in the exhaled breath (mean = 0.27 ppb, SD = 0.12 ppb). Exposed children have lower scores on crystalized composite and spelling compared to unexposed children. Several covariates have significant associations with outcome measure subtests and need to be adjusted in the full data analysis.

CONCLUSIONS: Our initial analysis suggests that PCE exposure might be associated with subtle changes to verbal reasoning and spelling. These observations need to be further examined in the full data analysis.

KEYWORDS: Tetrachloroethylene, Neurobehavioral performance, Children's health, Community exposure

P-0545 Gestational and Early Life Risk Factors for Childhood Food Allergies

Despina Karalis[1], Kari Nadeau[2], Yuka Moroishi[1,3], Juliette Madden[1,3,4], Margaret Karagas[1,3]
[1]Department of Epidemiology, The Geisel School of Medicine at Dartmouth, Lebanon, USA, [2]Sean N. Parker Center for Allergy and Asthma Research, Stanford University, Stanford, USA, [3]Department of Quantitative Biomedical Data Scienes, Geisel School of Medicine at Dartmouth, Lebanon, USA, [4]Department of Pediatrics & Psychiatry, Dartmouth Hitchcock Medical Center, Geisel School of Medicine at Dartmouth, Lebanon, USA

AIM(S):
The prevalence of food allergy among children has risen steadily over the past two decades, with 4 to 6% of children having at least one type of food allergy.[1,2] We investigated whether the occurrence of food allergies in childhood were related to factors known to influence the early microbiome and implicated in immune training (e.g., delivery mode, antibiotic use, proximity to a farm). We also assessed maternal consumption of foods during pregnancy for which children become allergic and maternal history of food allergies.

METHODS: Participants, enrolled in the New Hampshire Birth Cohort Study, included 2,011 women with a singleton pregnancy and their offspring. We used Cox Proportional Hazards models to estimate the risk of a medical diagnosis of food allergies during the first five years of life in relation to maternal-infant characteristics, adjusted for potentially confounding factors.

RESULTS: A greater risk of food allergies was associated with cesarean delivery (HR = 1.99; 95% CI: 1.06, 3.74) and prenatal antibiotic use (HR = 2.29; 95% CI: 1.15, 4.56). Daycare attendance (HR: 0.27; 95% CI: 0.15, 0.47) was inversely associated with risk. Children of mothers with a history of food allergies, consuming tree nuts or eggs during pregnancy and those living near a farm had a higher risk and those whose mothers ate peanuts prenatally had a lower risk, but these associations could have been due to chance.
CONCLUSION(S):
Prenatal factors related to the early acquisition of the microbiome, such as method of delivery, prenatal antibiotics, and day care correlated to risk of a food allergy diagnosis among children in the first 5 years of life. Developing a clearer understanding of allergy development and its risk factors is crucial to reducing the burden of food allergies.

P-0547 Characterization of the External Exposome and its Contribution to the Clinical Respiratory and Early Biological Effects in Children: PROMESA cohort in Colombia

Diana Marcela Marin Pineda[1], Diana Narvaez[3], Francisco Molina[2], Luz Yaneth Orozco[2], Lucelly Lopez[1], Olga Morales[2], Martha Cuellar[2], Diego Muñoz[1], John R Agudelo[2], MIlena Villamil[4], Isabel Ortiz[1], Maria V Toro[1], Helena Groot[3], Roberto Hincapie[1], Juan J Builes[5], Ricardo Morales[3], Luis J Hernandez[3], Veronica Lopera[7], Andrea Corredor[6], Carlos D Ramos[2], Ferney Amaya[1], Beatriz Marin[1], Enrique Henao[7], Daniela Uribe[2], Jose M Abad[8], Zulma Rueda[1]

[1]Universidad Pontificia Bolivariana, Medellin, Colombia, [2]Universidad de Antioquia, Medellin, Colombia, [3]Universidad de los Andes, Bogota, Colombia, [4]Fundación Hospital Pediátrico la Misericordia, Bogota, Colombia, [5]GENES Laboratory, Medellin, Colombia, [6]ONIROS centro especializado en medicina integral del sueño, Bogota, Colombia, [7]Secretaría de Salud, Medellin, Colombia, [8]SURA, Medellin, Colombia

BACKGROUND AND AIM: Air pollution contains a mixture of different pollutants from multiple sources. However, the interaction of these pollutants with other environmental exposures, as well as their harmful effects on children under five in tropical countries, is not well known. This study aims to characterize the external exposome (ambient and indoor exposures) and its contribution to clinical respiratory and early biological effects in children.

METHODS: A cohort study is conducted on children under five in two cities in Colombia. Enrolled children are followed monthly (phone call) post-enrollment with upper and lower Acute Respiratory Infections (ARI) examinations and will be followed at months 6 and 12 (in person) to evaluate asthma development, asthma control, and genotoxic damage. The asthma diagnosis is pediatric pulmonologist-based and a standardized protocol is used. Exposure, effect, and susceptibility biomarkers are measured on buccal cells and blood samples. for environmental exposures, PM2.5 was sampled in two moments of the year to chemical characterization. Additionally, the standardized questionnaire developed for HELIX is used and geographic information, dispersion models, and Land Use Regression models for PM2.5 and NO2 will be used.

RESULTS: these are preliminary data. of 135 children 47.4% are female and 49.6% are 4 years old. Exposure to pets 45.9%, cockroaches 41.5%, mold 47.6%, parental tobacco smoke in pregnancy and early childhood 14.3%, parental electronic cigarettes 4.44%, noise 20.7%, and never eaten vegetables or fruits 9.6% have been found. Prevalence of asthma is 29.4% with TRACK<80 in 83.3% of children with previous asthma. Comet assay damage indicator median 55 (IQR: 29 – 90.5).

CONCLUSIONS: This is the first exposome study on the region. There is a high prevalence of asthma with high exposure to unfavorable environmental conditions.

THEMATIC 08: COVID-19 and the Environment

P-0637 Attitudes toward COIVID-19 vaccination: cross sectional study in Iraq

Ahmed Al-Delaimy[1]
[1]*University of Anbar, Medical College, Baghdad, Iraq*

BACKGROUND:
In March 2020, the WHO announced that COVID-19 has become pandemic. In Iraq since the start of applying the national covid-19 vaccines campaign, a lot of people refused to take the COVID-19 vaccine.

METHODS: A cross-sectional study was done and a total of 814 participants were involved in the survey. A convenient sample approach was introduced in this study from 11 different areas (Central, Southern, and Northern) at Anbar governorate including urban and rural regions. A questionnaire form was distributed to people involved in the study and a self-administered answer was applied by the principal researcher. Analysis of data was carried out using simple descriptive statistics. This included calculation of percentages, risk factors, reasons, tables, and charts all done.

RESULTS: A total of 814 participation included in this study. Male was 52.5% while female 47.5%.71.7% population understudy didn't take any type of Covid-19 vaccine. and among those who took the covid-19 vaccine, of them, 58.4 % took only one dose of vaccination. a high percentage of 72.1% was among people understudy who didn't take any type of vaccine because they don't trust it. 14.3% of them didn't take it because their friends and relatives didn't take it. While 8.6% were afraid of its side effects. Almost 10% of people prefer to be infected with covid-19 rather than take the vaccination. Gender, age, marital status, occupation, and educational level all variables were significant differences with having or refusing the covid-19 vaccine.
CONCLUSION:
In Iraq, people are still refusing to uptake the COVID-19 vaccine. A lot of rumors through social media are influencing public opinion and trust about the COVID-19 vaccine. More efforts should be done by the primary health centers, health workers, and doctors to educate public about the COVID-19 vaccine

KEYWORDS: Attitude, COVID-19 vaccine, Iraq

P-0640 Differences in Silicone Wristband Exposure Profiles by COVID School Restrictions in Washington State Children

Drew Day[1], Nicholas Herkert[2], Heather Stapleton[2], Navya Gunaje[1], Sarah Wang[1], Sheela Sathyanarayana[1,3]
[1]Center for Child Health, Behavior, and Development, Seattle Children's Research Institute, Seattle, USA, [2]Nicholas School of the Environment, Duke University, Durham, USA, [3]Department of Pediatrics, University of Washington, Seattle, USA

BACKGROUND AND AIM: The school closure restrictions following the COVID-19 pandemic likely increased the time spent at home for school-age children and therefore may have impacted overall environmental burden. Silicone wristbands have been used as personal passive samplers measuring exposure to semi-volatile organic compound (SVOC) contaminants. We hypothesized that SVOC exposure levels would differ by pandemic restriction status.

METHODS: We assessed SVOCs in a pilot study of 55 children (24 boys and 31 girls) at ages 5-9 years within the GAPPS PATHWAYS Study at two study sites: Seattle (n=38) and Yakima (n=17), Washington from 2020-2021. Pre-cleaned silicone wristbands were worn for 5 days. Wristbands were analyzed for 109 SVOC compounds using GC-MS. Washington school closures were used to identify 7 wristbands worn outside of pandemic restriction periods. Regressions associated analytes with pandemic restrictions, controlling for age, sex, and site. Coefficient p-values underwent false discovery rate (FDR) adjustment. Exposure profiles were summarized using self-organizing maps (SOMs).

RESULTS: 40 compounds with >60% detection were included in our analysis. School closure restrictions were associated with 92% (FDR q=0.006), 91% (q=0.04), 88% (q=0.008), 88% (q=0.04), and 85% (q=0.04) lower concentrations of the organophosphate esters (OPEs) 2-isopropylphenyl diphenyl phosphate (2IPPDPP), triphenylphosphate, 4-isopropylphenyl diphenyl phosphate (4IPPDPP), triisobutylphosphate, and bis(2-isopropylphenyl) phenylphosphate (B2IPPPP), respectively. Other analytes; including pesticides, brominated diphenyl ethers, phthalates, and polycyclic aromatic hydrocarbons; were not associated with COVID-19 restrictions. SOMs revealed 12 profiles organized primarily by triaryl OPE levels, and wristbands collected outside of pandemic restrictions predominantly sorted into profiles with higher triaryl OPEs.

CONCLUSIONS: OPE exposures in children were lower during COVID-19-related school closures, suggesting that these exposures may be higher outside the home and within schools. Given that OPEs have shown endocrine-disrupting and obesogenic properties, understanding behavioral predictors of exposure can better protect of children's health.

P-0641 Association of short-term air pollution exposure with SARS-CoV-2 infection among young adults in Sweden

Zhebin Yu[1], Tom Bellander[1,2], Anna Bergström[1,2], Joakim Dillner[3], Kristina Eneroth[4], Magnuz Engardt[4], Antonios Georgelis[1,2], Inger Kull[5,6], Petter Ljungman[1,7], Göran Pershagen[1,2], Massimo Stafoggia[8], Erik Melén[5,6], Olena Gruzieva[1,2]

[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Centre for Occupational and Environmental Medicine, Stockholm, Sweden, [3]Medical Diagnostics Karolinska, Karolinska University Hospital, Stockholm, Sweden, [4]SLB-analys, Environment and Health Administration, Stockholm, Sweden, [5]Department of Clinical Sciences and Education, Karolinska Institutet, Södersjukhuset, Stockholm, Sweden, [6]Sachs Children's Hospital, Stockholm, Sweden, [7]Department of Cardiology, Danderyd Hospital, Stockholm, Sweden, [8]Department of Epidemiology, Lazio Regional Health Service, Rome, Italy

BACKGROUND AND AIM: Many ecological studies reported associations of short-term air pollution exposure with Corona-virus disease (COVID-19), however, no study examined this association on individual-level. We aimed to estimate the association between short-term exposure to ambient air pollution and severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection among Swedish young adults.

METHODS: We conducted a time-stratified case-crossover study within the Swedish prospective birth cohort BAMSE (Swedish abbreviation for Children, Allergy Milieu, Stockholm, Epidemiology). We linked the cohort to Swedish national infectious disease registry to identify SARS-CoV-2 PCR-test positive cases between May 5, 2020 and March 31, 2021. Daily air pollutant levels (particulate matter ≤2.5 µm [PM2.5], particulate matter ≤10 µm [PM10], black carbon [BC] and nitrogen oxides [NOx]) were estimated at residential addresses using dispersion models with high spatiotemporal resolution. Distributed-lag models combined with conditional logistic regression models were used to estimate the association.

RESULTS: A total of 425 cases were identified, of whom 229 (53.9%) were female and median age was 25.6 years. The median exposure level for PM2.5, PM10, BC and NOx was 4.4, 7.7, 0.3, 8.2 µg/m3 on case days and 3.8, 6.6, 0.2, 7.7 µg/m3 on control days, respectively. Each interquartile range (IQR) increase in short-term exposure to PM2.5 and PM10 on lag 2, BC on lag 1 was statistically significantly associated with a relative increase of 6.8% (95%CI: 2.1- 11.8), 6.9% (95%CI: 2.0 -12.1), and 5.8 % (95%CI: 0.3 – 11.6) of positive SARS-CoV-2 PCR test, respectively. There was no evidence of findings to be associated with NOx or modified by sex, smoking, asthma, overweight and self-reported COVID-19 respiratory symptoms.

CONCLUSIONS: Short-term exposure to PM and BC was associated with increased risk of testing PCR-positive for SARS-CoV-2 in young adults, supporting the broad public health benefits of reducing ambient air pollution levels.

P-0642 To what extend does exposure to air pollutants is linked with death in lung cancer patients with COVID-19 diagnosis? Primary observations by the Cancer Registry of Crete

Dimitra Sifaki-Pistolla[1], Dimitrios Mavroudis[2], Christos Lionis[1]
[1]*Clinic of Social and Family Medicine, Department of Social Medicine, School of Medicine, University of Crete, Heraklion, Greece,* [2]*Department of Medical Oncology, University General Hospital of Heraklion, Heraklion, Greece*

BACKGROUND: Emerging evidence, during the COVID-19 pandemic, supports a link between air pollution and other environmental factors and severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) transmission and COVID-19 susceptibility and severity. These effects seem to be even more intense in patients with chronic conditions, such as cancer.
Aim: To assess the differences in COVID-19 deaths, hospitalizations and survival in cancer patients with high or low exposure to air pollutants.

METHODS: We included 584 lung cancer patients with verified histological diagnosis from 2020 to March 2022 (107 of them had positive antigen or PCR test). The cases were obtained from the Cancer Registry of Crete and linked with data of outdoor air pollutants (OAP). The OAP indicators included measurements on particulate matter (PM)2.5, between 2.5 and 10 μm (PM2.5-10), PM10, PM2.5 absorbance (black carbon measure), nitrogen dioxide (NO2), and nitrogen oxides (NOx). The case fatality rate (CFR) of COVID-19 deaths in lung cancer patients per AOP exposure group was calculated and the Net-Survival was estimated (Kaplan-Meier Curves).

RESULTS: The prevalence of COVID-19 in lung cancer patients was 18.3% in the Cretan cohort. In these 107 case-series, the 71.9% required long hospitalization with median stay of 15 days. The vast majority of them (80.5%) were highly exposed to AOP, whereas only the 19.4% has low levels of AOP exposure ($p=0.03$). All patients were of stage I or II and presented an overall CFR of 74.6% during the 6-month follow-up period, with the majority being highly exposed to AOP ($p<0.001$). The 6-month Net-Survival for patients with high AOP exposure was 11.2% versus 33.5% in those with low AOP exposure.

CONCLUSIONS: The role of AOP seems to be integral in lung cancer patients survival during the COVID-19 pandemic, but further studies using genome-wide cohorts are required to establish a causal association.

P-0647 Atmospheric particulate matter effects on Sars-Cov-2 infection and its dynamics spreading: a spatio-temporal point process model

Jacopo Dolcini[1], Katiuscia Di Biagio[2], Marco Baldini[2], Pietro Serafini[3], Donatella Sarti[1], Andrea Ranzi[4], Gaetano Settimo[5], Remo Appignanesi[3], Irene Dorillo[6], Silvia Bartolacci[2], Thomas Valerio Simeoni[2], Emilia Prospero[1]
[1]Department of Biomedical Sciences and Public Health, Section of Hygiene – Polytechnic University, Ancona, Italy, [2]Environmental Epidemiology Unit - Regional Environmental Protection Agency of Marche, Ancona, Italy, [3]Medical Direction Department, Local Health Authority of Marche Region, Ancona, Italy, [4]Centre for Environmental Health and Prevention, Regional Agency for Prevention, Environment and Energy of Emilia-Romagna, Modena, Italy, [5]National Institute of Health, Rome, Italy, [6]Air Quality Unit, Regional Environmental Protection Agency of Marche, Ancona, Italy

BACKGROUND AND AIM: Particulate matter (PM) may play a role in differential distribution and transmission rates of SARS-CoV-2. Identification of factors affecting the transmission dynamics concerning the endemic (persistent sporadic) and epidemic (rapidly clustered) component of infection can helps to implement intervention strategies to reduce the disease burden. Aim of this study is to assess the effect of long-term residential exposure to PM on Sars-Cov-2 incidence and on the dynamics of infectious disease spreading in Marche Region (Central Italy).

METHODS: All individuals with first positive SARS-CoV-2 molecular test from February to May 2020, residing in the Marche region were analysed along with gender, age, employment, Nursing Homes and Long-Term Care Facilities (NH-LTCF) residence and socio-economic deprivation index (DI); long-term exposure to outdoor PM ≤ 10 µm (PM10) concentrations, Temperature and Relative Humidity were estimated at 10 km2 grid cells. The endemic-epidemic spatio-temporal regression model for individual-level data was used to identify factors influencing SARS-CoV-2 spreading and its infectious rate. Rate ratios (RR) and 95% confidence intervals (CI) were calculated.

RESULTS: 10-years average exposure to PM10 was associated with an increased risk of new endemic (RR 1.14, 95%CI 1.04-1.24) and epidemic (RR 1.15, 95%CI 1.08-1.22) infectious. Male gender, older age, living in NH-LTCF and the worsening of DI increased RR in epidemic component. Lockdown increase the risk of becoming positive to Sars-Cov2 as concerning endemic while it reduces virus spreading in epidemic component. Increased temperature was associated with a reduction of endemic and epidemic infectious.

CONCLUSIONS: Results show an increment of RR for exposure to increased levels of PM10 both in endemic and epidemic components. Targeted interventions are necessary to improve air quality in most polluted areas to minimize the burden of endemic and epidemic COVID-19 disease and to reduce unequal distribution of health risk.

KEYWORDS: air polltuion, Sars-Cov2, infectious disease

P-0654 Changes in household use of disinfectant and cleaning products during the first lockdown period in France

Emilie Pacheco Da Silva[1], Raphaëlle Varraso[1], Laurent Orsi[1], Emmanuel Wiernik[2], Marcel Goldberg[2], Céline Ribet[2], Rachel Nadif[1], Fabrice Carrat[3,4], Marie Zins[2], Orianne Dumas[1], Nicole Le Moual[1]

[1]Université Paris-Saclay, UVSQ, Univ. Paris-Sud, Inserm, Équipe d'Épidémiologie Respiratoire Intégrative, CESP, Villejuif, France, [2]Université de Paris, Unité "Cohortes en Population" INSERM, Université Paris Saclay, UVSQ, UMS 011, Paris, France, [3]Sorbonne Université, Inserm, Institut Pierre-Louis d'Epidémiologie et de Santé Publique, France, [4]Département de Santé Publique, APHP.Sorbonne Université, France

BACKGROUND: Since the beginning of the COVID-19 pandemic, health measures have been introduced to limit the risks of contamination, including recommendations for cleaning and disinfection of surfaces at home. The use of Household Disinfectant and Cleaning Products (HDCP) has only been evaluated during this pandemic from national poison centers or cross-sectional surveys, but has never been compared before and after its beginning based on longitudinal data from a large population-based cohort.
AIM: To study changes in the use of HDCP during the first lockdown period based on longitudinal data from the large French population-based Constances cohort.

METHODS: Analyses were carried on 49,491 participants (mean age: 47 years, 51% women, 13% current smoker) who completed standardized questionnaires on household cleaning tasks in 2019 and during the first lockdown period in France (17th March to 3rd May 2020). We compared the household help (yes/no) and the duration of weekly use of HDCP (<10 minutes/week; 10-30 minutes/week; >30 minutes/week) at these two surveys by a McNemar's and a Bhapkar test, respectively. Moreover, we assessed self-reported changes in the frequency of HDCP use specifically since the beginning of the lockdown period (unchanged/increased).

RESULTS: Compared to 2019, the household help decreased (56% versus 3%; p<0.0001) and the duration of HDCP use increased (>30 minutes:16% vs. 63%; p<0.0001) during the lockdown period, especially for women compared to men (>30 minutes:71% vs. 54%, respectively; p<0.0001). Regarding the frequency of HDCP use, 83% of participants (86% of women vs. 81% of men; p<0.0001) reported an increased use since the beginning of the lockdown period.

CONCLUSIONS: The frequency and the duration of HDCP use have significantly increased. Further studies are now needed to evaluate the potential impact of these changes in respiratory health.

KEYWORDS: Lockdown period, COVID-19, Household disinfectant and cleaning products

P-0657 A View at the COVID-19 Pandemic under the Light of Socio-economic Inequalities in Rio de Janeiro City, Brazil

Maria de Fatima Ebole Santana[1], Anna Beatriz Aguiar Araújo[1], Marcio Candeias Marques[1], Marcio Sacramento de Oliveira[1]
[1]*Oswaldo Cruz Foundation - FIOCRUZ, Rio de Janeiro, Brazil*

BACKGROUND AND AIM: Brazil was one of the countries most affected by COVID-19. The pandemic raises concerns about inequality in Rio de Janeiro city becoming clear that it will interact with dimensions such: age, gender, ethnicity and geography. This study aimed to analyze the association between socioeconomic inequalities with the greatest influence on hospitalization in Rio de Janeiro city/Br.

METHODS: The data were obtained from the SIVEP-Gripe database of the Health State Department, from January 2020 to January 2021. The descriptive analysis was conducted and stratified by socioeconomic variables and health conditions and to estimate the model a logistic regression was used in software R. The death cases due to other morbidities and hospital discharge were censored. for socioeconomic analysis, the Social Development Index of the neighborhoods was considered.

RESULTS: The number of notifications of severe positive cases was 42,781 (74.09%), which 53.81% were men and 46.18% were women. The median was 66 years and the highest number of notifications was above 80 years. Regarding race, 29.78% were white, 0.45% yellow, 0.05% indigenous, 34.77% black, 30.39% ignored. Concerning schooling, 1.03% had no schooling, 11.26% had Elementary and Middle School, 9.88% had High School, 5.68% had College, 47.03% had ignored and 3.04% had not applied. Respecting hospitalizations, there were 92.47% of the total number of severe cases. The spread of the disease occurred from more to less developed regions at the beginning and inverting this profile (2nd wave).

CONCLUSIONS: The results showed that gender is a factor that involves notifications. It was possible to observe an increase in hospitalizations and more serious outcomes along with increasing age and that men were more affected. It pointed out the disparities between ethnicities. In addition, one can understand a historical-social contexts that explain such socioeconomic profile and socio-spatial cases inequality.

KEYWORDS: Covid-19; Hospitalization; Inequalities.

P-0658 Greenness and adolescents ‘mental health after Covid-19 pandemic lockdown: longitudinal perspective

Nerea Lertxundi[1,2,3], Ainara Andiarena[1,2], Amaia Molinuevo[2], Asier Anabitarte[2], Mikel Subiza[1,2,3], Aitana Lertxundi[1,2,3]

[1]University of the Basque Country (UPV/EHU), Donostia-San Sebastian, Spain, [2]Health Research Institute BIODONOSTIA, Donostia-San Sebastian, Spain, [3]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Madrid, Spain

BACKGROUND AND AIM: Scientific evidences suggest that green space exposure can provide mental health benefits. The aims of this study are 1) to compare pre and post pandemic adolescents ‘mental health after Covid-19 pandemic lockdown 2) to compare mental health as a function of distance to a green environment greater than 5,000m2.

METHODS: The study participants were mother-adolescent pairs from the INMA Project (Environment and Childhood) from Gipuzkoa cohort (N=135). Adolescents ‘mental health (SDQ) and Quality of life (Kidscreen-27) were measured at 11 years follow up (pre pandemic) and (post pandemic). The distance to major green space (>5,000m2) was divided into 2 categories; >=100m or less than 100m).The statistical analysis consisted of making a descriptive analysis of the scales at "pre" and "post" pandemic lockdown, as well as the difference in these scores. Mixed effects models were fit to assess whether there were statistically significant differences in the "pre" and "post" scales and to observe the possible association with the other variables.

RESULTS: Differences have been observed between pre and post pandemic lockdown measures of total SDQ (mean dif CI95% 1.61 (1, 2.23)) and Kidscreen-27 (mean dif CI95% (-2.86 (-4.84, -0.89)). Total problem difficulties (SDQ) increased when stress perception was higher and they reduced at higher physical activity. Psychological wellbeing was inversely correlated with stress perception and with time spent resting; and adolescents 'psychological wellbeing was better when their mothers worked. These negative association is stronger when the exposition to greenness is >100metres.

CONCLUSIONS: Worsening mental health and quality of life of adolescents has been observed after pandemic lockdown. Protective mental health factors during confinement were physical activity and having a green environment of more than 5,000m2 near the home (<100metres).

KEYWORDS: Covid-19, Mental health, Greenness, adolescence

P-0659 Effects of long-term air pollution exposure on Covid-19 vaccine antibody response and “long-COVID” in a general population cohort (Covicat Study, Catalonia)

Manolis Kogevinas[1], Marianna Karachaliou[1], Ana Espinosa[1,2], Gemma Moncunill[1], Gemma Castaño-Vinyals[1,2], Betty Cortes[3], Rocio Rubio[1], Marta Vidal[1], Alfons Jimenez[1], Payam Dadvand[1], Mark Nieuwenhuijsen[1], Vanessa Pleguezuelos[4], Kurt Straif[1], Judith Garcia-Aymerich[1], Rafael de Cid[3], Carlota Dobaño[1], Cathryn Tonne[1]

[1]Isglobal- Barcelona Institute for Global Health, Barcelona, Spain, [2]CIBER Epidemiologia y Salud Pública (CIBERESP), Madrid, Spain, [3]Genomes for Life–GCAT laboratory, Germans Trias i Pujol Research Institute, Badalona, Spain, [4]Banc de Sang i Teixits, Barcelona, Spain

BACKGROUND/AIMS: Ambient air-pollution has been associated with COVID-19 disease, disease severity, and antibody response induced by infection. We examined the association between long-term exposure to air-pollution with vaccine-induced antibody response and with post-COVID-19 condition ("long COVID").

METHODS: We re-contacted 6,945 adult participants from a population-based cohort study in Catalonia in May-July 2021 who had been contacted pre-pandemic and in summer 2020. We drew blood samples in 2021 from 1,076 of 4,103 participants who had provided samples in 2020 and measured immunoglobulin (Ig)M, IgA, and IgG antibodies against five viral-target antigens including RBD (receptor-binding domain), S (spike-protein) and S2 (segment spike-protein) triggered by vaccines available in Spain. We estimated pre-pandemic (2018-2019) exposure to particulate matter (PM2.5) and nitrogen dioxide (NO2) at the residence using ELAPSE models. Long-COVID was defined as SARS-CoV2 infection and self-report of at least one symptom lasting for at least 4 weeks after 3 months from infection. Estimates were adjusted for individual- and area-level covariates, time since vaccination, vaccine doses, and type.

RESULTS: Among vaccinated persons not infected by SARS-CoV-2 (n=630), higher pre-pandemic air pollution levels were associated with lower vaccine antibody response. Percentage change in geometric mean IgG levels per interquartile range of PM2.5 (1.7µg/m3) were -8.2 (95%CI -16.0, 0.4) for RBD, -9.7 (-16.0, -2.8) for S and -8.4 (-13.5, -3.0) for S2. Corresponding changes for NO2 (IQR 10.6µg/m3) were -2.3 (-10.6, 6.6), -7.3 (-13.8, -0.4) and -6.9 (-12.0, -1.4). The relative risk of long COVID was 1.29 (1.00-1.66) for PM2.5, and 1.07 (0.84-1.37) for NO2.
DISCUSSION: Exposure to air pollution was associated with lower levels of COVID-19 vaccine antibody response and with a higher risk of long-COVID. Whether the effect on vaccine response affects protection against future breakthrough infections and disease severity, should be evaluated in a longer follow-up.

KEYWORDS: air pollution; covid-19; vaccines; immune-response; long-COVID

P-0660 Long-term exposure to ambient air pollution and COVID-19 fatality in Italy

Massimo Stafoggia[1], Andrea Ranzi[2], Carla Ancona[1], Lisa Bauleo[1], Antonino Bella[3], Giorgio Cattani[4], Simone Giannini[2], Federica Nobile[1], Patrizio Pezzotti[3], Ivano Iavarone[3], EPICOVAIR Study Group

[1]Lazio Region Health Service - Asl Roma 1, Rome, Italy, [2]Environmental Health Reference Centre, Regional Agency for Environmental Prevention of Emilia-Romagna, Modena, Italy, [3]Italian National Institute of Health (ISS), Rome, Italy, [4]Italian Institute for Environmental Protection and Research, ISPRA, Rome, Italy

BACKGROUND AND AIM: After the outbreak of SARS-CoV-2 pandemic in 2019, there has been a fast proliferation of epidemiological studies linking ambient air pollution to COVID-19 incidence or adverse prognosis. However, the role of chronic exposure to air pollutants in increasing COVID-19 fatality is still unclear.

METHODS: From the national surveillance database, we selected all COVID-19 cases from February 2020 to June 2021. We developed an air pollution exposure model with 1-km2 resolution for Italy, and assigned 2016-2019 mean concentrations of particulate matter < 10 micron (PM10), PM < 2.5 micron (PM2.5) and nitrogen dioxide (NO2) to each municipality (n=7,800) as estimates of chronic exposures. We applied a principal component analysis and a generalized propensity score (GPS) approach to an extensive list of area-level covariates related to geography and topography, population density, mobility, population health, socio-economic status, and access to healthcare services. Finally, we applied generalized negative-binomial regression models matched on GPS, age, sex, province and month.

RESULTS: We analyzed 3,995,202 COVID-19 cases which generated 124,346 deaths. Case-fatality rates (CFR) increased by 0.7% (95% confidence intervals [CI]: 0.5%, 0.9%), 0.3% (95% CI: 0.2%, 0.5%) and 0.6% (95% CI: 0.5%, 0.8%) per 1 µg/m3 increment in PM2.5, PM10 and NO2, respectively. Associations were higher among elderly subjects, they did not differ by sex or pre-existing diseases, and were higher during the first (Feb. 2020 – June 2020) and the third (Dec. 2020- June 2021) pandemic waves. In two-pollutant models, NO2 estimates were robust to PM adjustment, while PM estimates became null after adjustment for NO2.

CONCLUSIONS: We found suggestive evidence of association between long-term exposure to ambient air pollutants with mortality among ~ 4 million COVID-19 cases in Italy, highlighting the role of chronic air pollution exposure on the vulnerability of the exposed population.

BACKGROUND AND AIM: We aimed to study the socioenvironmental determinants of maternal mental health during the COVID-19 pandemic in Barcelona, for which there is limited evidence.

METHODS: We assessed 394 pregnant women or women with a recent delivery who had participated in the Barcelona Life Study Cohort (BiSC) before March 14th, 2020. Participants filled five online questionnaires during the lockdown period (March-June 2020) and one year after. We characterized the presence of balcony/garden, plants, amount of green space and frequency looking through windows, and social conditions at home, among others. We used the Perceived Stress Scale (short version) in all surveys. Hair cortisol was analyzed at the end of the lockdown. Depression and anxiety were assessed with the Symptom Checklist-90-Revised at the end of the lockdown and one year after. Pre-pandemic data on the urban environment and mental health was also available.

RESULTS: The mean (SD) age was 25.6 (4.4) years. Perceived stress, depression and anxiety were higher after than before the pandemic, but anxiety levels went back to normal one year after. Cortisol levels were lower at the end than before the lockdown. The lack of balcony/garden was associated with greater perceived stress at the beginning of the lockdown β=1.40 (95%CI=0.05; 2.76). Presence of plants and frequent view of green spaces through windows were non-significantly associated with less cortisol and less depression and anxiety, respectively, at the end of the lockdown. Economical insecurities, inadequate conflict resolution styles with partners and childcare inequities were also associated with perceived stress during the lockdown.

CONCLUSIONS: Preliminary results suggest that maternal mental health worsened during the pandemic, except for cortisol levels. Lack of green spaces, socioeconomical and family situations could influence maternal mental health during COVID-19.

KEYWORDS: Pregnant women, maternal stress, mental health, COVID-19.

P-0662 Antibody response to COVID-19 vaccines among workers with a wide range of exposure to per- and polyfluoroalkyl substances

Anna Porter[1], Sarah Kleinschmidt[2], Kara Andres[2], Courtney Reusch[2], Ryan Krisko[3], Oyebode Taiwo[2], Geary Olsen[2], Matthew Longnecker[1]

[1]Ramboll U.S. Consulting, Raleigh, USA, [2]3M Company, Corporate Occupational Medicine, St. Paul, USA, [3]3M Company, Environment, Health, Safety and Product Stewardship, St. Paul, USA

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) are a broad class of synthetic chemicals; some are detectable in serum in most humans in developed countries. Several studies have shown associations between certain PFAS, such as perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS), and reduced antibody concentration after vaccination against diseases such as Tetanus. Recent studies have reported associations between COVID-19 occurrence and severity and exposure to PFAS. However, studies of antibody concentration after COVID-19 vaccination in relation to PFAS serum concentrations have not been reported. We examined COVID-19 antibody responses to vaccines and PFAS serum concentrations among employees and retirees from two 3M facilities, one of which historically manufactured PFAS including PFOS, PFOA, and perfluorohexane sulfonic acid (PFHxS).

METHODS: Participants completed enrollment and follow-up study visits in the spring of 2021, when vaccines were widely available. In total 418 participants with 761 observations were included in the repeated measures analysis. Log-transformed concentrations of anti-spike IgG and neutralizing antibodies were modeled in relation to concentration of PFAS at enrollment after adjusting for antigenic stimulus group (11 groups determined by COVID-19 history and number and type of vaccination) and other variables.

RESULTS: The fully adjusted IgG concentration was 3.57% lower (95% CI -7.17, 0.17) per interquartile range increase in PFOS (14.6 ng/mL); results for neutralizing antibody and PFOS were similar. for PFOA, PFHxS, and perfluorononanoic acid (PFNA), the results were comparable to those for PFOS, though of smaller magnitude.

CONCLUSIONS: In our study data, the fully adjusted coefficients relating concentration of vaccine-induced antibodies to COVID-19 and interquartile range difference in serum concentration of PFOS, PFOA, PFHxS, and PFNA were inverse but small with confidence intervals that included zero. The coefficients for these four PFAS was considerably affected by adjustment for antigenic stimulus group.

KEYWORDS: antibody response, COVID-19, polyfluoroalkyl, perfluoroalkyl substances

P-0663 SARS-CoV-2 antibody prevalence and COVID-19 vaccination among industrial livestock operation workers and nearby community residents, North Carolina, USA

Carolyn Gigot[1], Nora Pisanic[1], Kristoffer Spicer[1], Kate Kruczynski[1], Margaret Carr[2], Devon (DJ) Hall[2], Unique Hall[2], Phyla Holmes[2], Angela Matthews[2], Arika Miller[2], Devon Hall[2], Kirsten Koehler[1], Christopher D. Heaney[1]
[1]Johns Hopkins School of Public Health, Baltimore, USA, [2]Rural Empowerment Association for Community Help, Warsaw, USA

BACKGROUND AND AIM: Industrial livestock operations (ILOs), particularly livestock processing facilities, emerged as centers of COVID-19 outbreaks across the USA early in spring 2020. We aimed to compare SARS-CoV-2-specific IgG positivity and COVID-19 vaccination status among ILO workers and their household members, neighbors of ILOs, and community residents in metropolitan areas of North Carolina, USA.

METHODS: This work represents a preliminary analysis within an ongoing study in North Carolina, the 2nd leading hog and turkey and 5th leading broiler chicken producing state. We enrolled 62 of a planned 100 ILO households with at least one adult working at an industrial hog or poultry operation, meatpacking plant, or animal rendering plant, 79 of 100 ILO neighbor (ILON) households, living in close proximity to these facilities but without occupational livestock exposure, and 53 of 100 households in metropolitan areas (Raleigh, Durham, Wilmington) between February 2021 and April 2022 via snowball sampling. Participants responded to a questionnaire and provided a saliva swab sample, which we analyzed for SARS-CoV-2-specific IgG using a multiplex immunoassay.

RESULTS: The prevalence of baseline SARS-CoV-2 anti-nucleocapsid IgG, which suggests recent/past SARS-CoV-2 infection, was higher among participants in the ILO compared to participants in the metro (PR=1.7; 95% CI 1.1, 3.0) and ILON (PR=1.6; 95% CI 1.0, 2.4) groups. Similar proportions across groups reached the CDC definition of fully vaccinated (53% of 234 total participants). The ILO group reached full vaccination later (median date: 8/29/21) than the metro (median date: 4/30/21) and ILON (median date: 4/13/21) groups.

CONCLUSIONS: Antibody results show high rates of exposure to SARS-CoV-2, especially among ILO workers and their household members. Delays in the timing of receipt of COVID-19 vaccination reinforce the importance of dismantling vaccination barriers for ILO worker populations.

P-0664 Prevalence and predictors of SARS-CoV-2 seropositivity among volunteer firefighters (October 2020 - August 2021)

Kaleigh M Hinton[1], Katherine Lubina[1], Zorimar Rivera-Núñez[1,2], Taylor M Black[1], Robert J Laumbach[1,2], Shou-en Lu[1], Nimit N Shah[1], Maria L Gennaro[3,4,1], Pratik Datta[3], Rahul Ukey[3], Brian S Kubiel[5], Jefferey L Burgess[6], Alberto J Caban-Martinez[7], Judith M Graber[1,2]

[1]Rutgers University School of Public Health, Piscataway, USA, [2]Rutgers University Environmental and Occupational Health Sciences Institute, Piscataway, USA, [3]Rutgers University Public Health Research Institute, Newark, USA, [4]Rutgers University New Jersey Medical School, Newark, USA, [5]Toms River Board of Fire Commissioners District 1, Toms River, USA, [6]University of Arizona Mel and Enid Zuckerman College of Public Health, Tucson, USA, [7]University of Miami Leonard M. Miller School of Medicine, Miami, USA

BACKGROUND AND AIM: First responders are at increased risk of SARS-CoV-2 infection (COVID-19). In the US, 67% of firefighters serve as volunteers, yet few studies have assessed COVID-19 prevalence and predictors within this occupational group. The aim of this cross-sectional study was to assess SARS-CoV-2 seropositivity in US volunteer firefighters enrolled in the Cancer Assessment and Prevention Study (CAPS), a research partner of the Fire Fighter Cancer Cohort Study (FFCCS).

METHODS: Between October 2020 and August 2021, 124 non-COVID-19 vaccinated firefighters from ten New Jersey (US) volunteer departments were tested for SARS-CoV-2 seropositivity (IgM and/or IgG). They were compared to seronegative firefighters by firefighting characteristics (# monthly calls; years of firefighting) and demographics (age, sex, education, marital status) using Fisher's exact and Wilcoxon's rank tests; associations were explored using multivariable logistic regression.

RESULTS: SARS-CoV-2 seroprevalence was 12.1% (n=15). Participants were predominately male (94.4%) and non-Hispanic White (86.3%). Compared to seronegative participants, seropositive participants responded to fewer monthly calls (median (IQR) 9 (7.0, 15.0) vs. 15 (10.0, 25.0)), were younger (median (IQR) 39.3 (24.2, 56.3) vs. 47.0 (34.5, 59.1) years), and a higher proportion were non-White and/or Hispanic (26.7% vs. 9.2%). In multivariable analysis, participants responding to fewer monthly calls had lower odds of SARS-CoV-2 seropositivity (OR 0.91; 95% CI: 0.84, 0.98), adjusting for age and years of firefighting.

CONCLUSIONS: There was a high seroprevalence of SARS-CoV-2 among this cohort of volunteer firefighters. The inverse association between median number of monthly firefighting calls was unexpected. Among firefighters who respond to more calls, this finding may be attributable to: better adherence to infection control measures; increased use of personal protective equipment (PPE); and/or exposure to COVID-19 at their primary occupation. The small number of cases means that these results should be interpreted with caution.

P-0665 Association of Outdoor and Indoor Environment with Mental wellbeing of Lebanese Mothers during COVID-19: Findings from the Environmental Exposures for Lebanese Infants (EELI) Study

Georges Abi Tayeh[1], Emile Whaibeh, Hadiya Leya Affara, Clara Chaiban, Myriam Mrad Nakhlé
[1]*Hotel Dieu de France and University of Saint Joseph Beirut, Beirut, Lebanon*

BACKGROUND AND AIM: COVID-19 containment efforts in Lebanon included movement restrictions, social distancing, and quarantine measures that confined EELI study participants in their homes during their pregnancy and in the early months of their maternity. Household characteristics and proximity and access to green spaces can potentially support wellbeing and mental health. The aim of this study is to explore the associations between factors of the immediate natural and built environments and mental health outcomes in a population of new mothers in Lebanon during the ongoing COVID-19 pandemic.
METHODOLOGY:
Participants were recruited as part of the ongoing EELI birth cohort study from Hôtel-Dieu de France hospital in Beirut, Lebanon. Participants (n=100) provided informed consent and data on variables of interest included in this analysis. The current wellbeing of the participants was assessed using WHO Wellbeing Index [WHO-5], pregnancy-specic and COVID-19-specic stress scales. Chi-square tests are used to analyze household and natural environment characteristics against wellbeing and mental health outcomes. An exploratory qualitative component is also conducted to inquire about the environmental factors affecting maternal mental health and wellbeing in the context of the pandemic.
FOCUS AND IMPLICATIONS: With its longitudinal design and its launch during the COVID-19 pandemic, the EELI Study is uniquely poised to assess the links between the deteriorating natural and built environments and its impact on maternal mental wellbeing and potentially the development of infants in the long run. We hope to inform mitigation strategies and home-based and/or internet-based interventions to address the damage that the pandemic has had on the mental health of new mothers.

P-0666 Relationship between meteorological and air quality parameters and COVID-19 in Casablanca region, Morocco

Mohamed Khalis[1], Aly Badara Toure[1], Imad Elbadisy[1], Kenza Khomsi[2], Houda Najmi[2], Oumnia Bouaddi[1], Abdelghafour Marfak[3], Wael K. Al-Delaimy[4], Mohamed Berraho[5], Chakib Nejjari[1]

[1]International School of Public Health, Mohammed VI University of Health Sciences, Casablanca, Morocco, [2]General Directorate of Meteorology, Casablanca, Morocco, [3]National School of Public Health, Rabat, Morocco, [4]Herbert Wertheim School of Public Health and Human Longevity Science, University of California, San Diego, USA, [5]Department of Epidemiology, Faculty of Medicine and Pharmacy of Fez, Sidi Mohamed Ben Abdellah University, Fez, Morocco

BACKGROUND AND AIM: COVID-19 and its emerging variants is continuing to spread around the world. Environmental factors may play a role in the transmission of COVID-19. The aim of this study was to investigate the relationship between meteorological parameters, air quality and daily COVID-19 transmission in Morocco, using General Additive Models.

METHODS: We collected daily data of confirmed COVID-19 cases in the Casablanca region- Morocco, as well as meteorological parameters (average temperature, wind, relative humidity, precipitation, duration of insolation) and air quality parameters (CO, NO2, 03, SO2, PM10) during the period of March 2nd, 2020, to December 31st, 2020. The General Additive Model (GAM) was used to assess the impact of these parameters on daily cases of COVID-19.

RESULTS: A total of 172,746 confirmed cases were reported in the study period. Positive associations were observed between COVID-19 and wind above 20m/s and humidity above 80%. However, temperatures above 25° were negatively associated with daily cases of COVID-19. PM10 and O3 had a positive effect on the increase in the number of daily confirmed COVID-19 cases, while precipitation had a borderline effect below 25mm and a negative effect above this value.

CONCLUSIONS: The findings in this study suggest that significant associations exist between meteorological factors, air quality pollution (PM10) and the transmission of COVID-19. Our findings may help public health authorities better control the spread of COVID-19.

P-0667 New York on PAUSE and traffic-related air pollution: quantifying diurnal changes in NO2 due to COVID-19 stay-at-home orders

Jenni Shearston[1], Ilan Cerna-Turoff[1], Markus Hilpert[1], Marianthi-Anna Kioumourtzoglou[1]
[1]*Columbia University Mailman School of Public Health, New York, USA*

BACKGROUND/AIM: Policy responses to the COVID-19 pandemic, including the NY on PAUSE stay-at-home order, substantially reduced traffic and traffic-related air pollution (TRAP) in New York City (NYC). We evaluated the magnitude of TRAP decreases and identified modifying factors such as weekend/weekday, road proximity, location, and time of day—important variables for planning future traffic interventions.

METHODS: Hourly nitrogen dioxide (NO_2) concentrations from 1/1/2018 through 6/8/2020 were obtained from the Environmental Protection Agency's Air Quality System for six monitors in the NYC area. We used an interrupted time series design to determine the impact of NY on PAUSE on NO_2, using a mixed effects model with random intercepts for monitor location, adjusted for meteorology and long-term trends. We evaluated effect modification by weekend/weekday, road proximity, and time of day in stratified models, and location by including random slopes for each monitor.

RESULTS: NO_2 concentrations decreased due to NY on PAUSE by -3.2 ppb (95% confidence interval [CI]: -3.5, -3.0), on average. We found no evidence for modification by weekend/weekday, but found greater decreases in NO_2 at non-roadside monitors. We found weak evidence for modification by location. for time of day, we found the largest decreases for 5 am (-4.5 ppb, 95% CI: -5.7, -3.3) through 7 am (-4.0 ppb, 95% CI: -5.2, -2.8), followed by 6 pm and 7 pm (-3.7 ppb, 95% CI: -4.8, -2.6 and -4.8, -2.5, respectively), while the smallest decreases occurred from 10 pm (-2.3 ppb, 95% CI: -3.5, -1.1) to 1am (-1.9 ppb, 95% CI: -3.1, -0.7).

CONCLUSIONS: NY on PAUSE's impact on TRAP varied greatly diurnally. for future large-scale traffic interventions, our findings suggest that blanket policies not targeting specific time windows will likely result in larger NO_2 decreases during rush hour windows.

KEYWORDS: nitrogen dioxide; traffic-related air pollution; pandemic; policy; New York City

P-0668 Impact of the COVID-19 pandemic on physical and mental health over time in relation to chronic disease status and urbanicity

Warner Van Kersen[1], Myrna M. T. De Rooij[1], Nekane S. Diez[1], Inka Pieterson[1], Marjan Tewis[1], Roel Vermeulen[1], Ulrike Gehring[1], Anke Huss[1], Lidwien A.M. Smit[1]
[1]*Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands*

Both direct and indirect health effects of living in COVID-19 pandemic conditions have been reported. General measures taken to manage the pandemic may impact physical and mental health and probably disproportionately affect chronically diseased individuals. Residents of urban and rural areas may be differently affected as well. The aim of this study is to assess the impact of the COVID-19 pandemic and the measures to manage the outbreak on physical and mental health, and whether the impact on wellbeing differs according to chronic disease status and urbanicity.
Participants of three Dutch prospective cohorts (AMIGO, VGO and PIAMA; n=27,763) were invited. The VGO cohort is situated mainly in a rural region, while the other two cohorts are mixed in terms of urbanicity. Respondents (n=5,420) were asked to complete an online baseline questionnaire regarding health status, followed by monthly follow-up questionnaires between September 2020 and October 2021. Questions on physical and mental health were answered using 5-point Likert scores (PHS/MHS). Chronic disease status included asthma, chronic obstructive pulmonary disease (COPD), diabetes and cardiovascular disease. Cumulative link mixed models adjusted for age, sex and BMI, were used to analyze the longitudinal data.
Preliminary results show that participants from the more rural cohort reported better PHS (OR=0.59,95%CI=0.48-0.71) and MHS (0.54,95%CI=0.43-0.66) compared to participants from the mixed urban/rural cohorts. Asthma and COPD were associated with worse PHS (OR=2.41;95%CI=1.90-3.09). The same was found for diabetes (OR= 2.23;95%CI=1.53-3.24) and cardiovascular disease (OR=2.16,95%CI=1.68-2.76). Similar associations were found for MHS.

Results suggest that both urbanicity and chronic disease status are relevant factors to consider when assessing (indirect) health effects of the COVID-19 pandemic. Additional multivariable analyses including detailed urbanicity indicators and stringency of governmental measures over time will be performed enabling deeper understanding of individual drivers of these effects.

KEYWORDS: COVID-19, urbanicity, urban-rural, chronic disease

P-0669 Long-term exposure to air pollution and COVID-19 mortality and morbidity in Denmark (AIRCODEN)

Jiawei Zhang[1], Youn-Hee Lim[1], Theis Lange[2], Steffen Loft[1], Laust Hvas Mortensen[3,4], George Maria Napolitano[1], Rudi GJ Westendorp[3,5], Jørgen Brandt[6,7], Cole-Hunter Tom[1], Zorana Jovanovic Andersen[1]

[1]Section of Environmental Health, Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [2]Section of Biostatistics, Department of Public Health, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, [3]Section of Epidemiology, Department of Public Health, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, [4]Denmark Statistics, Copenhagen, Denmark, [5]Center for Healthy Aging, University of Copenhagen, Copenhagen, Denmark, [6]Department of Environmental Science, Aarhus University, Roskilde, Denmark, [7]iClimate, Interdisciplinary Centre for Climate Change, Aarhus University, Roskilde, Denmark

BACKGROUND: Evidence on long-term exposure to air pollution and morbidity and mortality from coronavirus disease (COVID-19) is still sparse and inconclusive. We examined the association between long-term exposure to air pollution and COVID-19 incidence, hospitalization, and mortality.

METHODS: 3,721,813 subjects who were 30 years or older and resided in Denmark on March 1st, 2020 were followed for first COVID-19 positive test (incidence)/hospitalization/death until April 26th, 2021. We assigned annual mean concentrations to residential addresses in 2019, including particulate matter with a diameter <2.5 µm (PM2.5), nitrogen dioxide (NO2), black carbon (BC), and ozone (O3) estimated using 1x1km DEHM/UBM model. We linked air pollution levels with COVID-19 outcomes using random-effect (frailty) Cox proportional hazard models, adjusting for age, sex, and individual-level socioeconomic status (SES) (income, housing, occupation, marital status) with cluster term for parish. Additional analyses with adjustment for parish-levels SES will be presented at ISEE2022.

RESULTS: During 411–417 follow-up days, 138,742 individuals got tested positive for COVID-19, 11,270 were admitted to a hospital, and 2,557 died from COVID-19. PM2.5, NO2 and BC, but not O3, were significantly associated with COVID-19 mortality with hazard ratios (HRs) and 95% confidence intervals of 1.18 (1.10-1.27) per 0.53 µg/m3 increase in PM2.5, 1.82 (1.64-2.03) per 3.59 µg/m3 increase in NO2, and 1.10 (1.05-1.14) per 0.09 µg/m3 increase in BC. Somewhat weaker associations were found for COVID-19 related hospitalizations, with HRs of 1.21 (1.17-1.26) for PM2.5, 1.70 (1.60-1.81) for NO2, and 1.09 (1.05-1.13) for BC, and weakest with COVID-19 incidence, with HRs of 1.18 (1.15-1.21) for PM2.5, 1.55 (1.49-1.62) for NO2, and 1.09 (1.05-1.13) for BC. HRs for all-cause mortality were 1.02 (1.01-1.03) for PM2.5, 1.04 (1.02-1.06) for NO2, and 1.02 (1.01-1.03) for BC.
CONCLUSION: Long-term exposure to air pollution was associated with COVID-19 related morbidity and mortality.

KEYWORDS: Air pollution, COVID-19, hospitalization, incidence, mortality

P-0672 Sars-CoV-2 viral load in wastewater and its association with ambient temperature in the Athens, Greece, area

Anna Voulgari[1], Antonis Analitis[1], Aikaterini Galani[2], Konstantina Dimakopoulou[1], Dimitris Paraskevis[1], Nikolaos Thomaidis[2], Klea Katsouyanni[1,3]

[1]Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Athens, Greece, [2]Laboratory of Analytical Chemistry, Department of Chemistry, National and Kapodistrian University of Athens, Athens, Greece, [3]MRC Centre for Environment and Health, Environmental Research Group, Imperial College, London, London, UK

BACKGROUND: Measurements of SARS-CoV-2 viral load in wastewater represents an objective assessment of the viral load in a population as it does not suffer from selection bias. The objective of this study was to evaluate the role of ambient temperature in the spread of COVID-19 in the Athens by using data from the wastewater viral load.

METHODS: Data on the daily SARS-CoV-2 viral load (copies/100,000 inhabitants), ambient temperature, public health control measures for COVID -19 (as expressed by sector-specific mobility data) were obtained on a daily basis from 31 August 2020 to 14 October 2021. Distributed lag non-linear regression models were applied with log-transformed viral load as dependent variable. Separate lags were alternatively investigated. Twenty four hour temperature was used as main exposure, adjusting for mobility data and particulate matter pollution. Solar radiation and relative humidity were also used.

RESULTS: There was an indication of an association of higher ambient temperature with an increase in the viral load, which became apparent after 3 days but did not always reach the nominal level of statistical significance. The association with daily PM10 concentrations was also not statistically significant. However, a statistically significant positive association was observed between viral load and retail/ recreation mobility.

CONCLUSIONS: The variability of viral load in wastewater appears to be dominated by public health control measures resulting to changes in mobility and the mean number of contacts within the population. The role of ambient temperature is not clear. The potential effect of ambient temperature was probably modified by changes in virus transmissibility during the emergence of variants of concern dominating in different time periods. In our setting, statistical power may have been limited by the relatively short period of data availability.

KEYWORDS: COVID-19, wastewater viral load, ambient temperature

P-0673 Covid-19 in Workers of an environmental sanitation company: Overview of cases and impact of a Safety and Health Protocol in a unit with 7,000 Workers. 2020 to 2022

Telma Cassia dos Santos Nery[1,2], Ayrton Jouti[2], Uberam da Rocha Barros Junior[2], Maria Viana Mendes[2], Rosa B Santos[2], Luzia R Neves[2], Sandra Malaquias[2], MR Rodolfo S S Soares[2]

[1]Divisao de Pneumologia - Instituto do Coracao INCOR HCFMUSP, Sao Paulo, Brazil, [2]MIS - Companhia de Saneamento Basico do Estado de Sao Paulo - SABESP, Sao Paulo, Brazil

Since March 11, 2020, the planet has been living with a major pandemic. Human behavior and the environment are different at this point. Deaths are countless. Workers in environmental sanitation services, such as water and sewage, are characterized as essential and need a special approach to COVID-19. In Brazil the impact was important. This work describes safety measures in a group of 7 thousand workers of the largest environmental sanitation company in Latin America.
OBJECTIVE: to describe the measures adopted for COVID-19 through the safety and health protocol. METHODOLOGY: Describes the participation of the occupational service in the construction and institution of an appropriate protocol in the period from April 2020 to April 2022, considering bibliographic survey, management discussions, discussion with workers and measures implemented on site, visits to the work safety team, guidelines and preventive health care.

RESULTS: A specific protocol was implemented with occupational service in all areas for 7,000 workers. Implementation of telework in several areas, redistribution of teams with external activities, around 1,500 technical visits were carried out, implementation of measures in the places, adaptation of work stations, specific medical examinations. CONCLUSION: The adoption of specific measures and protocols increased worker participation and the impact of COVID-19 on environmental sanitation workers.

P-0675 Mitigating Indoor Risk of Airborne Infections: the MIRAI project

Tommaso Filippini[1,2], Marco Vinceti[1,3], Grazia Ghermandi[4], Alessandro Bigi[4]
[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, [2]School of Public Health, University of California Berkeley, Berkeley, USA, [3]Department of Epidemiology, Boston University School of Public Health, Boston, USA, [4]Department of Engineering "Enzo Ferrari", University of Modena and Reggio Emilia, Modena, Italy

BACKGROUND AND AIM: The risk of infection from SARS-CoV-2 and other airborne diseases is known to be higher in indoor environment, also depending on personal (e.g. individual susceptibility, modality of exposure, viral load) and environmental (e.g. airflow, temperature, humidity) factors. Measurements of CO_2 indoors are often used as a proxy for air quality and recent evidence suggests that its monitoring can be helpful to identify poorly ventilated multi-occupancy spaces like offices and classrooms, thus possibly evaluating the risk of exposure to indoor airborne contaminants, including infectious agents. In addition, the recent availability of portable low-cost sensors has been suggested to be effective in the prevention of SARS-CoV-2 infection and other airborne diseases.

METHODS: In this project, we will use low-cost sensors for the evaluation of CO_2 levels using Non-Dispersive InfraRed method. We will assess CO_2 levels in high school and university in Modena, Norther Italy from March 2022 up to end of the year. Information factsheets will be placed along with the sensors with detailed information about the project aim and purpose, guidelines for adequate CO_2 monitoring and alert thresholds (800 and 1400 ppm) indicating the need to increase the ventilation (e.g. opening doors and windows). Calibration and quality control of the low-cost monitors will be also performed to ensure the reliability of the measurements.

RESULTS: AND

CONCLUSIONS: The monitoring campaign has started as planned and the environmental and health data collection is ongoing. Considering the recommendations to prevent SARS-CoV-2 in Italy still indicate to wear masks for both students and personnel as well as the lowering of pandemic spread, no positive cases have been identified within the monitored classrooms. Project results will be presented during the conference.
Funded by grant "FAR 2021 Mission Oriented-Linea FOMO".

P-0676 Investigating links between air pollution, COVID-19 and lower respiratory infectious diseases – A review

Heather Walton[1], Dimitris Evangelopoulos[1,2], Maria-Iosiphina Kasdagli[3], Liza Selley[4], David Dajnak[1], Klea Katsouyanni[1,2,3]

[1]Environmental Research Group, MRC Centre for Environment and Health, Imperial CollegeImperial College London, London, UK, [2]NIHR Health Protection Unit in Environmental Exposures and Health at Imperial College, London, UK, [3]National and Kapodistrian University of Athens, Athens, Greece, [4]MRC Toxicology Unit, University of Cambridge, Cambridge, UK

BACKGROUND/AIM: Hundreds of air pollution and COVID-19 papers have been published in a short time varying widely in quality. The Greater London Authority commissioned a comprehensive overview of the most credible evidence for the links between air pollution and COVID-19 and other lung infections.

METHODS: Building on the Brunekreef et al (2021) review, a literature search was performed from November 2020 – May 2021, classifying the evidence by exposure, the potential mechanism and the health outcome. Studies on hospital admissions for lower respiratory infections were reviewed from 2011

RESULTS: Long-term exposure increased the risk of hospitalization in people already infected with COVID-19 in two good-quality cohort studies with individual data, perhaps due to respiratory and cardiovascular disease from air pollution increasing vulnerability to COVID-19 adverse outcomes. Mortality results were conflicting. Inconsistent results were found for long-term exposure and COVID-19 cases in ecological studies. Studies on short-term exposure were unclear and hard to evaluate.
Several studies demonstrated that inhaled pollutant increased expression of the ACE2 receptor and other host susceptibility genes in both alveolar epithelial cells and macrophages. Susceptibility to infection by SARS-CoV-2 can be inferred from these results but only one study used SARS-CoV-2 directly.
Several studies from 2011-2021 showed a link between air pollution and hospital admissions for lung infections although the studies were spread across different age groups and disease definitions.
Particulate matter does not appear to play any important part in transporting COVID-19 in the environment, as had been suggested by some earlier studies.

CONCLUSIONS: The publication of cohort studies with individual data in this time period is an important step forward. Results are suggestive for long-term exposure and hospital admissions for COVID-19 and some toxicological effects are plausible but further research will be necessary to strengthen these emerging findings.

KEYWORDS: Air pollution, COVID-19, lower respiratory infections.

P-0677 Associations of air pollution with COVID-19 test positivity, hospitalisations, and mortality: observational evidence from UK Biobank

Charlotte Sheridan[1], Jochem Klompmaker[2], Steven Cummins[3], Peter James[2,4], Daniela Fecht[1], Charlotte Roscoe[1,2,5]
[1]MRC Centre for Environment and Health, Department of Epidemiology and Biostatistics, School of Medicine, Imperial College London, London, UK, [2]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [3]Population Health Innovation Lab, Department of Public Health, Environments and Society, Faculty of Public Health and Policy, London School of Hygiene & Tropical Medicine, London, UK, [4]Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA, [5]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital, Boston, USA

BACKGROUND AND AIM: Individual-level studies with adjustment for COVID-19 risk factors suggest a weak positive association of long-term air pollution exposure (particulate matter and nitrogen dioxide) with COVID-19 positive test, hospitalisation, and mortality. The evidence, however, remains limited and mechanisms remain unclear. We aimed to investigate these associations within UK Biobank, and to examine the role of underlying chronic disease as a potential mechanism.

METHODS: UK Biobank COVID-19 positive test results were ascertained via Public Health England and general practitioner record linkage, COVID-19 hospitalisations via Hospital Episode Statistics, and COVID-19 mortality via Office for National Statistics mortality records from March – December 2020. We used annual average outdoor air pollution from a 2010 land-use regression model at residential addresses within England of UK Biobank participants (n = 424,721) and obtained important COVID-19 risk factors from baseline UK Biobank questionnaire responses (2006-2010) and general practitioner record linkage. We used logistic regression models to assess associations of air pollution with COVID-19 outcomes after adjustment for relevant confounders and conducted multiple sensitivity analyses.

RESULTS: We found positive associations of fine particulate matter (PM2.5) and nitrogen dioxide (NO2) with COVID-19 positive test result after adjustment for confounders, with odds ratio of 1.06 (95% confidence intervals (CI) = 1.03, 1.09), and 1.06 (95% CI = 1.02, 1.09) per interquartile range increase, respectively. PM2.5 and NO2 were positively associated with COVID-19 hospitalisations and deaths in minimally adjusted models but not in fully adjusted models. No associations for PM10 were found. In analyses with additional adjustment for pre-existing chronic disease, effect estimates were not substantially attenuated, indicating that underlying chronic disease may not fully explain associations.
CONCLUSION: We found some evidence that long-term exposure to PM2.5 and NO2 was associated with a COVID-19 positive test, though not with COVID-19 hospitalisations or deaths.

KEYWORDS: PM2.5, NO2, coronavirus

P-0681 Multi-strain integrated modelling for COVID-19

Dimosthenis Sarigiannis[1,2,3], Achilleas Karakiltzidis[1,2], Spyros Karakitsios[1,2]
[1]HERACLES Research Center – CIRI, Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]Environmental Engineering Laboratory, Department of Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece, [3]Environmental Health Engineering, School for Advanced Study IUSS, Pavia, Italy

BACKGROUND AND AIM: Quantitative forecasting of the COVID-19 pandemic evolution has become complex, due to the multiple parameters that affect disease dynamics, including (a) non-pharmacological interventions (such as social distancing, extensive (self)-testing), (b) pharmacological interventions (vaccines and antivirals), (c) weather and climate (d) different transmissibility, disease severity and reinfection capacities of the various co-existing strains.

METHODS: A multi-modal computational tool (CORE: COVID Risk Evaluation model), able to assess the impact of all the parameters mentioned above, has been developed to evaluate the COVID-19 health risk. The tool has been applied in Greece, Italy and USA. Contact matrices among the various population groups, accounting for their sociodemographic profiles (i.e. age, occupation etc), as well as the impact of targeted social distancing measures have been developed using agent-based modelling.

RESULTS: The evolution of the COVID-19 dynamics for Greece since February 2020, and the long-term prediction till the end of 2022, considering risk management has been successfully described. The implementation of the omicron strain dynamics in early December in Greece was critical, because it allowed us to identify at a very early stage the already significant dispersion of this highly contagious strain and warn in a timely manner public authorities, as well as to identify the timing and the height of the pandemics peak. Similarly, an early warning was issued on the advent of omicron 2 in the end of February.

CONCLUSIONS: CORE has demonstrated its efficacy in capturing the pandemic dynamics and issuing early warnings in time to take health risk management measures. Currently natural and acquired immunity declines gradually and a high rate of re-infections related to omicron 2 is observed. Thus, a high rate of booster vaccination in adults, rapid completion of schoolchildren vaccination and indoor air disinfection in public spaces are needed to adequately contain the COVID-19 dispersion.

P-0682 Associations of greenspace, including private residential gardens, with COVID-19 laboratory-confirmed positive test, hospitalisation and mortality in UK Biobank

Charlotte Roscoe[1,2,3], Charlotte Sheridan[3], Jochem Klompmaker[1], Peter James[1,4], Daniela Fecht[3]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Harvard University, Boston, USA, [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]MRC Centre for Environment and Health, Imperial College London, London, UK, [4]Division of Chronic Disease Research Across the Lifecourse (CoRAL) Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA

BACKGROUND AND AIM: Inequities in access to urban greenspace, such as gardens and parks, were highlighted by the COVID-19 pandemic, which underscored greenspace's utility for exercising and socialising. Initially, ecological studies suggested a protective association of greenspace with COVID-19 outcomes. The evidence, however, remains limited and lacking adequate adjustment for COVID-19 risk factors. We aimed to investigate associations of greenspace with COVID-19 positive test, hospitalisation and mortality using the UK Biobank cohort study.

METHODS: COVID-19 positive laboratory-confirmed test results, hospitalisations, and deaths were ascertained via UK Biobank linkage to Public Health England and general practitioner records, Hospital Episode Statistics and Office for National Statistics death records, from March – December 2020. We used Ordnance Survey Greenspace, categorised by function (e.g., private garden, public park, etc.), to assess greenspace in a 100 m distance buffer around residential addresses of UK Biobank participants who resided in urban areas of England (n = 276,805). We used logistic regression models to assess associations of greenspace with COVID-19 outcomes with adjustment for relevant COVID-19 risk factors and confounders, ascertained from baseline UK Biobank questionnaire responses (2006-2010) and general practitioner record linkage, and conducted multiple sensitivity analyses.

RESULTS: In age and sex-adjusted models, we found negative associations with all COVID-19 outcomes, however, in fully-adjusted models, associations were not significant. Unexpectedly, in fully-adjusted models, we found that both total greenspace (all types) cover and private residential garden cover within 100 m of addresses were positively associated with positive COVID-19 test (odds ratio (OR) 1.04 (95% confidence intervals (CI) = 1.01, 1.07); OR 1.08 (95% CI = 1.04, 1.13), respectively).
CONCLUSION: We found no evidence that greenspace was associated with COVID-19 hospitalisation or mortality in fully-adjusted models. Results suggest higher COVID-19 positive test result for those residing at addresses surrounded by higher total greenspace and private garden cover.

P-0686 Assessing COVID-19 Outcomes Among People Living Near Oil and Gas Wells in California

Helena Archer[1], David Gonzalez[1], Julia Walsh[1], Paul English[2], Peggy Reynolds[3], Rachel Morello-Frosch[1]
[1]Univeristy of California, Berkeley, Berkeley, USA, [2]Tracking California, USA, [3]University of California, San Francisco, San Francisco, USA

BACKGROUND AND AIM: Researchers have identified associations between COVID-19 outcomes and environmental stressors such as ambient air pollutants including fine particulate matter (PM2.5). Prior studies have found that operating oil and gas wells are associated with higher PM2.5 emissions, placing the estimated 17.6 million USA residents near wells (<1.6 kilometer) at risk of exposure. In this study, we assessed whether exposure to oil and gas production was associated with higher rates of COVID-19 infection and COVID-related death.
METHODS: We conducted a population-based ecological study in California using census block groups, which include 600-3000 people. We obtained geocoded data on COVID-19 cases and deaths between February 2020 and January 2021 from state records. We then assessed exposure to cumulative oil and gas production, reported as barrels of oil equivalent from 2018 to 2020 at all wells within 1 km of populated areas of each block group. We fit hierarchical random intercept Poisson and negative binomial models adjusting for individual age and sex and area rurality and sociodemographic characteristics, and with clustering at the census tract level. We included an interaction with time period, to account for variation in testing and reporting rates.
RESULTS: In the first 4 months of the study period (Feb-May 2020), block groups in the highest tertile of production exposure had higher rates of infection (IRR 1.36, 95% CI: 1.22, 1.52) and death (MRR 1.57, 95% CI 1.18, 2.07) than(s unexposed block groups. Over the entire study period, the cumulative rates were 1.01 (IRR 95% CI: 0.95, 1.06) and 1.15 (MRR 95% CI: 1.00, 1.32) respectively.
CONCLUSIONS: In adjusted models, we observed a positive association between residential proximity to high oil and gas well production levels and risk of COVID-19 infection and mortality in the first months of the pandemic.

THEMATIC 13: Exposure assessment

P-0817 Within-city variation in ambient carbon monoxide concentrations: Leveraging low-cost monitors in a spatiotemporal modeling framework

Jianzhao Bi[1], Christopher Zuidema[1], David Clausen[1], Kipruto Kirwa[2], Michael Young[1], Amanda Gassett[1], Paul Sampson[1], Timothy Larson[1], Adam Szpiro[1], Lianne Sheppard[1], Joel Kaufman[1]
[1]University of Washington, Seattle, USA, [2]Tufts University, Medford, USA

Exposure to ambient carbon monoxide (CO) may be associated with cardiovascular disease outcomes based on human and animal experimental evidence, but current epidemiologic research is limited. The number and distribution of ground-level regulatory agency monitors are insufficient to characterize potential fine-scale variation of CO. This study aimed to develop a high-resolution ambient CO prediction model at the daily scale based on both regulatory agency monitoring data and measurements from calibrated low-cost gas monitors in Baltimore, Maryland. We also evaluated the contribution of three novel parameters to model performance, including high-resolution meteorological data, satellite remote sensing data, and co-pollutant concentrations (PM2.5, NO2, and NOx). The CO model had spatial cross-validation (CV) R^2 (RMSE) of 0.70 (0.02 parts per million, ppm) and temporal CV R^2 (RMSE) of 0.61 (0.04 ppm). The predictions revealed spatially resolved CO hotspots associated with population, traffic, and other non-road emission sources (e.g., railroads and airport), as well as sharp concentration decreases within short distances from primary roads. The three novel parameters did not substantially improve model performance, suggesting that our spatiotemporal modeling framework based on geographic features was reliable and robust. As low-cost monitors become increasingly available, this approach to CO concentration modeling can be generalized to resource-restricted environments to facilitate comprehensive epidemiologic research.

P-0821 Solar and Geomagnetic Activity Enhance the Effects of Air Pollutants on Atrial Fibrillation

Carolina Zilli Vieira[1], Mark Link[3], Eric Garshick[2], Man Liu[1], Adjani Peralta[1], Diane Gold[1], Heike Luttmann-Gibson[1], Francine Laden[1], Petros Koutrakis[1]

[1]Harvard T. H. Chan School of Public Health, Boston, USA, [2]VA Normative Aging Study, Veterans Affairs Boston Healthcare System and the Department of Medicine, Boston University School of Medicine, Boston, MA, USA, Boston, USA, [3]Department of Medicine, Division of Cardiology, UT Southwestern Medical Center, Dallas, TX, Dallas, USA

Cardiac arrhythmias have been associated with intense solar and geomagnetic activity (SGA) and exposures to air pollution.We examined whether oscillations of SGA can modify the effect of hourly exposures to air pollutants on atrial fibrillation ≥30 seconds (AF) risk in patients with dual chamber implantable cardioverter defibrillators (ICD). The effects of SGA on ambient particulate matter <2.5 µm (PM2.5), black carbon (BC), ultrafine particles (PN), and associations with AF were assessed. Measures of SGA included solar wind proton density (SW), total interplanetary magnetic field strength (IMF), and Kp index, a measure of global geomagnetic activity. Over all time lags between 0 and 24hr, periods of increased SGA (>50th percentile in SGA) enhanced the effects of all three air pollutants on AF, while during periods of reduced SGA the associations were considerably weaker or absent. During periods of intense SW 6 hours prior to an AF event, the odds ratio (OR) for PM2.5 exposure per IQR of 5.6 µg/m3 was 1.7 (95% CI: 1.3 to 2.3, p-value: 0.0001). for periods of reduced SW, the OR for PM2.5 exposure per IQR was 1.2 (95% CI: 0.9 to 1.5; p-value: 0.27). There were similar effects for PN and BC exposures. In patients with multiple AF events per hour, the associations with air pollutants during intense SGA were even greater. The effects of air pollutants up to 24 h before AF events were enhanced during periods of increased SGA. Our results suggest that these effects may account for variation in AF risk.

P-0825 Occurrence and spread of antibiotic−resistant enterococci in pork processing plants

Anna Ławniczek-Wałczyk[1], Marcin Cyprowski[1], Małgorzata Gołofit-Szymczak[1], Agata Stobnicka-Kupiec[1], Rafał L. Górny[1]
[1]*Central Institute for Labour Protection – National Research Institute, Warsaw, Poland*

BACKGROUND AND AIM: Enterococci can form biofilms resistant to disinfectants. Moreover, due to their resistance to antibiotics, Enterococcus faecium and E. faecalis species are recognized as leading causes of infections worldwide. Detection of their reservoirs requires special attention not only in the context of food safety but also regarding the health of workers in meat processing plants. The aim of this study was to assess the prevalence of antibiotic−resistant enterococci in pork processing plants and to evaluate their biofilm-forming potential.
METHODS: In three pork processing plants, the samples of raw meat, swabs from work surfaces (tabletops, floors, machine parts, tools) and from employees' hands were collected. Bacteria were identified to species level using both the culture method and MALDI-TOF MS. The predominant enterococci were tested for susceptibility to 15 antibiotics by disc diffusion method. The assessment of biofilm-forming potential was studied by the microplate method.
RESULTS: The performed analyses indicate that all raw meat samples, plant surfaces and equipment were contaminated with enterococci. The highest level of enterococci was observed for floors, stainless tables and containers ($5.7*10^3$, $8.5*10^1$ and $13.5*10^1$ cfu/cm^2, respectively). Enterococcus faecium was the most frequently isolated species followed by E. faecalis. More than 63% of enterococci isolates had the ability to form a biofilm. E. faecium and E. faecalis isolates showed high resistance to penicillin (89%), vancomycin (71%), cefotaxime (68%), erythromycin (57%), rifampicin (56%) and imipenem (21%).
CONCLUSIONS: Resistance to several antibiotics and high adherence ability of enterococci isolates suggest that these agents may play an important role in the spread of drug resistance in the meat production chain through contaminated surfaces, raw meat and workers' hands. Controlling the contamination and antimicrobial resistance patterns of enterococci in meat processing plants is essential to public health and food safety.

P-0828 A validated analytical method for biomonitoring the mycotoxins exposure in urine

Kristina Čolak[1], Nuria Dasi[1], Guillermina Font[1], Lara Manyes[1], Ana Esplugues[1], Laura Escrivá[1], Juan Francisco Corrector[1], Juanjo Peiró[1], Jesús Vioque[3,4], Ferran Ballester[1,3,4], Mario Murcia[5], Pilar Vila-Donat[1], Sabrina Llop[4,5], Manuel Lozano[1,2]

[1]University of Valencia, Burjassot, Spain, [2]Epidemiology and Environmental Health Joint Research Unit, FISABIO–Universitat Jaume I–Universitat de València, Valencia, Spain, [3]University Miguel Hernandez, Elche, Spain, [4]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Madrid, Spain, [5]Foundation for the Promotion of Health and Biomedical Research of Valencia Region, Valencia, Spain

BACKGROUND AND AIM: Mycotoxin exposure from food may produce adverse effects in human health. Most mycotoxins are excreted in urine, but a reliable detection method is required considering the low levels present in this biological matrix. The aim of this work is to validate an analytical method for detecting and quantifying in urine different mycotoxins usually present in the food chain.
METHODS: HPLC-QTOF-MS method was used. The targeted mycotoxins were: Enniatin A (ENNA), Enniatin B (ENNB), Enniatin A1 (ENNA1), Enniatin B1 (ENNB1), Beauvericine, Aflatoxin B1 (AFB1), Aflatoxin B2 (AFB2), Aflatoxin G1 (AFG1), Aflatoxin G2 (AFG2) and Ochratoxin A. Different extraction procedures, liquid-liquid extraction, dilute and shoot, and Quick, Easy, Cheap, Effective, Rugged and Save (QuEChERS) methods were assessed followed by HPLC-QTOF-MS and different combinations of solvent extraction and mobile phases were tested. QuEChERS extraction was selected because better recoveries were achieved (>70%) for all mycotoxins. The method was applied to be validated in 150 samples of urine of women participating in the INMA (Environment and Childhood) Spanish project.

RESULTS: For all mycotoxins, matrix-matched calibration curves showed values of regression determination coefficients ranging from 0.998 to 0.999. The LOD and LOQ values ranged from 0.1 to 5.0 ng/ml and from 0.3 to 15.0 ng/ml, respectively. Assessed mycotoxins were detected in the 95% of samples and 8 out of 10 of them were quantified. Mostly quantified mycotoxins were: ENNB [% of detection (concentration range)] = 94% (0.54 – 2.83 ng/ml), ENNA = 47%, (0.30 – 0.68 ng/ml), ENNB1 = 35% (0.45 – 0.89 ng/ml), and AFB2 (18% (0.51 – 8.97 ng/ml).
CONCLUSIONS: The proposed analytical method quantified 8 out of 10 assessed mycotoxins (ENNA, ENNB, ENNA1, ENNB1, AFB1, AFB2, AFG1 and AFG2). These results support the methodology and provide a tool for identifying exposures in susceptible populations.

biomonitoring, mycotoxins, urine

P-0829 Influence of genetic polymorphisms on arsenic methylation efficiency during pregnancy

Raquel Soler-Blasco[1,2], Sabrina Llop[1,2], Manuel Lozano[3], Gabriel Riutort-Mayol[7], Ferran Ballester[1,2,3], Amaia Irizar[4,5], Loreto Santa Marina[4,5], Miren Begoña Zubero[4], Florencia Harari[6]

[1]Epidemiology and Environmental Health Joint Research Unit, FISABIO–UJI-UV, Valencia, Spain, [2]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Madrid, Spain, [3]Universitat de Valencia, Valencia, Spain, [4]University of Basque Country, Spain, [5]Biodonostia Health Research Institute, Spain, [6]University of Gothenburg, Sweden, [7]FISABIO, Valencia, Spain

BACKGROUND AND AIM: Inorganic arsenic (iAs) is a widespread toxic metalloid. It is well-known that iAs methylation and toxicity is mediated by polymorphisms in AS3MT. Evidence on the role of genetic polymorphisms in this and other genes during pregnancy is more limited. We aimed at examining the role of genetic polymorphisms in AS3MT, GSTO2, N6AMT1, MTHFR, MTR, FTCD, CBS and FOLH1 on iAs methylation efficiency (AME) during pregnancy.

METHODS: The study included 541 pregnant women of the INMA (Environment and Childhood) Spanish cohort. Arsenic (iAs and the metabolites monomethylarsonic acid (MMA) and dimethylarsinic acid (DMA)) were measured in urine samples collected during the first trimester of pregnancy, and the AME was determined by measuring the relative concentrations of the arsenic metabolites in urine. Single nucleotide polymorphisms (SNPs) in AS3MT, GSTO2, N6AMT1, MTHFR, MTR, FTCD, CBS and FOLH1 were determined in blood. Socio-demographic and dietary information was collected through questionnaires. The associations between genotypes and AME were assessed by using multivariate linear regression adjusted by confounding variables.

RESULTS: The median total urinary iAs concentrations (sum of MMA, DMA and iAs) was 7.1 µg/g of creatinine. The median %MMA and %DMA were 5.3%, and 89%, respectively. Four AS3MT SNPs (rs3740393, rs3740390, rs11191453 and rs11191454) were significantly associated with %MMA, %iAs and %DMA after adjustment for confounders. Statistically significant associations were also found for FOLH1 SNP rs202676 (β 0.89, 95%CI: 0.24, 1.55 for carriers of the G-allele vs. carriers of the A-allele).

CONCLUSIONS: Our study shows that genetic polymorphisms in AS3MT influence the arsenic methylation efficiency even in early pregnancy. FOLH1 seems to also play a role in arsenic methylation efficiency. These results provide support for the hypothesis that iAs metabolism is influenced by some polymorphisms, being a key element for identifying susceptible populations to As exposure.

P-0830 The Role of Solar Activity in Endothelial Activation and Inflammation in the NAS Cohort

Jessica Schiff[1], Carolina L.Z. Vieira[1], Eric Garshick[2,3,4], Veronica Wang[1], Annelise Blomberg[1], Diane R. Gold[1,4], Joel Schwartz[1], Samantha M. Tracy[1], Pantel Vokonas[5], Petros Koutrakis[1]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Heath, Boston, USA, [2]Pulmonary, Allergy, Sleep, and Critical Care Medicine Section, VA Boston Healthcare System, Boston, USA, [3]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, USA, [4]Harvard Medical School, Boston, USA, [5]VA Normative Aging Study, Veterans Affairs Boston Healthcare System and the Department of Medicine, Boston University School of Medicine, Boston, USA

BACKGROUND AND AIM: Solar activity, which induces disturbances of the Earth's magnetic field, periodically oscillates between minimum and maximum sunspot activity in cycles of approximately 11-years. Exposure to broad-spectrum electromagnetic solar activity can adversely affect human physiology, leading to adverse health outcomes. Recent epidemiological studies have shown that solar and geomagnetic activity are associated with chronic diseases, including cardiovascular diseases (CVD). However, the impact of solar activity on biomarkers for CVD, including biomarkers for endothelial function and inflammation in a large cohort, has not been previously studied. This study investigated the associations between solar and geomagnetic activity and circulating biomarkers of systemic inflammation and endothelial activation in the Normative Aging Study (NAS) cohort.

METHODS: Mixed effects models with moving day averages from day 0 to day 28 were used to study the associations between solar activity [sunspot number (SSN) and interplanetary magnetic field (IMF)], geomagnetic activity [planetary K index (Kp index)] and various inflammatory and endothelial markers. Biomarkers included intracellular adhesion molecule-1 (sICAM-1), vascular cell adhesion molecule-1 (sVCAM-1), C-reactive protein (CRP), and fibrinogen.

RESULTS: After adjusting for demographic and meteorological variables, we observed significantly positive associations between sICAM-1 and sVCAM-1 concentrations and solar and geomagnetic activity parameters: IMF, SSN, and Kp index. Additionally, a negative association was observed between fibrinogen and Kp index and a positive association was observed for CRP and SSN.
CONCLUSION: These results demonstrate that solar and geomagnetic activity might be upregulating endothelial activation and inflammation.

KEYWORDS: Endothelial Activation, Inflammation, Solar Activity, Geomagnetic Activity, Geomagnetic Disturbance

P-0832 Creating an ontology of environmental exposure that captures the main components of epidemiological research papers

Csilla Vamos[1], Simon Scheider[1]
[1]*Utrecht University, Utrecht, Netherlands*

BACKGROUND AND AIM: Environmental exposure is a central concept of the health and behavioral sciences needed to study the influence of the environment on the health and behavior of people within a spatial context. While numerous studies measure some form of exposure, including the influence of air quality, noise, crime, the built environment, and fast food outlets in neighborhoods, we lack a common conceptual model of environmental exposure that captures its main components across all this variety. In this article we propose an ontology design pattern that can be used for this purpose.
METHODS: To develop the pattern, we encoded the content of six scientific articles that each study a different urban environmental health issue. The ontology pattern specifies causal relations between concepts including persons, activities, exposures, environments and health risks on a conceptual level. On this basis, central notions like environmental stressors and active and passive exposure could be defined in Description Logic (DL) and automatically inferred from the content of a paper. Concepts were linked with data models and modelling methods used in a study in RDF. To test our pattern, we ask competency questions about main study characteristics and translate them to SPARQL queries over RDF content.
RESULTS: Results summarize epidemiological approaches, exposure concepts, findings, modelling methods, and data used for research in a transparent manner.

CONCLUSIONS: This ontology systematically distinguishes different methodological approaches. This not only helps us better understand and articulate methodological differences (and thus variations and validity of methods) in past studies, but also shows us the potential to better link the content of the vast amount of scientific publications on this topic regarding methods and data in a clear and systematic way.

Chan School of Public Health, Department of Environmental Health, Boston, USA, [8]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [9]Center for Perinatal, Pediatric and Environmental Epidemiology, Yale University Schools of Public Health and Medicine, New Haven, USA, [10]Yale School of Public Health, Department of Chronic Disease Epidemiology, New Haven, USA, [11]Yale School of Public Health, Department of Biostatistics, New Haven, USA

BACKGROUND/AIM: Epidemiologic studies have reported associations between residential proximity to unconventional oil and gas (UOG) development and adverse health outcomes. Proximity-based metrics are useful for retrospectively assessing aggregate exposures in large-scale studies, but do not provide information about specific exposures. We compared drinking water measurements of UOG-related chemicals to commonly-used proximity metrics and a newly-developed, groundwater-specific metric to advance understanding of exposure pathways.

METHODS: We compared UOG metrics with detection frequencies/concentrations of 64 organic and inorganic UOG-related chemicals/groups in residential groundwater from 255 homes (Ohio n=161, Pennsylvania n=94). Metrics included UOG well count within a buffer around the home, distance to nearest UOG well, inverse distance weighted (IDW) and ID-squared weighted (ID2W) well counts, and a water flow path-based metric (IDups: the inverse distance to the nearest UOG well upgradient of the residential groundwater source).

RESULTS: Twenty-seven chemicals were detected in ≥20% of water samples at concentrations generally below health-based standards. In Ohio, the odds of detecting toluene unexpectedly increased with increasing distance to nearest well (Odds Ratio [OR]: 1.48, 95% Confidence Interval [CI]: 1.12-1.95). In Pennsylvania, two organic chemicals/groups had reduced odds of detection with increasing distance to nearest well: 1,2-dichloroethene and benzene (OR: 0.46, 95%CI: 0.23-0.93) and m-and p-xylene (OR: 0.28, 95%CI: 0.10-0.80). Results were consistent across metrics. Correlations between inorganics and metrics were limited in both states (all $|\rho| \leq 0.28$).

CONCLUSIONS: Limited associations between metrics and UOG-related chemicals may indicate that water contamination by UOG occurs with low frequency/episodically, yielding temporal misalignments between measurements and metrics, chemical concentrations may reflect natural or other industrial sources, particularly for inorganics, more complex groundwater metrics may be needed to accurately capture drinking water exposure, and/or spatial metrics in health studies may be better reflecting exposure to other stressors or combinations of stressors.

P-0834 Predicting fine-scale daily NO_2 over Mexico City using an ensemble modeling approach

Mike He[1], Maayan Yitshak-Sade[1], Allan Just[1], Iván Gutiérrez-Avila[1], Michael Dorman[2], Kees de Hoogh[3,4], Robert Wright[1], Itai Kloog[1,2]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Department of Geography and Environmental Development, Ben-Gurion University of the Negev, Beer Sheva, Israel, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]University of Basel, Basel, Switzerland

BACKGROUND AND AIM: In recent years, there has been growing interest in developing air pollution prediction models to reduce exposure measurement error in epidemiologic studies. However, efforts for localized, fine-scale prediction models have been predominantly focused in the USA and Europe, with substantially less work conducted in low- and middle-income countries. Furthermore, the availability of new satellite instruments such as the TROPOspheric Monitoring Instrument (TROPOMI) provides novel opportunities for modeling efforts.

METHODS: We estimate daily ground-level nitrogen dioxide (NO_2) concentrations in the Mexico City Metropolitan Area at 1-km² grids from 2005 to 2019 using a multi-stage approach. In stage 1, we impute missing satellite NO_2 column measurements from the Ozone Monitoring Instrument (OMI) and TROPOMI using the random forest (RF) approach based on estimates from atmospheric ensemble models. In stage 2, we calibrate the association of column NO_2 to ground-level NO_2 using ground monitors and meteorological features using linear mixed-effects (LME) and RF models. In stage 3, we predict the stage 2 model over each 1-km² grid in our study area, then ensemble the results using a generalized additive model (GAM). In stage 4, we used RF to model the local component at the 200-m² scale by explaining the residual between predicted NO_2 from stage 3 and measured NO_2 at the monitoring stations.

RESULTS: The cross-validated R^2 of the LME and RF models in stage 2 were 0.69 and 0.75 respectively, and 0.83 for the ensembled GAM. Cross-validated root-mean-squared prediction error (RMSPE) of the GAM was 4.41 μg/m³. The RF model in stage 4 further explained on average 54% of the variation in the residual NO_2 concentrations.

CONCLUSIONS: Using novel approaches and newly available remote sensing data, our multi-stage model presented high cross-validated fits and reconstructs fine-scale NO_2 estimates for further epidemiologic studies in Mexico City.

P-0835 Horizon Shielding Factor: A Measure to Assess UV Exposure in Different Microenvironments

Jeanette Prinz[1], Arjan van Dijk[2], Douwe Siegersma[2], Edith van Putten[2], Gerjo Verhagen[2], Jan Vonk[2,3], Maartje Brouwer[2], John Bolte[1,2]

[1]Smart Sensor Systems Group, The Hague University of Applied Sciences, Delft, The Netherlands, [2]National Institute for Public Health and the Environment of the Netherlands (RIVM), Bilthoven, The Netherlands, [3]Wageningen Livestock Research, Wageningen, The Netherlands

BACKGROUND AND AIM: Skin cancer incidence rates have increased over recent decades worldwide. Ultraviolet radiation (UVR) is one of the main causes of skin cancer, as it induces mutations resulting from epidermal DNA damage. Exposure of people to UVR varies a lot depending on different factors such as the location of an individual. Additionally, UVR exposure can, for example, be lower due to shading effects. Being able to precisely measure UV exposure with a high repeatability on an individual level and to assess which microenvironments successfully reduce UV-exposure is, therefore, of high importance.

METHODS: In this analysis, we evaluated wearables at different body positions measuring ultraviolet radiation when worn during daily activities at different locations. First, we analyzed which of the body positions provide the most robust measurements. We then showed, that the measurements from the optimal body position can be used to infer the measurements taken at other positions. Using this optimal position, we devised a new measure, the horizon shielding factor, to evaluate the effect of horizon shielding. To explore if high/low horizon shielding factor values coincide with particular geospatial attributes, we inspected those values in their microenvironment on open street maps and found homogenous results per microenvironment.

CONCLUSIONS: The horizon shielding factor that has been developed in this project can be used to assess which microenvironments successfully reduce UV-exposure. It can be used in the future to find routes of transportation with less UV exposure due to horizon shielding. Systematic mapping of the horizon shielding factor in a given region may help policy makers and developers of new infrastructural projects to succeed in meeting the goals set by e.g. the National Climate Adaptation Strategy.

P-0837 Coordinated Program of Research on Multi-Pathway Community Exposures Associated with Unconventional Oil and Gas Development

Anna Rosofsky[1], Donna Vorhees[1]
[1]*Health Effects Institute, BOSTON, USA*

BACKGROUND AND AIM: People can be exposed to chemical agents (e.g., benzene) and non-chemical agents (e.g., noise, light, and vibration) released from unconventional oil and gas development (UOGD). Important knowledge gaps limit our understanding of the temporal and spatial variability of these exposures, as well as the UOGD processes leading to potential exposures. We aim to describe a new coordinated program of research funded by HEI Energy that will investigate potential exposure pathways between UOGD releases of noise and chemicals to air and water and people in communities affected by this development in major oil- and natural gas-producing regions of the USA.

METHODS: Three research teams from different institutions are collaborating to: 1) develop and evaluate a novel combined emissions and dispersion model (Tracking Community Exposures and Releases from UOGD [TraCER] model) that can be used for future UOGD emissions and exposure research nationally, and 2) conduct air quality and noise monitoring to improve understanding of potential acute and chronic human exposures and to evaluate the model in Colorado and Texas. Research teams assessing water-related exposures are combining existing data with machine learning and fate and transport models to evaluate exposure pathways between UOGD processes and water sources in Colorado, New Mexico, and Pennsylvania. The research will involve meaningful engagement with stakeholders in the study locations.

RESULTS: HEI Energy's coordinated program of research and stakeholder engagement will provide critical information to support decision making about how best to protect human health. It will produce publicly available data for use in future UOGD health studies and accountability research, as well as models and frameworks, that can be applied to any region in the USA, to connect specific UOGD processes to potential exposures to noise and chemicals in air and water.

P-0838 A large-scale personal monitoring of air pollution during pregnancy in the BiSC cohort

Ioar Rivas[1,2], Paula de Prado[1], Beatriz Jurado[1], Berta Miralles[1], Cecilia Persavento[1], Mar Álvarez-Pedrerol[1], Mark Nieuwenhuijsen[1], Cathryn Tonne[1], Teresa Moreno[2,3], Elisa Llurba[4], Maria Dolors Gómez-Roig[5], Maria Foraster[1], Xavier Querol[2,3], Payam Dadvand[1], Jordi Sunyer[1,2]

[1]Isglobal, Barcelona, Spain, [2]CSIC Associated Unit of Environmental Epidemiology and Air Quality (UA EEQ), Barcelona, Spain, [3]Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Barcelona, Spain, [4]Obstetrics and Gynaecology Department, High Risk Unit, Sant Pau University Hospital, Barcelona, Spain, [5]BCNatal, Hospital Sant Joan de Déu and Hospital Clínic, Universitat de Barcelona, Barcelona, Spain

BACKGROUND AND AIM: Large-scale monitoring of personal exposure to air pollution remains scarce, especially for pregnant women. We present the results of one of the largest monitoring campaigns of personal, home-indoor, and home-outdoor air pollution on pregnant women.

METHODS: The Barcelona Life Study Cohort (BiSC) is an ongoing cohort of 1086 mother-child pairs in Barcelona, Spain (2018 onwards). We monitored personal exposure to particulate matter ≤ 2.5 µm (PM2.5; filter samples for chemical characterisation), Black Carbon (BC; MicroAeth AE51), and personal, home indoor and outdoor nitrogen dioxide (NO2; Gradko passive tubes) at first (week 12, w12) and third trimester (w32) of pregnancy. The Covid pandemic forced us to stop data collection on PM2.5 and BC.

RESULTS: Weekly averaged concentrations (for both w12 and w32) for NO2 were 28.5 ± 12.0, 24.2 ± 11.7, and 38.9 ± 15.8 µg/m3 for personal exposure (N = 1680), indoors (N = 1685) and outdoors (N = 1570), respectively. Personal 48h average concentration was 21.0 ± 15.7 µg/m3 for PM2.5 (N = 498) and 1.63 ± 0.78 µg/m3 for BC (N = 374). Compared to current WHO 24-h outdoor air quality guidelines, 55.5% of PM2.5 samples and 89 % (outdoor) and 58.6% (personal) NO2 samples were above the recommendations (15 and 25 µg/m3, respectively). Correlations were higher between personal and indoor NO2 (spearman coefficient, r, >0.74) than between personal and outdoor (r <0.42) in both w12 and w32, due to a larger time spent at home (indoors). Moderate correlations between indoor and outdoor NO2 may be explained by potential indoor sources and indoor consumption of NO2 in gas-phase reactions.

CONCLUSIONS: BiSC is one of the largest studies on air pollution exposure measurements on pregnant women. Participants were exposed to a wide range of air pollutants' concentrations.

KEYWORDS: Pregnant women, Personal exposure assessment, Air Pollution

P-0840 High Resolution and Spatiotemporal Place-Based Computable Exposures at Scale

Erika Rasnick[1], Patrick Ryan[1,2], Andrew Vancil[1], Cole Brokamp[1,2]
[1]Cincinnati Children's Hospital Medical Center, Cincinnati, USA, [2]University of Cincinnati, Cincinnati, USA

BACKGROUND AND AIM: Place-based exposures, termed “geomarkers”, are powerful determinants of health, but are often understudied because of a lack of open data and integration tools. Existing DeGAUSS (Decentralized Geomarker Assessment for Mulitsite Studies) software has been successfully implemented in multi-site studies, ensuring reproducibility and protection of health information. However, DeGAUSS relies on transporting geomarker data, which is not feasible for high resolution spatiotemporal data too large to store locally or download over the internet. We aimed to expand the DeGAUSS framework for high resolution spatiotemporal geomarkers.

METHODS: In our approach, dates are coarsened to year and geographic coordinates are up-scaled to safe harbor geohashes, gridded locations with at least 20,000 residents created to adhere to legal privacy guidelines. The safe harbor geohashes are used to download appropriate subsets of exposure estimates from an online repository. Finally, exposure assessment is completed locally using exact date and location. We implemented this approach by curating spatiotemporal data by safe harbor geohash and year and developing an R software package to query the online database. We also developed a DeGAUSS container that wraps this functionality into portable software.

RESULTS: Two free and open source DeGAUSS containers for estimation of high resolution, daily ambient air pollutants were created. We compared the DeGAUSS approach to traditional ArcGIS and manual linkage methods using 5,000 locations and found >99% agreement. Further, DeGAUSS was implemented within the Environmental influences on Child Health Outcomes (ECHO) cohorts to estimate ambient air pollution for 17,587 study participants across 53 cohorts, representing 1,590,931 person-months of follow up time.

CONCLUSIONS: We developed a DeGAUSS approach that makes high resolution spatiotemporal datasets findable, accessible, interoperable, and reusable (FAIR). Further, we transformed a published exposure assessment model into a computable exposure for geomarker assessment at scale.

P-0842 Personal exposure to black carbon in Stockholm, Sweden, compared to fixed-site monitoring and dispersion modelling

Tom Bellander[1,2], Olena Gruzieva[1,2], Antonios Georgelis[2], Niklas Andersson[1], Christer Johansson[3,4], Anne-Sophie Merritt[1]

[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Centre for Occupational and Environmental Medicine, Region Stockholm, Stockholm, Sweden, [3]Department of Environmental Science, Stockholm University, Stockholm, Sweden, [4]Environment and Health Administration, SLB-analys, Stockholm, Sweden

INTRODUCTION AND AIM: Short-term studies of health effects from ambient air pollution usually rely on fixed site monitoring data or spatio-temporal models for exposure characterization, but the relation to personal exposure is often not known. We aimed to explore this relation for black carbon (BC) in central Stockholm.

METHODS: Families (n=36) with an infant, one parent working and one parent on leave, agreed to perform personal measurements of BC for the parents, with battery-operated aethalometers for 7 days. Routine monitoring data were from rural background (RB) and urban background (UB). Outdoor levels at home and work were estimated in 24h periods by dispersion modelling with real-time meteorological data. Global radiation, air pressure, precipitation, temperature, and wind speed data were achieved from an urban background station. All families lived within 4 km from the city center.

RESULTS: The average level of 24h personal BC was 370 (s.d. 200) ng/m3 for parents on leave, and 357 (s.d. 175) ng/m3 for working parents. The corresponding fixed-site monitoring observations were 148 (s.d. 139) at RB and 317 (s.d. 149) at UB. Modelled BC at home and at work were 493 (s.d. 228) and 331 (s.d. 173) ng/m3, respectively. UB, RB and air pressure explained only 21% of personal 24h BC variability for parents on leave and 25% for working parents. Modelled home BC and air pressure explained 23% of personal BC, and adding modelled BC at work increased the explanation to 34% for the working parents.
CONCLUSION: Both routine monitoring and modeled data explained less than 35% of variability in personal 24h observations of BC exposure. Any associated short-term health effects are likely to be underestimated in studies using such exposure data.

KEYWORDS: Black carbon, Personal exposure, Dispersion modelling

P-0845 Using mobile monitoring to map air pollution: A practical review

Jules Kerckhoffs[1], Kees de Hoogh[1,2], Gerard Hoek[1], Roel Vermeulen[1]
[1]Utrecht University, Utrecht, Netherlands, [2]Swiss Tropical and Public Health Institute, Basel, Switzerland

BACKGROUND AND AIM: Mobile platforms can capture the hyperlocal variation of air pollutants in a complex urban terrain, in a limited time, and with a limited number of (costly) high-resolution monitoring devices, but limited temporal coverage per location. In this practical review, we focus on the applicability of mobile monitoring to develop air pollution maps for use in epidemiological studies.

METHODS: We assessed a wide range of mobile monitoring studies and summarize findings and conclusions, focusing on the critical design issues. We highlight the trade-off between the temporal and spatial variability, as well as differences between pollutants. We specifically assessed spatial coverage, number of streets and repeats per street, on-road versus of-road measurements, need for a reference site and statistical modeling options.

RESULTS: Robust mobile LUR models can be made with about 10% of the streets in the domain and limited (or no) repeats. Street segments with similar characteristics serve as pseudo repeats, meaning LUR models can be developed based on street segments with mobile measurements only measured once, if there is enough spatial and temporal coverage by including all spatial characteristics of the domain and measure during different parts of the day, days of the week and season. This also means that there is no critical need to temporally correct all measurements. To retain the local variation as much as possible, it is advised to keep the spatial resolution as low as possible (< 200m). It is possible to add data-only mapping on top of a LUR model in a mixed-model framework. Here, a LUR model is used to create a base map, and with more measurements more local variation can be added to the map.

CONCLUSIONS: Mobile monitoring is a cost-effective scalable approach to map air pollution at fine spatial resolution.

P-0848 Exposure Errors due to Inaccurate Residential Addresses and their Impact on Epidemiological Associations: Evidence from a National Neonate Dataset

Ruthie Harari-Kremer[1,2], Ronit Calderon-Margalit[1], Yuval Yuval[3], David Broday[3], Itai Kloog[4], Raanan Raz[1]
[1]Braun School of Public Health and Community Medicine, The Hebrew University – Hadassah, Israel, Jerusalem, Israel, [2]The advanced School for Environmental Studies, The Hebrew University, Jerusalem, Israel, [3]Civil and Environmental Engineering, Technion, and Technion Center of Excellence in Exposure Science and Environmental Health, Haifa, Israel, [4]Department of Geography and Environmental Development, Ben-Gurion University of the Negev, Beer Sheva, Israel

BACKGROUND AND AIM: Studies assessing the associations between prenatal air pollution exposures and birth outcomes commonly use maternal addresses at the time of delivery as a proxy for residency throughout pregnancy. In large-scale studies, administrative addresses are widely used as a proxy for maternal residency throughout pregnancy under the assumption that they are up-to-date. However, if residential mobility is not reported, inaccurate addresses may introduce exposure estimation errors that might affect the study results.
The aim of this study is to examine the use of the Israeli population registry addresses to assign exposure estimations and evaluates the impact of inaccurate addresses on estimates and association measures of prenatal exposures with congenital hypothyroidism.

METHODS: We used morbidity data from the national program for neonatal screening for 2009-2015 and address data from two sources. We selected neonates with geocoded addresses from both sources (N=685,491) and developed an address comparison algorithm. Next, we assigned neonates with exposures, evaluated exposure assessment differences, and used multivariable logistic regression models to assess the impact that these differences have on association measures.

RESULTS: We found that most of the exposure differences between neonates with addresses from both sources were around zero and had a leptokurtic distribution density, with most values being zero. Additionally, associations between exposure and congenital hypothyroidism were comparable, regardless of address source and when we limited the model to neonates with identical addresses. .

CONCLUSIONS: For our study population and based on the exposure estimation models we used, we found that ignoring residential inaccuracies results in only a small bias of the associations towards the null. The results validate the use of administrative residential addresses for exposure assessment in studies of PM, NO2, and NOX exposures when more detailed residential data are not available.

KEYWORDS: Exposure errors, particulate matter, nitrogen oxides, congenital hypothyroidism.

P-0851 Application of hybrid modelling techniques in the assignment of estimates of personal exposure to ambient air pollution: the MELONS study

Dylan Wood[1,2], Dimitris Evangelopoulos[1,2], Benjamin Barratt[1,2], Heather Walton[1,2], Klea Katsouyanni[1,2,3]
[1]MRC Centre for Environment and Health, Environmental Research Group, Imperial College London, London, UK, [2]NIHR HPRU in Environmental Exposures and Health, Imperial College London, London, UK, [3]Department of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

KEYWORDS: Air pollution, Personal exposure

BACKGROUND/AIM:
Hybrid modelling of ambient air pollution has the potential to improve the accuracy of personal exposure estimates assigned to individuals in cohort studies. Traditional modelling techniques neglect the movement of individuals and the gradients of exposures observed when indoors and in transport microenvironments. The present study aimed to assess the changes in assigned personal exposures after adjustment by estimated time-activity patterns derived from a representative sample.

METHODS: Travel survey data for ~19,000 respondents aged 50 and older, in addition to hourly residential CMAQ-urban dispersion model estimates of NO_2, PM_{10} and $PM_{2.5}$, were applied to each individual. The difference between these estimates and those adjusted for estimated location, transport mode and microenvironment were then calculated before aggregation by age and spatially across London (LHEM concentration factors). Ninety members of the COPE study were included in the present analysis and annual average concentration estimates from the nearest monitor were assigned before adjustment via the aforementioned LHEM concentration factors.

RESULTS: Annual average concentrations ($\mu g/m^3$) from the nearest monitor were assigned to each COPE individual for NO_2 (mean: 43.8; SD: 17.3), PM_{10} (21.4; 4.7) and $PM_{2.5}$ (12.7; 2.37). After adjustment for estimated time-activity by LHEM concentration factors, assigned personal estimates reduced to 15.5 (6.14), 6.42 (1.47) and 7.61 (1.34), respectively. Before- and after- adjustment estimates were highly correlated for NO_2 (r: 0.95) and $PM_{2.5}$ (0.96); suggesting that the ranking of estimates showed little change after adjustment. However, for PM_{10} (0.82) there was some change in the ranking of exposures after adjustment. The determinants of this change are explored.

CONCLUSIONS: Leveraging previously collected representative data through methods similar to those presented here, epidemiological studies may have the ability to incorporate complex population-level time-activity information into personal exposure estimates; potentially enhancing assignment using fixed-site monitors or traditional modelling techniques.

P-0853 Spatio-temporal Land Use Regression Modelling of PM2.5 Levels in Athens, Greece

Vasiliki Grigoriadou[1], Konstantina Dimakopoulou[1], Evangelia Samoli[1], Klea Katsouyanni[1,2]
[1]Department of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, Athens, Greece, [2]MRC Centre for Environment and Health, Environmental Research Group, Imperial College London, UK NIHR HPRU in Environmental Exposures and Health, Imperial College London, London, UK., London, UK

BACKGROUND & AIM: There is sufficient evidence of the adverse effects of exposure to short- and long-term particulate matter (PM) on health. However, in some study areas the PM2.5 monitoring network is spatially sparse. This may limit the possibility to model PM2.5 for subsequent use in large scale epidemiological studies. Our aim was to enhance our PM2.5 database in order to develop a spatio-temporal land use regression (LUR) model that estimates PM2.5 within the greater Athens area, Greece.

METHODS: The PM2.5 database in Athens was enhanced by using PM10 and nitrogen dioxide (NO2), meteorological and spatial variables to predict daily PM2.5 concentrations at the location of fixed monitors measuring PM10 but not PM2.5. This analysis was performed using regression modelling and a machine learning method (Random Forest-RF), as well as a combination of the two. Following, we developed a spatio-temporal LUR model for predicting PM2.5, by including linear and smooth functions of spatial and temporal covariates and a bivariate smooth thin plate function. The final set of explanatory variables was selected based on the adjusted-R2. We tested the predictive ability of the final model using 10-fold cross validation (CV).

RESULTS: We found that the combination of predictions by the regression model and the RF performed best, with CV-R2 of 98.2% and a Mean Square Error of 2.1, for the study period 2007-2019. The CV-R2 for the developed spatio-temporal PM2.5 LUR model was 81.8%.

CONCLUSIONS: The applied database enhancement method provided improved input for modeling PM2.5 with adequate accuracy. This is a useful tool for subsequent use in health effect studies, since exposure to PM2.5 especially, is a strong risk factor of morbidity and mortality.

P-0855 Application of low-cost, commercially available, wearable particulate matter sensors: a comparison

Maartje Brouwer[1], Jan Vonk[1,2], Gerjo Verhagen[1], Edith van Putten[1], Wouter Hendricx[1], Douwe Siegersma[1], Arjan van Dijk[1], John Bolte[1,3]

[1]National Institute for Public Health and the Environment of the Netherlands (RIVM), Bilthoven, The Netherlands, [2]Wageningen Livestock Research, Wageningen, The Netherlands, [3]Smart Sensor Systems research group, The Hague University of Applied Sciences (THUAS), Delft, The Netherlands

BACKGROUND AND AIM: Low-cost, wearable PM sensors claim to measure air quality with high spatiotemporal resolution, potentially improving exposure assessment in studies on air pollution. Exposure during commutes or indoor/outdoor leisure activities is difficult to accurately estimate with models and activity diaries. Short-term fluctuations or peak concentrations could be more relevant than annual averages for some health endpoints. High resolution data from PM wearables can be linked to acute bodily responses, or for identification of high exposure activities and hotspots. Here, we investigated performance of different PM wearables.

METHODS: Five commercially available PM wearables were purchased in triplo: AirBeam2, Atmotube PRO, Plume Labs Flow 2, Wynd Air Quality Tracker and Nova Fitness SDL607. Devices were placed at two national air quality monitoring stations for several consecutive days (June/July 2020). Measurement intervals varied per wearable (1 sec. - 5 min). All provided PM2.5 data, which was the main interest as respirable fraction linked to several health effects. Agreement (spearman correlation) between and within wearables was investigated (5 min. averages), and with hourly reference data.

RESULTS: The AirBeam was omitted from analysis due to missing data. High agreement for PM2.5 was found within and between the Atmotube, Wynd and SDL607 wearables. Agreement with reference PM2.5 data was limited. Some short-term peaks did not appear in the (hourly) reference, but were consistently detected by several wearables.

CONCLUSIONS: Their absolute measurement value might not precise, but these PM wearables showed consistent and repeatable patterns, indicating that they can distinguish high vs. low exposure situations at a high temporal resolution. Missing data and connection problems and unknown internal calibration algorithms are issues for application. Based on several (user) parameters, the best performing wearable (Atmotube PRO) was further investigated and applied in volunteer experiments.

KEYWORDS:
Air pollution; PM; wearable; sensor; exposure assessment.

P-0858 2-Dimensional Benchtop X-ray Fluorescence Approaches to Exposure Assessment

Aaron Specht[1]
[1]*Purdue University, West Lafayette, USA*

INTRODUCTION: Advances in benchtop micro-XRF allow for the potential expansion of 2D exposure assessment for epidemiological and toxicological samples down to a spatial resolution of 10um for simultaneous 30+ element quantification. We aimed to identify the advantages of this method in comparison to other more traditional methods.

METHODS: We used a comparison of methodologies between synchrotron XRF at the Advanced Photon Source at Argonne National Lab, laser ablation inductively coupled plasma mass spectrometry (LA-ICP-MS), and micro-XRF using a Bruker M4 Tornado system in order to measure sectioned human tibia bone samples, paraffin embedded rat lung, and sectioned human teeth samples to identify potential variations among the techniques by specimen type, limits of detection, and quantification.

RESULTS: We found strong agreements between the quantification results from each method (>90% agreement for samples). for a 1 second dwell time, we identified a detection limit of 4.8 ppm for a single 10um pixel. Using a longer dwell time or summation of pixels results in correspondingly lower detection limits. Quantification differences between approaches, particularly with LA-ICP-MS where data is normalized to a major element, did not have broad impacts on the data.
CONCLUSION: The detection limit of the micro-XRF was within range to analyze teeth and bone effectively with short measurement times. for tissue based toxicological studies, the time per pixel will need to be increased to take advantage of the 10um resolution, but for many epidemiological tissues such as teeth, the benchtop XRF can accurately quantify exposures. Micro-XRF has significant advantages over LA-ICP-MS sample destruction or the necessity for beamtime at a synchrotron source.

P-0859 Measuring the commuter exposure to air pollution in Lyon

Marie Ramel-Delobel[1,2,3], Cosimo Peruzzi[3], Saverio De Vito[4], Grazia Fattoruso[4], Béatrice Fervers[1,2], Pietro Salizzoni[3], Thomas Coudon[1,2,3]

[1]Department Prevention, Cancer, Environment, Centre Léon Bérard, Lyon, France, [2]INSERM UMR 1296 Radiations Défense Santé Environnement, Centre Léon Bérard, Lyon, France, [3]UMR 5509 Fluid Mechanics and Acoustics Laboratory, Central College of Lyon, Ecully, France, [4]ENEA Centro Ricerche Portici, Dipartimento Tecnologie Energetiche e Fonti Rinnovabili, Divisione Fotovoltaico e Smart Devices (TERIN-FSD), Portici, Italy

BACKGROUND AND AIM: Daily travel can represent a significant part of personal exposure to air pollution, up to 30% of the daily inhaled dose, despite very short exposure times (3-6% of circadian time). This exposure varies considerably depending on the mode of transport. This study aims to quantify the difference in exposure during daily mobility by carrying out a microsensor measurement campaign. The data collected will be used in epidemiological studies evaluating the link between chronic exposure to air pollution and the risk of breast cancer.

METHODS: We have undertaken a six-week measurement campaign (from November to December 2021) on three different routes in the metropolitan city of Lyon (France). These routes were chosen to be representative of different urban areas (e.g. city centre, periphery, vegetated areas). The measurements were taken twice a day (during the morning and evening peak hours) using simultaneously four different modes (walk, bike, car and public transport). Two different portable air quality sensors were used: the MONICA sensors (developed by ENEA) measuring PM1, PM2.5, PM10, NO2, CO and O3 and the AirBeam 2 sensors (provided by ATMO AURA) measuring the particulate matters.

RESULTS: In total, 242 measurements were made. Concerning PM10, PM2.5 and PM1.0, the highest concentrations were observed in the underground microenvironment. Cycling and walking were the most exposed modes in terms of NO2. Except for CO, the lowest concentrations were measured by car. Concerning the exposure ratios between modes, the highest variation was observed for PM, the lowest for ozone.

CONCLUSIONS: Preliminary results show that private car users are generally affected by lower levels of pollutants compared to the other modes, except for CO. Nevertheless, the concentrations by car can be strongly influenced by the type of ventilation used (internal/external air recirculation, windows open/closed).

P-0860 Comparing air quality guidelines of fine particulate matter (PM2.5) on excess mortality: a country-wide small-area assessment in Great Britain

Rochelle Schneider[1,2,3,4], Pierre Masselot[2], Christina Mitsakou[5], Karen Exley[5], Antonio Gasparrini[2,4,6]
[1]European Space Agency, Φ-Lab, Frascati, Italy, [2]Department of Public Health, Environments and Society, London School of Hygiene & Tropical Medicine (LSHTM), London, UK, [3]European Centre for Medium-Range Weather Forecast (ECMWF), Reading, UK, [4]The Centre on Climate Change and Planetary Health, London School of Hygiene & Tropical Medicine (LSHTM), London, UK, [5]Air Quality and Public Health Group, Environmental Hazards and Emergencies Department, UK Health Security Agency, Chilton, UK, [6]Centre for Statistical Methodology, London School of Hygiene & Tropical Medicine (LSHTM), London, UK

BACKGROUND/AIM: The World Health Organization (WHO) has recently revised its air quality guidelines for fine particulate matter ($PM_{2.5}$), decreasing the recommended annual threshold from 10µg/m³ to 5µg/m³. Current limits in Great Britain are set to 25µg/m³ in England and Wales and 10µg/m³ in Scotland, and there is an ongoing debate to revise such thresholds. We provide a comprehensive assessment of the exposure to $PM_{2.5}$ and associated excess mortality in the whole population of Great Britain.

METHODS: We collected data on mortality and $PM_{2.5}$ for 41,739 small-area units during 2008-2018. Yearly exposure averages were assigned from a 1x1km grid of daily $PM_{2.5}$ levels produced by a spatio-temporal satellite-based machine learning model. Age-specific deaths were computed from small-area population data and regional age-specific rates. We estimated excess deaths and standardized rates associated with exposure to $PM_{2.5}$ overall and above different thresholds using published exposure-response functions.
RESULTS/DISCUSSION: The population-weighted yearly average of $PM_{2.5}$ across Great Britain decreased from 12.9µg/m³ to 10.4µg/m³ from 2008 to 2018. The percentage of the 60-million population exposed to levels higher than 10µg/m³ dropped from 93.1% to 63.8%. Despite the decrease, no area was compliant with the new WHO limit of 5µg/m³ in 2018. In 2018, we expected a total of 39,737 (95%eCI: 32,445-46,600) excess deaths due to exposure to $PM_{2.5}$, corresponding to a standardized rate of 74.4 (60.8-87.3) per 100,000 person-years. Restricting the levels below the 10µg/m³ and 5µg/m³ would have avoided 2,923 (2,372-3,448) and 20,307 (16,525-23,890) of these deaths, respectively.
CONCLUSION: This study indicates a strong decrease in $PM_{2.5}$ across Great Britain in the last decade. While all areas are below with current national limits, straightening these thresholds would bring substantial health benefits. Complying with the new WHO guideline of 5µg/m³ would require exceptional efforts, as such a level was not matched anywhere.

P-0861 Acquisition and Analysis of Crowd-Sensed Traffic Data at Multiple Spatial Scales

Jenni Shearston[1], Sebastian Rowland[1], Jemaleddin Cole[2], Steven Chillrud[3], Micaela Martinez[4], Markus Hilpert[1]
[1]Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [2]Website Developer, USA, [3]Lamont-Doherty Earth Observatory of Columbia University, Palisades, USA, [4]Department of Biology, Emory University, Atlanta, USA

BACKGROUND/AIM: Measuring traffic activity at high spatial (e.g., street level) and temporal (e.g., sub-hourly) resolution is critical for studying traffic-related exposures and evaluating the efficacy of traffic-reduction interventions, yet such data is not easily available. Crowd-sensed traffic data offer great promise to fill this resource gap, but often require complex collection pipelines, image processing, and GIS manipulation before use in exposure, health, or policy evaluations. We present a validated approach for acquiring and analyzing timeseries of crowd-sensed traffic data, at multiple spatial scales.

METHODS: We developed software to automatically download tiles of crowd-sensed Google traffic congestion maps for a user-specifiable region of interest. To support research, we used image-processing to identify the relevant features of interest (i.e., the congestion-color-coded streets), and aggregate the traffic data to user-specified time scales and spatial polygons (e.g., census tracts, zip codes). We performed quality assurance to assess the validity and reproducibility of our approach.

RESULTS: We demonstrate broad and international applicability of our method with examples of Manhattan in New York City and Mexico City. We also illustrate that the data has sufficient resolution and sensitivity to quantify decreases in traffic congestion due to COVID-19-related social distancing policies in the South Bronx in New York City. Our analysis identified decreases at the census tract level as well as for individual street segments, using traffic data at three-hour increments.

CONCLUSIONS: The methods presented here are broadly scalable and easy to replicate by other researchers across the globe, including communities with limited on-the-ground monitoring. Crowd-sensed traffic data have great promise for empirically modeling traffic congestion, evaluating interventions, assessing exposure for epidemiologic studies, and combining with other neighborhood level characteristics for environmental justice evaluations and other studies.

P-0862 Agreement between mothers and sons in early life exposures assessment in a multicentric case-control study investigating risk factors of testicular germ cell tumors in young adults (TESTIS study)

Astrid Coste[1], Aurélie Danjou[2], Olivia Pérol[1], Lény Grassot[1], Liacine Bouaoun, Joachim Schüz[2], Fervers Béatrice[1]
[1]Centre Léon Bérard, Prevention, Cancer, Environment Department, INSERM UMR 1296 Radiations: Defense, Health, Environment, Lyon, France, [2]International Agency for Research on Cancer, Lyon, France

BACKGROUND: Testicular germ cell tumor (TGCT) is the most common tumor usually occurring in young men between 15-45 years old. Environmental early life exposures are suspected to play a role in the etiology of TGCT. Assessment of early life exposures by subject in retrospective study designs might be prone to recall bias. Based on the TESTIS case-control study on TGCT, we investigated agreement between mothers and sons in early life exposures assessment.

METHODS: The TESTIS study is a multicentric case-control study, conducted between 2015 and 2018 in 20 University Hospitals in France, aiming to examine TGCT risk factors. 454 incident TGCT cases were recruited and matched to 670 controls on year of birth and hospital centers. Parental occupations at birth, prenatal and perinatal characteristics, and domestic use of pesticides during puberty were collected from both mothers and sons among 547 (48.6%) participants. Kappa coefficient, sensitivity, specificity and Pearson's correlation coefficient statistics were calculated to estimate the agreement, overall and separately between cases and controls.

RESULTS: Agreement varied from Cohen's Kappa values between 0.05 (use of pesticides on indoor plants during puberty) and 0.66 (maternal occupation status at birth) according to the types of exposure. The highest Kappa or correlation coefficients were observed for maternal occupation status at birth (Kappa, CI95%: 0.66[0.59-0.73]), some perinatal characteristics (admission to neonatology, Kappa: 0.61[0.48-0.74]; birth weight, correlation's coefficient: 0.85, $p<0.001$) and some domestic use of pesticides (pets' treatment, Kappa: 0.57[0.50-0.64]). Agreement was slightly higher among cases than controls.
CONCLUSION: Our study showed important variations in agreement between mother's and son's declarations in early life characteristics and pesticides exposures. These results provide important information for retrospective assessments in life-course epidemiology and potential recall bias in early life characteristics and exposures relevant to assess TGCT risk.

KEYWORDS: child-parent agreement, recall bias, retrospective study

P-0863 Reliability of low-mass toenail samples as biomarkers of chronic metal exposure

Joyce Lin[1], Lily Koffman[2], Mina Tehrani[1], Rui Chen[1], Dale Sandler[3], Katilyn Lawrence[3], W. Braxton Jackson II[4], Gurumurthy Ramachandran[1], Lawrence Engel[5], Ana Rule[1]

[1]Department of Environmental Health and Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA, [2]Department of Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA, [3]Epidemiology Branch, National Institute of Environmental Health Sciences, National Institutes of Health, Research Triangle Park, USA, [4]Social & Scientific Systems, Inc., Durham, USA, [5]Department of Epidemiology, University of North Carolina Gillings School of Public Health, Chapel Hill, USA

BACKGROUND/AIM: Toenails are a promising matrix to assess chronic metal exposure, but questions remain about the sample mass requirements and temporal variability of metals measured in this matrix. This study evaluates the reliability of a ~25 mg toenail sample (1 - 2 clippings) for metals analysis and the temporal variability of the toenail biomarker over 2 - 4 years in a cohort of men from the Gulf Long-term Follow-up (GuLF) Study.

METHODS: Toenail samples from 106 GuLF Study participants were collected at two visits 2 - 4 years apart and analyzed for 18 metals (Al, As, Ca, Cd, Co, Cr, Cu, Fe, Hg, Mg, Mn, Mo, Ni, Pb, Sb, Se, V, Zn) using inductively coupled mass spectrometry (ICP-MS). Participants with samples >120 mg (n=24) were selected for 3x repeated analysis using ~25 mg sub-samples. Intraindividual correlation coefficients (ICC) were used to assess the reliability of the sub-sample mass. Linear mixed models were used to assess toenail metal correlations over time.

RESULTS: ICCs and correlations over time were not reported for Cd, Co, Mo, Sb, and V which were detected in less than 60% of the samples. ICCs for the remaining metals ranged from 0.48 for Fe to 0.88 for Cu. Correlations of metal concentrations over time ranged from 0.06 to 0.66 with Ca (0.06), Zn (0.11), and Al (0.13) with the lowest estimated correlations and Cu (0.50), Hg (0.54), and Se (0.66) with the highest. As, Co, Mn, and Pb had correlations at 0.31, 0.32, 0.41, and 0.33, respectively.
CONCLUSION: Findings from this study suggest that a ~25 mg subset can be used for the analysis of most toenail metals with ICP-MS. As, Co, Cu, Hg, Mn, Pb and Se concentrations in toenail clippings can reasonably reflect chronic exposures over multiple years in the Gulf population.

KEYWORDS: Metals, Exposure Assessment

P-0865 Linking subject-specific environmental exposures to individual cohort data: an example with the UK Biobank

Jacopo Vanoli[1,2], Pierre Masselot[1], Malcolm Mistry[1], Antonio Gasparrini[1]
[1]London School of Hygiene and Tropical Medicine, London, UK, [2]Nagasaki University School of Tropical Medicine and Global Health, Nagasaki, Japan

BACKGROUND AND AIM: Health effects of spatially ubiquitous environmental factors are optimally assessed through cohort epidemiological analyses. However, their application requires the reconstruction of highly granular exposures summaries, which can show high variability within and between individuals. Availability of improved maps with finely resolved spatio-temporal measurements can address those limitations, but the linkage procedure poses methodological and practical problems. This study aims to describe a linkage framework to couple precise environmental measurements to subject-specific cohort data, maximizing the exposure information and accounting for privacy constraints and residential mobility.

METHODS: Accomplishment of this goal is conditional to the availability of subjects' residential mobility histories and geographical locations. The linkage process is carried out in three steps: (1) Spatial alignment of GIS exposure maps and the residential addresses, based on interpolation methods to avoid locations back-tracing; (2) Reconstruction of exposure histories accounting for residential changes in addresses during the follow-up; (3) Flexible definition of exposure summaries consistent with alternative research questions and epidemiological designs.

RESULTS: This procedure is illustrated with the linkage and processing of daily predictions of exposure of temperature and particulate matter to 502,408 participants of the UK Biobank cohort from gridded spatio-temporal maps across Great Britain. The outcome of the process is concretized with the extraction of exposure summaries defined at daily level, suitable for the investigation of complex temporal dependencies. Particularly, they can be applied to compute averages of the two stressors, subsequently included in traditional analyses of short- and long-term associations.

CONCLUSIONS: Embedding highly informative contextual data in cohorts characterized by extensive individual phenotypes and genetic information allows the quantification of independent and synergistic health risks associated with environmental exposures. Further frameworks development with public cohort data should be encouraged to ensure reproducibility and extension of epidemiological analyses.

P-0866 Predictors of dietary intake of acrylamide in pregnancy and teenage life - A Danish Birth Cohort Food Frequency Questionnaire Study

Manik Kadawathagedara[1], Anne A Bjerregaard[2,3], Thorhallur I Halldorsson[3], Anne Lise Brantsater[4], Sjurdur F Olsen[3], Marie Pedersen[1,3]

[1]Section of Epidemiology, Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [2]Center for Clinical Research and Prevention, Bispebjerg and Frederiksberg Hospital, Frederiksberg, Denmark, [3]Department of Epidemiological Research, Statens Serum Institut, Copenhagen, Denmark., [4]Division of Climate and Environmental Health, Norwegian Institute of Public Health, Oslo, Norway

BACKGROUND AND AIM: Acrylamide forms in a wide variety of commonly consumed food and beverages such as fried potatoes, chips, biscuits, breakfast cereals, bread, and coffee as a result of high temperature cooking. In animals, acrylamide cause tumors, neurotoxicity, developmental, and reproductive effects. Acrylamide crosses the human placenta. Prenatal exposure to acrylamide from diet has been associated with fetal growth restriction and obesity whilst exposure in adulthood have been linked with cancers. However, the impact on health remains poorly understood as most studies have focused on cancer in adults and on assessment of dietary intake at a single time in adult life. We aimed to estimate dietary intake and predictors of acrylamide during pregnancy and puberty of the Danish National Birth Cohort participants.

METHODS: We included 68,419 women who completed a 360-item food frequency (FFQ) questionnaire at 25 weeks during pregnancy and 36,903 adolescents who completed a 150-item FFQ at age 14 years. Median [p5 – p95] acrylamide intakes were estimated for 50 food items by combining FFQ data with Danish food monitoring data in µg/kg and µg/kg per kg body weight (BW).

RESULTS: The median acrylamide intake of mothers was 27.0 [12.4 – 53.6] µg/day (0.41 [0.18–0.87] µg/BW/day) and adolescents' median intake was 29.3 [13.1 – 68.0] µg/day (0.55 [0.23–1.32] µg/BW/day). Out of 12 food groups evaluated, the main contributors were fried potatoes (24% for women and 40% for adolescents), chocolate, licorice, and dried fruits (18% for women and 13% for adolescents), and sweet bakery items for women (13%) and crisps for adolescents (11%).

CONCLUSIONS: We observe a wide range of acrylamide intakes in both populations. The estimated median intake of the adolescents was higher than the intake of the mothers. Foods contributing to acrylamide intake differed slightly.

KEYWORDS: Acrylamide, diet, pregnancy, adolescent, food contaminant, food contributor's, critical windows

P-0869 Evaluating Predictions of ELAPSE and Google Air View-based Mixed-effects LUR Models for Air Pollution in Copenhagen, Denmark

Shali Tayebi[1], Zorana Andersen[1], Youn-Hee Lim[1], Roel Vermeulen[2], Jules Kerckhoffs[2], Jibran Khan[3,4], Thomas Ellermann[3], Marie Bergmann[1], Seyed-Mahmood Taghavi-Shahri[1], Tom Cole-Hunter[1], Laust Mortensen[1,5], Theis Lange[1], Esben Budtz-Jørgensen[1], Ole Hertel[6], Kees Meliefste[2], Kees de Hoogh[7,8], Jie Chen[2], Gerard Hoek[2], Bert Brunekreef[2], Rasmus Reeh[9], Christian Gaarde Nielsen[9], Joel Schwartz[10], Rudi Westendorp[1], Steffen Loft[1], Heresh Amini[1]

[1]University of Copenhagen, Copenhagen, Denmark, [2]Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, The Netherlands, [3]Department of Environmental Science, Aarhus University, Aarhus, Denmark, [4]Danish Big Data Centre for Environment and Health (BERTHA), Aarhus University, Roskilde, Denmark, [5]Statistics Denmark, Copenhagen, Denmark, [6]Department of Ecoscience, Aarhus University, Aarhus, Denmark, [7]Swiss Tropical and Public Health Institute (Swiss TPH), Basel, Switzerland, [8]University of Basel, Basel, Switzerland, [9]City of Copenhagen and Copenhagen Solution Lab, Copenhagen, Denmark, [10]Harvard TH Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Fine scale exposure-assessment is needed for epidemiological studies on long-term health effects of air pollution (AP). We aimed to evaluate a) predictions of hyperlocal Google Air View-based mixed-effects land use regression (G-LUR) models for long-term AP for 2018-2020, and of ELAPSE (Effects of Low-Level AP: A Study in Europe) project LUR models for 2010 in Copenhagen, Denmark, and b) agreement of predictions between these two models.

METHODS: We analyzed concentrations and Spearman correlations of ultra-fine particles (UFP), nitrogen dioxide (NO2), and black carbon (BC) by G-LUR models that predicted AP across ~30,000 streets for 2018-2020, and of NO2, BC, and fine particulate matter (PM2.5) by ELAPSE models that predicted 2010 concentrations at 100m spatial resolution (ELAPSE10). Correlation of pollutants between the two models were also assessed. Using annual mean data for 2010 and 2019 monitored at regulatory network stations, 2019 predictions were estimated for ELAPSE (ELAPSE19) NO2 and PM2.5.

RESULTS: According to the G-LUR predictions, the long-term mean (SD) was 14,120 (8,849) particles/cm³ for UFP, 16.8 (8.3) µg/m³ for NO2, and 1.1 (0.4) µg/m³ for BC. According to the ELAPSE19 predictions, these were 21 (3.4) µg/m³ for NO2, and 11 (1.3) µg/m³ for PM2.5. The mean (SD) for BC was 1.6 (0.3) µg/m³ based on ELAPSE10. The correlation amongst predictions was highest between BC and NO2 (0.79 for G-LUR; 0.64 for ELAPSE). Between G-LUR and ELAPSE predictions, the highest correlation was for G-LUR NO2 and ELAPSE BC (0.64). The estimates of NO2 between the two models were moderately correlated (0.63), while for BC this was 0.51.

CONCLUSIONS: Air pollution is a public health concern in Copenhagen, Denmark. There was moderate correlation between BC and NO2 predicted by both models. The moderate correlation between G-LUR and ELAPSE predictions suggests that spatial patterns have been fairly stable over 10-years.

P-0870 Analysis of chlorinated volatile organic compounds in exhaled breath using Proton Transfer Reaction Time-of-Flight Mass Spectrometry (PTR-TOF-MS)

Jung Hyun Lee[1], Marwan Alajlouni[1], Alaina Bryant[1], Brandon Tso[1], Sujana Anjani Vemuru[1], Wendi Yuan[1], Ian Gregory Kurz[1], Thomas Edward Wallace[2], Brandon E. Boor[3], Antonios Tasoglou[4]

[1]School of Health Sciences, Purdue University, West Lafayette, USA, [2]Martinsville Indiana Superfund Site Association, Martinsville, USA, [3]Lyles School of Civil Engineering, Purdue University, West Lafayette, USA, [4]RJ Lee Group Inc., Monroeville, USA

BACKGROUND: Tetrachloroethylene (PCE) and Trichloroethylene (TCE) are neurotoxic and probable/known human carcinogens. Inhabitants' exposure to these and other chlorinated volatile organic compounds in communities near hazardous waste sites is common, but difficult to characterize.
AIM: The objective of this study is to quantify PCE and TCE in exhaled breath as an exposure measure in an epidemiological study of children 6 to 11 years of age living in a community that overlays multiple groundwater contamination sites with PCE and TCE being primary contaminants.

METHODS: Exhaled breath samples were collected from each participant on two days, one school day and one weekend day. Participants were instructed to avoid certain activities prior to the sample collection to reduce potential interferences. Information on children's activities on the sampling day was collected by a short survey. Participants were instructed to blow through a mouthpiece into a proton transfer reaction time-of-flight mass spectrometer (PTR-TOF-MS). Side-by-side breath samples were collected from a subgroup of participants using Tedlar bags that were analyzed by a U.S. EPA standard method (TO-15). Forty-one children participated in the breath testing, with thirty-nine tested on two days and two tested on one day.

RESULTS: Eleven participants (27%) had detectable concentrations of PCE in their exhaled breath on both days (overall mean = 0.27 ppb, SD = 0.12 ppb). Two participants had detectable levels of TCE (0.28 and 0.37 ppb). The differences in PCE concentrations were significant between school days and weekend days ($p = 0.035$) and between samples collected in the morning and in the afternoon ($p = 0.021$).

CONCLUSIONS: PTR-TOF-MS proved to be a more sensitive method than Tedlar bags analyzed by TO-15. The results will be used to estimate PCE exposure to assess the association between exposure and neurobehavioral performance among children.

KEYWORDS: Tetrachloroethylene, Exhaled breath, PTR-TOF-MS, Superfund site

P-0871 Vegetation Index Processing and Implications for Calculating Greenness in Population Health Studies

Kelvin Fong[1], Karen Chen[2], Michelle Bell[1]
[1]Dalhousie University, Halifax, Canada, [2]Yale University, New Haven, USA

BACKGROUND: Surrounding vegetation (greenness) is an emerging exposure in population health studies. Yet, methods for processing satellite remote sensing data to calculate greenness are inconsistent across studies, which undermines comparisons of the extent of greenness health effects.
AIM: We surveyed the literature for differences in calculating greenness indices and compared their summary values and classification into greenness quartiles (i.e., least to most green).

METHODS: We identified three main differences in vegetation index processing: 1) averaging period (growing season vs. entire year), 2) exclusion of negative values, and 3) cloud masking (filtering out high cloud cover pixels). for each processing regime, we calculated the normalized vegetation difference index (NDVI) and enhanced vegetation index (EVI). We then assessed area-weighted averages at the Census tract level and compared greenness from the different methods in North Carolina.

RESULTS: Differences in processing led to considerable differences in greenness summary values. NDVI and EVI were higher when the averaging period was restricted to the growing season instead of the entire year, or when negative values were omitted. In general, cloud masking led to higher NDVI or EVI. When categorizing North Carolina Census tracts into quartiles, cloud-masking reclassified as much as 70% of one quartile to another (i.e., third greenest to others). Comparing tracts' quartiles averaged over the entire year to only the growing season, there was less reclassification with cloud masking.

CONCLUSIONS: Methodological differences in data processing affect greenness exposure assessment (e.g., average NDVI / EVI, greenness quartiles). When comparing the magnitude and direction in health effects from greenness, such as in reviews or meta-analyses, researchers must account for methodological differences between each study's handling of satellite remote sensing data. Future research should identify best practices (e.g., cloud masking) for calculating greenness in population health studies.

P-0873 Children's exposure to bisphenols, phthalates and non-phthalate plasticizers in Poland

Mercè Garí[1,2], Holger Koch[3], Daniel Bury[3], Rebeca Moos[3], Claudia Pälmke[3], Wojciech Hanke[4], Agnieszka Jankowska[4], Kinga Polańska[4]

[1]Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Barcelona, Spain, [2]Computational Health Department. Helmholtz Munich, Munich, Germany, [3]Institute for Prevention and Occupational Medicine of the German Social Accident Insurance, Institute of the Ruhr-University Bochum (IPA), Bochum, Germany, [4]Nofer Institute of Occupational Medicine (NIOM), Lodz, Poland

BACKGROUND AND AIM: Bisphenols, phthalates and non-phthalate plasticizers are a group of chemical compounds widely used in the industry, e.g., in the production of plastics, and as precursor of epoxy resins. Some of them may affect the hormonal balance in both children and adults. This study aims to determine the urinary concentrations of bisphenols and metabolites of phthalates and non-phthalate plasticizers in children from Poland, estimate their daily intakes and cumulative risk assessment, and examine the main factors of exposure.

METHODS: A total of 400 urine samples of 7 year-old children from the Polish Mother and Child Cohort (REPRO_PL) were analyzed using high performance liquid chromatography with online sample clean-up coupled to tandem mass spectrometry (online-SPE-LC-MS/MS). Daily intakes from each compound were calculated based on urinary excretion rates, specific Fue values for each compound and children's body weights.

RESULTS: The main compounds were ΣDEHP, ΣDnBP, MEP and ΣDEHTP, quantifiable in all samples at median concentrations of 69.5 µg/l, 58.2 µg/l, 42 µg/l and 35.4 µg/l, respectively. BPA accounted for the majority of bisphenols exposure (64%), although around 20% of the children had quantifiable concentrations of BPF and BPS. Certain socio-demographic and life-style characterisitcs were found to have a positive trend with the concentrations of the aforementioned compounds. The individual and cumulative risk assessment of exposure to the studied compounds confirmed that children in Poland are still broadly exposed to several phthalates, bisphenols and non-phthalate plasticizers. Daily intakes and hazard index calculations revealed that a small percentage of children (around 3-10%) exceeded the tolerable daily intakes established by international institutions in relation to phthalates.

CONCLUSIONS: Further studies are required in order to recognize other compounds used as phthalates and BPA replacements, and their exposures among critical life stages such as pregnant women and children.

P-0875 Review of air pollution monitoring designs in new monitoring paradigms for epidemiology

Sun-Young Kim[1,2], Lianne Sheppard[2]
[1]National Cancer Center, Goyang, Republic of Korea, [2]University of Washington, Seattle, USA

BACKGROUND AND AIM: Both exposure monitoring and exposure prediction have played key roles in assessing individual-level long-term exposure to air pollutants and their associations with human health. While there have been notable advances in exposure prediction methods, improvements in monitoring designs are also necessary, particularly given new monitoring paradigms that leverage low cost sensors and mobile platforms. We aim to investigate characteristics of novel monitoring designs for air pollution cohort studies that leverage new technologies in order to provide practical guidance to future studies.

METHODS: We focus on two overarching types of monitoring designs, mobile and non-mobile, as well as their subtypes. We define the mobile monitoring design as monitoring from a mobile platform, and the non-mobile monitoring design as stationary monitoring from permanent or temporary locations that incorporates cost-effective sampling devices. In our scoping review, we discuss similarities and differences in these designs across previous studies with respect to spatial and temporal representation, data compatibility between design classes, and the data leveraged for model development.

RESULTS: In published studies applying mobile or non-mobile designs, monitoring sites were mostly selected based on land use instead of residences, and deployed over a short time period which makes representation of long-term average spatial variability challenging. A limited number of studies applied multiple design and/or sub-design classes to the same area, period, or instrumentation, to allow comparison across measurement approaches. There were fewer studies that leveraged monitoring data from different designs to improve exposure assessment by capitalizing on the different strengths of the designs.

CONCLUSIONS: In order to maximize the benefit of new monitoring technologies in assessing the health effect of long-term air pollution, our review suggests specific monitoring designs that prioritize residence-based site selection with comprehensive temporal coverage and leverage data from different designs for model development given good data compatibility.

P-0876 Representativeness of the 2010 EPA PM Monitoring Site Locations to the US Population

Meredith Pedde[1], Sara Adar[1]
[1]*University of Michigan, Ann Arbor, USA*

BACKGROUND AND AIM: Exposure prediction modeling establishes relationships between measurements and geographical characteristics to infer concentrations at locations without measurements. Since monitors are limited in number, predictions can be generated for locations very different than those used to train the model. The epidemiologic impacts of this potential mismatch hinge on whether the population resides in areas not well-represented by monitoring sites. Here we quantify the fraction of the US population with geographical characteristics reflected by regulatory monitoring sites to determine the effectiveness of US monitoring in capturing the population experience.

METHODS: We compared 2010 US Census blocks to the 1km area around EPA monitoring sites for particulate matter (PM2.5 and PM10) in terms of several characteristics often used by prediction models: elevation, population density, and road density. We then quantified the fraction of the US population that resided in census blocks with predictor values observed at the EPA monitoring sites. We also evaluated these fractions by state since not all exposure modeling is conducted nationally.

RESULTS: In 2010, over 98% of the US population resided in census blocks with population densities, road densities, and elevations that were represented by EPA PM2.5 sites. PM10 results were similar, although only 93% of the population was covered by monitors in terms of population density. These results varied by state, however, especially in terms of population density, where 25 states had less than 75% of their population represented by their PM2.5 monitoring sites (34 states for PM10).

CONCLUSIONS: While PM regulatory monitoring sites are very representative of the US population, results were less consistent within states. This suggests that sub-national exposure modelling should carefully consider the representativeness of monitors for their populations. It also highlights that exposure models often need to borrow information from more distal places to predict exposures for the full population.

P-0878 Effects of exposure to noise, PM2.5 and NO2 on emotional well-being during daily travel

Huyen Le[1], Joseph Bayer[1], Jerry Mount[2]
[1]*The Ohio State University, Columbus, USA,* [2]*The University of Iowa, Iowa City, USA*

BACKGROUND AND AIM: Urban residents are exposed to the environment during everyday travel. While previous studies have shown the potential impacts of environmental exposure on mental health and subjective well-being, few studies have examined this relationship in the dynamic transportation context. We aim to address this gap by using smartphone-survey data to quantify the impacts of exposure to PM2.5, NO2, traffic noise, and green/blue space on monetary mood and energy level during daily travel.

METHODS: We conducted a smartphone-app survey in the Columbus metropolitan area in Ohio, USA in 2019 (n=465 people). We used the ecological momentary assessment approach and GPS tracking to track travelers' movement and subjective well-being over the course of 14 days. Using a buffer of 300m along the travel routes, we tabulated the area of green space, traffic noise level, PM2.5 and NO2 concentrations, and travel time by each mode every day. We calculated the dose inhaled based on exposure duration during transportation by each travel mode. We then quantified the impacts of exposure to these environmental factors on positive mood, energy level, calmness, and stress.

RESULTS: Our multilevel models show that PM2.5 and noise level were associated with a decrease in positive feeling. On the other hand, NO2 and noise were associated with an increase in stress level, while PM2.5 shows the opposite effect. Noise was found to reduce energy level while green space and water show the opposite effect.

CONCLUSIONS: Our study adds further evidence to the relationship between environmental exposure and momentary subjective well-being during daily transportation. The findings imply the need for cities to provide open space and reduce noise and air pollution to promote well-being, especially for vulnerable mode users such as pedestrians and cyclists. Who are more exposed to these factors at a higher level.

KEYWORDS: GPS, mental health, exposure

P-0880 Environmental determinants of serum selenoproteins concentrations and composition in the Aragon Workers Health Study - SelenOmics project.

Zulema Rodriguez-Hernandez[1,2], Anabel Paredes-Douton[1], Maria Grau-Perez[3], Jose L Gomez-Ariza[4], Tamara Garcia-Barrera[4], Martin Laclaustra-Gimeno[5], Belen Moreno[5], Fernando Civeira[5], Jose Puzo[5], Jose A Casasnovas[5], Roberto Pastor-Barriuso[1], Maria Tellez-Plaza[1]

[1]Department of Chronic Diseases Epidemiology, National Center for Epidemiology, Carlos III Health Institute, Madrid, Spain, [2]Department of Biotechnology, Universitat Politècnica de València, Valencia, Spain, [3]Cardiometabolic and Renal Risk Unit, Biomedical Research Institute INCLIVA, Spain, [4]Department of Chemistry, University of Huelva, Spain, [5]IIS Aragon, CIBERCV, Zaragoza University, Zaragoza, Spain

BACKGROUND: Identifying potencial determinants of serum selenoproteins and selenometabolites can help understanding selenium-related metabolism and health consequences. We evaluated the cross-sectional association between environmental factors and serum selenoproteins and total selenometabolites concentration and composition in the Aragon Workers Health Study (AWHS), a participating cohort in the SelenOmics project.
MATERIALS AND

METHODS: Serum selenoproteins (glutathione peroxidase [GPx], selenoprotein P [SeP], selenoalbumin [SeAlb]), selenometabolites (Se-metabolites) and total selenium and urine metals were measured using HPLC/ICP-MS in 862 AWHS participants. We estimated a Healthy Lifestyle Score (HLS), which included diet, physical activity, smoking, BMI and alcohol consumption. Selenoproteins and Se-metabolites concentrations (log-transformed) and composition (logit-transformed specific species proportion) were introduced as dependent variables in linear regression models adjusted by age, sex and education.

RESULTS: Serum GPx, SeP, SeAlb, total Se-metabolites and selenium median concentrations were, 15.82, 66.07, 14.04, 0.07 and 96.44 µg/L, respectively. We observed statistically significant associations [GMR (95% CI), two-fold change for continuous variables] between ever smoking [0.96(0.93,0.99)], HLS [1.02(1.00,1.05)], total serum selenium [1.08(1.04,1.13)] and tungsten [1.03(1.01,1.05)] with GPx and tungsten with GPx% [1.04(1.02,1.06)]; arsenobetain-corrected arsenic [1.01(1.00,1.02)], chromium [0.98(0.97,1.00)] and total selenium [1.13(1.09,1.16)] with SeP, and age[1.07(1.01,1.13], ever smoking [1.04(1.00,1.07)] and HLS [0.98(0.95,1.00)] for SeP%; ever smoking [0.93(0.90,0.97)], HLS [1.03(1.01,1.06)], BMI [0.81(0.69,0.94)], arsenic [1.02(1.00,1.03)], chromium [1.03(1.00,1.05)] and total selenium [1.10(1.05,1.15)] with SeAlb, and ever smoking [0.95(0.92,0.99)], chromium [1.04(1.01,1.07)] and vanadium [0.96(0.93,1.00)] with SelAlb%; and sex [1.80(1.13,2.89)], physical activity [1.17(1.01,1.38)] and tungsten [0.91(0.85,0.97)] with Se-metabolites and sex[1.68(1.04,2.69)], tungsten [0.92(0.86,0.98)] and selenium[0.84(0.73,0.96)] with Se-metabolites%. The association of tungsten with GPx, selenium with SeP, smoking and BMI with SeAlb, and sex with Se-metabolites, remained after additional adjustment for statistically significant determinants.
CONCLUSION: Serum selenoproteins and selenometabolites concentrations and composition were associated with several environmental determinants, which support that the environment play a relevant role in selenium-related metabolic pathways.

P-0881 Determinants of agricultural pesticide concentrations in homes located in wine-growing areas

Raphaëlle Teysseire[1,2,3], Cécile Proust-Lima[1], Isabelle Baldi[1,2], Emanuelle Barron[4], Carole Bedos[5], Alexis Chazeaubeny[4], Karyn Le Menach[4], Audrey Roudil[2], Hélène Budzinski[4], Fleur Delva[1,2]

[1]Bordeaux Population Health Research Center, Inserm Umr 1219, University of Bordeaux, Bordeaux, France, [2]Department of Occupational and Environmental Medicine, Bordeaux Hospital, Bordeaux, France, [3]Regional Health Agency of Nouvelle-Aquitaine, Bordeaux, France, [4]University of Bordeaux, CNRS, UMR5805 EPOC-LPTC, Talence, France, [5]ECOSYS, INRAE-AgroParisTech- Paris-Saclay University, Thiverval-Grignon, France

BACKGROUND AND AIM: Epidemiological studies have shown that populations residing near agricultural areas were more exposed to pesticides than the general population. However, the determinants of exposure are poorly known. The main objective of the PESTIPREV study is to identify the determinants of agricultural pesticide exposure among residents of wine-growing areas in France.

METHODS: A sampling campaign was conducted in 31 homes adjacent to vineyards in 2020 and 2021 during summer. at total, 1079 samples were collected (surfaces and animals sampled with wipes, waters from hand washings, carpet/doormat dust) of which 116 were unwashed, indoor surfaces in height. Protected from sunlight and microbial degradation, these surfaces represent the prolonged residential exposure to pesticides. Eight fungicides were searched (benalaxyl, boscalid, cyflufenamid, cymoxanil, folpet, pyraclostrobin, tebuconazole, trifloxystrobin). Limits of quantification per wipe ranged from 0.05ng for pyraclostrobin to 5ng for folpet. Information on the potential determinants of exposure (agricultural activities, meteorological data, buildings and occupants' characteristics) was collected by questionnaire and database consultation. We performed structural equation models (SEM) to explore the role of these parameters on the pesticides concentrations found on surfaces in height.
RESULTS: First results showed that while tebuconazole and trifloxystrobin were quantified in nearly 100% of the samples, the quantification rates were lower for the other pesticides (from 19.8% for cymoxanil to 85.3% for boscalid). Median surface loadings ranged from 13.8ng/m² for pyraclostrobin to 2370ng/m² for folpet. Statistical analyses (SEM) are currently being processed.

CONCLUSIONS: The observed quantification rates are partly explained by the differences in quantification limits between the eight compounds. The surface loading measured will be used to study the effect of several determinants on the residents' exposure. The knowledge of these determinants is crucial to improve the conduct of epidemiological and regulatory studies, and to elaborate preventive measures.

P-0882 Aircraft noise and cardiovascular disease hospitalization and mortality near major airports in the UK

Glory Atilola[1], Calvin Jephcote[2], Garyfallos Konstantinoudis[1], Kathryn Adams[2], John Gulliver[2], Paul Elliot[1], Marta Blangiardo[1], Anna Hansell[2]

[1]MRC Centre for Environment and Health, Dept Epidemiology and Biostatistics, School of Public Health, Imperial College London, W2 1PG, UK, London, UK, [2]Centre for Environmental Health and Sustainability, University of Leicester, Leicester, UK, Leceister, UK

BACKGROUND AND AIM: Transport noise in Europe has an associated disease burden reported as next highest after air pollution, but most studies to date relate to road traffic noise. We quantified associations between long-term aircraft noise and cardiovascular disease hospitalizations and deaths due to all cardiovascular disease (CVD), coronary heart disease (CHD) and stroke in a population of 3.1 million living near four major English airports in 2006-15 in a small-area study.

METHODS: Health outcome data for 2006-10 and 2011-15 and annual average aircraft noise exposure measurements for day/evening/night time (Lden ≥ 50dB) and night time (Lnight ≥45dB) noise in 2006 and 2011 were obtained for 9,860 census output areas near London Heathrow (8,147), London Gatwick (228), Manchester (898), and Birmingham (587) airports. To overcome the issue of data sparsity, hierarchical Poisson regression models were specified, accounting for airport-specific heterogeneity and overdispersion. Additionally, spatial random effects were included, to model local correlation. Adjustment was made for potential confounders including ethnicity, deprivation, road traffic noise and NO2 at small area level.

RESULTS: We reported evidence of increased risk of hospital admissions for CHD per 5dB increment in Lden (1.057; 95% Credible Interval: 1.027-1.089) and Lnight (1.047; 1.018-1.076). A Heathrow-specific analysis showed evidence of elevated risk of an association between daytime noise and risk of CHD hospital admissions (1.043; 1.000-1.084) and mortality (1.083; 1.007-1.165); some evidence of an effect on mortality risk was also seen for all CVD (1.051; 0.994-1.111) and stroke (1.071; 0.951-1.206) per 5dB Lden.

CONCLUSIONS: Findings from our study have important implications for aircraft noise policies and evaluation of ongoing public health initiatives to reduce noise pollution around major airports in England and its impact on cardiovascular health.

P-0884 Optimization and Process Design Tools for estimation of weekly exposure to air pollution integrating travel patterns during pregnancy

Valentin Simoncic[1], Mario Pozzar[2], Severine Deguen[3], Wahida Kihal[1]
[1]Laboratoire Image Ville Environnement, Strasbourg, France, [2]ENSAI School for Statistics and Data Science, Bruz, France, [3]Université de Bordeaux, Bordeaux, France

A growing number of international studies have highlighted that exposure to air pollution contributes substantially to the burden of preterm birth and infant death. Several other epidemiological studies have also suggested associations between air pollutants' concentrations and adverse birth outcomes including low birth weight and preterm birth.To do so, researchers need to estimate exposure levels to air pollution throughout everyday life. In the literature, the most commonly used estimate is based on home address only or taking into account, in addition, the work address. However, several studies have shown the importance of daily mobility in the estimate of exposure to outdoor air pollutants.
In this context, we developed an R procedure that estimates individual exposures combining home addresses, several important places, and itineraries of the principal mobility during a week. It supplies researchers a useful tool to calculate individual daily exposition to air pollutants weighting by the time spent at each of the most frequented locations (work, shopping, residential address, etc.) and while commuting. This task requires the efficient calculation of travel time matrices or the examination of multimodal transport routes. This procedure is freely available from the Equit'Area project website: (www.equitarea.org)
This procedure is structured in three parts: the first part is to create a network, the second allows to estimate mains itineraries of the daily mobility and the last one tries to reconstitute the level of air pollution exposure. One main advantage of the tool is that the procedure can be used with different spatial scales and for any air pollutant.

P-0887 Rapid bioanalytical screening for the assessment of internalized exposure to Polycyclic Aromatic Hydrocarbons in clinical samples of Florida Firefighters

Alexia Lydia Kafkoutsou[1,2,3], Umer Bakali[1,2,3], Katerina Santiago[3,4], Emre Dikici[1,2,3], Natasha Schaefer Solle[3], Erin Kobetz[3,5], Sapna Deo[1,2,3], Sylvia Daunert[1,2,3,5], Alberto Caban-Martinez[3,4]

[1]Department of Biochemistry and Molecular Biology, University of Miami, Miller School of Medicine, Miami, USA, [2]John T. Macdonald Foundation Biomedical Nanotechnology Institute (BioNIUM), University of Miami, Miami, USA, [3]Sylvester Comprehensive Cancer Center, University of Miami, Miami, USA, [4]Department of Public Health Sciences, University of Miami, Miller School of Medicine, Miami, USA, [5]Clinical and Translational Science Institute (CTSI), University of Miami, Miami, USA

BACKGROUND AND AIM: Polycyclic aromatic hydrocarbons (PAHs) are toxic byproducts of combustion and ubiquitous environmental pollutants which can cause carcinogenesis. Firefighters are routinely exposed to these contaminants and numerous studies have described a high incidence of various cancer types in firefighters compared to the general population. Our aim was to develop a streamlined process that allows accurate quantitative evaluation of PAH exposure in clinical samples collected from Florida Firefighters.

METHODS: Urine samples were collected from twenty-five (25) active firefighters stationed in Florida at the beginning and end of a 24-hour shift, and twenty-one (21) new recruits after the completion of different fire trainings. We developed a rapid, non-invasive method to assess their internalized exposure to PAHs as part of the Firefighter Cancer Initiative (FCI). The use of automated extraction systems and Gas Chromatography – Mass Spectrometry enabled the accurate, qualitative, and quantitative detection of PAHs identified as priority pollutants by the USA Environmental Protection Agency.

RESULTS: Total PAH exposure levels of the 25 active firefighters were significantly higher after the completion of the 24-hour shift, with those that answered fire-related calls, rather than EMS calls, exhibiting the highest concentrations of individual and gross PAHs. Similarly, total internalized exposure was increased in firefighter trainees compared to controls. We observed that participation in a Class B fire training, which involves flammable liquid materials, is associated with higher exposure to PAHs compared to participation in Class A exercises that employ ordinary combustible materials.

CONCLUSIONS: Our findings showcase the unsafe levels of carcinogen exposure faced routinely by firefighters, highlighting the need for further investigation of the link between occupational exposure and health-related effects. The novel biomonitoring tool we developed facilitates large-scale screening of clinical samples and can be used for real-time assessment of carcinogen exposure.

KEYWORDS: PAHs, exposure assessment, firefighters, biomonitoring, occupational exposure

P-0889 Environmental urban exposure to rubidium in a healthy group of Spanish adolescents.

Antonio Peña-Fernández[1], Manuel Higueras[2], M.Carmen Lobo Bedmar[3]
[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, LE1 9BH, UK, [2]Scientific Computation & Technological Innovation Center (SCoTIC), Universidad de La Rioja, Logroño, Spain, [3]IMIDRA, Alcalá de Henares (Madrid), Spain

BACKGROUND AND AIM: Rubidium (Rb) is a rarely studied alkali metal with different applications in the manufacture of photocells and engines for vehicles/machines, which can biomagnify in the food web. The study evaluates the environmental exposure to Rb in a teenage population group living in Alcalá de Henares (Spain).

METHODS: Scalp hair was collected from 96 adolescents (13-16 years-old; 68 girls) born and residing in Alcalá. Rb was analysed by ICP-MS after removal of exogenous contamination using Triton X-100/bath sonication. Data was processed using statistical methods applied to censored data ('NADA' statistical package).

RESULTS: Rb was only detected in 25.8% of the hair samples (LoD=0.011 µg/g), specifically in male (13/29) compared to female (12/68) participants. Owing to the high levels of censored data, 95th percentile and range for Rb in scalp hair of female participants is provided (µg/g): 0.041 (0.013-0.073); meanwhile the median and range for the male population was (µg/g): 0.0101 (0.011-0.106). The presence of Rb in scalp hair show sex dependency (p=0.00127), which agrees with a study performed in Italian teenagers (11-13 years), although they did not observe significance. The geometric mean and median in Alcalá hair samples were (0.0359, 0.0038) higher than in the Italian study (6.0E-03, 6.3E-03; µg/g), which suggests some environmental exposure to this element in our monitored population. Rb salts are used in glasses and ceramics, important industrially in Alcalá which might explain the exposure. Thus, significantly higher concentrations of Rb were found in males living close to glass/ceramic manufacturers (0.0493 vs. 0.0116, 0.0154 and 0.0136 µg/g)

CONCLUSIONS: Although preliminary, our results could suggest that Alcalá's teenage population would have been environmentally exposed to Rb, especially male teenagers, which logically could be due to boys spending more time outdoors and therefore more exposed to this element.

P-0890 Estimating spatiotemporally resolved PM2.5 concentration across the contiguous USA using Super learning

Alexandra Shtein[1], Joel Schwartz[1]
[1]*Harvard TH Chan School of Public Health, Boston, USA*

BACKGROUND AND AIM: Spatiotemporally resolved predictions of PM2.5 concentration are essential for studying associations between long-term and short-term exposures and adverse health outcomes in epidemiological studies. An improved statistical ensemble modeling approach with novel covariates was used to estimate daily 1x1 km PM2.5 concentrations across the contiguous US for the years 2000-2019, and 250 m resolution in urban areas.
METHODS: The approach integrates the predictions from five different base learners (random forests (RF), support-vector machine, stochastic gradient boosting, extreme gradient boosting and neural networks) using a super learner model that combines the individual predictors with another machine learner. This machine learning (ML) ensemble model aims to provide a prediction with minimized root mean square error compared to the base learners. The following spatial and temporal variables were used as predictors: satellite-based products (aerosol optical depth (AOD), land surface temperature, surface reflectance, vegetation indexes, light at night, fires), human modification of land, land use variables, meteorology, topography, population density, proximity, and density of multiple possible sources of air pollution. 30% of monitors were left out for testing and hyperparameter tuning for the models was done using 5-fold cross validation on the training data. Missing satellite based AOD were filled using a RF model with the following predictors: estimated AOD from different chemical transport models, meteorology, topography, land use, climatic regions, and cloud cover.
RESULTS: The performance of the RF model that aims to fill in missing AOD observations was evaluated for one year based on the out-of-bag samples and showed good performance with R2 = 0.90.
CONCLUSIONS: The ensemble model suggests an improved statistical approach for integrating PM2.5 concentration predictions from multiple ML models.

P-0891 The use of snapshot personal exposure monitoring in estimating annual exposure to air pollutants for epidemiological studies

Benjamin Barratt[1,2], Hanbin Zhang[1,2], Dimitris Evangelopoulos[1,2], Heather Walton[1,2], Klea Katsouyanni[1,2,3]
[1]1MRC Centre for Environment and Health, Environmental Research Group, Imperial College London, London, UK, [2]NIHR HPRU in Environmental Exposures and Health, Imperial College London, London, UK, [3]Department of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

BACKGROUND:
While advancements in sensor technology have broadened the use of personal monitors to estimate individual exposure to air pollution in recent years, significant challenges remain in extending their use for application in epidemiological studies. By collating measurements from several personal exposure (PE) campaigns in London, we aimed to develop a method for extending snapshot PE monitoring to estimates of annual mean exposure to pollution from outdoor sources at individual level.

METHODS: Our conceptual model for annual extrapolation included three factors: a) variation in ambient concentrations, b) variation in infiltration efficiency of residence and other frequently inhabited buildings, and c) mobility behaviour. We utilised a dataset of 200+ million PE measurements from 427 participants of diverse demographics - school children, COPD patients, professional drivers and healthy adults - to characterise these three factors during snapshot monitoring (varying from four days to six months). Location-adjusted ambient concentrations, coupled with seasonal infiltration factors were used to extend results to annual mean personal exposure estimates for PM2.5, NO2, O3 and BC. Methods described elsewhere were used to censor exposure to indoor sources from the measurements.

RESULTS: Residential infiltration factors did not show significant variation between seasons, suggesting that ventilation behaviour was not a major determinant. Each demographic exhibited distinct patterns in mobility behaviour, although impact was limited by relatively small proportion of time spent travelling. Behaviour modelling of participants with at least four months' PE measurements showed that some participants had repeated routines, but others were unpredictable.

CONCLUSIONS: The extension of snapshot PE monitoring to annual mean exposure estimates requires assumptions relating to participant behaviour over time, notably mobility and residential ventilation. The impact of these assumptions will vary between individuals and demographics. Extrapolation of snapshot monitoring is more robust for those with predictable routines.

P-0892 Assessing exposure to pesticides with short biological half-lives: Use of a repeated longitudinal biomonitoring strategy to estimate glyphosate exposure during pregnancy

Cynthia Curl[1], Carly Hyland[1], Meredith Spivak[1]
[1]*Boise State University, Boise, USA*

BACKGROUND: Glyphosate is the most heavily used herbicide in the world, and recent studies raise concern about previously unrecognized toxic effects at environmentally-relevant levels, particularly during fetal development. Despite glyphosate's extensive use and potential toxicity, little data exists to characterize human exposures. Use of such data is further complicated by the fact that – like many modern pesticides – glyphosate is metabolized quickly, with an estimated half-life of less than 12 hours. Individual spot urine samples have been used to estimate glyphosate exposure but may result in exposure misclassification. We employed a temporally-rich longitudinal biomonitoring strategy to assess between- and within-individual variability in glyphosate exposure throughout pregnancy.

METHODS: We recruited pregnant women living both near and far from agricultural fields from Women, Infants and Children (WIC) clinics in southern Idaho. We collected weekly urine samples from enrollment through delivery, and daily urine samples during a two-week dietary intervention. Samples are currently being analyzed by the Centers for Disease Control and Prevention for glyphosate concentrations.

RESULTS: We recruited a cohort of 40 pregnant women during their first trimesters of pregnancy, and maintained a 97.5% retention rate through delivery. Half of the participants lived within 500 m of the nearest agricultural field. Mean study duration was 21 weeks, and we collected a total of 1,395 spot urine samples, including 864 weekly and 531 daily samples, representing 96.9% of the study goal. These data will allow us to estimate the number of individual samples needed to stably assess glyphosate exposure across pregnancy, and to understand exposure variability within and across individuals.
CONCLUSION: This is the first study to longitudinally assess glyphosate exposure throughout pregnancy, and the results of this work have important implications for developing appropriate exposure assessment methods for other chemicals with short biological residency.

KEYWORDS: glyphosate; pesticide exposure; biomonitoring

P-0894 Particulate Matter (Pm2.5) concentration among hypertensives primary cooks in Obuasi Municipality, Ghana

Theresa Tawiah[1], Matthew Shupler[2], Stephaney Gyaase[1], Rachel Anderson de Cuevas[2], Jason Saah[1], Emily Nix[2], Mieks Twumasi[1], Elisa Puzzolo[2], Reginald Quansah[3], Daniel Pope[2], Kwaku Poku Asante[1]
[1]Kintampo Health Research Centre, Kintampo, Ghana, [2]Department of Public Health, Policy and Systems, University of Liverpool, Liverpool, UK, [3]University of Ghana, Accra, Ghana

BACKGROUND/AIM:
There is a paucity of epidemiological evidence on the potential association between exposure to household air pollution (HAP) from combustion of solid fuels (SF) (e.g., wood, charcoal) for cooking and raised blood pressure in sub-Saharan Africa.

METHODS: As part of the CLEAN-Air(Africa) project, we measured 24-hour exposure to particulate matter (PM2.5) among cooks primarily using either SF (n=35) or liquefied petroleum gas (LPG) (n=35) in Obuasi, Ghana. The cook's blood pressure (systolic/diastolic) was assessed two months prior to measurement of air pollution using standardized methods. Blood pressure (BP) levels were then categorized into two levels: normal and severe. Basic descriptive statistics were used to describe the data.

RESULTS: Personal exposure to PM2.5 was higher in cooks primarily using SF (geometric mean (GM)=65.6 µg/m3 (range: 15.3-234.4) than those using LPG (GM=45.9 µg/m3 (CI: 5.2-232.6). Blood pressure was higher in cooks using SF (mean systolic blood pressure was 118.5 (±17.1) mmHg) than those using LPG (115.9 (±16.6) mmHg; mean difference 2.55 mmHg (p=0.5291)). Average diastolic blood pressure was 77.3 (±12.4) mmHg in SF users compared to 76.2(±13.2) mmHg in LPG users; mean difference 1.1 mmHg (p=0.7300). Primary cooks with normal BP were exposed to 60.8 µg/m3 (CI:49.7– 74.5) PM2.5 and 52.0 µg/m3(CI: 30.7 – 88.2) for cooks with severe BP.
CONCLUSION:
Average exposure to PM2.5 is significantly greater than the World Health Organizations Interim Target 1 level (35µg/m3) in both hypertensive and non- hypertensive primary cooks. Therefore, more efforts are required to reduce household air pollution and ambient air pollution.

KEYWORDS: Particulate matter, exposure assessment, LPG, blood pressure, Ghana

P-0895 Radon Exposure to Community Members Living Near a Uranium Procession Plant

John Reichard[1], Swade Barned[1], Susan Pinney[1]
[1]*University of Cincinnati College of Medicine, Cincinnati, USA*

BACKGROUND: Members of the Fernald Community Cohort (FCC, N=9782) are persons who lived within 5 miles of the uranium processing plant at Fernald, Ohio, USA. From 1951 to 1989 the site processed uranium ore and recycled materials to make highly refined uranium metal products used in the USA Department of Energy nuclear weapons production. The aqueous raffinate or waste from the chemical digestion process was pumped into two large concrete silos for storage and were found to be sources of radon decay products. Vents in the protective dome covers were not sealed until 1979. Source terms and dosimetry algorithms for exposure to both uranium particulates and radon were developed by CDC.

METHODS: Based on the CDC prior work, we developed a mathematical model to estimate yearly outdoor radon exposure persons in the cohort from the K-65 silos during 1952-1988. We collected and verified residential history information from members of the cohort. We used the radon source terms developed by CDC, yearly wind speed and direction data, and applied the model to the residential history for each member of the cohort.

RESULTS: 9306 members of the cohort had sufficient residential history information to be used for radon dosimetry calculations for individual cohort members. The population mean value (sd) of total cumulative exposure (over the years 1952-1988) was 460.70 (508.84) pCi/m2-years, median 299.60 pCi/m2-years, with a large range of 0-4625.75 pCi/m2-years. Arithmetic median exposure also was calculated for each person, or the median of yearly exposure, with a population mean of 20.43 pCi/m2, also with a large range 0 to 200.57 pCi/m2.

CONCLUSIONS: Using reliable data and well-developed algorithms we estimated environmental (outdoor) radon exposure for members of the FCC and found a wide range of cumulative outdoor radon exposure.

KEYWORDS: uranium, radon, community cohort
