BACKGROUND AND AIM: Air pollution remains a major health concern in Europe, despite the adoption of mitigation policies over the last decades. The LIFE Index-Air project developed a novel policy support tool, aiming to cover the gap between ambient air quality management and real-life exposure of urban populations and related health risks. This work presents the main features of the Tool and results from its implementation in five European cities: Lisbon and Porto (Portugal), Treviso (Italy), Athens (Greece) and Kuopio (Finland).

METHODS: The tool is based on an integrated exposure-dose-burden of disease assessment. It incorporates a number of specialised models and provides (1) the spatial distribution of pollutants emissions, ambient concentrations, citizens' exposure, and respective Burden of Disease; (2) the PM dose deposited in the respiratory system. The Tool also allows users to build scenarios of emission control measures and exposure scenarios, based on modified time activity patterns.

RESULTS: PM concentration and exposure mapping, provided by the Tool, revealed the pollution hot spots in each city. Exposure was found higher for young children, in comparison to adults. The school / work microenvironments and outdoor physical activities were responsible for the highest doses of PM. The implementation of control measures related to vehicular traffic resulted in 7 - 10% reduction in mortality in Lisbon, Porto and Athens. A reduction of 10% in mortality was also estimated for Treviso if efficient wood burning devices were to be used for residential heating.

CONCLUSIONS: Index-Air Tool provides, for the first time, quantitative assessment of the effectiveness of control policies, with respect to citizens' exposure and related health. It also addresses measures aiming at reducing citizens' exposure through the adoption of alternative, less impacted by air pollution, everyday schedules.

KEYWORDS: Policy tool, Particulate pollution, Population exposure, Deposited dose, Burden of disease, Emission / exposure scenarios.

THEMATIC 16: Neurobehavioral changes in children/adults

P-1001 Maternal Urinary Fluoride levels during pregnancy and ADHD symptoms during childhood

Jesus Ibarluzea[1], Mikel Zubiza[2], Loreto Santa Marina[1], Amaia Molinuevo[1], Ana Jimenez[3], Enrique Arranz-Freijo[2], Manuel Sánchez de Miguel[2], Aitana Lertxundi[2]

[1]BIODONOSTIA Health Research Institute, Donostia-San Sebastian, Spain, [2]University of the Basque Country (UPV-EHU), Donostia-San Sebastian, Spain, [3]Ministry of Health of Basque Government, Donostia-San Sebastian, Spain

BACKGROUND AND AIM: There is little evidence linking fluoride in urinary levels and symptoms or diagnosis of ADHD. In the Basque Country, the fluoridation of drinking water is compulsory for municipalities >30,000 inhabitants. The objective is to analyze the relationships between fluoride levels in urine collected during pregnancy and ADHD symptomatology at 4, 8 and 11 y

METHODS: Data from 201 to 255 mother-child pairs from the Infancia y Medio Ambiente (INMA) birth cohort with maternal urinary F adjusted for creatinine (MUFcr) during pregnancy and child assessments of ADHD-like behaviors at age of 4, 8 and 11 years was available. ADHD symptoms were reported by ADHD-DSM-IV checklist at age 4, and Conners' Rating Scales-Revised at age 8 and 11. Clinical approach was also carried out using the cut offs of each test. Multiple linear regression and zero inflated binomial regression were used when the outcomes were analyzed as continuous; for a clinical approach, logistic regression was used. Covariates, and biomarkers of neurotoxicants were available.

RESULTS: MUFcr levels in pregnancy varied according to the source of drinking water [(mean (95% CI)] being 0.85 (0.77, 0.93) in mothers drinking fluoridated water and 0.45 (0.40, 0.51) in those drinking non-fluoridated water ($p<0.01$). No association was found between MUFcr levels during pregnancy and inattention, hyperactivity or ADHD score of symptoms at 4, 8 or 11 years. E.g. at the age of 4, for each 1 mg F/g increase across the whole pregnancy, inattention, hyperactivity-impulsivity and ADHD scores did not change significantly: (β =0.16, CI 95%:-1.58, 1.90), (β =0.19, CI 95%: 1.56, 1.95) and (β = 0.35, CI 95%: -2.75, 3.46). Nor was any association observed when a clinical approximation of the problem was used.

CONCLUSIONS: Higher levels of MUFcr in pregnant women were not associated with global measures of ADHD during childhood

P-1003 Fetal exposure to cannabis and childhood behavior at age 5 years: The Healthy Start study

Brianna Moore[1,2], Kaytlyn Salmons[3], Adrienne Hoyt[4], Karli Swenson[5], Emily Bates[5], Katherine Sauder[2,5], Allison Shapiro[2,5], Greta Wilkening[5], Gregory Kinney[1], Dana Dabelea[1,2,5]

[1]Department of Epidemiology, Colorado School of Public Health, Aurora, USA, [2]Lifecourse Epidemiology of Adiposity and Diabetes (LEAD) Center, Colorado School of Public Health, Aurora, USA, [3]Department of Epidemiology, Human Genetics, and Environmental Sciences, The University of Texas Health Science Center, Austin, USA, [4]Department of Health Promotion and Behavior, The University of Texas Health Science Center, Austin, USA, [5]Department of Pediatrics, University of Colorado School of Medicine, Aurora, USA

OBJECTIVE: To assess whether fetal exposure to cannabis is associated with childhood behavior, independent of fetal exposure to nicotine.

Study design: This pilot study included 97 mother-child pairs from a Colorado-based cohort. Maternal urine was collected at ~27 weeks gestation and analyzed for cotinine and twelve cannabinoids/metabolites (including delta 9-tetrahydrocannabinol and cannabidiol). Fetal exposure to cannabis was dichotomized as exposed (any cannabinoid≥limit of detection [LOD]) and not exposed. Fetal exposure to nicotine was dichotomized as exposed (cotinine≥LOD) and not exposed. Generalized linear models examined the associations of fetal exposure to cannabis with Child Behavior Checklist T-scores at age 5 years, with and without adjustment for fetal exposure to nicotine.

RESULTS: Compared to non-exposed offspring, cannabis-exposed offspring exhibited more externalizing behaviors (β: 4.3; 95% CI: 0.2, 8.5; p=0.04). However, this association was attenuated after adjusting for fetal exposure to nicotine (β: 2.1; 95% CI: -2.5, 6.6; p=0.38). Fetal exposure to nicotine was associated with several behavioral outcomes, including externalizing behaviors (β: 10.2; 95% CI: 2.9, 17.5; p<0.01), sleep problems (β: 4.5; 95% CI: 2.5, 7.6; p<0.01), and attention problems (β: 4.8; 95% CI: 1.7, 8.0; p<0.01), independent of cannabis exposure.

CONCLUSIONS: Our study confirms that fetal exposure to nicotine is associated with childhood behavioral outcomes, but more studies are needed to understand the long-term impact of fetal exposure to cannabis. Nevertheless, the potential risks of nicotine and cannabis use during pregnancy should be more widely communicated to limit behavioral problems in the offspring.

P-1005 Childhood exposure to per- and polyfluoroalkyl substances and neurodevelopment in the CHARGE case-control study

Jiwon Oh[1], Hyeong-Moo Shin[2], Rebecca Schmidt[1,3], Irva Hertz-Picciotto[1,3], Deborah Bennett[1]
[1]University of California, Davis, Davis, USA, [2]Department of Environmental Science, Baylor University, Waco TX, USA, [3]UC Davis MIND (Medical Investigations of Neurodevelopmental Disorders) Institute, Sacramento, USA

BACKGROUND/AIM: Per- and polyfluoroalkyl substances (PFAS) are shown to have neurotoxic effects on animals. Several epidemiological studies reported associations between childhood exposure to PFAS and neurodevelopment in childhood, but the results remain inconclusive. We examined if childhood PFAS concentrations were associated with a diagnosis of autism spectrum disorder (ASD), developmental delay (DD), and other early concerns (OEC).

METHODS: We included 551 children 2 to 5 years old from the CHildhood Autism Risks from Genetics and Environment (CHARGE) study. Children were clinically diagnosed and classified into ASD (n = 190), DD (n = 103), OEC (n = 78), and typical development (TD; n = 180) groups. Fourteen PFAS were quantified in their serum samples collected when diagnostic assessments were performed. We used multinomial logistic regression models to investigate the associations of individual PFAS concentrations with neurodevelopmental outcomes and weighted quantile sum (WQS) regression models to assess the mixture effects of PFAS.

RESULTS: Childhood perfluorooctanoate (PFOA) was associated with increased odds of ASD (odds ratio [OR] = 2.41, 95% confidence interval [CI]: 1.43, 4.08) and DD (OR = 2.28, 95% CI: 1.25, 4.16) versus TD. Perfluoroheptanoate (PFHpA) was associated with increased odds of ASD (OR = 1.71, 95% CI: 1.29, 2.28). However, perfluoroundecanoate (PFUnDA) was associated with decreased odds of ASD (OR = 0.44, 95% CI: 0.27, 0.71). From mixture analyses, one unit increase in the WQS index was associated with increased odds of ASD (OR = 1.70, 95% CI: 1.19, 2.43).

CONCLUSIONS: In this case-control study, childhood PFOA, PFHpA, and a PFAS mixture was associated with increased odds of ASD, while PFUnDA was associated with decreased odds of ASD. Because we used concurrent measurements of PFAS, our results do not imply causal relationships and thus need to be interpreted with caution.

KEYWORDS: PFAS, mixture, child serum, autism spectrum disorder, developmental delay

P-1008 Topological network properties of resting-state functional connectivity patterns are associated with metal mixture exposure in adolescents

Azzurra Invernizzi[1], Elza Rechtman[1], Demetrios Papazaharias[1], Elena Colicino[1], Stefano Renzetti[3], Claudia Ambrosi[2], Lorella Mascaro[2], Alessandra Patrono[4], Daniele Corbo[2], Giuseppa Cagna[3], Roberto Gasparotti[3], Abraham Reichenberg[5], Cheuk Tang[6], Donald Smith[7], Donatella Placidi[3], Roberto Lucchini[1,3,8], Robert Wright[1], Megan Horton[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]ASST Spedali Civili Hospital, Brescia, Italy, [3]Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, University of Brescia, Brescia, Italy, [4]Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy, [5]Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, USA, [6]Department of Diagnostic, Molecular, and Interventional Radiology, Icahn School of Medicine at Mount Sinai, New York, USA, [7]Department of Microbiology and Environmental Toxicology, University of California Santa Cruz, Santa Cruz, USA, [8]Department of Environmental Health Sciences, Robert Stempel College of Public Health and Social Work, Florida International University, Miami, USA

BACKGROUND: Exposure to neurotoxic metal adversely impact cognitive, motor, and behavioral development. Only few studies have addressed the underlying brain mechanisms of metal-associated developmental outcomes. Furthermore, metal exposure occurs as a mixture, yet often consider only a single exposure. In this cross-sectional study, we investigated the relation between exposure to neurotoxic metals and topological brain metrics, such as global, local efficiency and centrality measures, in adolescents.

METHODS: In 193 participants (53% females, ages: 13-25 years) enrolled in the Public Health Impact of Metals Exposure (PHIME) study, we measured concentrations of five metals (manganese, lead, zinc, copper and chromium) in biological matrices (blood, urine, hair, and saliva) and acquired resting-state functional magnetic resonance imaging scans. Using graph theory metrics, we computed caudate eigenvector centrality (EC) and efficiency (global:GE; local:LE) in 111 brain areas (Harvard Oxford Atlas). Weighted quantile sum (WQS) regressions were used to examine association between metal mixtures and each graph metric (GE, LE or EC), adjusted for sex and age.

RESULTS: We observed significant negative associations between the metal mixture and GE and LE (β_GE = -0.004, 95% CI [-0.006, -0.002]; β_LE= -0.011, 95% CI [-0.02, -0.003]). Blood lead (18%) and hair chromium (17%) contributed most to this association. The metal mixture was positively associated with EC in the caudate (β_EC = 0.625, 95% CI [0.144, 0.825]). Blood manganese (24%) and copper (11%) contributed most to the mixture association.

CONCLUSIONS: Our results suggest that exposure to the metal mixture during adolescence reduces the efficiency of integrating information in brain networks at both local and global levels. Results further suggest these associations are due to combined join effects to different metals, rather than to a single metal.

P-1012 Maternal exposure to life events, daily stressors and green spaces during pregnancy is associated with changes in NR3C1 and IGF2/H19 ICR methylation patterns three decades later

Stijn Vos[1], Bea Van den Bergh[2], Dries Martens[1], Hanne Kindermans[3], Zhiv Shkedy[4], Klaus Huse[5], Tim Nawrot[1,6]
[1]Centre for Environmental Sciences, Hasselt University, Diepenbeek, Belgium, [2]Health Psychology Research Group, KU Leuven, Leuven, Belgium, [3]Department Care Ethics, Hasselt University, Diepenbeek, Belgium, [4]Centre for Statistics, Hasselt University, Diepenbeek, Belgium, [5]Genome Analysis Group, Fritz Lipmann Institute - Leibniz Institute on Aging, Jena, Germany, [6]Department of Public Health & Primary Care, Occupational & Environmental Medicine, KU Leuven, Leuven, Belgium

BACKGROUND AND AIM: Maternal mental state has been associated with offspring NR3C1 promotor and IGF2/H19 imprinting control region (ICR) methylation patterns. However, more prospective studies with long-term follow-up are needed, and protective factors such as proximity to green spaces during pregnancy remain understudied. In this study, we investigated the associations between these maternal exposures, and the methylation patterns in adult offspring (28-29 y/o).

METHODS: 51 mother-newborn pairs were followed up from 12-22 weeks of pregnancy until 28-29 years after birth. During pregnancy, participants filled out questionnaires measuring the impact of important life events and of daily stressors. Using addresses, quantities of green space around the residence were determined using high-resolution map data (1 m2). 28-29 years later, blood and saliva samples were collected from the offspring. DNA methylation levels were determined on the NR3C1 promotor, and on the IGF2/H19 ICR using a bisulfite PCR and sequencing method. Mixed effect models were used to test the associations between maternal exposure to stressors and green spaces, and methylation patterns.

RESULTS: We found significant associations between the life events and daily stressor scores, and methylation patterns on two out of the four NR3C1 promotor region amplicons in offspring blood 28 years later. The same maternal stress measures were not associated with IGF2/H19 methylation levels. Maternal exposure to green spaces 1000m around the residence was associated with IGF2/H19 ICR methylation, but not with NR3C1 promotor methylation.
CONCLUSION:
We observed significant effects of maternal stress exposure during the pregnancy on the methylation patterns on the NR3C1 promotor into adulthood, which implies that maternal mental states during the pregnancy can induce HPA-axis regulation changes that can be persistent into adulthood. The observation that prenatal exposure to green spaces is associated with IGF2/H19 ICR methylation generates new hypotheses around the environmental determinants of DNA methylation patterns.

P-1014 Prenatal, early-life, and childhood exposure to source-specific air pollution and behavioural problems in the ALSPAC cohort

Yingxin Chen[1], Yutong Cai[1], John Gulliver[1], Charlotte Clark[2], Anna Hansell[1]
[1]University of Leicester, Centre for Environmental Health and Sustainability, Leicester, UK, [2]Population Health Research Institute, St George's, University of London, London, UK

BACKGROUND AND AIM: Particulate matter ≤10 µm in aerodynamic diameter (PM10) exposure may influence brain development and be related to emotional and behavioural problems in children.
This study aims to investigate emotional and behavioural problems at ages 9 and 16 years in relation to PM10 exposures during pregnancy, infancy, and childhood in the Avon Longitudinal Study of Parents and Children (ALSPAC).

METHODS: We assessed individual exposures to modelled PM10 (PM10_total) as well as PM10 specifically from road traffic (PM10_road) during pregnancy, 0–6 months, 7–12 months, and up to age 16 years. We used parent-completed Strengths and Difficulties Questionnaire (SDQ) to assess emotional and behavioural development at age 9 (N=5,209) and 16 (N=3,609) years. Associations between PM10 and behaviour problems were examined using linear regression models, adjusted for individual-level confounders.

RESULTS: We found adverse associations with behavioural problems at age 9 but not age 16 years. Exposure to PM10_total during the whole pregnancy period was positively associated with higher total difficulties score (0.049; 95% confidence interval [CI], 0.004 to 0.095) per 1 µg/m3 higher, suggesting more frequent behavioural problems. We did not find clear evidence of a sensitive exposure period for PM10_road. at age 9 years, 1 µg/m3 higher PM10_total during pregnancy was associated with lower prosocial scores (-0.115; 95% CI, -0.185 to -0.044), indicating less well developed prosocial behaviour, but similar associations were seen for 0–6 months, 7–12 months, and 0–8 years. We also found associations between higher PM10_road with conduct problems .
CONCLUSION: Exposure to higher PM10 during pregnancy in the early 1990s was associated with increased behavioural problems in children at age 9 years in the ALSPAC cohort.

KEYWORDS: Air pollution; behavioural problems; ALSPAC

P-1016 Exposure to urban environmental stressors in pregnancy and postpartum depression: A meta-analysis of 11 European birth cohorts

BACKGROUND AND AIM: Urban environmental stressors have been associated with adult depression, but few studies on postpartum depression (PPD) exist. We investigated associations between exposure to urban environmental stressors in pregnancy and PPD.

METHODS: We included women from 11 European birth cohorts within the EU Child Cohort Network with singleton pregnancies between 1990-2016 and no previously reported depression. Exposures included ambient air pollution (NO2, PM2.5 and PM10), road traffic noise, natural spaces (Normalised Difference Vegetation Index; NDVI, access to major green and blue spaces) and built environment (population density, facility richness and walkability). PPD was assessed using self-report questionnaires collected 3 – 18 months after birth (e.g. Edinburgh Postnatal Depression Questionnaire). We used adjusted logistic regression to estimate cohort-specific associations between single exposures and PPD and pooled results via meta-analysis using DataSHIELD. We also fit multiple exposure models where we hypothesised one exposure may confound the relationship between another exposure and PPD.

RESULTS: Rates of PPD ranged from 2 – 17% across cohorts (n = 39,329). In the pooled sample higher levels of NDVI were associated with reduced odds of PPD (OR per IQR difference in NDVI = 0.94, CI 0.89, 1.00), although results were not consistent across indicators of green spaces. We also found a trend for higher levels of traffic noise to be associated with increased odds of PPD (OR Lden >70dB = 1.19, CI 0.89, 1.59). for all other urban stressors associations were close to null and there was considerable heterogeneity between cohorts. Multiple exposure models showed similar results.

CONCLUSIONS: Overall, this large European meta-analysis provides little evidence for an association between urban environmental stressors and PPD, although our findings provide some evidence that lack of green spaces may be associated with greater risk of PPD.

KEYWORDS: post-partum depression, air pollution, natural spaces, traffic noise

P-1017 Long-term exposure to air pollution and traffic noise and incidence of mental disorders: a large administrative cohort of adults

Federica Nobile[1], Anna Forastiere[1], Paola Michelozzi[1], Francesco Forastiere[2], Massimo Stafoggia[1]
[1]Department of Epidemiology, Lazio Region Health Service / ASL Roma 1, Rome, Italy, [2]Environmental Research Group, Imperial College, London, UK

BACKGROUND AND AIM: Air pollution is related to a global increase in mortality and morbidity. The literature on the adverse effects on mental disorders is limited. We aimed to investigate the associations between air pollutants and traffic noise with incidence of different categories of mental disorders and drug prescriptions in a large administrative cohort.

METHODS: We enrolled 1,739,277 individuals 30+ years living in Rome at 2011 census, and followed them up until 31st December 2019. We excluded subjects with prevalent mental disorders at baseline to evaluate the incidence of schizophrenia, bipolar, anxiety, personality and substance use disorders, as well as prescriptions of antipsychotics, antidepressants and mood stabilizers. We assigned annual average concentrations of fine particulate matter ($PM_{2.5}$), nitrogen dioxide (NO_2), black carbon (BC), ultrafine particles (UFPs) and traffic noise to baseline residential addresses. We applied Cox proportional hazards models with adjustment for individual and area-level covariates.

RESULTS: This study identified variable numbers of incident cases, from 1,280 cases for personality disorders to 200,549 for antidepressants. Each interquartile range increase in $PM_{2.5}$ (1.13 μg/m³) was associated with a hazard ratio (HR) of 1.070 (95% confidence interval: 1.017, 1.127) for schizophrenia spectrum disorder, 1.135 (1.086, 1.186) for depression and 1.097 (1.030, 1.168) for anxiety disorders. Positive associations were also detected for the other exposures and with the three categories of drug prescriptions. In two-exposure models, $PM_{2.5}$, UFPs and noise remained associated with schizophrenia spectrum disorders, depression and antidepressant drugs use. The effects were higher in the age group 30-64 than in the 65+. Sensitivity analyses generally yielded similar results.

CONCLUSIONS: Long-term exposure to air pollutants and noise was associated with increased risks of schizophrenia spectrum disorders, depression and anxiety disorders. The associations with prescriptions of specific drugs increased the credibility of the results.

KEYWORDS: air pollution, noise, mental disorders, drug prescriptions.

P-1018 Exposure to phthalates, non-phthalate plasticizers and bisphenols and neurodevelopmental outcomes in school age children from Poland

Kinga Polanska[1], Agnieszka Jankowska[1], Holger Koch[2], Daniel Bury[2], Claudia Pälmke[2], Rebecca Moos[2], Wojciech Hanke[1], Mercè Garí[3,4]

[1]Nofer Institute of Occupational Medicine, Lodz, Poland, [2]Institute for Prevention and Occupational Medicine of the German Social Accident Insurance, Institute of the Ruhr-University Bochum (IPA), Bochum, Germany, [3]Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Barcelona, Spain, [4]Computational Health Department, Helmholtz Munich, Germany.

BACKGROUND AND AIM: Exposures to phthalates, non-phthalate plasticizers and bisphenols may play a role in the development of child behavioral and psychomotor problems. The aim of the study was to evaluate the association between childhood exposures to these compounds and neurodevelopmental outcomes in the REPRO_PL birth cohort (Poland).

METHODS: Urine samples were collected at the time of children's neurodevelopmental assessment (age 7). HPLC-MS/MS was used for the determination of BPA and 21 phthalate metabolites (n=400) and their replacement alternatives BPF, BPS, three metabolites of DEHTP and three metabolites of DINCH (n=150). Behavioral, cognitive and psychomotor development of children were assessed by the Strengths and Difficulties Questionnaire (SDQ) and the Intelligence and Development Scales (IDS). Multivariate linear regression models accounting for sex-specific effects were applied, including the use of stratification and interactive approaches.

RESULTS: BPA and BPF were found to be associated with emotional symptoms (0.54 [0.035; 1.0] and 0.93 [0.051; 1.8], respectively), and the latter was additionally associated with total difficulties (2.8 [0.30; 5.2]) and peer-relationship problems (0.90 [0.13; 1.7]) in boys. In addition, boys with higher exposures to DEHTP performed worst for conduct problems (1.1 [0.41; 1.7]) and the pro-social behavior (-1.0 [-1.9; -0.15]). Conversely, among girls, the compounds which were significantly associated with poorer behavioral scores were MMP, ΣDnBP and ΣDiBP. for IDS, higher exposures to BPF were associated to lower scores in Fluid IQ (-6.7 [-12.6; -0.88]) and Cognition (-6.0 [-10.8; -1.3]) in boys. Among girls, however, we found a negative association between DINCH and MMP and mathematical scores, with statistically significant results.

CONCLUSIONS: This study indicates that children's exposure to several replacement compounds of BPA and phthalates, such as BPF and DEHTP, are associated with adverse effects on behavioural and cognitive development of school age children, with a divergent sex-specific effects.

P-1020 Prenatal Exposure to Tailpipe and Non-Tailpipe Particulate Matter Pollution and Autism Spectrum Disorders

Mostafijur Rahman[1], Jane Lin[2], Sarah Carter[2], Ting Chow[2], Xin Yu[3], Mayra Martinez[2], Pat Levitt[4], Zhanghua Chen[1], Jiu-Chiuan Chen[1], Sandrah Eckel[1], Joel Schwartz[5], Frederick Lurmann[6], Michael Kleeman[7], Rob McConnell[1], Anny Xiang[2]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [2]Department of Research & Evaluation, Kaiser Permanente Southern California, Pasadena, USA, [3]Spatial Science Institute, University of Southern California, Los Angeles, USA, [4]Department of Pediatrics, Keck School of Medicine, Program in Developmental Neuroscience and Neurogenetics, The Saban Research Institute, Children's Hospital Los Angeles, University of Southern California, Los Angeles, USA, [5]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [6]Sonoma Technology, Inc., Petaluma, USA, [7]Department of Civil and Environmental Engineering, University of California, Davis, Davis, USA

BACKGROUND: Traffic-related air pollution is associated with increased risks for autism spectrum disorders (ASD). However, it is unknown whether carbonaceous material from exhaust emissions or redox-active non-tailpipe metals emissions are responsible for this association. We examined ASD risk associated with fine particulate matter (PM2.5) tracers of tailpipe (elemental carbon [EC] and Organic Carbon [OC]) and non-tailpipe (copper [Cu]; iron [Fe] and manganese [Mn]) sources during pregnancy.

METHODS: This retrospective cohort study included 189,480 children born in Kaiser Permanente Southern California (KPSC) hospitals during 2001-2009. Children were followed until ASD diagnosis or age 5, whichever occurred first. Monthly estimates of PM2.5 EC, OC, Cu, Fe, and Mn with 4 km spatial resolution were obtained from a source oriented chemical transport model. Prenatal exposure to these trace elements was assigned to each maternal address during pregnancy; associations with ASD diagnosis were assessed using Cox regression models adjusting for covariates. To evaluate independence of these associations, we further adjusted the models for PM2.5. To disentangle ASD risk attributable to non-tailpipe from tailpipe sources, we conducted separate two-pollutant models examining the associations with Cu, Fe, and Mn, additionally adjusting for EC and OC.

RESULTS: 2127 children had ASD diagnosis. ASD was positively associated with exposure to tracers of both tailpipe and non-tailpipe emissions in single pollutant models. Observed associations with trace metals reflecting non-tailpipe source of PM2.5 were robust to the adjustment for total PM2.5 and to adjustment for EC and OC.
CONCLUSION: Results suggest that non-tailpipe emissions may be contribute to ASD. Implications are that future conventional vehicles with reduced tailpipe emissions may not eliminate ASD associations with traffic-related air pollution. In contrast, widespread adoption of electric vehicles with zero tailpipe emissions and lower non-tailpipe emissions due to regenerative braking may reduce future ASD associations with traffic-related air pollution.

KEYWORDS: ASD; tailpipe; non-tailpipe

P-1023 Age Acceleration is Associated with Reduced Cognitive Function in Older Men: Results from the Normative Aging Study

Koshiq Hossain, Cuicui Wang, Joel Schwartz, Marc G. Weisskopf, Lifang Hou, Robert O. Wright, Avron Spiro III, Pantel Vokonas, Howard Hu, Andrea Baccarelli, Diddier Prada[1]
[1]*Mailman School of Public Health - Columbia University, New York City, USA*

BACKGROUND AND AIM: DNA methylation (DNAm) has been used to quantify the biological effects of external factors on aging processes. This study examined the association between age acceleration and cognitive function in older men using DNAm-based clocks.

METHODS: We evaluated the associations of age acceleration on cognitive function among participants in the Normative Aging Study (NAS). We tested GrimAgeAccel (a biomarker linked with mortality), PhenoAgeAccel (capturing risks for diverse outcomes), Intrinsic (IEAA), and Extrinsic (EEAA) Age Acceleration, and the DNAm-related mortality risk score (DNAmRS). DNAm was determined using Illumina 450K arrays. We modeled six cognitive tests (Mini-Mental State Examination [global function], Word List Memory Task [recent memory], Digit Span Backwards [executive function], Verbal Fluency Test [language], Sum of Drawings [visuospatial ability], and Pattern Comparison Task [visuospatial function]) in linear mixed models adjusted for chronological age, alcohol, smoking status, fish consumption, physical activity, hypertension, diabetes mellitus, English as the first language, computer experience, education, body mass index, and methylation technical covariates.

RESULTS: We evaluated 549 men (mean age: 74.3 years, standard deviation: 6.5 years), mostly white (91.23%). GrimAgeAccel showed significant negative associations with global cognition (β = -0.029, 95% Confidence Interval [95%CI] -0.043, -0.015, p-value < 0.001) and visospatial ability (β = -0.018, 95% CI -0.033, -0.003, p-value = 0.019). PhenoAgeAccel was negatively associated with executive function (β = -0.009, 95% CI -0.017, -0.001, p-value = 0.041) and visuospatial ability (β = -0.019, 95% CI -0.029, -0.008, p-value < 0.001). DNAmRS was negatively associated with recent memory and executive function. IEAA and EEAA did not show consistent results.

CONCLUSIONS: Selected age acceleration biomarkers were associated with accelerated cognitive decline in older men. DNAm-based biological clocks may help identify individuals at higher risk for age-related cognitive decline.

KEYWORDS: Aging, age acceleration, cognitive function, age-related, DNA methylation.

P-1024 Higher surrounding green space is associated with better attention in Flemish adolescents

Esmée Bijnens[1,2], Stijn Vos[1], Veerle Verheyen[3,4], Liesbeth Bruckers[1], Adrian Covaci[4], Stefaan De Henauw[5], Elly Den Hond[6], Ilse Loots[4], Vera Nelen[6], Michelle Plusquin[1], Greet Schoeters[3,4], Tim Nawrot[1,7]
[1]Hasselt University, Diepenbeek, Belgium, [2]Ghent University Hospital, Ghent, Belgium, [3]VITO, Flemish Institute for Technological Research, Mol, Belgium, [4]University of Antwerp, Antwerp, Belgium, [5]Ghent University, Ghent, Belgium, [6]Provincial Institute of Hygiene, Antwerp, Belgium, [7]KU Leuven, Leuven, Belgium

BACKGROUND AND AIM: Previous studies suggested that green space is beneficial for the cognitive development in children. However, evidence in adolescents is limited. Therefore, we aim to investigate green space exposure in association with attention and behaviour in adolescents.

METHODS: This study includes 596 Flemish adolescents between 13 and 17 years old. Attention was assessed with Stroop Test (selective attention) and Continuous Performance Test (sustained and selective attention). Behaviour was determined based on the Strengths and Difficulties Questionnaire. Green space was estimated in several radius distances around their current residence and school based on high-resolution land cover data. Multilevel regression analyses were used adjusting for participant's age, sex, education level of the mother, and area deprivation index.

RESULTS: Surrounding green space in a 2000 m radius is associated with a faster reaction time in adolescents. An IQR (13%) increment in total green space within 2000 m of the residence and school combined, is associated with a 32.7 milliseconds (95%CI: -58.9 to -6.5; p = 0.02) and a 7.28 milliseconds (95%CI: -11.7 to -2.8; p = 0.001) shorter mean reaction time between the presentation of a stimulus and the response based on the Stroop Test and the Continuous Performance Test. Subdividing green space based on vegetation height, shows that green space higher than 3 meters is associated with a faster reaction time (-6.50 milliseconds; 95%CI: -10.9 to -2.2; p = 0.004), while low green is not. We did not find an association between green space and behavioural development in adolescents.

CONCLUSIONS: Our study shows that green space, especially trees, surrounding the residence and school combined is associated with better sustained and selected attention in adolescents. These findings indicate that the availability of green is important for adolescents that are growing up in a rapidly urbanizing world.

KEYWORDS: Green space, attention, behaviour, adolescents.

P-1025 Does low-level cadmium exposure affect cognitive functions? Results from the Malmö Diet and Cancer Study

Gunilla Wastensson[1,2], Florencia Harari[1,2], Eva M Andersson[1,2], Lars Barregard[1], Gerd Sallsten[1], Katarina Nägga[3,4], Gunnar Engström[5]

[1]School of Public Health and Community Medicine, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, [2]Occupational and Environmental Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden, [3]Clinical Memory Research Unit, Department of Clinical Sciences Malmö, Lund University, Malmö, Sweden, [4]Department of Acute Internal Medicine and Geriatrics, Linköping University, Linköping, Sweden, [5]Department of Clinical Sciences Malmö, Lund University, Malmö, Sweden

BACKGROUND AND AIM: Elevated cadmium exposure is toxic for the brain, but it is unclear if low-level exposure is a risk factor for cognitive impairment. We aim at examining the association between blood cadmium and cognitive functions in a Swedish population-based cohort with a follow-up period of 20 years.

METHODS: The Malmö Diet and Cancer Study – Cardiovascular Cohort (aged 46-67 years) was recruited in 1991-1994. After 20 years, a subsample of individuals underwent a clinical reexamination including a global cognitive screening test (Mini-Mental State Examination, MMSE) and a test of processing speed, attention and executive function (A Quick Test of Cognitive Speed, AQT). Associations with blood cadmium (in quartiles, Q1-Q4) at baseline were analyzed using linear regression and adjusted for confounders and known risk factors for cognitive impairment in 2805 individuals with data on blood cadmium and cognitive screening.

RESULTS: The mean total score of MMSE was 28.3 (SD 1.7) points (maximum score 30). The MMSE score was 0.38 points lower (95% CI -0.62, -0.13) among individuals in Q4 (median blood cadmium 1.0 µg/L) compared with those in Q1 (median blood cadmium: 0.13 µg/L). The mean total test time for AQT was 136 (SD 30) seconds. Individuals in Q4 of blood cadmium were on average 7.2 seconds slower (95% CI 2.69, 11.8) than those in Q1. Associations were similar among men and women, and among never, former, or current smokers.

CONCLUSIONS: Blood cadmium in the highest quartile was associated with worse results in two common cognitive tests in a sample from the general population with cadmium exposure comparable to those of most European countries and the U.S. Our findings strengthen the need for further actions to reduce cadmium exposure in the general population.

KEYWORDS: cadmium, cognitive tests, general population

P-1026 Behavioral and Emotional Outcomes in a Cohort of Healthy Young Adults Before and After the COVID-19-related Lockdown

Alessandra Patrono[1], Donatella Placidi[1], Giuseppa Cagna[1], Stefano Calza[1], Manuela Oppini[1], Roberto G Lucchini[1,2], Elisa Ongaro[1], Matteo Rota[1], Donald R Smith[3], Robert O Wright[4], Megan Horton[4], Stefano Renzetti[1]
[1]University of Brescia, Brescia, Italy, [2]Florida International University, Miami, USA, [3]University of California, Santa Cruz, USA, [4]Icahn School of Medicine, New York, USA

BACKGROUND AND AIM: The COVID-19 related lockdowns and social restrictions aiming to curb disease transmission negatively impacted mental health. This longitudinal study aims to examine the impact of covid-related lockdowns on the mental health of young adults residing in the Brescia province, Northern Italy, one of the first epicenters of the pandemic in Europe.
METHODS: The Public Health Impact of Metals Exposure (PHIME)study is an ongoing environmental health study of adolescents and young adults living in Northern Italy. 167 PHIME participants completed the Adult Behavioral Checklist (ABCL) by email or phone interview between April 2017-January 2020 (pre-pandemic). We repeated the ABCL in June-July 2020, following the first COVID-19 lockdown in Italy (March-May 2020). 65 subjects (38.5% male) completed pre- and post-ABCL. We used sign test and multiple linear regression models to examine changes in pre- and post-COVID lockdown ABCL scores adjusting for sex, age, IQ, and time (weeks) in lockdown and social restrictions. We also examined differences by sex including an interaction term between time and gender.
RESULTS: Time in lockdown and social restriction until the day of the second interview ranged from 12 to 18 weeks. Overall, thought problems increased between pre- and post-lockdown (median difference: 1.0; 1st, 3rd quartile: -1.0, 4.0; p=0.049).Among males, a longer time in lockdown and social restrictions (> 14 weeks) was associated with increased rule-breaking behaviors (β = 2.8, 95%CI 0.08, 5.5).
CONCLUSIONS: This survey was carried out on a particularly significant sample: the survey participants had already answered previously to the same questionnaire proposed even after the lock-down.These results confirm a negative impact of the pandemic-related lockdown on behavior of young adults with greater impacts on males.These results may inform interventions aimed at minimizing or eliminating the consequences of social isolation experience in youth.

P-1027 Real-life panel study on the associations between electromagnetic fields (RF-EMF) from mobile phones and cognitive performance, sleep, and health-related quality of life

Marloes Eeftens[1,2], Sophie Pujol[3,4], Frédéric Mauny[3,4], Thomas Gehin[3,4], Gilles Chopard[5], Benjamin Flückiger[1,2], Nicolas Loizeau[1,2], Taghrid Mazloum[6], Shanshan Wang[6], Joe Wiart[6], Martin Röösli[1,2]

[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]University of Basel, Basel, Switzerland, [3]Laboratoire Chrono-environnement, Université de Bourgogne-Franche-Comté, Besancon, France, [4]Centre Hospitalier Régional Universitaire de Besançon, Besancon, France, [5]Laboratoire de Recherches Intégratives en Neurosciences et Psychologie Cognitive - UR LINC, UFC, UBFC, Besancon, France, [6]Telecom ParisTech, Chair C2M, Paris, France

INTRODUCTION:
The SPUTNIC study (Study Panel on Upcoming Technologies to measure Non-Ionizing radiation and Cognition) aimed to investigate real-life short-term associations between electromagnetic fields (RF-EMF) from mobile phones and cognitive performance, sleep, and health-related quality of life (HRQoL), which have not been well studied.

METHODS: Participants tracked their RF-EMF exposures (cordless calls, mobile calls, and mobile screen time four hours prior to each assessment) as well as health outcomes over ten study days: 1) cognitive performance, through a platform, consisting of six "game-like" tests which assessed verbal and spatial memory repeatedly; 2) HRQoL, reported as mood, tiredness and stress on a Likert-scale and 3) sleep duration and quality measured using Fitbit activity trackers. We fitted mixed models with random intercepts per participant on eight cognitive, three HRQoL and seven sleep scores. Possible time-varying confounders were assessed at daily intervals by questionnaire and used for model adjustment.

RESULTS: We included 121 participants (63 from Besancon and 58 from Basel). We found sporadic significant associations between cordless call duration and a decrease in "Rotations" and combined spatial memory test score, and between mobile phone call duration and an increase "Spatial span" test score. Cordless or mobile phone calls were not associated with any HRQoL indicators but we found a significant association between screen time and decrease in mood score and increased stress. No RF-EMF indicators were associated with any of the 7 sleep duration and quality indicators, except a single association between cordless phone calls and a reduced deep sleep duration, which may have occurred by chance.
DISCUSSION:
We did not find conclusive evidence for adverse health effects of RF-EMF on cognitive performance, HRQoL, or sleep duration and quality. The most consistent finding was a worse mood and increased stress in relation to more screen time, which is consistent with previous studies.

P-1028 Prenatal exposure to polycyclic aromatic hydrocarbons and cognition in preschool-aged children

Bob Sun[1,2], Yu Ni[1], Christine Loftus[1], Erin Wallace[1], Adam Szpiro[1], Drew Day[2], Emily Barrett[3], Ruby Nguyen[4], Kurunthachalam Kannan[5], Morgan Robinson[5], Nicole Bush[6], Sheela Sathyanarayana[1,2], Catherine Karr[1], Kaja LeWinn[6]

[1]University of Washington, Seattle, USA, [2]Seattle Children's Research Institute, Seattle, USA, [3]Rutgers University, New Brunswick, USA, [4]University of Minnesota, Minneapolis, USA, [5]New York University, New York, USA, [6]University of California, San Francisco, USA

BACKGROUND AND AIM: Prenatal exposure to polycyclic aromatic hydrocarbons (PAH) is linked to adverse child neurodevelopmental outcomes, including cognition, but epidemiological evidence is inconsistent and little is known about modifying factors or critical windows of exposure. We investigated associations between prenatal PAH exposure and child cognition in a large, multi-site study.

METHODS: We included nonsmoking mother-child dyads from two prospective pregnancy cohorts (CANDLE and TIDES) in the ECHO-PATHWAYS Consortium. Mono-hydroxylated PAH metabolites (1-hydroxypyrene;1- and 2-hydroxynaphthalene; 1/9-, 2-, and 3-hydroxyphenanthrene; and 2/3/9-hydroxyfluorene) were measured in second trimester urine in both cohorts and additionally in first and third trimesters in TIDES. Full-scale intelligence quotient (FSIQ) was assessed between ages 4-6. Associations between individual PAH metabolites and FSIQ were estimated with multivariable linear regression adjusted for numerous potential confounders. In a TIDES-only sample, we estimated associations with metabolites in each trimester. We assessed modification by child sex and maternal obesity and explored associations of PAH metabolite mixtures with FSIQ using weighted quantile sum regression with a permutation test to control Type I errors.

RESULTS: The pooled sample (N =1,223 dyads) spanned five US regions and was sociodemographically diverse. All associations between PAH metabolites, whether assessed individually or as mixtures, and FSIQ were null after full adjustment. Associations were similar across trimesters of exposure (TIDES-only analysis). We did not observe modification by sex or maternal obesity, except in associations between 2-hydroxynaphthalene and FSIQ, which were adverse in males (β_males= -0.67 [95%CI: -1.5, 0.13] and β_females= 0.31 [95%CI: -0.52, 1.1] per two-fold increase in metabolite; p_interaction = 0.04).
CONCLUSION: In this longitudinal multi-cohort analysis with rigorous adjustment for potential confounders, we found little evidence that prenatal PAH exposure adversely impacts cognition in early childhood. Prenatal PAH could exert neurodevelopmental toxicity but affect endpoints other than cognition, such as behavior.

KEYWORDS: polycyclic aromatic hydrocarbons; neurodevelopment; mixtures

P-1030 Developmental language disorders in preschool children after high exposure to perfluoroalkyl substances from contaminated drinking water in Ronneby, Sweden

Charlotte Stübner[1,2], Matilda Ebel[3], Kristina Jakobsson[4,5], ChristopherGillberg[1,6], Christel Nielsen[3], Carmela Miniscalco[1,2,6]

[1]Gillberg Neuropsychiatry Centre, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [2]Department of Pediatric Speech and Language Pathology, Queen Silvia Children´s Hospital, Sahlgrenska University Hospital, Gothenburg, Sweden, [3]Division of Occupational and Environmental Medicine, Department of Laboratory Medicine, Lund University, Lund, Sweden, Lund, Sweden, [4]School of Public Health and Community Medicine, Sahlgrenska Academy, University of Gothenburg, Sweden, Gothenburg, Sweden, [5]Occupational and Environmental Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden, Gothenburg, Sweden, [6]Department of Child Neuropsychiatry, Queen Silvia Children´s Hospital, Sahlgrenska University Hospital, Gothenburg, Sweden, Gothenburg, Sweden

BACKGROUND: There are indications that prenatal exposure to perfluoroalkyl substances (PFAS) might impact neurodevelopment, including language and communication, but results from epidemiological studies are inconclusive and studies from high-exposed populations are sparse.
OBJECTIVE AND AIM: To investigate associations between prenatal exposure to primarily PFHxS and PFOS and developmental language disorder in children up to seven years of age.

METHODS: Register-based cohort of children, born 1998-2013 in the county of Blekinge, Sweden. Maternal residency in Ronneby municipality, with or without highly PFAS contaminated drinking water during the five-year period before childbirth, was used as a proxy for increased prenatal exposure. We included 646 Ronneby children with high PFAS exposure, 1,650 children with intermediate exposure and 9,599 children from county with background exposure. We used Cox proportional hazards regression to estimate hazard ratios (HR) for 1) referral to speech- and language pathologist (SLP) after screening at Child Health Services and 2) ICD-10 diagnosis from at least two clinical assessments by a SLP. Models were adjusted for parity, maternal age, education level, and smoking. We explored effect modification by sex.

RESULTS: The overall adjusted HR for referral to SLP for children with high prenatal exposure was 1.23 (95% CI: 1.03-1.47). Girls had a higher risk than boys.
The HR for ICD-10 diagnosis for children with high prenatal exposure was 1.13 (95% CI: 0.97-1.56), and the association was among girls. Children with intermediate PFAS exposure did not differ from background exposed children.

CONCLUSIONS: Children, particularly girls, with high prenatal exposure to PFAS had an increased risk of developmental language delay and disorders. Further research is needed on the role of PFAS in the context of general neurodevelopment, for which language development is a proxy.

P-1032 Joint Associations of phthalates with social responsiveness in Singaporean Children and potential effect modification by child sex and folate levels: Growing Up in Singapore Towards healthy Outcomes

Michael Mascari[1], Katherine Reeves[1], Raji Balasubramanian[1], James Chan[3], Zhenhua Liu[1], Mary Daniel[7], Sharon Ng[2], Chia-Yang Chen[4], Jerry Kok Yen Chan[5], Shiao-yng Chan[6], Jonathan Huang[2,5], Youssef Oulhote[1]

[1]University of Massachusetts, Amherst, USA, [2]Singapore Institute for Clinical Sciences, Singapore, Singapore, [3]Singapore Institute of Food and Biotechnology Innovation, Singapore, [4]Institute of Environmental Health, National Taiwan University, Taipei, Taiwan, [5]Duke-NUS Medical School, Singapore, Singapore, [6]Department of Obstetric and Gynaecology, Yong Loo Lin School of Medicine, National University of Singapore, Pelham, Singapore, [7]Department of Child Development, KK Women's and Children's Hospital, Singapore, Singapore

BACKGROUND AND AIM: Previous research shows associations between phthalates and folate, and autistic traits, but little is known about their interplay in the etiology of autistic traits. We sought to investigate the joint association of multiple phthalates and social responsiveness in Singaporean children, and the potential effect modification by folate levels.

METHODS: We used data on 431 mother-child dyads from the Growing Up in Singapore Toward healthy Outcomes cohort with available data on phthalates, folate, and social responsiveness scale (SRS-2) scores in 7-years children. We measured six phthalate metabolites in cord blood and used quantile g-computation with interaction terms to assess the joint associations of phthalates with SRS-2 scores and specific sub-scores and potential effect modification by folate concentrations measured at 26-weeks of pregnancy. We also evaluated effect modification by child sex.

RESULTS: The mean SRS-2 score was 55.4 (SD: 7.1). Higher SRS-2 scores indicate more autistic traits. Overall, phthalate metabolites were positively associated with total SRS scores, whereas folate levels were negatively associated with total SRS-2 scores, but none reached the level of significance at $p<0.05$. Mono-2-ethylhexyl phthalate showed stronger association in boys (β for a twofold increase = 1.5; 95% CI: 0.2, 2.8) compared to girls (β = -0.1; 95% CI: -1.2, 1.1). We did not find associations between the joint mixture and SRS-2 scores, however, folate significantly modified the association between the mixture and the SRS-2 social motivation sub-score (p-EM = 0.01), with associations stronger at lower levels of folate (β = 2.1; 95% CI: 0.5, 3.7 when folate at the 25th percentile and β = 0.3; 95% CI: -1.3, 1.8 when folate at the 75th percentile).

CONCLUSIONS: In this cohort study, folate was found to modify the association between phthalates and specific SRS sub-scores and the results varied by child sex.

P-1033 Meta-analysis of head trauma and subsequent risk of brain cancer comparing R and Stata statistical packages

David F Goldsmith[1], Garrett Fuselier[1]
[1]*George Washington University, Silver Spring, USA*

BACKGROUND AND AIM: Epidemiology research has demonstrated a link between traumatic brain injury (TBI) and subsequent risk of gliomas and meningiomas. McElvanny et al (2021). conducted a meta-analysis using Stata biostatistical methods and found all brain cancer meta-analysis relative risk (MRR) of 1.40 (95% CI 1.11, 1.77). for gliomas the MRRs was 0.96 (0.49, 1.88) and 1.53 (1.02, 2.27) for cohort and case-control studies, respectively. for meningiomas they found MRRs of 1.22 (0.95, 1.76) and 1.88 (0.84, 4.19) for cohort and case control methods.

METHODS: We utilized the same studies selected by McElvanny but used the R statistical software to conduct the meta-analysis to contrast the findings.

RESULTS: For all brain tumors, the cohort MRR was 1.19 (95% CI 0.88, 1.61), while the case-control MRR was 1.58 (1.09, 2.29). Overall, the MRR was 1.40 (1.11, 1.77). for gliomas we found MRR of 1.53 (1.02, 2.99) using case-control design, using cohort studies the MRR 0.96 (0.49, 1.88). Overall, the MRR was 1.33 (0.94, 1.89). for meningiomas cohort studies the MRR was 1.22 (0.85, 1.76); for case-control study designs the MRR was 1.88 (0.84, 4.19); and overall, the detected MRR was 1.65 (0.97, 2.81). for all brain tumors, gliomas, and meningioma studies there was significant heterogeneity between studies ($p < 0.001$). Funnel plots and Egger's test were used to assess publication bias. There was no strong evidence ($p>0.05$) for publication bias for all brain tumors, gliomas, and meningioma meta-analyses.
CONCLUSION:
Contrasting R and Stata for this meta-analysis suggest both packages are measuring the same risk levels for brain cancers after head trauma. These results support further studies focusing on the association between TBI and brain cancer, especially gliomas. Our assessment also suggests the need for more research on TBI and brain tumors among veterans.

KEYWORDS: meta-analysis, head trauma, brain cancer

THEMATIC 19: Reproductive outcomes

P-1176 Association between ambient air pollution and polycystic ovarian syndrome: A 2010-2019 national populational-based cohort study in Korea

Ju Hee Kim[1], Na Lae Moon[1], Se Hwa Hong[2], Hyunjin Kang[1], Min Hyung Jung[3], Jae-Hong Ryoo[4], Dae Ryong Kang[5]
[1]College of Nursing Science, Kyung Hee University, Seoul, Republic of Korea, [2]Department of Biostatics, Wonju College of Medicine, Yonsei University, Wonju, Republic of Korea, [3]Department of Gynecology, College of Medicine, Kyung Hee University, Seoul, Republic of Korea, [4]Departments of Occupational and Environmental Medicine, School of Medicine, Kyung Hee University, Seoul, Republic of Korea, [5]Department of Precision Medicine, Wonju College of Medicine, Yonsei University, Wonju, Republic of Korea

BACKGROUND: Several studies have indicated that prenatal exposure to ambient air pollution is associated with an increased risk of gestational diabetes mellitus, hypertensive disorder during pregnancy, preterm birth, and stillbirth. However, no previous study has focused on the association between the number of pregnancy complications and exposure to ambient air pollution.
Objectives: To investigate the association between prenatal exposure to ambient air pollutants and the number of pregnancy complications in high-risk pregnancies.

METHODS: We collected data on gestational diabetes mellitus, hypertensive disorder during pregnancy, preterm birth, and stillbirth from the National Health Information Databases, provided by the Korean National Health Insurance Service. To assess individual-level exposure to air pollutants, a spatial prediction model and area-averaging approach were used.

RESULTS: From 2015 to 2018, data of 789,595 high-risk pregnancies were analyzed. The ratio of gestational diabetes mellitus in the country was the highest, followed by preterm birth, hypertensive disorder during pregnancy, and stillbirth. Approximately 71.7% of pregnant women (566,143) presented with one pregnancy complication in identical pregnancies, 27.5% (216,714) presented with two, and 0.9% (6738) presented with three or more. Multiple logistic regression models with adjustments for age, residence, and income variables indicated that the risk of having two or more pregnancy complications was positively associated with the exposure to higher levels of PM10 (odds ratio [OR], 1.11; 95% confidence interval [CI], 1.09–1.12) and PM2.5 (OR, 1.14; 95% CI, 1.12–1.15). The highest quartile presented higher odds of two or more pregnancy complications compared with the lower three quartiles of PM10, PM2.5, CO, NO2, and SO2 exposures ($p < 0.001$).
CONCLUSION: The results indicate that the risk of pregnancy complications is positively associated with the exposure to the high concentrations of PM10, PM2.5, CO, NO2, and SO2.

P-1183 Cumulative risk assessment of phthalates exposure for recurrent pregnancy loss in reproductive-aged women population using multiple hazard indices approaches

Po-Chin Huang[1,2,3], Wei-Hsiang Chang[4,5], Wei-Chun Chou[6], Alexander Waits[7], Kai-Wei Liao[8], Pao-Lin Kuo[9]
[1]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli, Taiwan, [2]Research Center for Environmental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, [3]Department of Medical Research, China Medical University Hospital, China Medical University, Taichung, Taiwan, [4]Department of Food Safety/ Hygiene and Risk Management, College of Medicine, National Cheng Kung University, Tainan, Taiwan, [5]Research Center of Environmental Trace Toxic Substances, College of Medicine, National Cheng Kung University, Tainan, Taiwan, [6]Institute of Computational Comparative Medicine (ICCM), Department of Anatomy and Physiology, College of Veterinary Medicine, Kansas State University, Manhattan, USA, [7]Institute of Public Health, National Yang Ming Chiao Tung University, Taipei, Taiwan, [8]School of Food Safety, College of Nutrition, Taipei Medical University, Taipei, Taiwan, [9]Department of Obstetrics and Gynecology, National Cheng Kung University Hospital and College of Medicine, Tainan, Taiwan

BACKGROUND AND AIM: Phthalates, which are commonly used in flexible plastics and consumer products, have been reported to be toxic to reproductive and developmental function in mammals. Past studies have focused on the toxic effects on male reproduction, with only a few studies conducted on the risks that cumulative exposure to phthalates have on the female reproductive system.

METHODS: We recruited 260 patients with recurrent pregnancy loss (RPL) of unknown etiology and 203 controls from the clinics of Obstetrics and Gynecology at a medical center in southern Taiwan from 2013 to 2020. The daily intake of phthalates was estimated from urine samples using the back-calculation method, after which the cumulative risk was determined using multiple hazard indices, including a dose-addition model, a receptor effect model, and a hazard index approach.

RESULTS: The patients with RPL had a significantly higher cumulative exposure to phthalates ($p < 0.05$) than did the controls with a hazard index above one. After adjusted logistic regression analysis, we found that the risk of RPL was strongly related to the higher quartiles of DEHP, the DEHPTEQ for the antiandrogenic effect and adverse effects of the female reproductive system and the ERα binding effect ($p < 0.05$).

CONCLUSIONS: Our work suggests that more attentions should be paid to the adverse effects induced by phthalates on female reproduction, especially the effects caused by the cumulative exposure to phthalates in women of reproductive age.

KEYWORDS: Phthalates; Cumulative risk assessment; Relative potency factor; Recurrent pregnancy loss

P-1184 Associations between Gestational Exposure to Air Pollution and Maternal Vitamin D Levels

Akhgar Ghassabian[1], Anne-Claire Binter, Hanan El Marroun, Kinga Polanska, Karen Switkowski, Tanja G. Vrijkotte, Rosie McEachan, Ana Fernández Somoano, Marisa Estarlich, Aitana Lertxundi, Jordi Sunyer, Mònica Guxens
[1]*New York University Grossman School of Medicine, New York, USA*

BACKGROUND AND AIM: Individuals living in areas with higher air pollution have lower levels of vitamin D than residents of areas with lower pollution. Evidence suggests non-optimal gestational vitamin D as an important determinant of pregnancy and child health outcomes. We investigated the association between gestational exposure to air pollution and maternal vitamin D levels.
METHODS: Participants were 16,553 pregnant women from birth cohorts in the UK (BiB), US (Project Viva), Netherlands (ABCD and Generation R), Poland (REPRO_PL), and Spain (INMA). Averaged concentrations of air pollutants from conception until vitamin D measurement were estimated at participants' residential addresses using land-use regression or other spatiotemporal models. Cohorts measured 25-hydroxy vitamin D [25(OH)D] and/or 25(OH)D3 in serum or plasma at early or mid-pregnancy. We performed linear regression models in each cohort to estimate the association between air pollution exposure and vitamin D levels and pooled cohort-specific results in a random-effect meta-analysis. Models were adjusted for sociodemographic characteristics, smoking and alcohol use, parity, body mass index, and month of conception.
RESULTS: Concentrations of nitrogen dioxide and fine PM (PM2.5) were lower and had less variation in Project Viva and BiB than other cohorts. In REPRO_PL, 95% of women had vitamin D<20 ng/ml; this rate was 85% in BiB, 52% in Generation R, and <50% in other cohorts. We found an inverse association between PM2.5 and vitamin D levels (-1.4 ng/mL, 95%CI:-2.6,-0.2, per 5 µg/m3 increase in PM2.5). Heterogeneity was high among cohorts, with associations driven by ABCD, BiB, and INMA. There was no association between nitrogen oxide exposure and vitamin D levels.
CONCLUSIONS: PM2.5 exposure might contribute to non-optimal levels of vitamin D in pregnancy. Future studies should focus on underlying mechanisms, including biological pathways, e.g., inducing metabolism of vitamin D, or other factors, e.g., reduced outdoor activity.

KEYWORDS: 25(OH)D; PM2.5; pregnancy; women

P-1187 Relationship between PM2.5 and low birth weight infant in Ho Chi Minh City: a spatial nested case control study

Tran Ngoc Dang[1], Le Thuy Loi[1], Le Truong Vinh Phuc[1]
[1]*University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh City, Vietnam*

BACKGROUND AND AIM: The study aims to determine the average PM2.5 concentration and the association between PM2.5 and low birth weight infant in Ho Chi Minh City (HCMC), Vietnam 2020.

METHODS: The concentration of PM2.5 is extrapolated from 31 monitoring air stations of PAMAIR network that distributed across districts in HCMC, and the individual exposure was assigned base on their living address. The relationship between PM2.5 and low birth weight infant was determined through odds ratio and multivariable logistic regression model.

RESULTS: The annual average concentration of PM2.5 was 27.8 µg/m3, which was higher than the WHO standard (PM2.5 < 10 µg/m3) and higher than the Vietnamese standard (PM2.5 <25µg/m3). The study found that exposure to high levels of PM2.5 during maternal pregnancy was a risk factor for having a low birth weight infant with OR: 1.01 (95% CI: 1.003- 1.019). The study proposes that there should be measures to minimize the harmful effects of PM2.5 on the birth outcomes of the maternal women.

KEYWORDS: PM2.5, air pollution; low birth weight, infant; birth outcomes

P-1190 Disentangling the influence of temperature and season on weekly birth rates in Vienna, Austria

Hanns Moshammer[1]
[1]*Medical University Vienna, Vienna, Austria*

BACKGROUND: Before examining other environmental predictors of weekly birth- and conception rates, we set out to investigate seasonal and meteorological predictors in a time series of births given by Viennese women between 1999 and 2019.

METHODS: We extracted week of birth and duration of gestation in weeks to calculate number of conceptions and of births per week. for both outcomes (birth and conception numbers) we first applied negative binomial regression models. But, when we saw that over-dispersion was negligible, we reverted to Poisson regression models. As predictors, we included a linear term, sine-cosine functions with a wave-length of one year, and another one with a wavelength the average duration of a lunar cycle. In addition, we included temperature as a linear and a quadratic term.

RESULTS: On average 341.4 births and 344.1 conceptions occurred per week. The number of births and conceptions increased over the years and within each year seasonal variation was visible. Birth numbers according to the annual sine-cosine model were lowest in January and February and highest in July and August. The number of conceptions were lowest in May and highest in November. Adding another sine-cosine function for the lunar cycle did not improve the model fit much. Nevertheless, that parameter was still significant, with the highest birth numbers occurring roughly between the waxing crescent and the first quarter moon, and the highest conception numbers conceptions occurring at the full moon. Extremer temperatures (both hot and cold) decreased conception numbers and increased birth numbers.
CONCLUSION: While the effects of temperature and the annual variation resembled our expectations, the lunar influence was unexpected. This latter finding should be treated with care, because it was not hypothesis driven.

KEYWORDS: annual & lunar cycle, births, temperature, births, conceptions

P-1192 Traffic-related air pollution and fetal growth in Eastern Massachusetts, USA

Michael Leung[1], Anna M Modest[2,3], Michele R Hacker[1,2,3], Blair J Wylie[2,3], Yaguang Wei[1], Joel Schwartz[1], Brent Coull[1], Francine Laden[1,3,4], Marc G Weisskopf[1], Stefania Papatheodorou[1]

[1]Harvard TH Chan School of Public Health, Boston, USA, [2]Beth Israel Deaconess Medical Center, Boston, USA, [3]Harvard Medical School, Boston, USA, [4]Brigham and Women's Hospital, Boston, USA

BACKGROUND AND AIM: Previous studies have examined the association between prenatal nitrogen dioxide (NO2) —a traffic emissions tracer— and fetal growth based on ultrasound measures during pregnancy. Yet, most have used exposure assessment methods with low temporal resolution, which limits the identification of critical exposure windows given that pregnancy occurs over a relatively short period. Here, we used NO2 data estimated from a high-resolution spatiotemporal model to examine the association between weekly NO2 exposure during pregnancy and fetal growth in a Massachusetts-based cohort.

METHODS: We used data from 9,446 singleton births at Beth Israel Deaconess Medical Center in 2011-2016. Fetal growth parameters included birth weight, and ultrasound measures of biparietal diameter (BPD), head circumference (HC), femur length, and abdominal circumference. Ultrasound parameters were classified into three distinct gestational periods: 16-23 weeks, 24-31 weeks, and 32+ weeks. We used distributed lag models to estimate the time-varying association between weekly NO2 exposure and fetal growth. All models were adjusted for sociodemographic characteristics, time trends, particulate matter less than 2.5 microns (PM2.5), and temperature.

RESULTS: We found that higher NO2 was negatively associated with all fetal growth parameters. The critical window differed depending on the fetal growth parameter and when it was assessed, with associations particularly strong for head parameters. for example, for BPD and HC measured after week 32, the critical exposure window appeared to be around weeks 15-25; a 10-ppb higher NO2 exposure sustained from conception to the time of measurement was associated with a lower mean z-score of -0.26 (95% CI: -0.39, -0.13) and -0.13 (95% CI: -0.25, 0.00) for BPD and HC, respectively.

CONCLUSIONS: Higher NO2 was associated with smaller fetal growth measures. We identified several critical exposure windows that varied by parameter and timing of measurement.

KEYWORDS: air pollution, traffic, nitrogen dioxide, fetal growth, ultrasound, pregnancy, critical window

P-1194 Traffic-related air pollution and birth weight: the roles of noise, placental function, green space, physical activity, and socioeconomic status (FRONTIER)

Payam Dadvand[1,2,3], Maria Dolores Gómez-Roig[4], Elisa Llurba[5,6], Maria Foraster[1,2,3], Gustavo Arévalo[7], Mariona Bustamante[1,2,3], Xavier Basagaña[1,2,3], Mireia Gascon[1,2,3], Michael Jerrett[8], Jose Lao[7], Edurne Mazarico Gallego[4], Teresa Moreno[9], Tim Nawrot[10], Mark J Nieuwenhuijsen[1,2,3], Xavier Querol[9], Ioar Rivas[1,2,3], Neus Rosell[1,2,3], Joel Schwartz[11], Cathryn Tonne[1,2,3], Jordi Sunyer[1,2,3]

[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [3]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [4]BCNatal, University of Barcelona, Barcelona, Spain, [5]Sant Pau University Hospital, Barcelona, Spain, [6]RICORS RD21/0012/0001, Instituto de Salud Carlos III, Madrid, Spain, [7]Barcelona Regional, Barcelona, Spain, [8]Fielding School of Public Health, University of California, Los Angeles, Los Angeles, USA, [9]IDAEA-CSIC, Barcelona, Spain, [10]Hasselt University, Hasselt, Belgium, [11]Harvard School of Public Health, Boston, USA

BACKGROUND AND AIM: FRONTIER aims to study the impact of maternal exposure to traffic-related air pollution (TRAP) on fetal growth while disentangling the effects of noise, elucidating the role of placental function as an underlying mechanism; and exploring the potential of greenspace to mitigate it.

METHODS: FRONTIER has established a new pregnancy cohort of 1,086 pregnant women in Barcelona (BiSC), Spain. Fetal growth was characterized by anthropometric measures at birth together with ultrasound-based measures of fetal development. We are integrating objective data on time-activity patterns with a hybrid modeling framework combining dispersion and land use regression models and campaigns of personal and home-outdoor air pollution monitoring to estimate maternal exposure level and inhaled dose of NO2, PM2.5, and PM2.5 light absorption and contents at the main microenvironments (home, workplace, and commuting routes). We are assessing maternal exposure to noise by integrating measurements at participants' home-outdoor using noise monitors together with modeled microenvironmental noise levels and data on noise sensitivity, annoyance, and protections against noise. We will develop single- and multi-pollutant models to evaluate the impact of air pollution exposure and inhaled dose on fetal growth and the mediatory role of placental function.

RESULTS: BiSC mothers had an average age of 34.8 years with 31.1% having high school education and less and 73.6% having European origin. The mean (SD) of the first and third trimester measured personal NO2 levels were respectively 31.9(11.7) and 31.0(12.1)µg/m3 for the pre-pandemic period and 26.6(10.9) and 25.1(12.1)µg/m3 for the pandemic period. The mean (SD) of measured home-outdoor noise levels (LAeq,24h) was 61.5 (6.7)dB(A). 49.2% of newborns were girl and the mean (SD) of birthweight was 3276.8 (508.2)g The analyses are still ongoing.

CONCLUSIONS: FRONTIER will provide a robust and comprehensive evaluation of the impact of TRAP exposure on fetal growth using high-resolution exposure data.

P-1195 A comparison of the systematic reviews and meta-analyses conducted to explore the effect of air pollution exposure during pregnancy and the risk of preterm birth

Shawn Lee[1,2], Rachel B Smith[1,3], Karen S Exley[1,4], Heather Walton[1,2]
[1]NIHR HPRU in Environmental Exposures and Health, London, UK, [2]Environmental Research Group, Imperial College London, UK, [3]Mohn Centre for Children's Health and Wellbeing, Imperial College London, UK, [4]UK Health Security Agency, UK

BACKGROUND AND AIMS:
There has been a rapid rise in systematic reviews and meta-analyses (SR/MAs) conducted on the association between air pollution exposure during pregnancy and the risk of preterm birth in recent years. Few studies have examined differences in their quality and if they have provided additional insight into the field. This study analysed previous SR/MAs to explore their practices and identify gaps and opportunities for the research field. This work was done to determine if an upcoming SR/MA was needed.

METHODS: A literature search using major English and Chinese databases was performed to find SR/MAs published from 2010 onwards. Information regarding publication date, methods of quality assessment, consideration of population overlap, and primary studies included in their analysis were extracted and compared.

RESULTS: Seventeen SR/MAs, which included thirteen MAs were conducted from 2010 onwards. A large variety of quality assessment tools were used, but the Newcastle-Ottawa Scale was the most common (n=6). Seven MAs explicitly mentioned that they took population overlap into account. Four SR/MAs were found in 2021 alone, but three did not examine the whole literature and focused on specific study designs or exposure assessment methods. They were thus unable to build on finding of previous work due to exclusion of studies that were included in other SR/MAs.

CONCLUSIONS: A considerable number of SR/MAs provided limited addition to the field as they were conducted without sufficient rigour. This may hinder coming to a consensus on the effect estimate of interest and overlook field-specific biases. Therefore, a new SR/MA with improvements in transparency in reporting, replicability of findings, and quality assessment of studies is required. The protocol of this SR/MA is now registered on PROSPERO and will begin in due course.

P-1198 The association between metals, vitamin D and preterm birth in the MIREC Cohort Study

Mandy Fisher[1], Leonora Marro[1], Tye Arbuckle[1], Beth Potter[2], Julian Little[2], Hope Weiler[1], Anne-Sophie Morisset[3], Bruce Lanphear[4], Youssef Oulhote[5], Joseph Braun[6], Premkumari Kumarathasan[1], Mark Walker[7], Michael Borghese[1], Jillian Ashley-Martin[1], Robin Shutt[2], William Fraser[8]

[1]Health Canada, Ottawa, Canada, [2]University of Ottawa, Ottawa, Canada, [3]Laval Université, Québec, Canada, [4]Simon Fraser University, Burnaby, Canada, [5]University of Massachusetts, Amherst, USA, [6]Brown University, Providence, USA, [7] The Ottawa Hospital Research Institute, Ottawa, Canada, [8]University of Sherbrooke, Sherbrooke, Canada

BACKGROUND:
Toxic metals, like lead, are risk factors for preterm birth (PTB), but few studies have explored this association at the low levels currently found in the Canadian population. Conversely, studies suggest that vitamin D may have antioxidant activity and protect against PTB. In this study, we sought to investigate associations between toxic metals (lead, mercury, cadmium and arsenic) and PTB, and to determine if maternal plasma vitamin D concentrations modify these associations.
METHODS: We investigated whether metals in whole blood measured in early and late pregnancy were associated with PTB (<37 weeks) and spontaneous PTB (a subset of PTBs with spontaneous labour) in 1,851 pregnancies resulting in live births from the Maternal-Infant Research on Environmental Chemicals Study (MIREC) using discrete time survival analysis. In addition, we investigated whether the risk of PTB was modified by plasma 25OHD concentration measured in the 1st trimester.
RESULTS: Six percent (n=117) of live births in the MIREC study were PTBs; 4% (n=89) were spontaneous PTBs. A 1 µg/dL increase in blood lead concentrations during pregnancy was associated with increased risk of PTB (OR=1.5, 95% CI: 1.0, 2.3) and spontaneous PTB (OR=1.7, 95% CI: 1.1, 2.8). In stratified analysis, the risk of PTB (OR=2.7, 95% CI: 1.0, 7.2) and spontaneous PTB (OR=3.4, 95% CI: 1.1, 10.8) was higher in women with insufficient vitamin D concentrations (25OHD <50 nmol/L). However, a statistical interaction was not seen. Arsenic was associated with a higher risk of PTB (OR=1.1, 95% CI: 1.0, 1.2) and spontaneous PTB (OR=1.1, 95% CI: 1.0, 1.2) per µg/L, but these associations were not modified by vitamin D.
CONCLUSIONS: Low levels of lead and arsenic may increase the risk of PTB and spontaneous PTB; the association with lead was stronger in participants with insufficient plasma vitamin D. Replication of these findings is warranted.

P-1200 Internal exposure levels of persistent organic pollutants, ovarian function and in vitro fertilization outcomes: a multipollutant analysis

Tiphaine Lefebvre[1,2,3], Thomas Fréour[2,3,4], Stéphane Ploteau[3,5], Philippe Marchand[1], Bruno Le Bizec[1], Jean-Philippe Antignac[1], German Cano-Sancho[1]

[1]Laberca, Oniris, Inrae, Nantes, France, [2]CHU Nantes, Nantes Université, Service de médecine et biologie de la reproduction, gynécologie médicale, Nantes, France, [3]Faculty of Medicine, Nantes University, Nantes, France, [4]Nantes Université, CHU Nantes, INSERM, Center for Research in Transplantation and Translational Immunology, UMR 1064, Nantes, France, [5]CHU Nantes, Department of Gynecology and Obstetrics, Nantes, France

BACKGROUND AND AIM: Women are exposed to complex mixtures of persistent organic pollutants (POPs), with the potential to interfere with the reproductive system. This study aimed 1) to characterize the internal exposure levels of polychlorinated biphenyls (PCBs), organochlorine pesticides (OCPs) and perfluoroalkylated substances (PFAS) in women undergoing In vitro fertilization (IVF); and 2) evaluate their association with markers of ovarian function and IVF outcomes.

METHODS: Women (n=136) attending the Assisted Reproductive Technology service from Nantes University Hospital (France) were prospectively recruited. Serum samples were analysed using liquid chromatography with tandem-mass spectrometry for 14 PFAS. Follicular fluid was analysed with gas chromatography coupled to high resolution mass spectrometry for 30 PCBs and 14 OCPs. Ovarian function markers, biological and clinical IVF outcomes were ascertained by embryologists or clinicians using standardized protocols. The associations were assessed with multivariate regression models and Bayesian Kernel Machine Regression (BKMR).

RESULTS: Twenty-seven POPs were frequently quantified in almost all women attending IVF. Positive associations were found between the pesticides hexachlorobenzene, β-hexachlorocyclohexane and epoxy-heptachlor with Follicular Output RaTe (FORT). Our results globally showed that most POPs were not associated with clinically relevant IVF outcomes, like live birth rates. Nonetheless, negative associations between PCB138 and trans-nonachlor with the number of usable blastocysts were observed, β -0.28 (95%CI [-0.52; -0.04] p=0.02) and β -0.22 (95%CI [-0.40; -0.03] p=0.02.

CONCLUSIONS: Altogether, our results indicate a lack of associations between most individual chemicals or their mixtures with markers of ovarian function and IVF outcomes. Nonetheless, some highly prevalent OCPs were linked with markers of ovarian responsiveness like FORT and the number of usable blastocysts, supporting the need of conducting further studies in a larger populations sample in order to ensure sufficient statistical power to identify mild effects and a robust stratification analysis to account for the large underlying disease heterogeneity.

P-1202 Per- and polyfluoroalkyl substances in early to mid-pregnancy and gestational diabetes mellitus: A multi-racial/ethnic longitudinal study

Assiamira Ferrara[1], Sophia Fuller[1], Juanran Feng[1], Stacey Alexeeff[1], Yeyi Zhu[1]
[1]*Kaiser Permanente Northern California, Oakland, USA*

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) as endocrine disruptors have been linked to glucose homeostasis. Data on PFAS and gestational diabetes (GDM) are scarce and inconclusive. We examined prospective associations of PFAS in early to mid-pregnancy with GDM risk.

METHODS: Within the prospective Pregnancy Environment and Lifestyle Study, we conducted a nested case-control study of 41 GDM cases diagnosed at gestational weeks 24-28 and 87 controls. Fourteen PFAS analytes were measured in serum collected in the first and second trimesters, with cumulative concentrations estimated by area-under-the-curve (AUC). Weighted logistic regression examined seven PFAS with at least 50% of values above the limit of detection in association with GDM risk, adjusting for age, race/ethnicity, pre-pregnancy body mass index, and parity. P-values were corrected using false-discovery-rate (FDR). We examined effect modification by Asian/Pacific Islander (A/PI) or non-A/PI given the higher risk of GDM in A/PI.

RESULTS: Per interquartile range (IQR) increase in first-trimester concentrations of perfluorodecanoic acid [PFDA; adjusted odds ratio (95% CI): 1.23 (1.09-1.38)], perfluorononanoic acid [PFNA; 1.40 (1.24-1.58)], and perfluorooctanoic acid [PFOA; 1.15 (1.04-1.27)] were associated with a higher GDM risk; results were similar for the second-trimester and AUC concentrations (all FDR <0.01). Per IQR increase in concentrations of perfluorooctanesulfonic acid [PFOS; 1.41 (1.17,1.71)] and perfluroundecanoic acid [PFUnDA; 1.49 (1.18-1.89)] in the second trimester were associated with a higher GDM risk (both FDR <0.01). These associations were more prominent among A/PI who had higher PFAS concentrations than non-A/PI. Perfluorohexane-1-sulphonic acid (PFHxS) concentrations across different times were inversely associated with GDM risk (aOR ranged 0.46-0.49); however; these associations were positive among A/PI (all FDR <0.001).

CONCLUSIONS: Early to mid-pregnancy serum concentrations of PFDA, PFOA, PFOS and PFUnDA were positively, whereas PFHxS were inversely associated with GDM risk. Future work examining PFAS in mixture and GDM risk is underway.

P-1204 Longitudinal Associations between Air Pollution and Angiogenic Factors among Pregnant Women

Yi Zheng[1], David Cantonwine[2], Thomas McElrath[2,3], Hui Hu[1]

[1]Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [2]Division of Maternal Fetal Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Exposures to air pollution during pregnancy have been linked to adverse pregnancy outcomes, such as spontaneous preterm birth and preeclampsia (PE), and to later life risk of cardiovascular disease (CVD). Disordered angiogenesis is one potential linking mechanism between the impact of air pollution on pregnancy outcomes like PE and later life outcomes like CVD.We aimed to examine longitudinal associations between air pollution exposure and angiogenic factors among pregnant women in the Boston, MA based biorepository, LIFECODES.

METHODS: Placental growth factor (PlGF) and soluble fms-like tyrosine kinase 1 (sFlt-1) were measured between 2006-2008 among pregnant women using plasma samples collected at 10, 18, 26, and 35 weeks' gestation. Women's time-varying exposures to ozone and fine particulate matter (PM2.5) between plasma sample collections during pregnancy were estimated based on geocoded residential addresses using U.S. Environmental Protection Agency's Fused Air Quality Surface Using Downscaling Files. Mixed effect linear regression models were fitted to assess the associations between ozone (ppb), PM2.5 (ug/m3) and PlGF (pg/mL), sFlt-1 (ng/mL) and sFlt-1:PlGF ratio. Coefficients for log-transformed outcomes (interpreted as percentage changes) for each interquartile range increase in exposures were reported, along with their 95% confidence intervals (95% CI).

RESULTS: A total of 718 pregnant women were included in this study. In the co-pollutant models, higher exposures to ozone and PM2.5 were associated with a 20.8% (95% CI: 5.3%, 36.2%) increase in sFlt-1 and a 16.6% (95% CI: 4.6%, 28.6%) decrease in PlGF during pregnancy, respectively.

CONCLUSIONS: Exposures to air pollution during pregnancy were associated with lower PlGF and elevated sFlt-1 among pregnant women, which may be a potential mechanism underlying air pollution's impacts on adverse pregnancy outcomes like PE and later life outcomes like CVD.

KEYWORDS: air pollution, angiogenic factors, fine particulate matter, ozone.

P-1205 Associations of blood cadmium, lead, and mercury levels with age of menarche, menopause, and reproductive lifespan of Korean women: KNHANES 2008-2017

Suhyun Park[1], Inae Lee[2], Kyungho Choi[1,2]
[1]School of Public Health, Seoul National University, Seoul, Republic of Korea, [2]Institute of Health and Environment, Seoul National University, Seoul, Republic of Korea

BACKGROUND AND AIM: Lead and cadmium have been suggested for delayed pubertal development and menopause of women, but these findings are often inconsistent or based on a small number of humans, and have not been studied in the Korean populations.

METHODS: The multi-cycle data from Korea National Health and Nutrition Examination Survey (KNHANES) 2008-2017, were used and two groups of women (15≤, and 55≤ years of age) were identified. Survey regression analysis was conducted to find the relationship of blood levels of cadmium, lead, mercury, with age of menarche, age of menopause, and reproductive lifespan. for these analyses, women with pathological menarche/menopause, artificial menopause, current pregnancy, and breast cancer, were excluded. Multivariable analysis models were constructed with relevant covariates.

RESULTS: Age of menarche was significantly increased with higher blood cadmium, lead, and mercury levels ($p<.0001$). for the age of menopause, blood cadmium levels were positively associated ($p=0.03$). However, blood lead and mercury levels did not show significant relationship with menopause. Positive relationship between cadmium and age of menarche and menopause was also observed in sensitivity analyses employing different age groups (15≥, and 55≥ years of age). Reproductive lifespan was increased as blood cadmium level increased ($p=0.04$).

CONCLUSIONS: In a large group of Korean women, we observed that the ages of menarche and menopause were associated with blood cadmium levels, and increased the reproductive lifespan. Underlying mechanisms of delayed pubertal onset and menopause by metal exposure, and public health implication of longer endogenous estrogen exposure deserve further investigation.

KEYWORDS: Heavy metals, menarche, menopause, reproductive lifespan
This research was supported by a National Research Foundation of Korea (NRF) grant funded by MSIT (No. 2020R1A2C3011269) and a grant of the Korea Health Technology R&D Project through KHIDI, funded by the Ministry of Health & Welfare, Republic of Korea (grant number : HI19C1194).

P-1206 Adverse neonatal outcomes among high-risk pregnant women in the State of Rondônia, Amazon, Brazil

Mônica PL Cunha[1], Rafael Buralli[2], Me. Rejane F Nogueira[3], Izabela V Cunha[3], Rejane C Marques[4]
[1]University of Rondônia (UNIR), Porto velho, Brazil, [2]Department of Environmental and Occupational Health, and Surveillance of Public Health Emergencies, Brazilian Ministry of Health (DSASTE), Brasília, Brazil, [3]Health Secretary of the State of Rondônia (SESAU/RO), Porto Velho, Brazil, [4]Federal University of Rio de Janeiro (UFRJ), Macaé Campus, Macaé, Brazil

Amazon urbanization drives profound changes in the environment, and rising exploitation of natural resources, resulting in greater exposure to environmental contaminants and pregnancy complications.
AIM: To describe the adverse outcomes of high-risk pregnant women attending a reference hospital in Rondônia State (RO).

METHODS: Cross-sectional study with high-risk pregnant women residing in RO for at least two years, with a singleton pregnancy, and no alcohol, cigarettes, and drugs consumption during pregnancy. Information on pregnancy, adverse pregnancy outcomes (malformation, low birth weight, preterm infants), sociodemographic characteristics, gestational history, and birth data were collected throughout the questionnaire. Data were described as absolute and relative frequencies.

RESULTS: Among 330 mother/child binomials assessed, 57% of newborns were premature, 53% had low birth weight, and 37% had congenital malformations, being the most frequent those related to the cardiovascular, digestive, musculoskeletal, and neurological systems. About 68% of newborns required neonatal intensive care. Most mothers were younger than 35y (70%), were married or had a stable partner (70%), had completed high school or more (58%), had family income of up to two minimum wages (74%), and used water from a well (51%). The majority had six or more prenatal consultations (61%) and were multiparous. The most frequent clinical complications were urinary tract infection, hypertension, preeclampsia, and anemia. Most women (56%) reported using some “household pesticides” (mainly insecticides and herbicides). Some women have worked in agriculture (16%), livestock (9%), and gold mining (2%). and about 80% reported having a partner currently or previously working in these activities.

CONCLUSIONS: Adverse pregnancy outcomes can be related to individual, socio-environmental and clinical factors. Therefore, understanding these risk factors makes it possible to glimpse paths towards an assistance capable of protecting maternal and child health, with particular attention to vulnerable populations.

P-1207 Associations between follicular fluid trace elements and ovarian reserve during in vitro fertilization

Michael Bloom[1], Jenna Krall[1], Aubrey Galusha[2,3], Patrick Parsons[2,3], Celeste Butts[4], Evelyn Mok-Lin[5], Victor Fujimoto[5]

[1]George Mason University, Fairfax, USA, [2]Wadsworth Center, Albany, USA, [3]University at Albany, SUNY, Rensselaer, USA, [4]University of North Carolina, Chapel Hill, USA, [5]University of California at San Francisco, San Francisco, USA

BACKGROUND AND AIM: Exposure to trace elements (TE) has been associated with female reproductive function, including among women using in vitro fertilization (IVF). Our aim was to estimate associations between TEs in ovarian follicular fluid (FF) and measures of ovarian reserve among women using IVF.

METHODS: We collected up to 4 individual ovarian FF specimens from 56 women. We determined concentrations (µg/L) of essential and non-essential TEs in FF (As, Cd (ng/L), Co, Cu, Hg, Mn, Mo, Pb, Se, Sr, and Zn) using inductively coupled plasma-tandem mass spectrometry. We estimated associations between women's averaged individual FF TEs, per interquartile range (IQR) difference, and measures of ovarian reserve using linear (peak estradiol (E2), baseline anti-mullerian hormone (AMH), and peak endometrial thickness) and negative binomial (baseline antral follicle count (AFC)) regression, adjusted for age, race/ethnicity, and BMI. We also estimated associations of joint exposure to FF TE with ovarian reserve using principal component analysis (PCA).

RESULTS: Higher FF Cu was individually associated with a 22.88% greater E2 (95%CI:4.24% 44.85%). Higher FF Pb and Se were individually associated with -35.78% (95%CI:-53.43%, -11.45%) and -16.44% (95%CI:-32.28%, 3.11%) differences in AMH, and joint exposure to greater FF Cd and Pb was associated with a -22.25% (95%CI:-39.82%, 0.45%) difference in AMH. Higher FF Co was individually associated with 21.79% (95%CI:4.20%, 42.67%) greater AFC. Higher FF Co was individually associated with a 1.24 mm (95%CI:0.23, 2.25) thicker endometrium, and greater joint FF Se, Cu, and Zn (β=0.60 mm; 95%CI:-0.11, 1.30), lower joint Co and Mn combined with higher Hg and Sr (β=-0.72 mm; 95%CI:-1.48, 0.04), and higher joint Cd and Pb (β=-0.86 mm; 95%CI:-1.60, -0.11) were associated with greater and lesser endometrial thickness, respectively.

CONCLUSIONS: Our results suggest that essential and non-essential TEs in FF were associated with ovarian reserve among women using IVF.

KEYWORDS: Metals, ovary

P-1208 Associations between Preterm Birth and Wastewater Injection-Induced Earthquakes in Oklahoma

Maggie Li[1], Heather McBrien[1], Samantha Gailey[2], Tim Bruckner[3], Joan Casey[1]
[1]Columbia University Department of Environmental Health Sciences, New York, USA, [2]Minnesota Population Center at the University of Minnesota, Minneapolis, USA, [3]Program in Public Health and Center for Population, Inequality, and Policy, University of California, Irvine, Irvine, USA

BACKGROUND AND AIM: Oil and gas wastewater injection has contributed to increased seismicity in Oklahoma. Prior work has linked gestational exposure to single large earthquakes to higher risk of adverse birth outcomes. We aimed to assess the effect of exposure to all earthquakes with a moment magnitude 4.0 or greater (≥M 4.0) during pregnancy on preterm birth risk in Oklahoma.

METHODS: We used Oklahoma live birth data from the US National Center for Health Statistics and seismic data from the USA Geological Survey between 2010 and 2017. for our main analysis, we assigned exposure by counting the number of ≥M 4.0 earthquakes that occurred within 100km of each Oklahoma county and linked these to pregnant individuals during each week of gestation by county of residence. We assigned secondary exposures using a crowdsourced earthquake catalog, Did You Feel It. We ran Cox proportional hazards models to estimate the association between pregnancy-wide earthquake count and preterm birth adjusting for maternal age, parity, race, and educational attainment and county-level poverty, income, temperature, and $PM_{2.5}$ concentration. We assessed potential effect modification by trimester of exposure using interaction terms between earthquake exposure and trimester.

RESULTS: We examined 420,485 live births in Oklahoma and 86 earthquakes ≥ M 4.0 from 2010–2017. We observed associations in primary analyses between counts of pregnancy-wide earthquakes ≥M 4.0 and preterm birth (hazard ratio (HR) = 1.018; 95%CI: 1.008, 1.028) and first trimester earthquake exposure (HR = 1.064; 95%CI: 1.047, 1.082), with no significant association observed in exposure during the second or third trimesters. Secondary analyses with Did You Feel It data yielded slightly attenuated pregnancy-wide results (HR = 1.01; 95%CI: 1.00, 1.01).

CONCLUSIONS: Policymakers may wish to consider these findings to inform oil and gas wastewater regulation to protect maternal and child health.

KEYWORDS: earthquakes, Oklahoma, preterm birth

P-1209 Associations between Residential Proximity to Major Roads and Semen Quality: Results from a North American Preconception Cohort Study

Mary Willis[1,2], Lauren Wise[2], Kipruto Kirwa[3], Perry Hystad[1], Adam Szpiro[4], Joel Kaufman[4], Tanran Wang[2], Marlon Joseph[2], Jennifer Yland[2], Michael Eisenberg[5], Elizabeth Hatch[2], Amelia Wesselink[2]
[1]Oregon State University, Corvallis, USA, [2]Boston University, Boston, USA, [3]Tufts University, Boston, USA, [4]University of Washington, Seattle, USA, [5]Stanford University, Palo Alto, USA

BACKGROUND: Metrics related to semen quality are clinically relevant markers of male fertility, and they could plausibly be affected by traffic-related air pollution. Existing studies yielded conflicting results.

METHODS: In a large preconception cohort study (Pregnancy Study Online [PRESTO]), we examined associations between traffic-related air pollution exposure and semen quality. From 2015-2019, male participants aged ≥21 years who resided in the USA were invited to complete semen testing using a validated at-home testing kit that provides quantitative measures of semen quality parameters (semen volume, sperm concentration, sperm motility). Using geocoded residential addresses at baseline, we estimated exposure by calculating the distance from residential location to the nearest major road and traffic intersection. We estimated the association between roadway proximity measures and log-transformed semen parameters by linear regression, adjusting for demographic and reproductive characteristics and used generalized estimating equations to account for correlation from participants who contributed two semen samples.

RESULTS: 196 participants contributed 333 samples for preliminary analysis. Mean sperm count was 243.2 million (142.4 motile), and mean sperm concentration was 66.5 million/mL (39.6 motile). Compared to participants who resided ≥400 m from a major road, we found suggestive evidence of reductions in semen parameters among participants who resided <100 m from a major road for sperm concentration (-15.3, 95% CI: -31.9, 1.3), motile sperm concentration (-10.4, 95% CI: -24.1, 3.4), total sperm count (-48.9, 95% CI: -120.0, 22.3), and total motile sperm count -39.5, (95% CI: -94.3, 15.3) . We did not find evidence of an association with distance to the nearest intersection.
CONCLUSION: Residing close to a major road might be associated with small reductions in semen parameters, adding to the growing body of evidence that traffic-related air pollution may affect male fertility.

KEYWORDS: reproductive outcomes, traffic-related air pollution, male fertility, semen quality, sperm

P-1210 Drinking Water Arsenic, Hemoglobin, and Anemia among Pregnant Women in Rural Northern Bangladesh

Tyler Smith[1], Jessie P. Buckley[1,2], Ana Navas-Acien[3], Rebecca C. Fry[4], Alexander van Geen[5], Hasmot Ali[6], Towfida Jahan Siddiqua[6], Keith P. West Jr.[7], Alain B. Labrique[7], Christopher D. Heaney[1,2,7]

[1]Department of Environmental Health & Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA, [2]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA, [3]Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [4]Department of Environmental Sciences & Engineering, University of North Carolina at Chapel Hill Gillings School of Global Public Health, Chapel Hill, USA, [5]Lamont-Doherty Earth Observatory, Columbia University, Palisades, USA, [6]JiVitA Maternal and Child Health and Nutrition Research Project, Rangpur, Bangladesh, [7]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA

BACKGROUND AND AIM: Anemia afflicts ~40% of pregnant women worldwide, increasing risks of maternal and perinatal mortality. Arsenic exposure has been positively associated with anemia in adults, but evidence during pregnancy is limited. We assessed whether drinking water arsenic was associated with anemia among pregnant women in an area of rural northern Bangladesh where a high prevalence of anemia without iron deficiency was reported.

METHODS: We enrolled pregnant women (n=784) in the second trimester (median [IQR] gestational week: 14 [13-15]) in Gaibandha District, Bangladesh, 2018-2019. We measured drinking water arsenic (w-As) and iron (w-Fe) by ICPMS and capillary blood hemoglobin (Hb) by photometry at enrollment (Visit 1, n=778) and ~4 weeks post-enrollment (Visit 2, n=733). Anemia was defined as Hb <11 g/dL. We estimated expected differences in Hb and odds ratios for anemia per IQR-unit increase in w-As, adjusting for w-Fe, age, gestational week, parity, education, living standards index, mid-upper arm circumference, husband's smoking, and visit. We used generalized estimating equations with an exchangeable correlation structure.

RESULTS: At Visits 1 and 2, median (IQR) w-As, w-Fe, and Hb were 5.1 (0.5-25.1) and 5.3 (0.39-26.8) µg/L, 4.7 (0.49-19.0) and 4.5 (0.57-18.3) mg/L, and 11.8 (11.2-12.5) and 11.3 (10.7-11.9) g/dL, and anemia prevalence was 16.5 and 33.4%, respectively. In crude models, the per-IQR-unit w-As expected difference (95% confidence interval [CI]) in Hb was 0.18 (0.07-0.30) g/dL and the odds ratio (95% CI) for anemia was 0.68 (0.54-0.85). After adjustment, the expected difference (95% CI) in Hb was 0.15 (0.00-0.30) g/dL and the odds ratio (95% CI) for anemia was 0.65 (0.47-0.92).

CONCLUSION:

Contrary to prior research in adults, arsenic was positively associated with Hb and negatively associated with anemia in pregnancy. Results might be attributable to reduced plasma volume expansion and hemodilution, but further research is needed.

P-1212 Urinary paraben and phenol concentrations driving markers of inflammation among pregnant women in Puerto Rico

Savannah Sturla[1], Amber Cathey[1], Jose Cordero[2], Akram Alshawabkeh[3], Zaria Rosario-Pabón[4], Carmen Vélez-Vega[4], Deborah Watkins[1], John Meeker[1]

[1]University of Michigan, Ann Arbor, School of Public Health, Department of Environmental Health Sciences, Ann Arbor, USA, [2]University of Georgia, College of Public Health, Department of Epidemiology and Biostatistics, Athens, USA, [3]Northeastern University, College of Engineering, Department of Civil and Environmental Engineering, Boston, USA, [4]University of Puerto Rico, Medical Sciences Campus, Graduate School of Public Health, Department of Social Sciences, San Juan, USA

BACKGROUND AND AIM:
Widespread exposure to phenols and parabens is a potential contributing factor for increased inflammation and adverse birth outcomes, but these effects are not well-studied in humans. This study aimed to investigate relationships between urinary concentrations of 8 phenols and 4 parabens with 6 inflammatory biomarkers (C-reactive protein (CRP), matrix metalloproteinases (MMP) 1, MMP2, MMP9, intercellular adhesion molecule 1 (ICAM-1), and vascular cell adhesion molecule 1 (VCAM-1)) repeatedly measured across pregnancy in the Puerto Rico PROTECT birth cohort. We hypothesized that biomarkers of phenol and paraben exposure would be associated with upregulation of inflammatory markers.

METHODS: Phenol and paraben concentrations in spot urine samples were measured using tandem mass spectrometry. Inflammation biomarkers were measured in blood serum using customized Luminex assays. Linear mixed models were used to assess relationships between exposures, outcomes, and covariates (maternal age, education, pre-pregnancy BMI, and specific gravity), and in sensitivity analyses, models were stratified by fetal sex. Results are expressed as the percent change in outcome per interquartile range increase in exposure.

RESULTS: Significant positive associations were found between bisphenol-A and CRP (9.68%, CI: 0.56, 19.62); bisphenol-S and MMP9 (6.41%, CI: 0.92, 12.19); and methylparaben and MMP1 (10.94%, CI: 2.31, 20.30). Many associations were stronger among women carrying a female fetus in sex-stratified models. However, significant negative relationships were also observed between several phenols and inflammatory markers.

CONCLUSIONS: Our preliminary results suggest that bisphenol-A, bisphenol-S, and methylparaben may upregulate inflammatory processes pertaining to systemic inflammation and uterine remodeling, with important implications for pregnancy outcomes. However, several phenols may also interfere with inflammatory regulation, leading to downregulation. More research is needed to further our understanding of these relationships in an effort to improve reproductive and developmental outcomes.

BACKGROUND AND AIM: A growing body of evidence has suggested various associations between prenatal exposure to heavy metals and newborn anthropometric measures. However, little is known about the effect of various metal mixtures at relatively low concentrations. Hence, this study aimed to investigate the associations between prenatal exposures to a wide scope of individual metals and mixtures to newborn's anthropometric measures.

METHODS: We recruited 975 mother-infant pairs, from two major hospital in Israel. Associations between eight metals (arsenic, cadmium, chromium, mercury, lead, nickel, selenium and thallium) detected in maternal urine samples from day of delivery to weight, length and head circumference at birth were estimated using linear and Bayesian Kernel Machine Regression (BKMR) models.

RESULTS: Most metals examined in our study observed in lower concentrations compared to other studies, except of selenium. Birthweight was found negatively associated to levels of chromium and thallium in the linear models. In the BKMR analysis positive association for selenium was found with birthweight. Inverse association of selenium and birth length was detected, and positive association between nickel and both weight and length. Cubic shaped associations for chromium and selenium to weight and length suggested metals interactions that were further analyzed. Associations between most metals and head circumference were U-shaped, suggested interactions among them.

CONCLUSION: Maternal urinary concentrations of chromium and thallium were individually associated to decreased birthweight. The application of novel statistical approach enabled us to detect various relations between metals in the analysis and anthropometric measures, which can be a result of complex biochemical processes, that should be further investigated.

P-1218 Young women's reproductive and health effects from the Chernobyl nuclear accident: a qualitative historical study

Julie Cwikel[1], Alison Perez[1]
[1]*BGU Center for Women's Health and Promotion, Beer Sheva, Israel*

BACKGROUND AND AIM: s: The Chernobyl disaster of April 26, 1986 is still considered the worst nuclear power accident in terms of its long-term health effects, including both thyroid and reproductive effects. This study aims to give voice to exposed women, highlighting reproductive and chronic health issues.

METHODS: In-depth, narrative interviews were conducted with 18 women who experienced the Chernobyl nuclear accident as children or adolescents and later immigrated to Israel, aged 2-19 at the time of the accident and 31 to 50 at interview. Half of the women originated in high contamination towns in terms of ionizing radiation (based on cesium-137 measured at the time), and the 9/18 from low-contamination towns . The interviews were analyzed by thematic, content analysis.

RESULTS: Thyroid and hormonal imbalances were the most widespread health issues reported (10/18). Most had some chronic health issues (14/18), which often started in the years immediately following the accident. Once treated, full-term pregnancies resulted in healthy children for 14 of the 18 women. Fears of cancer and birth defects led two to decide not to procreate, one to decide to procreate at an early age, and another to decide not to get pregnant again after having one healthy child. In recalling the accident and its impact, they often fused personal memories with media accounts and stories heard. We explored whether respondents with current health problems attributed them to the radiation exposure and found that those who had family members who were ill or developed cancer, were more likely to attribute these outcomes to the Chernobyl exposure.
CONCLUSION: Exposure to Chernobyl during their formative years was a significant life event that affected their physical, reproductive and emotional health as adults for most respondents.

P-1221 Extending non-targeted exposure discovery of environmental chemical exposures during pregnancy and their association with pregnancy complications

Jessica Trowbridge[1], Dimitri Abrahamsson[1], Ting Jiang[2], Miaomiao Wang[2], June-Soo Park[2], Rachel Morello-Frosch[3], Marina Sirota[4], Dana Going[1], Marya Zlatnick[1], Tracey Woodruff[1]

[1]University of California San Francisco, San Francisco, USA, [2]California Environmental Protection Agency, Berkeley, USA, [3]University of California, Berkeley, Berkeley, USA, [4]University of California, San Francisco, San Francisco, USA

BACKGROUND: Non-targeted Analysis (NTA) methods identify novel exposures; however, few chemicals have been quantified and interrogated with pregnancy complications.
OBJECTIVES: We characterize levels of nine exogenous and endogenous chemicals in maternal and cord blood identified, and confirmed in prior NTA steps including: linear and branched isomers perfluorooctane sulfonate (PFOS); perfluorohexane sulfonate (PFHxS); monoethylhexyl phthalate; 4-nitrophenol; tetraethylene glycol; tridecanedioic acid, octadecanedioic acid; and deoxycholic acid. We evaluate the relationship gestational diabetes mellitus (GDM) and hypertensive disorders of pregnancy in a diverse pregnancy cohort in San Francisco.

METHODS: We collected matched maternal and cord serum samples from 302 pregnant people at delivery from the Chemicals in Our Bodies cohort in San Francisco. We calculate distributions and Spearman correlation coefficients testing the relationship of chemicals within and between the maternal and cord blood matrices. We used logistic regression to calculate the odds of GDM and hypertensive disorders of pregnancy associated with an interquartile range (IQR) increase in maternal chemical exposures.

RESULTS: We detected linear PFOS, PFHxS, octadecanedioic acid, and deoxycholic acid in at least 97% of maternal samples. Correlations ranged between -0.1 and 0.9. We observed strong correlations between cord and maternal levels of PFHxS (coefficient = 0.9), linear PFOS (0.8), and branched PFOS (0.8). An IQR increase in linear PFOS, branched PFOS, and octadecanedioic acid is associated with increased odds of GDM [OR (95%CI): 1.43 (0.96, 2.14), 1.56 (1.00, 2.44), and 1.26 (0.83, 1.92) respectively] and tridecanedioic acid positively associated with hypertensive disorders of pregnancy [1.28 (0.90, 1.86)].
DISCUSSION: We identified both exogenous and endogenous chemicals, two of which (octadecanedioic acid and tridecanedioic acid) have both endogenous and exogenous sources, and which have seldom been quantified in pregnant people or related to pregnancy complications.

KEYWORDS: Non-targeted analysis, linear and branched PFOS, tridecanedioic acid, fatty acids, gestational diabetes mellitus, pregnancy hypertension

P-1222 Agricultural Pesticides During Pre-Conception and Pregnancy, and Associations With Extremely Preterm Birth: a Pesticide-Wide Association Study

Melissa Furlong[1], Kim Paul, Kim Parra, Paloma Beamer, Beate Ritz
[1]*University of Arizona, Tucson, USA*

BACKGROUND/AIM: Although pesticides have unique mechanisms of action, most pesticides also affect common biologic pathways relevant for preterm birth, including oxidative stress, inflammation, and detoxification. However, virtually no epidemiology studies have studied pesticide associations with extremely preterm birth (EPTB; <28 weeks). We adopted an agnostic methodology to conduct a pesticide-wide association study of all pesticides applied in Arizona, with EPTB <28 weeks.

METHODS: We linked all active ingredients (AIs) reported to Arizona's (AZ) Pesticide Use Registry from 2011-2016 with AZ birth certificates of women living in agricultural regions during this period. Women were considered exposed to a specific pesticide if that pesticide had been applied within a given buffer (2000m, 1500m, 1000m, 500m, 100m) during pre-conception or pregnancy. We calculated exposures separately for pre-conception (90 days before last menstrual period), and 1st and 2nd trimesters, and used logistic regressions to estimate associations for each pesticide, and common pesticide classes, during each time window and each buffer, with EPTB. We controlled for maternal race/ethnicity, child sex, maternal education, and birth year, and applied FDR-adjustment.

RESULTS: The study sample consisted of 119,090 births in agricultural regions. of 233 unique AIs studied, 44 were significantly associated at FDR<0.05 during at least one window. of these, 29 were associated during pre-conception, 14 during 1st trimester, and 6 during 2nd trimester. for most AIs, we observed dose-response relationships according to buffer size, with effect estimates weakening and confidence intervals becoming more precise as buffer size increased. Pesticides with the strongest effect sizes included Reynoutria sachalinensis, rimsulfuron, mecoprop-p, potassium laurate, and bromoxynil octanoate. Other notable AIs with consistent effects across buffers and FDR<0.05 included malathion, and the classes of pyrethroids and carbamates.

CONCLUSIONS: Several lesser-studied pesticides may be associated with EPTB, and Pre/peri-conception and early gestation may be sensitive windows of exposure.

KEYWORDS: pesticides, preterm birth

P-1223 Perinatal morbidity and mortality associated with reductions in household air pollution: results from Poriborton:the CHANge trial

Camille Raynes-Greenow[1], Masum Billah[2,1], Sajia Islam[2], A Neeloy Alam[1], SM Rokonnuzzaman[2], Shams El Airfeen[2], AI Chowdhury[2], A Kingsley Agho[3], A Alison Hayes[1], The Poriborton Trial Team[1,2,3,4], Jon Thornburg[4], Michael Dibley[1]
[1]The University of Sydney, Australia, [2]icddr,b, Dhaka, Bangladesh, [3]Western Sydney University, Sydney, Australia, [4]RTI, International, Research Triangle Park, USA

BACKGROUND: Household air pollution is a leading health risk for global morbidity and mortality and a major health risk in South Asia. However, there are no prospective investigations powered to detect the impact of reduced exposure to household air pollution on perinatal morbidity and mortality.
AIM: To assess the impact of liquefied petroleum gas (LPG) for cooking to reduce household air pollution exposure on perinatal morbidity and mortality compared to usual cooking practices in Bangladesh

METHODS: A two-arm community-based cluster randomised controlled trial in the Sherpur district, Bangladesh. In the intervention arm, pregnant women receive an LPG cookstove and LPG in cylinders supplied throughout pregnancy until birth. In the control or usual practice arm, pregnant women continue their usual cooking practices, predominately traditional stoves with biomass fuel. Eligible women are pregnant with a gestational age of 40–120 days, aged between 15 and 49 years, and permanent residents of the study area. The primary outcome is the difference in perinatal mortality between the LPG arm and the usual cooking arm.

RESULTS: We recruited 4972 pregnant women beginning in 09/2019 thru to 03/2022, the trial has been impacted by COVID which has delayed analysis. Data are being cleaned. The perinatal mortality rate difference between the intervention and the control arm will be presented. Other outcomes will be preterm birth (birth before 37 completed weeks gestation), birth weight, cost-effectiveness, satisfaction and acceptability of the LPG stove.

CONCLUSIONS: This trial will provide high-level evidence of the effect of reduced exposure to household air pollution from cooking with LPG on pregnancy outcomes, specifically perinatal mortality and morbidity.

KEYWORDS: Household air pollution, Perinatal mortality, Cluster randomised controlled trial

THEMATIC 20: Respiratory disorders in children/adults

P-1224 Comparison of factors affecting parameters of pulmonary function test between Taiwan and UK

Ke-Ting Pan[1,2], Giovanni S. Leonardi[3,4], Shih-En Tang[1,5], Kun-Lun Huang[1,5], Mark Unstead[6], Marcella Ucci[2], Ben Croxford[2]

[1]Graduate Institute of Aerospace and Undersea Medicine, National Defense Medical Center, Taipei City, Taiwan, [2]Bartlett Faculty of the Built Environment, UCL, London, UK, [3]Radiation, Chemical and Environmental Hazards Directorate, UK Health Security Agency, Didcot, UK, [4]Department of Public Health, Environments and Society, London School of Hygiene and Tropical Medicine, London, UK, [5]Department of Internal Medicine and Hyperbaric Oxygen Therapy Center, Tri-Service General Hospital, Taipei, Taiwan, [6]Royal Berkshire Hospital, Berkshire, UK

BACKGROUND AND AIM: Demographic, physiological and behavioural factors affect the parameters of the pulmonary function test (PFT). We aimed to investigate selected predictors of DLCO, VA and KCO in Taiwan and the UK.
MATERIALS AND

METHODS: We collected selected demographic, physiological and behavioural factors and PFT data from medical records in Tri-Service General Hospital (TSGH) in Taiwan from June 2017 to May 2018 and Royal Berkshire Hospital (RBH) from January to June 2019 in the UK. There were 1943 subjects in the TSGH group and 691 subjects in the RBH group. Then, we analyzed factors that might affect the PFT data. We created predictive models for DLCO, VA and KCO based on two hospitals' datasets, and therefore the estimated DLCO, VA and KCO for each individual with different characteristics could be calculated.

RESULTS: The predictive model for DLCO in TSGH estimated: (Male) 6.607-0.216×Age(yr) +0.119×Height(cm)+0.107×weight(kg); (Female) -3.089-0.121×Age(yr) +0.131×Height(cm)+0.119×weight(kg) and the predictive model for DLCO in RBH: (Male) -4.963-0.189×Age(yr) +0.243×Height(cm); (Female) -10.651-0.142×Age(yr)+0.240×Height(cm). The results showed that males had a higher value of DLCO and VA than females; DLCO and VA were positively associated with height; DLCO and KCO were negatively associated with age. Asian population showed a slightly lower value of DLCO compared to the Caucasian population, which could be explained by VA and height differences. Smoking status may not affect DLCO.

CONCLUSIONS: Overall, we found that sex, age, height and weight affected the PFT data, including DLCO, VA and KCO in both TSGH and RBH groups. Further research on the combined effects of ageing and smoking on PFT data could be explored.

KEYWORDS: PFT, Pulmonary function, DLCO, VA, KCO

P-1225 Phthalate Exposures and Oxidative/ Nitrosative Stress among Childhood Asthma: A nested Case-Control Study with Propensity Score Matching

Jung-Wei Chang[1], Po-Chin Huang[2], I-Jen Wang[3], Hsin-Chang Chen[4], Heng-Zhao Hu[1], Wan-Ting Chang[2]
[1]National Yang Ming Chiao Tung University, Taipei 112, Taiwan, [2]National Health Research Institutes, Miaoli county 350, Taiwan, [3]Department of Pediatrics, Taipei Hospital, New Taipei 242, Taiwan, [4]Tunghai University, Taichung 407224, Taiwan

BACKGROUND AND AIM: Whether low-dose phthalates exposure trigger children's asthma and underlying mechanisms are still under debate. Recent studies revealed that oxidative/ nitrosative stress and lipid peroxidation may play as a mediator of phthalate exposure on certain respiratory outcomes. We aims to evaluate the individual and mixed effects of low-dose phthalate exposure on asthmatic children, and to assess the mediating effect of five (oxidative/nitrosative stress/ lipid peroxidation stress) mechanistic biomarkers, 8-OHdG, 8-NO_2Gua, HNE-MA, 8-isoPF2α and MDA, on the association between phthalate exposure and asthmas.

METHODS: We conducted a case-control study using propensity score matching, including 41 asthma and 111 controls. Eleven phthalate metabolites and oxidative/nitrosative stress biomarkers have been analyzed by LC-MS/MS and ELISA, respectively. The association among high oxidative/nitrosative stress biomarker, high urinary phthalate metabolites level (75th %tile) and risk of asthma was analyzed by conditional logistic regression. Weighted Quantile Sum Regression will also be used to estimate the contribution of individual exposure.

RESULTS: The median MBzP concentrations in the case groups was significantly higher than those in the control group (3.94 vs. 2.52 ng/mL, p= 0.02), which indicated dust could be an important source. After adjustment for confounding factors, some associations between certain oxidative stress biomarkers and phthalate metabolites were found, such as MMP with 8-NO_2Gua (OR: 2.66, 95% CI: 1.03–6.92) and 8-isoPF2α (OR: 4.04, 1.51–10.8), and MiBP with 8-isoPF2α (OR: 2.96, 1.13–7.79). We found MBzP contributed more than a half of the association (56.8%), followed by MiBP (26.6%) and MiNP (8.77%). However, there is no significant association between higher phthalate metabolites levels or oxidative stress biomarkers with risk of asthma.

CONCLUSIONS: Our findings supported the adjuvant effect of phthalates in enhancing immune system response. However, no clear evidence of a link between higher oxidative stress biomarkers and asthma, possibly due to limited sample size and exposure window.

P-1226 Longitudinal assessment of maternal depression and later life childhood asthma and wheeze: effect modification by child sex

Cecilia Alcala[1], Maria José Rosa, Paloma Orozco Scott[2], Marcela Tamayo-Ortiz[3], Carmen Hernández[4], Lourdes Schnaas[5], Kecia Carroll[1,6], Megan Niedzwiecki[1], Robert Wright[1,7], Martha Maria Téllez-Rojo[8], Rosalind Wright[1,6,7], Hsiao-Hsien Leon Hsu[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Occupational Health Research Unit, Mexican Social Security Institute, Mexico City, Mexico, [4]National Institute of Perinatology, Mexico City, Mexico, [5]Department of Developmental Neurobiology, National Institute of Perinatology, Mexico City, Mexico, [6]Kravis Children's Hospital, Department of Pediatrics, Icahn School of Medicine at Mount Sinai, New York, USA, [7]Institute for Exposomic Research, Icahn School of Medicine at Mount Sinai, New York, USA, [8]Center for Nutrition and Health Research, National Institute of Public Health, Cuernavaca, Morelos, Mexico

BACKGROUND AND AIM: Studies report associations between maternal mental health and adverse respiratory outcomes in children; however, the impact of timing and duration of maternal distress remains understudied. We sought to longitudinally examine associations between maternal depression and childhood asthma and wheeze, and explore sex differences.

METHODS: We assessed 605 mother- child dyads enrolled in the Programming Research in Obesity, Growth, Environment, and Social Stressors birth cohort in Mexico City. Maternal depression was assessed using the Edinburgh Depression Scale questionnaire a) during pregnancy, b) postpartum, and c) at both postpartum and subsequent time points postnatally (recurrent depression). Report of wheeze in the past 12 months (current wheeze), and asthma were obtained using the validated survey at 48 and 72 months. Associations were analyzed using modified Poisson regression adjusted for covariates, and in interaction models. Models were then stratified by child sex to assess effect modification.

RESULTS: Prenatal depression was observed in 17%, postpartum depression in 25%, and recurrent depression in 16% of mothers. Current wheeze and asthma at either time point was reported in 14% and 5% of children, respectively. Both postpartum and recurrent depression were associated with higher risk of current wheeze (RR: 1.88, 95% CI: 1.21, 2.92; RR: 2.39, 95% CI: 1.52, 3.78) and asthma at 48 months (RR: 2.79, 95% CI: 1.13, 6.87; RR: 3.14, 95% CI: 1.26, 7.84). Recurrent depression was also associated with higher risk of ever wheeze at 72 months (RR: 1.76, 95% CI: 1.12, 2.77). In interaction analyses, associations were stronger in females than males.
CONCLUSION: Postpartum and recurrent depression were associated with higher risk of wheeze and asthma in children, and associations were stronger in females than males. Our results highlight the importance of maternal depression on respiratory disease.

KEYWORDS: respiratory outcomes; maternal stress; asthma; wheeze; children's environmental health; non-chemical stressors

P-1228 Early life exposure to $PM_{2.5}$ and lung function: A pooled analysis from two North American longitudinal pregnancy cohort studies

Maria José Rosa[1], Hector Lamadrid-Figueroa[2], Cecilia Alcala[1], Elena Colicino[1], Marcela Tamayo-Ortiz[3], Adriana Mercado-Garcia[4], Itai Kloog[5], Allan Just[1], Douglas Bush[6], Kecia Carroll[1,6], Martha Maria Téllez-Rojo[4], Robert Wright[1,6], Chris Gennings[1], Rosalind Wright[1,6]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Department of Perinatal Health, Center for Population Health Research, National Institute of Public Health (INSP), Cuernavaca, Mexico, [3]Occupational Health Research Unit, Mexican Institute of Social Security (IMSS), Mexico City, Mexico, [4]Center for Nutrition and Health Research, National Institute of Public Health (INSP), Cuernavaca, Mexico, [5]Department of Geography and Environmental Development, Ben-Gurion University of the Negev, Beer Sheva, Israel, [6]Kravis Children's Hospital, Department of Pediatrics, Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND: Exposure to particulate matter <2.5 microns in diameter ($PM_{2.5}$) produces pediatric respiratory morbidity. Lung development occurs in stages and the effects of $PM_{2.5}$ may differ based on timing of exposure. Data integration of multiple epidemiologic studies can provide enhanced power and exposure contrast to examine associations between $PM_{2.5}$ and respiratory outcomes.
AIM: To combine data from two longitudinal cohorts while accounting for underlying heterogeneity and examine effects of early childhood $PM_{2.5}$ exposure on lung function.

METHODS: Analyses included children from the Asthma Coalition on Community Environment and Social Stress Project in Boston, Massachusetts and the Programming Research in Obesity, Growth, Environment and Social Stressors study in Mexico City. Propensity scores were estimated from logistic models and 1-1 nearest neighbor matching method was used (n=300). Residential daily $PM_{2.5}$ exposure was estimated from 2 months prior to birth to age 6 years using a validated satellite-based spatiotemporal model. Lung function was tested at ages 6-11 years and age, height, race and sex adjusted z-scores were estimated for FEV_1, FVC, FEF25-75% and FEV_1/FVC. Using distributed lag models, we examined associations between monthly averaged $PM_{2.5}$ levels and lung function outcomes adjusting for maternal age, education, postnatal environmental tobacco smoke exposure and monthly temperature.

RESULTS: $PM_{2.5}$ exposure between postnatal months 23-40 was associated with a lower FEV_1 z-score. A 5 $\mu g/m^3$ increase in $PM_{2.5}$ throughout this window was associated with a reduction in FEV_1 z-score of -0.36 (95% CI:-0.66, -0.05). Similarly, a 5 $\mu g/m^3$ increase in $PM_{2.5}$ throughout 18-39 months postnatal was associated with a reduction in FEF25-75% z-score of -0.56 (95% CI:-0.99, -0.14).

CONCLUSIONS: Methodological tools enhanced our ability to combine multi-site data while accounting for study heterogeneity. Ambient $PM_{2.5}$ exposure in early childhood was associated with an obstructive pattern on spirometry in middle childhood.

KEYWORDS: air pollution, respiratory, children's health

P-1230 Early-life exposure to ambient air pollution and asthma in the children of the Danish National Birth Cohort – does asthma definition and adjustment for cohort-specific covariates matter?

[1]University of Copenhagen, Copenhagen K, Denmark, [2]Department of Environmental Science, Aarhus University, Roskilde, Denmark, [3]COPSAC, Copenhagen Prospective Studies on Asthma in Childhood, Herlev and Gentofte Hospital, University of Copenhagen, Gentofte Hospital, Copenhagen, Denmark,, [4]Global Centre for Clean Air Research (GCARE), University of Surrey, Guildford, the UK,, [5]Danish Big Data Centre for Environment and Health (BERTHA), Aarhus University, Roskilde, Denmark,, [6]University of Illinois at Chicago, School of Public Health, the USA,, [7]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, the Netherlands,

BACKGROUND AND AIM: Ambient air pollution exposure has been associated with asthma, but evidence from children is mixed. We examined associations between early-life exposure to air pollution and childhood asthma.

METHODS: We included singletons of the Danish National Birth Cohort born in 1997-2003 to women with complete address, registry-based, self-reported data on health and asthma risk factors (e.g. smoking, breastfeeding, pets, mold) collected from pregnancy and follow-up questionnaires until age 11. We defined asthma incidence from hospital admission, emergency room or outpatient contact using ICD-10 codes and prevalence of doctor-diagnosed asthma from parental recalls at age 7.

RESULTS: Out of the 22,084 children included, 1,475 children had asthma according to the ICD-10 code, of which 51% had asthma according to parental recall of a doctor-diagnosis, whilst 35% of children with a parental recall of doctor-diagnosis also had an ICD-10 code for asthma. The prenatal mean (SD) exposure to PM2.5 and NO2 at the home addresses was 11.5 (1.4) and 18.6 (7.3) µg/m3, respectively. A 5 µg/m3 increase in prenatal exposure to PM2.5 was associated with an HR of 1.05 (95%CI: 0.81, 1.36) for ICD-10-defined asthma and an OR of 0.85 (0.70, 1.04) for doctor-diagnosed asthma in the adjusted models. The corresponding effect estimates associated with a 10 µg/m3 increase in prenatal exposure to NO2 were 1.03 (0.92, 1.15) and 0.95 (0.87, 1.03), respectively. All point estimates were higher among children with the same address at birth as at age 11 when data on home characteristics was collected than movers. Results from models adjusted with register-based covariates were similar to models above that included cohort-specific covariates.

CONCLUSIONS: These findings suggest that the associations between ambient air pollution and asthma in children depend more on the asthma definition than further adjustment for cohort-specific variables in settings like Denmark with rich registry data.

P-1233 Decoupling race/ethnicity from pediatric lung function metrics to investigate potential misclassification bias in environmental epidemiologic research

Matthew Bozigar[1], Robyn Cohen[2], Catherine Connolly[1], William Adams[3], Jonathan Levy[1], Patricia Fabian[1]
[1]Environmental Health Department, Boston University School of Public Health, Boston, USA, [2]Department of Pediatrics, Boston Medical Center; Department of Pediatrics, Boston University School of Medicine, Boston, USA, [3]Department of Pediatrics, Boston Medical Center; Boston University Clinical and Translational Science Institute, Boston University School of Medicine, Boston, USA

BACKGROUND AND AIM: Electronic health records (EHR) are increasingly being used in environmental epidemiologic research. Respiratory studies of asthma commonly use derived spirometry metrics, such as percent predicted forced expiratory volume in one second (FEV1%predicted), that are calculated from age, height, sex, and – controversially – race/ethnicity. We examine potential misclassification bias introduced by historically race/ethnicity-adjusted pediatric lung function metrics.

METHODS: Spirometry results for children with asthma ages 5-17 years were obtained from a clinical EHR data repository at Boston Medical Center (BMC) from 2003 to 2019. BMC is New England's largest safety net hospital, serving a racio-ethnically diverse pediatric population. Recorded lung function metrics included FEV1 (liters), forced vital capacity (liters), and previously calculated FEV1%predicted (%) that adjusted for race/ethnicity. We recalculated FEV1%predicted values by standardizing to a global, multiethnic population using the Global Lung Initiative equations and compared to original FEV1%predicted from the EHR data repository.

RESULTS: The EHR included 1141 children that had 2651 spirometry measurements. Mean FEV1%predicted was 91.6% from the EHR and 87.2% when recalculated. Original FEV1%predicted values were higher compared to recalculated values for Black children (mean=89.3% [standard error=0.56] vs. 82.5% [0.42], n=1526, $p<0.01$), but not for Asian (93.8% [3.72] vs. 92.0% [3.59], n=32, p=0.72), Hispanic (96.5% [1.65] vs. 94.4% [1.56], n=129, p=0.37), Other (93.8% [3.55] vs. 91.3% [2.52], n=47, p=0.57), Not Recorded (94.7% [0.73] vs. 94.1% [0.66], n=720, p=0.25), and White (94.1% [1.72] vs. 94.1% [1.42], n=195, p=0.97).

CONCLUSIONS: Race/ethnicity-adjustment of a commonly used "objective" lung function metric in EHR may artificially improve lung function test results, particularly for Black children with asthma, resulting in a potential source of misclassification bias in environmental epidemiologic research. Continued use of historically race/ethnicity-adjusted lung function metrics warrants critical reevaluation, especially in research aimed at disentangling the environmental drivers of health disparities driven by structural racism.

P-1235 Effects of short- and long-term air pollution exposure on the course of idiopathic pulmonary fibrosis

Konstantina Dimakopoulou[1], Ioannis Tomos[2], Effrosyni D. Manali[2], Spyros A. Papiris[2], Anna Karakatsani[2]
[1]Department of Hygiene, Epidemiology and Medical Statistics, National and Kapodistrian University of Athens, Medical School, Athens, Greece., Athens, Greece, [2]2nd Pulmonary Medicine Department, National and Kapodistrian University of Athens, Medical School, "ATTIKON" University Hospital, Haidari, Greece., Athens, Greece

BACKGROUND & AIM: Urban air pollution has recently emerged as a significant risk factor for developing IPF Acute Exacerbation (AE-IPF). The aim of this study was to simultaneously investigate the effects of short- and long-term ambient air pollution exposure at patients' residence, on the clinical course of IPF.

METHODS: Stable IPF patients, residents of the Greater Athens Area, and closely monitored at regular intervals in our interstitial lung disease (ILD) referral center were followed intensively for a total of 13 non-consecutive weeks between July 2020 and September 2021. Information on lifestyle, medical history, daily symptoms (cough, dyspnea, wheezing, expectoration, common cold) and activities was collected through questionnaires. Exposure to daily mean NO2, PM10 and 8h-max O3 concentrations at patients' residence was estimated using spatio-temporal land use regression models. We used multiple mixed effects logistic regression models to investigate the simultaneous short- and long-term effects of exposure to air pollutants on the risk of symptoms' occurrence, adjusting further for confounders.

RESULTS: Data collected from up to 24 IPF patients (male: 66.7%; mean age:72.3±7.7 years) were analyzed. A 10 μg/m3 increase in short-term exposure of NO2, PM10 and O3 was associated with an increased risk of cough (OR=1.72, 95%CI: 1.10-2.69; OR=2.73, 95%CI: 1.69-4.42; OR=1.18, 95%CI: 1.00-1.40) and an increased risk of any symptom occurrence (OR=2.10, 95%CI: 1.22-3.63; OR=3.29, 95%CI: 1.78-6.09; OR=1.21, 95%CI:0.94-1.55). In contrast, no association was found between long-term exposures to PM10, NO2 and O3 and risk of symptom occurrence.

CONCLUSIONS: Short-term personal exposure to increased concentrations of air pollutants is an independent risk factor for IPF aggravation leading to appearance of symptoms.

P-1236 Toenail metal concentrations and lung function among residents living near urban oil site

Arbor Quist[1], Yoshira Van Horne[1], Shohreh Farzan[1], Jill Johnston[1]
[1]*Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA*

BACKGROUND AND AIM: Urban communities may be exposed to various toxic metals, especially communities near industries. Given prior evidence suggesting that toxic metals exposure may influence respiratory health, we aimed to assess the relationship between toenail metal concentrations and lung function in a diverse cohort of residents living near an urban oil drilling site.

METHODS: Through a community-academic partnership, we recruited 161 Latinx, Black, and Asian adults who lived within 1 km of an active oil drilling site in south Los Angeles. We assessed lung function using spirometry and collected toenail clippings to assess exposure to arsenic (As), cadmium (Cd), manganese (Mn), nickel (Ni), lead (Pb), and antimony (Sb). We conducted linear regression between individual metal concentrations and forced vital capacity (FVC) and forced expiratory volume in the first second of exhalation (FEV1), adjusting for sex, age, height, asthma diagnosis, distance to freeway, cigarette smoking status, and lung function assessor. We examined effect measure modification by sex using stratified models.

RESULTS: We observed an inverse association between toenail Mn concentration and FEV1 (difference=-83mL, 95% confidence interval (CI): -159, -7) and no association for As, Cd, Ni, Pb, and Sb. We observed a similar association for FVC with Mn (Mn: -82 mL, 95% CI: -163, 0) and no significant associations for the other metals. The associations between Mn and lung function were predominantly observed in men (Men: FEV1 difference: -91, 95% CI: -194, 11; FVC difference: -74, 95% CI: -181, -33; Women: FEV1 difference: 10, 95% CI: -137, 157; FVC difference: -32, 95% CI: -212, 149).

CONCLUSIONS: We found higher toenail Mn concentration to be associated with lower lung function among residents—particularly male residents—near an urban oil well.

KEYWORDS: Metals, mixtures, respiratory outcomes, environmental epidemiology

P-1237 The environmental factors for different seasonal attack patterns in asthmatic children

Yi-Sheng Yang[1,2], Chi-Hsien Chen[1,3], Bing-Yu Chen[3], Yue Leon Guo[1,2,3,4]
[1]Department of Environmental and Occupational Medicine, National Taiwan University Hospital, Taipei, Taiwan,, [2]Institute of Environmental and Occupational Health Sciences, National Taiwan University College of Public Health, Taipei, Taiwan,, [3]Department of Environmental and Occupational Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan,, [4]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli, Taiwan,

BACKGROUND AND AIM: Asthma is the most common chronic childhood disease worldwide. The incidence and mortality of asthma, outpatient visits, and hospital admission all vary by seasons, and are also affected by various environmental factors. However, limited studies have classified asthmatic children into subgroups according to their seasonal attack patterns. This study aims to identify the specific hereditary and environmental factors associated with different seasonal attack patterns of childhood asthma.
METHODS: The study collected the Taiwanese children's allergic status, hereditary and living environmental factors from one elementary and one middle schools in each of the 22 cities/counties in 2016. Ambient temperature, relative humidity, and air pollution were obtained from air monitoring stations. The weighted moving average of monthly attack score in current asthmatic children was calculated, and principal component analyses was then applied to categorize asthma attack subtypes. Multinomial logistic regression and Generalized Estimating Equation were used to study the effects of environmental exposure on each asthma attack subgroup.
RESULTS: Among 11,585 respondents in the study, 6.6% reported asthma attack in the past 1 year. Four attack patterns were identified: spring, summer/fall, winter and perennial. Younger age, parental atopic diseases, and exposure to secondhand smoke at home are important factors for childhood asthma. As for each seasonal attack pattern of asthmatic children, spring-attack was related to molds in residence; winter-attack was related to lower temperature, male gender, parental higher education, and the presence of cockroaches in the house; perennial-attack was related to water damage at home and traffic-related air pollutants.
CONCLUSIONS: Schoolchildren with current asthma demonstrate different seasonal attack patterns, which are related to specific environmental factors. Consideration of the individual subtypes of childhood asthma will help to develop appropriate preventive and therapeutic strategies.

P-1242 Respiratory diseases caused by anthropogenic activities in children and adults of rural communities of Brazil. Review of epidemiological status following fuel policy changes

Claudia Ribeiro Pereira Nunes[1], Pedro Diaz Peralta[1]
[1]*Yale School of The Environment- Michelle L. Bell´s Research Group, New Haven, USA*

BACKGROUND AND AIM: Research points out that emission from diesel-powered vehicles such as trucks and buses, account for about half of the pollutants of the atmosphere including benzene, toluene and particulate matter (ICCT, 2018).
According to the Brazilian National Agency for Road Transportation- ANTT, in charge of monitoring of road freight transport activity, the average age of Brazilian trucks, owned by self-employed haulers, companies and cooperatives, was 14.32 years in 2020. The average age of more than one million Brazilian self-employed haulers' trucks is over 20 years. As an example Diesel-powered heavy-duty vehicles accounts for almost half of the emissions of air pollutants.
This fact exacerbates the health impact of other relevant sources of air pollution as intentional wildfires affecting rural communities in Brazil, associated with deforestation, generalized agricultural malpractices and climate change adverse effects (droughts)
As a negative example, the opening of highway MS-156 in Mato Grosso do Sul, Brazil, worsened the health status and chronic health problems of the indigenous population living in the Itaporã peri-urban indigenous reserve in Dourados (MS), which this road split in two.
METHODS: A qualitative document analysis based on the synthesis of existing literature has been complemented with the critical review of relevant outcome of health surveys.
RESULTS: The traffic-related air pollution aggravates existing health problems impacting the health status of the Guarani-Kaiowá community worsen the adverse common trends measured in other Brazilian communities, with a increase of adverse health indicators associated with environmental stress as pneumonia and other respiratory disorders.
CONCLUSIONS: We observed an increase in morbidity in less populated, rural areas close to transport hubs linked to poor fuel quality, aggravating the negative impact of other concomitant anthropogenic factors as wildfires and agriculture malpractices.

O-SY-133 Association between drinking water arsenic and urinary inorganic arsenic in the US: NHANES 2003-2014

Maya Spaur[1], Melissa Lombard[2], Benjamin Bostick[3], Ana Navas-Acien[1], Anne Nigra[1]
[1]Columbia University Mailman School of Public Health, New York, USA, [2]New England Water Science Center, USA Geological Survey, Pembroke, USA, [3]Lamont-Doherty Earth Observatory of Columbia University, Palisades, USA

BACKGROUND AND AIM: Important inequalities exist in arsenic (As) in drinking water across US populations. A critical research gap is how water As corresponds to internal dose, measured by urinary biomarkers. We evaluated the association between assigned private well and regulated community water system (CWS) As and urinary As concentrations in the National Health and Nutrition Examination Survey (NHANES).

METHODS: We assigned 13,163 NHANES 2003-2014 participants county-level population- weighted CWS concentrations (μg/L) and private well estimates (probability >10 μg/L) using published nationwide estimates from US Environmental Protection Agency and US Geological Survey datasets, respectively. The internal dose of inorganic As related to drinking water was estimated by recalibrating urine dimethylarsinate (DMA) concentrations to adjust for arsenobetaine, seafood, smoking status, and past 24-hour intake of rice and other dietary sources. We evaluated geometric mean ratios (GMRs) of DMA across tertiles of water As, the lowest tertile as reference, for all participants and stratified by census region and quartile of geologic risk of elevated water As.

RESULTS: Among CWS users, participants in the highest tertile of CWS As had significantly higher DMA overall (GMR= 1.17, 95% CI 1.09, 1.26) and in the South (GMR =1.23, 95% CI 1.09, 1.38), compared to participants in the lowest tertile. Among private well users, participants in the highest tertile of private well As had significantly higher DMA overall (GMR = 1.23, 95% CI 1.01, 1.50) and in the West (GMR = 1.34, 95% CI 1.18, 1.53).

CONCLUSIONS: Arsenic in private wells and CWSs contributes to As exposure, measured in urine, in general US populations. Water As and urine DMA were more strongly associated among private-well users compared to CWS users nationwide, with differences by region. Positive associations were also observed among CWS users in the highest two quartiles of geologic risk.

KEYWORDS: arsenic, exposure, water quality

DAY 2 (Tuesday, 20 Sept 2022)

THEMATIC 02: Aging and Environment

P-0039 Association of residential road proximity with cognitive decline and dementia: The Atherosclerosis Risk in Communities (ARIC) Study

Naa Adoley Parker-Allotey[1], Erin E. Bennett[1], Katie Lynch[1], Xiaohui Xu[2], Eric A. Whitsel[3], Richard L. Smith[3], James D. Stewart[3], Eun Sug Park[2], Qi Ying[2], Melinda Power[1]

[1]George Washington University, Washington, USA, [2]Texas A&M, College Station, USA, [3]University of North Carolina, Chapel Hill, University of North Carolina

BACKGROUND AND AIM: Increasing evidence links higher air pollution exposures to increased risk of cognitive impairment, and there is growing interest in the role of noise in cognitive aging. Although risk factor associations with incident dementia are often strongest when midlife values of risk factors are considered, few studies have considered associations between midlife exposures to traffic-related air pollution or road noise and late life cognition. Our aim was to determine if midlife residential proximity to major roads, a proxy for traffic-related air pollution exposure and road noise, is associated with increased risk of incident dementia in the Atherosclerosis Risk in Communities (ARIC) study.

METHODS: ARIC participants were enrolled from 4 US sites in 1987-1989 at ages 45 to 65. We considered data from 12,135 participants of ARIC Visit 2 (1990-1992, study baseline). We calculated midlife residential Euclidean distance to a major (A1, A2, or A3) road based on geocoded residential addresses at Visit 2. We ascertained dementia status through 2019 via in-person study visits with neurocognitive assessment, telephone cognitive interview, informant interview, and access to hospitalization and death records. We estimated the association between midlife residential road proximity and incident dementia using adjusted Weibull models.

RESULTS: at study baseline, the mean age of participants was 57 years, 22% were black, 56% were female. 48% lived within 200m and 36% lived within 200 to 500m of a major road. 20% developed dementia during follow-up. While residing closer to major roads in midlife was associated with increased risk of incident dementia in unadjusted models, this association did not persist in adjusted analyses.

CONCLUSIONS: Residence near a major road in midlife, a proxy for higher exposure to traffic-related air pollution and noise, does not appear to increase risk of dementia.

KEYWORDS: dementia, air pollution, roadway, roads, particulate matter, cognition, aging, epidemiology

P-0041 The role of polygenic susceptibility on air pollution-associated asthma between Caucasian and Asian elderly women

Sara Kress[1,2], Akinori Hara[3], Claudia Wigmann[1], Takehiro Sato[4], Keita Suzuki[3], Kim-Oanh Pham[3], Qi Zhao[1,5], Atsushi Tajima[4], Holger Schwender[6], Hiroyuki Nakamura[3], Tamara Schikowski[1]

[1]IUF – Leibniz Research Institute for Environmental Medicine, Düsseldorf, Germany, [2]Medical Research School Düsseldorf, Heinrich Heine University, Düsseldorf, Germany, [3]Department of Hygiene and Public Health, Graduate School of Advanced Preventive Medical Sciences, Kanazawa University, Japan, [4]Department of Bioinformatics and Genomics, Graduate School of Advanced Preventive Medical Sciences, Kanazawa University, Japan, [5]Department of Epidemiology, School of Public Health, Cheeloo College of Medicine, Shandong University, China, [6]Mathematical Institute, Heinrich Heine University, Düsseldorf, Germany

BACKGROUND AND AIM: Polygenic susceptibility likely influence the individual response to air pollutants and the risk of asthma. We compared the role of polygenic susceptibility on air pollution-associated asthma between Caucasian and Asian elderly women.

METHODS: Women enrolled in the German SALIA cohort study (n=771, mean age=73 years) and Japanese Shika cohort study (n=847, mean age=67 years) with asthma status available (self-response on doctors' diagnosis) were investigated. Adjusted main environmental, main polygenic, and gene-environment interaction (GxE) logistic regression models were fitted with average concentrations of particulate matter with a median aerodynamic diameter ≤2.5µm ($PM_{2.5}$) and respectively nitrogen dioxide (NO_2) at residential addresses 5 years prior to the asthma assessments or/and weighted polygenic risk scores (PRS).

RESULTS: We found high-risk effects of low exposures on asthma in Asian women ($PM_{2.5}$: median=12.7µg/m³, p-value<0.001, NO_2: median=8.5µg/m³, p-value<0.001), and protective polygenic effects in Caucasian women (p-value=0.008). While we found no significant GxE effects on asthma, the main effects remained stable in the GxE models. In both ancestry groups, the PRS increased the effect of $PM_{2.5}$ exposure and decreased the effect of NO_2 exposure on asthma. The trends were mostly robust to potential effect modifications according to smoking and residential moves.

CONCLUSIONS: Our study confirmed high-risk effects of low exposures on asthma in Asian elderly women and provided indications for polygenic effects in Caucasian, but no evidence for GxE effects in Asian or Caucasian elderly women. Further genome-wide GxE studies exploring the role of ancestry-specific polygenic susceptibility on air pollution-associated asthma are required.

P-0042 Association of long-term exposure to ambient air pollution with retinal neurodegeneration on optical coherence tomography: the prospective Alienor study

Laure Gayraud[1], Marion Mortamais[2], Cédric Schweitzer[1,3], Kees De Hoog[4,5], Audrey Cougnard-Grégoire[1], Jean-François Korobelnik[1,3], Marie-Noelle Delyfer[1,3], Marie-Bénédicte Rougier[1,3], Karen Leffondré[1], Catherine Helmer[1], Danielle Vienneau[4,5], Claudine Berr[2], Cécile Delcourt[1]

[1]Univ. Bordeaux, Inserm, Bordeaux Population Health Research Center, UMR 1219, F-33000 Bordeaux, France,, [2]Univ Montpellier, Inserm, Institute for Neurosciences of Montpellier INM, UMR 1298, 34091- Montpellier, France,, [3]Service d'Ophtalmologie, Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France,, [4]Swiss Tropical and Public Health Institute, Allschwil, Switzerland,, [5]University of Basel, Basel, Switzerland,

BACKGROUND AND AIM: Chronic exposure to air pollution may have adverse effects on the central nervous system (CNS). The retinal nerve fiber layer (RNFL) is a part of the CNS. RNFL thinning is a hallmark of glaucoma, the second leading cause of blindness worldwide and may constitute a biomarker of neurodegenerative processes. We investigated the relationship of air pollution exposure with longitudinal RNFL thickness changes.

METHODS: The Alienor study is a cohort of residents of Bordeaux, France, aged 75 years or more. RNFL thickness was measured using optical coherence tomography imaging every 2 years from 2009 to 2017. Exposure to air pollutants during the 10 years preceding the first RNFL measurement (particulate matter with diameter ≤2.5 µm (PM2.5 (µg/m3), black carbon (BC (10-5/m)) and nitrogen dioxide NO2 (µg/m3)) were estimated at the participants' geocoded residential address using Land-Use Regressions models. Longitudinal associations of air pollution exposure with RNFL thickness were assessed using linear mixed models adjusted for potential confounders.

RESULTS: The study included 694 subjects, 62% were female and the mean age was 82 years. The median concentration (Interquartile Range (IQR)) were 22.03 (1.57) µg/m3 for PM2.5, 2.26 (0.30) 10-5/m for BC and 29.04 (6.32) µg/m3 for NO2. Exposure to higher levels of PM2.5 and BC in the previous 10 years was significantly associated with a faster RNFL thinning during the 8-year follow-up (-0.39 microns/year (95% confidence interval (CI) [-0.57;-0.20]) and -0.33 microns/year (95% CI [-0.50;-0.16]) per IQR increment; p<0.001 for both). The size of the effect was similar to one year of age (-0.36 microns/year). No statistically significant associations were found with NO2.

CONCLUSIONS: This study evidenced a strong association of chronic exposure to fine particulate matter with retinal neurodegeneration, at air pollution levels below the current recommended thresholds in Europe.

KEYWORDS: air pollution, retina, neurodegeneration

P-0046 Ambient air pollution, cardiovascular burden, and incident depression among older adults

Jing Wu[1], Federico Triolo[1], Giulia Grande[1], Linnea Sjöberg[1], Petter Ljungman[2,3], Andrei Pyko[2,4], Kristina Eneroth[5], Tom Bellander[2,4], Debora Rizzuto[1,6]

[1]Aging Research Center, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet and Stockholm University, Stockholm, Sweden, Solna, Sweden, [2]Institute of Environmental Medicine (IMM), Karolinska Institutet, Stockholm, Sweden, Sweden, [3]Department of Cardiology, Danderyd Hospital, Stockholm Sweden, Sweden, [4]Center for Occupational and Environmental Medicine, Stockholm Region, Stockholm, Sweden,, [5]Environment and Health Administration, City of Stockholm, Sweden, [6]Stockholm Gerontology Research Center, Stockholm, Sweden

BACKGROUND AND AIM: Studies suggest a harmful effect of air pollution on mental health including depression, but neither results are concordant, nor the mechanisms are clear. We aimed to examine the association between exposure to long-term ambient air pollution and depression incidence among older adults and to understand the modifying effect of age and cardiovascular diseases (CVDs).

METHODS: Depression-free older adults (n=2812) from the Swedish National Study on Aging and Care in Kungsholmen (SNAC-K) were followed up over 12 years. Incident minor and major depression cases were ascertained using the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV). The time-varying 3-year average level of particulate matter (PM2.5 and PM10) and nitrogen dioxide (NOx) were obtained using spatial dispersion models. We estimated hazard ratios of depression (HRs) according to 1-µg/m3 increase of PM2.5 and PM10 and 10-µg/m3 increase of NOx considering potential confounders (age, sex, neighborhood and individual social-economic status, smoking, alcohol consumption, physical activity, medications, exposure to road traffic noise, and greenspace accessibility). The modifying effects were tested by adding interaction terms of age and CVDs (including ischemic heart disease, atrial fibrillation, heart failure, and stroke) to the models.

RESULTS: During the follow-up, 137 incident depression cases were identified. Higher hazard ratios of incident depression were observed with each 1-µg/m3 increase of PM2.5 (HR=1.68, 1.30-2.16) and PM10 (HR=1.07, 0.97-1.18) and each 10-µg/m3 increase of NOx (HR=1.23, 0.97-1.57). The observed association was enhanced among individuals with stroke (PM2.5: HR =2.71, 1.59-4.64; PM10: HR =1.34, 1.12-1.61; and NOx: HR =2.14, 1.41-3.25) and aged 78+ (PM2.5: HR =1.82, 1.42-2.34; PM10: HR =1.14, 1.03-1.26; and NOx: HR =1.45, 1.14-1.83).

CONCLUSIONS: Air pollution was associated with an increased risk of depression among older adults. Importantly, stroke and advanced age may amplify such associations.

P-0049 Potential modifying factors for the older people feeling cold/warm in the English dwellings

Shih-Che Hsu[1], Ian Hamilton[1], Tadj Oreszczyn[1], Jenny S Mindell[2], Cesar De Oliveira[2], Andrew Steptoe[2], Shaun Scholes[2], Alison Moody[2], Feifei Bu[2]

[1]Energy Institute, University College London, London, UK, [2]Institute of Epidemiology & Health Care, University College London, London, UK

BACKGROUND AND AIM: Excess winter mortality (EWM), estimated at more than 36,000 in 2019 in the UK, is an important health issue among older households who are vulnerable to cold-related diseases. EWM is related to exposure to low indoor temperature; many English homes experience indoor winter conditions <18oC. This study aims to understand the relationship between building energy performance, indoor temperature and reported indoor thermal experience of older households.

METHODS: In a sub-survey of the 2010/2011 English Housing Survey, 823 homes with temperature loggers, monitored indoor temperatures at different seasons to assess the risk of cold exposure and self-reported feelings of discomfort among older households (aged 60+). Linear regression and chi-square automatic interaction detection (CHAID) was used for indoor temperature and indoor thermal experience respectively. The analyses compared conditions against younger households (<60) as a basis for understanding the difference in risk factors.

RESULTS: Dwelling energy performance and household characteristics are important determinants affecting living and bedroom temperatures. for the bedroom, older households had higher odds of keeping warm in the wintertime (OR=1.02, 95%CI=1-1.05) and of feeling too warm in the summertime (OR=1.9, 95%CI=1.62-2.62). In the living room, the younger households had higher odds of feeling cold in the wintertime (OR=1.08, 95%CI=1-1.16) and too warm in the summertime (OR=1.61, 95%CI=1.43-1.82). The determinants of discomfort also differed by age with older households, mainly affected by property energy performance (e.g., having double glazing windows and air conditioning), while younger households related to socio-economic factors (especially household income and tenure type).

CONCLUSIONS: This research highlights the need to focus on older households and risk factors of low temperature that can help reduce temperature-related disease, such as the energy performance of housing, which has been shown to improve indoor temperatures.

Chan School of Public Health, Boston, USA, [3]Channing Division of Network Medicine, Department of Medicine; Brigham and Women's Hospital and Harvard Medical School, Boston, USA

BACKGROUNDS AND AIMS: Our study adds to the sparse literature that examines whether arterial stiffness, related to cardiovascular risk, increases with exposure to air pollution. We assessed the associations between spatio-temporally resolved air pollutants and vascular and hemodynamics parameters in an elderly population based in Eastern Massachusetts.

METHODS: Among 401 men living in Eastern Massachusetts between 2007 and 2019, we utilized time-varying linear mixed-effects regressions to examine associations between central augmentation index (%) and central pulse pressure (mmHg) and short-term (0-5 days) exposure to air pollution concentrations (fine particulate matter (PM2.5), ozone (O3), nitrogen dioxide (NO2)) and temperature adjusted for known cardiovascular risk factors. Central augmentation index and pulse pressure were measured at each visit by using radial artery applanation tonometry for pulse wave analysis. Each air pollutant and temperature were geocoded to the participant's residential address using validated ensemble and hybrid exposure models and gridMET predictions.

RESULTS: We found consistent results that higher PM2.5 concentrations at a one-day distributed lag was associated with significantly higher measures of arterial stiffness. Each 5.24 µg/m3 interquartile range (IQR) increase in daily PM2.5 for a 1-day distributed lag was associated with a 3.19% (95% confidence interval (CI): 1.54, 4.83) increase in augmentation index and a 1.87 mmHg (95% CI: 0.38, 3.36) increase in pulse pressure. Also, each 5.64 µg/m3 IQR increase in daily PM2.5 for a 0-day distributed lag was associated with a 1.39 mmHg (95% CI: 0.18, 2.59) increase in pulse pressure. We found no clear association between O3, NO2 and temperature and the outcomes.

CONCLUSIONS: Short-term exposure to PM2.5 was associated with markers of arterial stiffness and central hemodynamics.

KEYWORDS: Air pollution; arterial stiffness; pulse pressure; temperature; hemodynamics.

P-0053 Health promoting environments for an ageing population: A register and GIS-study of associations between urban greenness and formal social services in Sweden

Kristoffer Mattisson[1], Emilie Stroh[1], Gunilla Carlsson[2], Agneta Fänge Malmgren[2], Connie Lethin[2], Anna Axmon[1]
[1]Division of Occupational and Environmental Medicine, Lund University, Lund, Sweden, [2]Department of Health Science, Lund University, Lund, Sweden

BACKGROUND AND AIM: The ongoing urbanization and densification of cities is intensifying the competition of available space in urban areas. The resulting decrease in urban greenness may have a negative health impact for residents, with possible sociodemographic injustices. Our overarching aim is to investigate if access to urban greenness increases the chances of independent living among older people, measured by use of formal social services and taking sociodemographic factors into account. However, this abstract focuses on access to urban greenness and sociodemographic factors.

METHODS: This register-based study investigates all people aged 65+ years in two Swedish municipalities in 2010, 2015 and 2019. Data include sociodemographic variables (type of housing, place of birth, cohabitation, sex, and year of birth on individual level, and socioeconomic status [SES] on area level) and coordinates of residential location. The proportion of total, publicly available and quiet urban green spaces, respectively, in 300m and 100m buffers around the residency were assessed with Geographical Information systems (GIS).

RESULTS: In Malmö, a high proportion of urban green spaces was found for those living in house, living alone, being born before the median year of birth, and living in an area with low SES. A similar pattern was found for public green spaces, except for living in a house where the results were opposite. Although having access to more public green, being born abroad and living in an area with low SES were associated with having access to less quiet green. In Kristianstad living in a house and being born abroad were associated with higher access to urban green spaces, whereas living in a house was associated with lower access to public green spaces.

CONCLUSIONS: There may be sociodemographic differences in access to urban green.

P-0054 Factors associated with middle-aged adult obstructive lung function deficits in the grass pollen season

N. Sabrina Idrose[1,2], Don Vicendese[1,3], Michael Abramson[4], E. Haydn Walters[1,5], Garun Hamilton[4], Adrian Lowe[1,2], Jo Douglass[1,6], Caroline Lodge[1], Shyamali Dharmage[1,2]

[1]University of Melbourne, Melbourne, Australia, [2]Murdoch Children's Research Institute, Melbourne, Australia, [3]La Trobe University, Melbourne, Australia, [4]Monash University, Melbourne, Australia, [5]University of Tasmania, Hobart, Australia, [6]Royal Melbourne Hospital, Melbourne, Australia

BACKGROUND AND AIM: Impact of grass pollen season (GPS) on lung function is not well-studied at a community level. We assessed this in middle-aged participants from the Tasmanian Longitudinal Health Study (TAHS), and potential modifiers of this association.

METHODS: Spirometry was performed at the TAHS 53-year follow-up (n=2478). We compared lung function for those tested in the GPS (Oct-Jan) to those tested outside GPS using linear regression. Interactions were investigated for: questionnaire-reported asthma, hay fever, eczema and grass pollen allergy symptoms in the past 12 months; traffic-related air pollution (TRAP) exposure defined by living <200m from a major road; and glutathione S-transferase (GST) polymorphisms (GSTM1, GSTT1, GSTP1) for a subsample.

RESULTS: An association between GPS and reduced lung function was observed among those with allergic disease, also those living <200m from major roads or with a GSTM1 genotype (p for interaction≤0.1). Participants with current asthma tested in the GPS had increased mid- to small-airway obstruction compared to out of GPS, with $zFEV_1/FVC$ ratio = -0.3 (95% CI = -0.6,-0.1) and zFEF25-75% = -0.4 (95% CI= -0.6,-0.07). Similar evidence of obstruction was observed in current hay fever, eczema, grass pollen allergy or living <200m from major roads. A modest association was found with bronchodilator responsiveness = 18 ml (95% CI = -18,54) in those with GSTM1 null genotypes.

CONCLUSION: Middle-aged adults with allergic disease or TRAP exposure may be more susceptible to obstructive lung function deficits during the grass pollen season. Genetics may also play a role, but further research on this is required.

KEYWORDS: Asthma, air pollution, eczema, grass pollen, genetics, lung function

P-0055 Lack of association between air pollutants and telomere length: findings from the UK Biobank study

Anna Hansell[1], Vasiliki Bountziouka[2,3], Christopher Nelson[2,3], Veryan Codd[2,3], Nilesh Samani[2,3]
[1]Centre for Environmental Health and Sustainability, University of Leicester, Leicester, UK, [2]Dept. Cardiovascular Sciences, University of Leicester, Leicester, UK, [3]NIHR Leicester Biomedical Research Centre, Glenfield Hospital, Leicester, UK

BACKGROUND: Air pollution has been extensively associated with diseases more common in the elderly, and with disease risk factors associated with ageing such as atherosclerosis and reduced lung function. Shorter telomere length (TL) is often considered a biological marker of advanced biological ageing, also and is associated with the risk of many age-related degenerative diseases. Common mechanisms of oxidative stress and inflammation have been identified for TL shortening and air pollution damage. There are few studies of air pollution and TL in adults, but associations were seen between in utero and early life air pollution exposures and shorter TL at age 8 years in the HELIX study (Clemente, 2019).

METHODS: We investigated cross-sectional associations between European Study of Cohorts and Air Pollution Effects (ESCAPE) modelled air pollutants (NO2, NO, PM10, PM2.5, PM2.5absorbance, PMcoarse) and leucocyte TL (LTL) in 299,786 UK Biobank participants. We used multivariable linear regression models adjusted for age, sex, ethnicity, white cell blood count, deprivation, family income, education, and smoking.

RESULTS: The association between any air pollutant and LTL was negligible, after accounting for major determinants of LTL, socio-economic status and smoking. Findings were unchanged in multiple imputation models to investigate impact of missing confounders, and when stratifying by deprivation quintile.

CONCLUSIONS: Studies using UK Biobank have found associations between air pollution and organ damage also associated with ageing such as reduced lung function (Doiron, 2019), but we did not find associations with TL shortening in cross-sectional analyses, suggesting air pollution mediated TL damage is unlikely to be a key mechanism. However, findings need confirmation in longitudinal analyses, ideally complemented by experimental studies and further epidemiological studies investigating other air pollutants.

KEYWORDS: Air pollution; Ageing; Telomere length

P-0057 Association between climate and skin aging: A cross-sectional analysis from three metropolitan cities of India

Nidhi Singh[1], Pia Jahan[1], Prince Vijay[2], Harish Phuleria[2], Jean Krutmann[1], Tamara Schikowski[1]
[1]IUF-Leibniz Research Institute for Environmental Medicine, Düsseldorf, Germany, [2]Indian Institute of Technology Bombay, India

BACKGROUND AND AIM: Skin aging is driven by a large extent by environmental factors such as air pollution. However, it is unknown if and how climate parameters contribute to skin aging and/or if the association is modified by air pollution. To address the above research gap, we analyzed the association between skin aging traits and ambient temperature (AT), relative humidity (RH), and solar radiation (SLR).

METHODS: This study was conducted in three metropolitan Indian cities; Delhi, Mumbai, and Bangalore with 1510 women aged between 20-91 years between May 2018 to Feb 2019. SCINEXA™, a validated visual score was used to measure extrinsic facial skin aging. We used an ordinal multiple logistic regression model for the analysis adjusting for air pollutants (PM2.5 and NO2) and psychological stress each at a time with AT.

RESULTS: We here report a positive and significant association between AT, and skin aging parameters- wrinkles under the eyes (OR: 1.10, 95% CI; 1.03, 1.19), hyperpigmentation on the forehead (OR: 1.19, 95% CI; 1.08, 1.31), and dark circles under eye (OR: 1.64, 95% CI; 1.51, 1.78). These skin aging signs also showed a positive and significant association with RH and SLR. The association of skin aging signs with AT was robust after accounting for the confounding effect of PM2.5 and NO2 and psychological stress.

CONCLUSIONS: The study shows epidemiological evidence of an association between long-term exposure to high AT, RH, and SLR and skin aging parameters and that it might increase the effect of particulate and traffic-related air pollution on skin aging.

P-0062 Differential association of metabolomic patterns with bone mineral density and fractures by metal exposure biomarker levels in The Hortega Study

Marta Galvez-Fernandez[1], Zulema Rodriguez-Hernandez[1], Maria Grau-Perez[2], Tamara Garcia-Barrera[3], Jose L. Gomez-Ariza[3], F. Javier Chaves[2], Daniel Monleon[2], Maria Tellez-Plaza[1,2], Josep Redon[2], Juan C. Martin-Escudero[4]
[1]National Center of Epidemiology, Madrid, Spain, [2]Institute for Biomedical Research, Hospital Clinic of Valencia (INCLIVA), Valencia, Spain, [3]Research Center for Natural Resources, Health and the Environment (RENSMA), Department of Chemistry, Faculty of Experimental Sciences, University of Huelva, Huelva, Spain, [4]Department of Internal Medicine, Hospital Universitario Rio Hortega, University of Valladolid, Valladolid, Spain

BACKGROUND AND AIM: The bone remodeling process may be influenced by metabolic factors. We evaluated the cross-sectional association of metabolic patterns with reduced bone mineral density (BMD) and the prospective association of metabolic patterns with incident osteoporosis-related bone fractures. Since copper, selenium, zinc, arsenic, antimony, cadmium and cobalt have been related to metabolic patterns and oxidative stress biomarkers in our study population, and redox balance play a key role in bone metabolism, we also assessed potential differential associations in subgroups defined by metals above and below median (p50) biomarker levels.

METHODS: In 507 participants older than 50 years from the Hortega Study, a representative sample from a region in Spain, we estimated metabolic principal components (mPC) from 54 plasma metabolites with NMR-spectrometry. BMD was calculated in the right calcaneus using Peripheral Instantaneous X-ray Imaging system. Copper, selenium and zinc were measured in plasma by AAS, arsenic, antimony, cadmium and cobalt were measured in urine by ICPMS, and arsenobetaine was measured by HPLC-ICPMS.

RESULTS: In reduced BMD models, the association was inverse mPC1 (reflecting non-essential and essential amino acids, including branched chain, and bacterial co-metabolism versus fatty acids and VLDL subclasses) and positive for mPC2 (reflecting essential amino acids, including aromatic, and bacterial co-metabolism), and mPC3 (reflecting LDL subclasses). In incident bone fracture models, the association was inverse for mPC2, but positive for mPC1 and mPC4 (reflecting HDL subclasses). The association between mPC2 and bone fractures showed statistically significant interactions by antimony (p50=0.07 µg/g) and arsenobetaine-corrected arsenic (p50=6.81 µg/g), and selenium (p50=85.3 µg/L) (P interaction = 0.02, 0.001 and 0.03 respectively).

CONCLUSIONS: Our results support the hypothesis that bone remodeling is influenced by metabolic factors, including amino acids, lipids and microbiota co-metabolism. Ageing individuals may benefit from intensified preventive interventions to reduce bone disease based on their metal exposure levels.

P-0063 Urinary Zinc and Incident Diabetes: Prospective Evidence from the Strong Heart Study

Marta Galvez-Fernandez[1], Martha Powers[2], Maria Grau-Perez[3], Arce Domingo-Relloso[1], Nancy Lolacono[1], Walter Goessler[4], Ying Zhang[5], Amanda Fretts[6], Jason G Umans[7], Nisa Maruthur[8], Ana Navas-Acien[1]

[1]Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [2]Department of Sociology and Anthropology, Northeastern University, Boston, USA, [3]Biomedical Research Institute of Valencia (INCLIVA), Valencia, Spain, [4]Institute of Chemistry; University of Graz, Graz, Austria, [5]Department of Biostatistics and Epidemiology, The University of Oklahoma Health Sciences Center, Oklahoma, USA, [6]Department of Epidemiology, Cardiovascular Health Research Unit, University of Washington, Seattle, USA, [7]Division of Nephrology and Hypertension, Department of Medicine, Georgetown University Medical Center, Washington DC, USA, [8]Division of General Internal Medicine, Department of Medicine and Welch Center for Prevention, Epidemiology and Clinical Research, Johns Hopkins University, Baltimore, USA

BACKGROUND AND AIM: Diabetes, a chronic metabolic condition, is a major risk factor for cardiovascular disease. Hyperglycaemia can increase zinc excretion due to its insulin-mimetic function. We aimed to assess the association between urinary zinc and incident diabetes in two populations with a high burden of diabetes from Arizona, Oklahoma, North Dakota and South Dakota.

METHODS: Baseline urinary zinc was measured using Inductively Coupled Plasma Mass Spectrometry (ICP-MS) in 1,339 adults free of diabetes at baseline (1989-1991) and followed through 1998-1999 in the Strong Heart Study (SHS) and in 1,905 family members of SHS participants free of diabetes at baseline (1998-1999) followed as part of the Strong Heart Family Study (SHFS) through 2006-2009.

RESULTS: In the SHS, diabetes incidence was 14.7% (mean follow-up 6.6 years). Median urinary zinc was 0.46 mg/g and 0.50 mg/g for participants without and with diabetes, respectively. After adjustment for sex, site, education, smoking status, and BMI, the hazard ratio (HR) (95%CI) of diabetes comparing IQR percentiles of urinary zinc distribution was 1.21 (1.08, 1.36). In the SHFS, diabetes incidence was 13.5% (mean follow-up 5.6 years). Median urinary zinc was 0.59 and 0.65 for participants without and with diabetes, respectively. The HR(95%CI) in the SHFS was 1.12 (0.96, 1.31). These associations were attenuated in the SHS after adjustment for insulin levels, fasting glucose levels and HOMA-IR score. Excluding participants with prediabetes at baseline, the association of urinary zinc with incident diabetes remained significant in the SHS and suggestive for the SHFS.

CONCLUSIONS: Baseline urinary zinc concentrations were associated with diabetes incidence even after adjustment for fasting plasma insulin and plasma glucose levels in adult populations with a high burden of diabetes. These results highlight the need for greater understanding of zinc metabolism in diabetes pathology and identify possible treatment approaches for diabetes prevention.

P-0065 Associations between personal fine particulate matter elemental constituent mixtures and blood lipid profiles: A panel study in Chinese people aged 60-69 years

Jiaonan Wang[1], Tiantian Li[1], Jianlong Fang[1], Song Tang[1], Xiaoming Shi[1]
[1]*National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND AND AIM: Dyslipidemia may be a potential mechanism linking Fine Particulate Matter (PM2.5) to adverse cardiovascular outcomes. However, the associations between PM2.5 and blood lipid have been inconsistent and the joint effect of PM2.5 elemental constituent on lipid profiles and the role of each constituent are still unclear. We aims to investigate the overall associations of PM2.5 elemental constituent with lipid parameters, and assess the relative importance of each constituent for lipid parameters.
METHODS: Sixty-nine older individuals were visited between September 2018 and January 2019 with five repeated measurements (237 blood samples in total). Each participant wore a PM2.5 monitor for 72 hours before each health examination, including a questionnaire survey, physical examination, and biological sample collection. Bayesian kernel machine regression (BKMR) model was implemented to estimate the joint effect of the seventeen elemental constituent on various lipid parameters.
RESULTS: We found that significant increases in total cholesterol (TC), lowdensity lipoprotein cholesterol (LDL-C), and non-high-density lipoprotein cholesterol (non-HDL-C) levels in older adults when exposed to the mixture of PM2.5 elemental constituents. Copper and titanium had higher posterior inclusion probabilities than the other constituents ranging from 0.76 to 0.90 and 0.74 to 0.94. Copper and titanium in the PM2.5 elemental constituent mixture played a significant role in the changes observed in the blood lipid profiles.
CONCLUSIONS: This study highlights the importance of identifying critical hazardous PM2.5 constituents that may cause adverse cardiovascular outcomes in the future.

PM2.5 constituents; Lipid parameters; Personal exposure monitoring; Complex mixtures； BKMR models

P-0072 Associations of long-term exposure to community noise and traffic air pollution with cause-specific morbidities in older adults

Muwu Xu[1], Kexin Zhu[1], Haomin Li[2], Tszshan Ma[2], Liuhua Shi[2], Meng Wang[1]
[1]University at Buffalo, Suny, Buffalo, USA, [2]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA

BACKGROUND AND AIM: Cardiovascular health of long-term exposure to noise and air pollution has been examined worldwide while few studies have been conducted in U.S. especially in aging population. We examined the effects of community noise and traffic air pollution exposures on incidences of cardiovascular (CVD) and neurological diseases in older adults.

METHODS: We constructed a cohort comprising Medicare beneficiaries aged over 65 years in New York state from 2000 to 2018. Annual mean nitrogen dioxides (NO2) and noise exposures combining road traffic and aviation sources were estimated using advanced geo-statistical models and assigned to the participants according to their ZIP-code of residence. We applied Cox proportional hazards models to examine the associations of exposure to community noise and NO2 with incidences of CVD and its subtypes, depression, and Alzheimer's disease and related dementias (ADRD), adjusting for potential confounders.

RESULTS: of 742,366 participants, 38% developed their first CVD and 7% and 9% had new ADRD and depression during 9.3 years mean follow-up. Community noise exposure (per 25 dB) was significantly associated with increased hazard ratio (HR) of ADRD (1.047, 95%CI: 1.023, 1.073) and overall CVD incidences (1.092, 95% CI: 1.079, 1.105) including its subtypes (ischemic heart disease: 1.099, 95%CI: 1.086, 1.113; heart failure: 1.079, 95%CI: 1.064, 1.095; stroke: 1.116, 95%CI: 1.095, 1.137), but not with depression, acute myocardial infraction and atrial fibrillation, after mutual adjustment for NO2 exposure. for NO2 (per 10 ppb) exposure, the associations remain significant with incidences of ADRD and CVDs (except stroke) though the estimated HRs were attenuated compared to the effects of community noise.
CONCLUSION: Long-term exposure to community noise and traffic air pollution are associated with increased risks of CVD and ADRD in older adults, with noise effects being dominant.

KEYWORDS: Community noise; traffic air pollution; cardiovascular disease; dementia

P-0079 Effect of Frailty on Cancer Mortality Among Never Smoking Older Adults: The Moderating Role of Exposure to Secondhand Smoke

Molly Schwalb[1], Ting-ju Hsu[1], Miranda Jones[1]
[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, USA*

BACKGROUND AND AIM: Exposure to secondhand smoke is a major cause of cancer morbidity and mortality. Additionally, frailty, an aging-related condition of decreased physical functioning, increases the risk for mortality. However, studies have not evaluated the possible joint effects of frailty and exposure to secondhand smoke on cancer mortality. We investigated whether exposure to secondhand smoke modifies the association between frailty and cancer mortality among never smoking older adults in the U.S.

METHODS: We studied 3,308 never smoking adults aged ≥60 years who participated in the National Health and Nutrition Examination Survey (NHANES) from 2007-2014 and were followed for cancer mortality through December 2015. Exposure to secondhand smoke was assessed based on detectable serum cotinine concentrations. Frailty was defined using an adapted Fried criteria. We estimated multivariable adjusted hazard ratios (HR) for cancer mortality comparing joint categories of secondhand smoke exposure (exposed vs. unexposed) and frailty status (frail, prefrail vs. robust) with robust unexposed adults as the reference group.

RESULTS: 52% percent of never smokers were exposed to secondhand smoke. The prevalence of prefrailty and frailty in the study population was 50% and 5%, respectively. After a mean of 4.5 years of follow-up, there were 89 deaths due to cancer. After multivariable adjustment, the risk for cancer mortality was markedly higher for adults who were both frail and exposed to secondhand smoke (HR: 4.35, 95% CI: 1.33, 14.23) than for adults who were frail and unexposed (HR: 2.54, 95% CI: 0.79, 8.19), compared to robust unexposed adults.

CONCLUSIONS: In a representative sample of the U.S. population, joint exposure to secondhand smoke and frailty was associated with higher risk for cancer mortality among never smokers. These findings support the need for legislation measures that ensure complete protection from secondhand smoke for older adult populations.

KEYWORDS: secondhand tobacco smoke, mortality, aging, cancer

P-0080 Association of Tobacco Exposure and Biomarkers of Tobacco Exposure with Frailty Among US Older Adults: the 2007-2018 National Health and Nutrition Examination Survey (NHANES)

Molly Schwalb[1], Ting-ju Hsu[1], Miranda Jones[1]
[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, USA*

BACKGROUND AND AIM: Adults with a history of cancer and those who use tobacco are at increased risk for frailty. However, studies have not evaluated the impacts of smoking on frailty among those with a history of cancer. We investigated the association of tobacco use, and exposure to secondhand smoke (SHS), and biomarkers of tobacco use on frailty among adults with and without a history of cancer.

METHODS: We studied 8,542 adults aged ≥60 years, including 1,705 adults with a prior cancer diagnosis, who participated in NHANES 2007-2018 and had data on self-reported smoking characteristics and biomarkers of tobacco smoke exposure (serum cotinine and blood cadmium). Exposure to SHS was assessed based on detectable serum cotinine levels among nonsmokers. Frailty was defined using an adapted Fried criteria.

RESULTS: The prevalence of frailty was 5%. After multivariable adjustment, the odds ratio (OR, 95% CI) for frailty was 1.51 (1.19, 1.91) for former smokers and 1.63 (1.19, 1.22) for current smokers, compared to never smokers. The impact of tobacco smoking on frailty was stronger for adults with a history of cancer (OR for frailty comparing current smokers to never smokers was 1.75 for adults with a cancer history vs. 1.54 for adults without a history of cancer). Serum cotinine and blood cadmium concentrations were more strongly associated with frailty compared to self-reported measures. Among nonsmokers, the OR for frailty was 1.19 (95% CI: 0.92, 1.55) for nonsmokers exposed to SHS compared to unexposed participants.

CONCLUSIONS: In a representative sample of the U.S. population, tobacco use and exposure to SHS were associated with greater odds of frailty among adults with and without a history of cancer. These findings support the need for smoking cessation efforts and access to smoke-free environments for older adults, especially older cancer survivors.

KEYWORDS: tobacco, secondhand smoke, aging, cancer

THEMATIC 03: Air pollution (ambient & indoor) and Sources

P-0086 Acute ambulatory blood pressure response to short-term black carbon exposure: the MobiliSense sensor-based study

Sanjeev Bista[1], Giovanna Fancello[1], Basile Chaix[1]
[1]*Sorbonne Universite, INSERM, Paris, France*

BACKGROUND/AIM: Documented relationships between black carbon (BC) exposure and blood pressure (BP) have been inconsistent. Very few studies measured both BC exposure and ambulatory BP across the multiple daily environments visited in the general population, and none adjusted for personal noise exposure, a major confounder. Our study addresses these gaps considering 245 participants living in the Grand Paris region.

METHODS: Personal exposure to BC was monitored for 2 days using AE51 microaethalometers. Ambulatory BP was measured every 30 minutes after wake up using Arteriograph 24 monitors (n =6772). Mixed effect models with a random intercept at the individual level and time-autocorrelation structure adjusted for personal noise exposure were used to evaluate the associations between BC exposure (averaged from 5-minutes to 1-hour before each BP measurement) and BP. To increase the robustness of findings, we eliminated confounding by unmeasured time-invariant personal variables, by modelling the associations with fixed-effect models as well. All models were adjusting for potential confounders and short term time trends. Results from mixed models show that a 1-µg/m3 increase in 5-minutes averaged BC exposure was associated with an increase of 0.57 mmHg in ambulatory systolic blood pressure (SBP) (95% CI: 0.30, 0.83) and with an increase of 0.36 mmHg in diastolic blood pressure (DBP) (95% CI: 0.14, 0.58). The slope of the exposure-response relationship gradually decreased for both SBP and DBP with the increase in the averaging period of BC exposure from 5 minutes to 1 hour preceding each BP measurement. Findings from the fixed-effect models were consistent with these results.
CONCLUSION: We found evidence of a relationship between BC exposure and acute increase in ambulatory SBP and DBP after adjustment for personal noise exposure, with potential implications for the development of adverse cardiovascular outcomes.

P-0087 Time trends of PM2.5 exposure between 2000 to 2018 in the SCAPIS cohort

Peter Molnár[1], Cecilia Bennet[2], Kristina Eneroth[3], Susanna Gustafsson[4], Jenny Lindvall[3], David Segersson[2], Mårten Spanne[4], Petter Ljungman[5], Leo Stockfelt[1]

[1]Occupational and Environmental medicine, University of Gothenburg, Gothenburg, Sweden, [2]Swedish Meteorological and Hydrological Institute, Norrköping, Sweden, [3]SLB-analys, Environment and Health Administration, Stockholm, Sweden, [4]Environmental Department, City of Malmö, Malmö, Sweden, [5]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

BACKGROUND AND AIM: The Swedish CArdioPulmonary bioImage Study, SCAPIS, is a nationwide population-based cohort for the study of cardiovascular and pulmonary disease. A total of 31,265 men and women aged 50-64 years old were recruited and investigated including detailed imaging of the cardiovascular and pulmonary systems. The database currently covers over 1,300 different variables and is growing.

METHODS: We modelled yearly PM2.5 levels in the six SCAPIS regions, including major source types, traffic exhaust, road wear and resuspension, residential heating, shipping, with a spatial resolution of 50 x 50 m and assigned participants exposure 2000, 2011, and 2018. These areas cover over 40% of the total population in Sweden.

RESULTS: The time trend within the cohort showed a strong decrease in Long Range Transported (LRT) pollutants for the 2000s for all study regions, but for Stockholm Uppsala and Umeå the LRT exposure levels levelled out during the 2010s. There was a decreasing gradient of LRT concentrations from the highest levels in the south to the lowest levels in the north. The relative importance of the different local sources, and their respective temporal trends, were site dependent. Malmö was strongly influenced by the closeness to Copenhagen, especially in the beginning of the study period. Gothenburg had the strongest influence from shipping, and the relative importance of residential heating was strongest in Umeå in the north. Another general trend was that traffic exhaust particles decreased over time, while the particle concentrations from traffic road wear and resuspension instead increased, illustrating the tail pipe emission reduction and the traffic increase.

CONCLUSIONS: Exposure to air pollution in Sweden have decreased in the last two decades, but the pattern varies for the different regions and sources.

P-0088 Long-term exposure to air pollution and the development of airflow obstruction in the population-based Dutch Lifelines cohort

Dimitra Sifaki-Pistolla[1,2], Judith M. Vonk[2,3], Ioanna Tsiligianni[1], H. Marike Boezen[4]
[1]Department of Social Medicine, School of Medicine, University of Crete, Greece, Heraklion, Greece, [2]University of Groningen, University Medical Center Groningen, Department of Epidemiology, Groningen, The Netherlands, The Netherlands, [3]University of Groningen, University Medical Center Groningen, GRIAC, Groningen, The Netherlands, The Netherlands, [4]Deceased in Oct 2021. University of Groningen, University Medical Center Groningen, Department of Epidemiology, Groningen, The Netherlands, The Netherlands

BACKGROUND: Recent evidence reports a strong association between PM2.5 and NO2, and the development of chronic obstructive pulmonary disease, contrary to PM10 which showed no association. However, longitudinal data from large cohorts are lacking.
Aim: We studied the longitudinal association between air pollution exposure at the home-address and the development of airflow obstruction (AO) in the large population-based Lifelines cohort study.

METHODS: We included subjects from the Lifelines cohort study (http://www.lifelines.nl) without airflow obstruction (AO - defined as FEV1/FVC < lower limit of normal) at baseline and spirometry after 4.5 years of follow-up (n=25,506). Exposure levels at the home-address at baseline for black carbon (BC), NO2, PM10, and PM2.5 were estimated using land-use regression models from the ESCAPE study. A multiple logistic regression on the development of AO at follow-up was performed with adjustment for age, sex, body mass index, pack-years, educational level, monthly income and FEV1/FVC at baseline. We conducted both single and two pollutant models.

RESULTS: of the 25,506 individuals without AO at baseline, 2,464 (9.7%) had developed AO at follow up. Higher levels of BC, NO2, and PM2.5 were significantly associated with a higher odds to develop AO in the single pollutant models.In the two pollutant models NO2 and PM2.5 still showed a significant association with AO development while BC was no longer significant. Due to high correlation between BC, NO2 and PM10, two pollutant models could not be performed for these combinations. When, stratifying by gender and by smoking status, similar associations were observed mainly in males and current smokers.

CONCLUSIONS: This novel longitudinal study suggests that exposure to NO2 and PM2.5 are strong independent risk factors for the development of AO. In future studies we will focus identifying the most genetically susceptible individuals for these air pollutants.

P-0089 Impact of Air Pollution on the Health of Trees in Dhaka, Bangladesh

Saif Shahrukh[1], Muhammad Nurul Huda[2], Mohammad Moniruzzaman[3], Mominul Islam[4], Aftab Ali Shaikh[5], Shahid Akhtar Hossain[6], Mohammad Enayet Hossain[7]

[1]Department of Soil, Water and Environment, University of Dhaka, Bangladesh, [2]Centre for Advanced Research in Sciences, University of Dhaka, Bangladesh, [3]Central Analytical and Research Facilities, Bangladesh Council of Scientific and Industrial Research, Bangladesh, [4]Department of Chemistry, University of Dhaka, Bangladesh, [5]Department of Chemistry, University of Dhaka, Bangladesh, [6]Department of Soil, Water and Environment, University of Dhaka, Bangladesh, [7]Department of Soil, Water and Environment, University of Dhaka, Bangladesh

BACKGROUND AND AIM: In cities, air pollution exposure may affect the roadside species by impacting their physiology, morphology, and biochemistry. In the present study, an investigation was conducted to evaluate the tolerance or sensitivity of four roadside tree species (Ficus benghalensis, Ficus religiosa, Mangifera indica, and Polyalthia longifolia) in four locations of Dhaka towards air pollutants, including particulates.

METHODS: Air pollution tolerance index (APTI) of the studied species was assessed employing their total chlorophyll content, ascorbic acid content, relative water content, and the pH of their leaves' extract. Anticipated performance index (API) was also calculated to assess the overall performance of a plant in a particular region where some socioeconomic and biological characteristics were taken into consideration.

RESULTS: The total chlorophyll content was found to decrease with the increasing particulate matter loads. The highest percentage change in the chlorophyll a/b ratio was found in M. indica (12.3%) at the highest traffic-intensity location. A significantly strong positive correlation was found between APTI and relative water content and between APTI and ascorbic acid content. Different tolerance orders of species were found for the four sampling sites owing to the varying level of air pollution. APTI of the investigated plants ranged from 10.31 to 12.51 meaning they were either sensitive or intermediately tolerant. M. indica was found to be intermediately tolerant in three sampling sites. From the API, M. indica was judged as good performer maintaining the highest score (68.75%) amongst the selected plant species irrespective of different sites.

CONCLUSIONS: The results suggested that these plant species are good indicators of air pollution and can be employed as an early warning tool for air pollution level.

P-0090 Nationwide assessment of ambient monthly fine particulate matter (PM2.5) and its associations with total, cardiovascular and respiratory mortality in the USA

Austin Rau[1], Azar Abadi[2], Mark Fiecas[1], Yeongjin Gwon[2], Jesse Bell[2], Jesse Berman[1]
[1]University of Minnesota, Minneapolis, USA, [2]University of Nebraska, Omaha, USA

KEYWORDS: PM2.5, time series, cardiovascular disease, respiratory disease, mortality

BACKGROUND AND AIM: High air pollution events spanning multiple months caused by environmental perturbations such as droughts and wildfires are increasing in frequency, intensity and duration due to climate change. While both daily and annual exposure to PM2.5 have regulatory standards in the USA, mid-scale exposure at the monthly interval remains unregulated and the public health impacts of mid-duration ambient air pollution exposure are poorly understood. These present a new public health challenge in mitigating harmful effects of ambient air pollution on community health.

METHODS: We executed an ecological study of the associations between monthly mean PM2.5 exposure with total, cardiovascular and respiratory mortality counts, stratified by age, sex and race, from 698 counties in the conterminous USA from 1999 – 2018. A two-stage model was used to estimate the risk and number of deaths associated with this exposure reported as incidence rate ratios (IRR) and absolute risk differences per million persons (ARD).

RESULTS: Increased mortality of all types was positively associated with monthly mean PM2.5 exposure (total mortality IRR: 1.011, 95% CI: (1.009,1.013), ARD: 8.558, 95% CI: (6.869,10.247); cardiovascular mortality IRR: 1.014, 95% CI: (1.011,1.018), ARD: 3.716, 95% CI: (2.924,4.509); respiratory mortality IRR: 1.016, 95% CI: (1.001, 1.023), ARD: 1.676, 95% CI: (1.261,2.091)). Our results suggest the elderly, non-black minorities and males to be the most impacted subgroups along with metropolitan and highly socially vulnerable communities. Heterogeneities in the magnitude and direction of association were detected across climate regions of the U.S.

CONCLUSIONS: In the general population, monthly PM2.5 was associated with an increased risk and number of deaths of total, cardiovascular and respiratory mortality. Our results demonstrate a need for future public health policy to be initiated for this currently unregulated interval of ambient air pollution exposure.

P-0091 Variation in PM2.5, PM10 and atmospheric conditions in the three (3) ecological zones in Ghana

Ali Moro[1], Raymond Aborigo[1], Engelbert Nonterah[1], Kaali Seyram[2], Kenneth Nartey[3], Ireneous Soyiri[4]
[1]Navrongo Health Research Center, Navrongo, Ghana, [2]Kintampo Health Research Centre, Kintampo, Ghana, [3]Dodowa Health Research Center, Dodowa, Ghana, [4]University of Hull, Hull, UK

INTRODUCTION:
While clean air is a basic human requirement, air pollution continues to be a major global health problem. This is largely due to its impact on climate change and significant association with morbidity and mortality. This study focused on particulate matter with an aerodynamic diameter less than 2.5 microgram (PM2.5) and 10 micrograms (PM10) with atmospheric conditions in the three ecological zones (Savannah Belt, Forest Belt and Coastal Belt) of Ghana which exhibit different climatic characteristics.
MATERIALS AND METHODS: The Community Air Pollution Study (CAPS) installed 18 Purple Air Monitors across Ghana, 6 in each ecological zone. The data was extracted, cleaned and aggregated based on zones. The median (IQR) was used to summarize skewed PM values and mean (±SD) was used for the weather data analysis. Correlation between PM levels and weather data were computed using spearman's correlation.
RESULTS: The study collected data from June 2020 to February 2022. Humidity correlated negatively with PM2.5 and PM10 concentrations, but positively with temperature. In terms of ecological variations, the savannah zone had the best air quality levels with median PM2.5 and PM10 values of 16.07µg/m3 and 19.47µg/m3 respectively. The corresponding mean temperature was 31.67oC and 35% humidity. This was followed by the forest zone with PM2.5 = 29.17 µg/m3, PM10 = 36.96 µg/m3, mean temperature = 31.11 oC and humidity levels of 50%. The Coast ecological zone of Ghana had the worst air quality measuring PM2.5 and PM10 levels at 42.11 µg/m3 and 51.81 µg/m3 respectively and temperature of 30 oC with humidity of 88%.
CONCLUSION:
The three ecological zones studied had average PM2.5 and PM10 levels higher than recommended by the Air Quality Guidelines of the World Health Organization (WHO). The Savannah zone which recorded the least had levels about two or three times higher than recommended by WHO.

P-0093 Environmental monitoring air pollution of Santa Cruz industrial district in Rio De Janeiro using a plant fertility model

Cristina Ferreira Lemos[2], Rosalina Jorge Koifman[1], Evanelza Quadros[3], José Carlos Ortiz Jr[3], Girlaine Rodrigues Negreiros de Oliveira[3], Rafael do Nascimento Pinheiro[3], Ilce Ferreira da Silva[1]

[1]National School of Public Health, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil, [2]Graduate Program in Environment and Public Health, National School of Public Health, FIOCRUZ, Rio de Janeiro, Brazil, [3]Superintendence of Health Surveillance, Municipal Health Secretariat, Rio de Janeiro, Brazil

BACKGROUND: Pollen abortion assay is considered a bioindicator of genotoxic air effects. In 2010, a Steel company was settle in Santa Cruz, Rio de Janeiro. In 2012 occurred silver rains arising concerns on human and environmental impact. In 2013, the company signed an adjustment of conduct term(ACT).Aim:to evaluate air pollution in steel company vincinity based on plant fertility essay.

METHODS: A pollen abortion assay was performed with flower buds of Bauhinia Forficata in 2013, and Delonix Regia in 2015. Unexposed sites were those over 5km from steel company, highway and tunnels; exposed sites were those up to 5km from highways/tunnels; and from to Steel company only. During dry and rainy season, over 10plants were randomly collected per site, 300cells were evaluated per slide. Aborted grains were analyzed using a microscope under 400-fold magnification. Statistical analyses considered a significant level of 5%.

RESULTS: In 2013 were selected 02unexposed, 18exposed to highway/tunnel, and 07exposed to Steel company sites. In 2015 were selected 14unexposed, 18exposed to highway/tunnel, and 02exposed to Steel company sites. In both years, pollen abortion percentage medians were statistically higher in dry season for sites exposed to highway/tunnel(p=0.000), and to Steel company(p=0.005). In 2013 pollen abortion were significantly higher in sites exposed to highway/tunnel compared to unexposed(p=0.004), and for sites exposed to Steel company compared to highway/tunnel(p=0.034). In 2015, compared to unexposed sites, pollen abortion averages were significantly higher in sites exposed to highway/tunnel(p=0.014), and in exposed Steel company(p=0.000). Overall, compared to unexposed sites, pollen abortion averages were 5.79-fold in exposed to Steel company sites, and 4.08-fold in exposed highway/tunnel sites.
CONCLUSION: for both years, stronger effects on pollen abortion were observed on sites exposed Steel company as compared to unexposed, and exposed to highway/tunnel. Air pollution effect was higher in sites exposed Steel company regardless of ACT.

P-0094 Poultry house as point source of intense bioaerosol emission

Rafal Gorny[1], Malgorzata Golofit-Szymczak[1], Marcin Cyprowski[1], Anna Lawniczek-Walczyk[1], Agata Stobnicka-Kupiec[1]
[1]*Central Institute for Labour Protection – National Research Institute, Warsaw, Poland*

BACKGROUND AND AIM: Intensive poultry farming is usually associated with massive exposure to organic dust, which is largely composed of microbiological origin particulates. This study aimed to assess occupational and environmental exposures to airborne bacteria and fungi emitted from poultry house.

METHODS: The concentrations of airborne microorganisms in henhouse and its vicinity (250–500m) at 3 different stages of production cycle (i.e. in clean and disinfected poultry house without chickens, with 7-day-old, and 42-day-old chickens, i.e. one day before they departure to the slaughterhouse) were measured using impactor, impinger, and filter samplers. The collected microbiota was taxonomically identified using biochemical and molecular methods to characterize occupational exposure and its spatial dissemination.

RESULTS: Intensive chicken breeding resulted in very high bacterial and fungal concentrations (up to 8.1×10^7cfu/m³ and 3.3×10^4cfu/m³, respectively) in poultry house exceeding at the end of production cycle the threshold limit values proposed for such working environment. The presence of numerous human (e.g. Actinomyces, Clostridium, Corynebacterium, Enterococcus, Klebsiella, Proteus, Prevotella, Escherichia, Staphylococcus, Streptococcus, Listeria, Salmonella, Shigella, Pseudomonas, Bacteroides, Burkholderia, and Aspergillus) and chicken (e.g. Salmonella and Escherichia) pathogens posed a real health threat to both employees and animals. Efficiently working ventilation system in this facility was able to capture majority of airborne particulates released during breeding cycle (on average 8-fold/14-fold decreases between the henhouse and 250m/500m circles around it); however, the indoor-outdoor migration of microbial contaminants with fine aerodynamic diameters was constantly visible.

CONCLUSIONS: The employees in poultry house were exposed to high concentrations of airborne microorganisms, including pathogens that may lead to adverse health outcomes. To protect them, highly efficient hygienic and technical measures regarding henhouse interior and its ventilation, respectively, should be introduced to prevent both unwanted pollution and subsequent emission of microbial contaminants during intensive chicken breeding.

KEYWORDS: bioaerosol, poultry house, point emission, occupational exposure, spatial dissemination

P-0101 Association between traffic density exposure during pregnancy and low birthweight in Spain, 2000-2017

Marcelle V Cantó[2], Mònica Guxens[3,4], Rebeca Ramis[1,4]
[1]Carlos III Institute of Health (ISCIII), Madrid, Spain, [2]San José y Santa Adela Red Cross Central Hospital, Spain, [3]ISGlobal, Barcelona, Spain, [4]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Madrid, Spain

BACKGROUND AND AIM: Low birthweight (LWB) is an indicator of intrauterine growth restriction and birth outcomes. Several pollutants have been associated with adverse birth outcomes, especially those involved in traffic-related air pollution exposure. A good approximation to measure the exposure is the traffic density. The aim of this study is to estimate the association between traffic density exposure during pregnancy and low birthweight in Spain, for the period 2000-2017.
METHODS: A retrospective, cross-sectional study was conducted. Data from Spanish Birth Registry database was used with a total number of 4.934.810 birth records from all the regions of Spain, only full-term pregnancy (37 to 42 weeks) with one single live fetus. We defined LBW as newborn who weigh less than 2.500gr. We estimated traffic density exposure using the annual average daily traffic, calculated as the total volume of traffic of a road for a year divided by 365 days, measured at the mother's home address. The variable was categorized in quartiles in order to compare the highest level of traffic density with the lowest level. Socio-economic covariates were included in the analysis too.
RESULTS: Traffic density exposure was associated with a risk of LBW, with an OR=1.08 (95%CI 1.06, 1.10) for very high traffic density compared to low traffic density. Mothers that lived in cities with more than 100.000 inhabitants, with lower socio-economic condition and higher economic activity rate had LBW children.
CONCLUSIONS: This study found an association between high traffic-density exposure and LBW in a large nation-wide study.

KEYWORDS:
Low birthweight; Traffic-density; Air pollution.

P-0104 Associations between grass pollen counts and allergen (Phl p 5) levels with respiratory allergic health outcomes

Elaine Fuertes[1,2], Debbie Jarvis[1,2], Holly Lam[1,2], Bethan Davies[2,3], Daniela Fecht[2,3], Joana Candeias[4], Jeroen TM Buters[4], Lorenzo Cecchi[5], Stephen J. Till[6,7]

[1]National Heart and Lung Institute, Imperial College London, London, UK, [2]MRC Centre for Environment & Health, Imperial College London, UK, [3]Small Area Health Statistics Unit, Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, UK, [4]Center of Allergy and Environment (ZAUM), Member of the German Center for Lung Research (DZL), Technische Universität München/Helmholtz Center, Germany, [5]SOS Allergy and Clinical Immunology, USL Toscana Centro, Italy, [6]Peter Gorer Department of Immunobiology, King's College London, UK, [7]Department of Allergy, Guy's & St Thomas' NHS Foundation Trust, UK

BACKGROUND/AIM:
Previous studies have linked daily pollen counts to respiratory allergic health outcomes, but none have considered allergen levels, although daily allergen release from a single pollen grain can vary 10-fold. This study assessed associations of grass pollen counts and allergen levels with respiratory allergic health symptoms in a panel of 93 adults with moderate-severe allergic rhinitis living in London.

METHODS: Participants in an allergy clinical trial scored their daily symptoms and medication use from 17 May to 31 August, 2013. Daily combined symptom and medication (CSM), overall symptom, and overall medication scores were calculated. Daily grass pollen counts (grains/m3) and allergen levels (Phlp 5, pg/m3) were measured at a monitoring site in central London and categorized into tertiles. Associations of health scores with pollen counts and allergen levels were assessed using generalized estimating equations linear models, adjusted for sex, age, as well as daily mean temperature, relative humidity, precipitation and nitrogen dioxide levels.

RESULTS: Daily CSM scores ranged from 0.77 to 16.42. Compared to the lowest exposure tertile, CSM scores were on average 2.42 [95% confidence interval: 2.00, 2.83] and 6.65 [5.87, 7.43] higher for the medium and highest tertile of pollen counts (p-trend <0.001), respectively. The corresponding values were 1.47 [1.12, 1.81] and 8.21 [7.21, 9.22] for allergen levels (p-trend <0.001). In models mutually adjusted for pollen counts and allergen levels, associations with allergen levels remained similar (1.26 [0.96, 1.57] and 7.30 [6.33, 8.27]) whereas those for pollen counts were attenuated (0.53 [0.29, 0.77] and 1.50 [1.18, 1.82]).

RESULTS: were consistent across various sensitivity analyses (e.g. analysing symptom and medication scores separately, adjusting for PM2.5 instead of nitrogen dioxide).

CONCLUSIONS: In mutually adjusted models, associations were stronger for allergen levels than pollen counts, suggesting measurement of allergen levels may improve risk prediction.

KEYWORDS: Pollen, allergens, air pollution, allergies

P-0106 Traffic density exposure and metabolomics in a population-based sample: The HORTEGA Study

Larua Sanchez[2], Marta Galvez-Fernandez[3], Guillermo Saez[5], Vannina Gonzalez-Marrachelli4[4], Tamara Garcia-Barrera[6], Jose Gomez-Ariza[6], Maria Tellez-Plaza[1], Juan C. Martin-Escudero[7], Josep Redon[4], Daniel Monleon[4], Rebeca Ramis[1]

[1]Carlos III Health Institute, ISCIII, Madrid, Spain, [2]Hospital General Nuestra Sra. Del Prado, Toledo, Spain, [3]Madrid Autónomus University, Madrid, Spain, [4]INCLIVA, Valencia, Spain, [5]University of Valencia, Valencia, Spain, [6]University of Huelva, Huelva, Spain, [7]University of Valladolid, Valladolid, Spain

BACKGROUND AND AIM: Metabolites participate in biological responses to exposure to various external factors such as disease, or environmental pollution, among others. Although the literature in humans is still scarce, several studies have shown that exposure to air pollution causes changes in various metabolic pathways. The aim of this study is was to evaluate the association between traffic density at the street of residence with plasma metabolomic profiles of a population-based sample.

METHODS: The subjects of this study belong to the Hortega Study cohort, which is a representative sample of the population of Valladolid, Spains. To assess the effect of traffic exposure and metabolite levels the Annual average daily traffic of the roads in the studied region was used, calculated as the total volume of transportation traffic of a road or highway for a year divided by 365 day. Metabolomic profile was determined by Nuclear Magnetic Resonance Spectroscopy in non-fasting plasma.

RESULTS: Traffic density was positively associated with lipoprotein profile and fatty acids levels and inversely associated with amino acid levels, the metabolites associated with fluid balance and the products derived from bacterial co-metabolism. As for oxidative stress markers, MDA levels show a decrease of one tenth in the most exposed subjects. In relation to energy metabolism, the association is positive for lactate and acetone.

CONCLUSIONS: We observed a strong association of high traffic density exposure with changes in certain metabolic patterns.

KEYWORDS:
Metabolomics; Traffic-density; Air pollution.

P-0108 Can the UK achieve the $PM_{2.5}$ WHO 10 µg m-3 interim target by 2030?

Sean Beevers[1], Nutthida Kitwiroon[1], Nosha Assareh[1], Gregor Stewart[1], David Dajnak[1]
[1]*Imperial College London, London, UK*

BACKGROUND: The UK Government is currently setting two $PM_{2.5}$ targets for its Environment Bill. The first is a concentration target to be met by some future date and the second a population exposure reduction target, aimed at reducing exposure gradually over time.
AIM: The aim of this research was to combine existing UK 2030 emissions forecasts, the UK's Climate Change Committee (CCC) Net Zero vehicle forecasts, and the Greater London Authority's policy forecasts, to establish whether the UK can meet the $PM_{2.5}$ WHO 10 µg m-3 interim target by 2030, and to assess the likely exposure reduction.
METHOD: We used a combination of European, UK National and London Atmospheric Emissions Inventory forecasts between 2018 and 2030. for road transport we calculated emissions for the Balanced Net Zero Pathway, published by the CCC, which includes widespread vehicle electrification, and two London specific policies aimed at reducing $PM_{2.5}$. The emissions were combined with the WRF met. model and the CMAQ-urban coupled model, providing UK $PM_{2.5}$ concentrations down to 2km spatially and then every 20m close to major roads.

RESULTS: UK $PM_{2.5}$ concentrations in 2030 were below 10 µg m^{-3}, for over 99% of the UK population. In London, the second scenario reduced $PM_{2.5}$ locally, with <1% of the area of London predicted to be above 10 µg m-3. Accounting for model uncertainty resulted in ~4% of the UK remaining at risk of exceeding 10 µg m-3 albeit in cities such as Birmingham and Manchester.

CONCLUSIONS: We have shown the combined benefits of UK air quality, Net Zero and local policies for $PM_{2.2}$ control, in almost achieving the $PM_{2.5}$ WHO interim target. We identified important but uncertain emissions sources, such as non-exhaust vehicle emissions, cooking aerosol and domestic and industrial wood burning. This work has been submitted to the UK Environment Bill consultation.

P-0110 Characterisation of volatile organic compounds in hospital indoor air and the potential impact on healthcare worker health

Thiphanie Riveron[1,2,3], Michael Wilde[1], Wadah Ibrahim[4], Paul Monks[1], Neil Greening[4], Chris Brightling[4], Salman Siddiqui[4], Anna Hansell[2,3], Rebecca Cordell[1,3]

[1]School of Chemistry, University of Leicester, Leicester, UK, [2]Centre for Environmental Health and Suitability, University of Leicester, Leicester, UK, [3]Leicester NIHR Health Protection Research Unit in Environmental Exposures and Health, University of Leicester, Leicester, UK, [4]Leicester NIHR Biomedical Research Centre (Respiratory theme), Glenfield Hospital, Leicester, UK

BACKGROUND AND AIM: Indoor air quality is affected by various activities, including activities taking place inside the building, the outdoor air quality and the building materials themselves. This study focused on the characterisation of volatile organic compounds (VOCs) present in Respiratory Departments of two hospitals, due to their widely recognized impact on human health. There is evidence that the occurrence of adverse respiratory symptoms is higher in hospital workers compared to other occupations, and a recent study has shown that there are significantly higher numbers of complaints from healthcare workers compared to administrative workers at the same hospital. Recently, the UK Health and Safety Executive (HSE) has updated the workplace exposure limits for several VOCs, but some known for their detrimental impact on human health are absent from this list.

METHODS: VOCs were quantified at two hospital sites; over 600 samples of air were collected over 31 months (2017-2020) onto sorbent tubes and analysed by two-dimensional gas chromatography.

RESULTS: 99 VOCs were present in every sample and 557 VOC in 50% of samples. The most abundant compounds found were 2-propanol, acetone, hexane and 2-butanone, with respectively median concentrations of 358.41 µg/m3, 84.40 µg/m3, 58.55 µg/m3 and 4.90 µg/m3. Our results showed that the most frequently detected VOCs, at the highest concentrations are most likely released by healthcare activities such as the use of hand sanitiser as well as ingress of vehicle emissions.

CONCLUSIONS: Whilst these VOC concentrations are under the workplace exposure limits for long-term (8-hours) defined by HSE, the mean concentration of acetone, 2-propanol and hexane measured were 4, 9 and 30-fold higher compared to similar studies performed in other hospitals. Long-term exposure to VOCs at moderate concentration could still have an impact on healthcare workers, especially those which pre-existing conditions.

KEYWORDS: hospital, indoor air, VOCs, exposure, healthcare workers

P-0114 Source-Apportioned Particulate Air Pollution and 30-day Readmissions Among Heart Failure Patients

Aleah Walsh[1], Joshua Moyer[1], Anne M. Weaver[1], Lauren Wyatt[1], Armistead Russell[2], Cavin Ward-Caviness[1]
[1]Center for Public Health and Environmental Assessment, US Environmental Protection Agency, Chapel Hill, USA, [2]Georgia Institute of Technology, Atlanta, USA

BACKGROUND AND AIM: Fine particulate air pollution (PM2.5) exposure is associated with increased risk of hospital readmissions. This study aims to determine if this association differs according to the attributable source of the PM2.5.

METHODS: We used zero-inflated poisson mixed-effects models to associate source-apportioned PM2.5 with the number of 30-day readmissions after HF diagnosis. The study cohort included patients diagnosed with HF who had a hospital visit at a University of North Carolina Healthcare System facility between July 5, 2004, and December 31, 2010. The exposure was the annual average source-apportioned PM2.5 at the date of HF diagnosis. Patient zip code was included as a random effect and models were adjusted for year of diagnosis, sex, race, age, smoking status and 2010 census block group measures of urbanicity, percent receiving public assistance, median income, and median house value. PM2.5 was apportioned into the sources using a Chemical Mass Balance Gas Constrained-Iteration model. Results are presented as the percent change in number of expected readmissions per interquartile range increase in source-apportioned PM2.5 and the associated 95% confidence interval (CI).

RESULTS: We observed associations with 30-day readmissions for gasoline (16.89%; 95% CI = 4.82-30.36), diesel (9.87%; 95% CI = 1.72-18.69), and secondary organic carbon (SOC; 20.44%; 95% CI = 8.29-33.95) PM2.5. Associations were greater for study participants in a census block group with an income below the median value. Associations were also greater for Black HF patients compared to white HF patients.
CONCLUSIONS: Associations between 30-day readmissions and PM2.5 appear greatest for traffic and SOC-related sources which may be due to a combination of differential toxicity as well as the distribution of these sources amongst HF patients. This abstract does not necessarily represent the views or policies of the US Environmental Protection Agency.

KEYWORDS: Heart failure, hospital utilization, particulate matter, air pollution

P-0115 Modification of Associations Between PM2.5 and Blood Pressure by Anti-Hypertensive Medication Usage in Heart Failure Patients

Morgan Narain[2], Miyuki Breen[1], Joshua Moyer[1], Cavin Ward-Caviness[1]
[1]US Environmental Protection Agency, Chapel Hill, USA, [2]University of North Carolina Chapel Hill, Chapel Hill, USA

BACKGROUND:
Fine particulate matter (PM2.5) is associated with cardiovascular morbidity and mortality. Medications that target similar pathophysiologic pathways as PM2.5 may modify PM2.5-related health risks. Here, we used EPA CARES, a collection of electronic health records (EHRs) linked to environmental data, to examine whether anti-hypertensive medications modify associations between PM2.5 and blood pressure (BP).

METHODS: For this study, we used EHRs from 27,953 heart failure patients observed from 2014-2016. Daily PM2.5 was measured at the nearest US EPA monitor to each study participant's primary residence. Linear mixed models adjusted for age, sex, race, season, relative humidity, temperature, and a natural spline term for time since study start were used to estimate associations between systolic and diastolic BP and daily PM2.5 on the day of measurement and up to 4 days before measurement as well as the 5-day average. Associations were stratified on use of anti-hypertensive medications and a multiplicative interaction term was used to estimate the interaction between PM2.5 and medication usage. Results are presented as the change in BP (mmHg) per 10 µg/m3 PM2.5 and the associated 95% confidence interval (CI).

RESULTS: The pattern of associations was consistent for all time periods examined so we present here just the 5-day average PM2.5 associations. for BP assessed when on anti-hypertensive medications we observed negative associations for systolic (-0.30, CI= -0.42, -0.18) and diastolic (-0.19; CI= -0.27, -0.12) BP. Conversely, for time-periods not on anti-hypertensive medications associations were positive for systolic (0.42, CI= 0.27, 0.57; interaction P= 5.3x10-12) and diastolic (0.13; CI= 0.04, 0.23; interaction P= 2.3x10-9) BP.

CONCLUSIONS: Anti-hypertensive medication usage likely has interactions with short-term PM2.5 and medication usage in general should be accounted for when possible and explored for its ability to modify PM2.5-related health risks. This abstract does not necessarily reflect the policies of the US EPA.

P-0116 Exposure to Ambient Air Pollution is Associated with Expression of Breastmilk miRNAs

Elizabeth Holzhausen[1], William Patterson[1], Andrea Baccarelli[2], Allison Kupsco[2], Fred Lurmann[3], Michael Goran[4], Tanya Alderete[1]

[1]Department of Integrative Physiology, University of Colorado - Boulder, Boulder, USA, [2]Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [3]Sonoma Technology Inc., Petaluma, USA, [4]Children's Hospital of Los Angeles, Los Angeles, USA

BACKGROUND AND AIM: Breastmilk EV-miRNAs are RNAs contained within extracellular vesicles, which regulate post-transcriptional gene expression. EV-miRNAs potentially function as mother-infant messages with implications for infant growth and immune development. Several EV-miRNAs are associated with cigarette exposure, which contains particles found in ambient air pollution (AAP). Previous research has not explored whether prenatal AAP exposure is associated with breastmilk EV-miRNAs.

METHODS: Participants included 110 mother-infant dyads from the Southern California Mother's Milk Study, EV-miRNAs were measured 1-month postpartum, and AAP was modeled using spatial interpolation of monitoring stations via an inverse distance-squared algorithm. Principal components analysis (PCA) was used to assess associations between EV-miRNA profiles and maternal characteristics. Negative binomial models were used to estimate associations between AAP and EV-miRNA counts. Analyses adjusted for proportion of rRNA reads, EV extraction date, and volume of skim milk. The Benjamini-Hochberg procedure was used to adjust for multiple testing, with $P<0.05$. DIANA MirPATH was used to predict mRNA targets (extracted from Tarbase) of AAP-associated EV-miRNAs, followed by KEGG pathway analysis.

RESULTS: Principal component 1 (PC1) and PC2 explained 18.6% and 15.6% of the variance in miRNA, respectively. Breastfeeding frequency (PPC1=0.03, PPC2=0.002), breastmilk collection time (PPC1=0.007), and pregnancy PM2.5 exposure (PPC2=0.02) predicted EV-miRNA profiles. Pregnancy AAP exposure was also associated with EV-miRNAs; NO2 was associated with three EV-miRNAs, PM2.5 with 17, and PM10 with two, after additional adjustment for breastfeeding frequency and breastmilk collection time. All AAP exposures were positively associated with miR-200b-3p and miR-200c-3p. The top pathways for AAP-associated EV-miRNAs were fatty acid biosynthesis, hippo signaling pathway, and fatty acid metabolism.

CONCLUSIONS: This analysis provides preliminary evidence that breastmilk EV-miRNAs may be impacted by pregnancy AAP exposure. AAP exposure was associated with expression of miR-200b-3p and miR-200c-3p. Expression of these miRNAs is linked with breast cancer.

KEYWORDS:

P-0117 Alpha particle radioactivity from indoor radon decay products and pulmonary function among chronic obstructive pulmonary disease patients

Veronica Wang[1], Petros Koutrakis[1], Longxiang Li[1], Man Liu[1], Carolina L. Zilli Vieira[1], Brent Coull[1,2], Edward F. Maher[1], Choong-Min Kang[1], Eric Garshick[3,4,5]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [2]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, USA, [3]Pulmonary, Allergy, Sleep and Critical Care Medicine Section, Veterans Administration Boston Healthcare System, Boston, USA, [4]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital, Boston, USA, [5]Harvard Medical School, Boston, USA

BACKGROUND AND AIM: Radionuclides attached to particulate matter (PM), referred to as particle radioactivity (PR), are mainly from radon decay and continue to emit radiation after inhalation. Decay products that emit α-radiation have the greatest potential of pulmonary damage due to high energy transfer to surrounding tissues.

METHODS: Our study included 143 patients (90% male, mean age±SD=72.8±8.2 years) with chronic obstructive pulmonary disease (COPD) in Eastern Massachusetts, USA who were not current smokers. Up to four one-week long seasonal indoor samples of PM ≤2.5 μg/m3 (PM2.5) were collected for each patient (n=467), followed by spirometry pre- and post-bronchodilator (BD). α-activity was measured on archived sampling-date-matched ambient and indoor PM2.5 Teflon filter samples (α-PR), which represents the decay of 210Pb, the longest-lived radionuclide (t1/2=22 years), to 210Po. Indoor/ambient sulfur ratio in the filter samples was used as a measure of air infiltration.
Exposure surrogates indicating greater exposure to radon decay products from an indoor source were derived: indoor/ambient α-PR and high indoor α-PR (>median) with low air infiltration (<median sulfur ratio). We fitted generalized additive mixed models adjusted for meteorological variables, seasonality, and patient characteristics. PM2.5 mass was additionally adjusted for as sensitivity analysis.

RESULTS: An interquartile range increase in indoor/ambient α-PR was associated with a -8.9 (-24.2, 6.3) mL and a -7.7 (-31.6, 16.2) mL reduction in average post-BD forced expiratory volume in 1 second (FEV1) and forced vital capacity (FVC), respectively. The greatest effects were found for homes with high indoor PR and low air infiltration compared to others, a -26.9 (95% CI: -61.4, 7.7) mL reduction in post-BD FEV1 and a -75.4 (95% CI: -128.6, -22.2) mL reduction in post-BD FVC. Associations remained after PM2.5 adjustment.

CONCLUSIONS: Indoor sources of α-PR from radon decay products may reduce pulmonary function in COPD patients.

KEYWORDS: air pollution, radiation, pulmonary function

P-0118 Prediction of Short-Term Ultrafine Particle Exposures using Street-Level Images and Air Quality Data Based on Mobile Monitoring

Junshi Xu[1], Mingqian Zhang[1], Arman Ganji[1], Keni Mallinen[1], An Wang[2], Marshall Lloyd[3], Alessya Ventura[3], Leora Simon[3], Junwon Kang[1], James Gong[1], Yazan Zamel[1], Scott Weichenthal[3], Marianne Hatzopoulou[1]
[1]University of Toronto, Toronto, Canada, [2]Massachusetts Institute of Technology, Cambridge, USA, [3]McGill University, Montreal, Canada

BACKGROUND: Within-city UFPs vary sharply since they are influenced by various factors, e.g., local sources, built environment, and meteorology. The long-term spatial distribution of UFPs has been investigated using mobile platforms. As computer vision techniques develop rapidly, recent studies employed convolutional neural networks (CNNs) to investigate the spatial variations in UFPs. This study developed prediction models for short-term UFP exposures using street-level images and air quality data based on mobile measurements.

METHODS: UFP concentrations were measured in a large-scale mobile monitoring campaign between August 2020 and August 2021 in Toronto, Canada. Second-by-second level measurements were paired with street-view images collected by a 360degree camera on the vehicle rooftop. We systematically designed routes to capture exposures across various road types, land use, and built environments. The dataset includes over 1 million data points, covering about 1400 unique kilometers and 8000 unique roads. CNN models were trained to extract detailed traffic characterization and built environment features from images captured by the rooftop camera. Using only 10s averaged features extracted from images as well as regional meteorology and air quality at fixed stations, a machine learning model was used to predict UFPs.

RESULTS: The prediction accuracies for 'Low' and 'High' UFP levels achieved 77% and 70%. NO2 levels measured at Toronto's downtown air quality station had an impact on model output. Larger green areas and building footprints in images were associated with lower UFP exposures, while the presence of trucks and other traffic parameters were associated with higher UFPs.

CONCLUSIONS: This study demonstrates that a picture captured on an urban street, associated with regional air quality and meteorology, can adequately predict short-term exposure. This approach can be deployed through crowdsensing platforms to track the frequency and severity of UFP spikes in urban environments.

P-0119 The Design, Calibration, and Evaluation of a Mobile Sensor System for Air Pollution Measurement and Prediction in Urban Areas

Arman Ganji[1], Junshi Xu[1], Mingqian Zhang[1], Marshall Lloyd[2], An Wang[4], Alessya Ventura[2], Leora Simon[2], Shoma Yamanouchi[1], Kris Hong[2], Joshua Apte[3], Scott Weichenthal[2], Marianne Hatzopoulou[1]
[1]University of Toronto, Toronto, Canada, [2]McGill University, Montreal, Canada, [3]University of California Berkeley, California, USA, [4]Massachusetts Institute of Technology, Cambridge, MA, USA

BACKGROUND: The increasing ubiquity of low-cost air quality sensors has been recently met with a growing body of research on sensor calibration and validation. While most studies documenting low-cost sensor performance are limited to the analysis of fixed sensors, there is still much to be learned from the performance of air quality sensors in a mobile environment. This study presents the design and testing of a mobile platform for simultaneous air quality, traffic, and built environment characterization.

METHODS: The Urban Scanner is a platform mounted on the rooftop of a vehicle and equipped with air quality sensors (NO2, O3, PM2.5, PM10, CO) and ancillary instruments such as GPS, 360degree camera, LIDAR 3D scanner, and wind anemometer. It also includes a data acquisition module with real-time analytics for traffic characterization from video imagery (cars, trucks, buses) and built environment features (trees, sidewalk, building façade, building height). Air quality sensor calibration was conducted through co-location against reference instruments with novel signal processing techniques. A year-long data collection campaign in the City of Toronto, along routes carefully designed to maximize the variability in road types, land-use, and built environment features.

RESULTS: After urban scanner development and calibration, all sensors exhibited small standard errors and significant relationships with reference data. Traditional land-use regression models explained spatial variations in NO2 and O3 across Toronto, with R2 = 0.64 and 0.65, respectively. In addition to linear regression, a principal component analysis of the predictors was first conducted and subsequently used in Bayesian Regularized Neural-Networks models (BRANN). This approach yielded R2 of 0.82 and 0.80 for O3 and NO2.

CONCLUSIONS: The combination of a fully calibrated sensor system and a carefully designed data collection protocol that optimizes spatial variability and temporal representation, can give rise to a powerful tool for air quality prediction in urban areas.

P-0122 Land Use Regression Model for Exposure Assessment to Pollutant Gases in Rio de Janeiro City, Brazil

Marcio Sacramento de Oliveira[1], Marcio Candeias Marques[1], Maria de Fátima Ebole Santana[1], Antônio Carlos Monteiro Ponce de Leon[2]

[1]Oswaldo Cruz Foundation - FIOCRUZ, Rio de Janeiro, Brazil, [2]Rio de Janeiro State University - UERJ, Rio de Janeiro, Brazil

BACKGROUND AND AIM: Air pollution is a public health problem. The data from WHO show that nine out of 10 people breathe air containing high levels of pollutants and the exposure to fine particles caused about 4.2 million deaths in 2016. Therefore, the aim of this study was to elaborate a model for long-term exposure assessment to air pollution gases.

METHODS: This study was developed in Rio de Janeiro city, Brazil; it has 1,200.255 km² large, about 6.7 million residents and located in the southeastern region of country. The information of O_3, SO_2 and predictor variables were obtained from government agencies. The potential predictor variables have been used: temperature, relative humidity, vehicular traffic, Census, altitude, vegetation cover, land use, rock masses, hydrographic and hydrographic sub-basins, urban zoning and road network. Linear regression models were specified using the supervised stepwise procedure for the development of Land Use Regression models. Cook-D statistics were used to detect influential observations. The overall model performance was evaluated by leave-one-out cross validation (LOOCV).

RESULTS: The annual average of O_3 and SO_2 was 117.68 (SD=±36.83) and 8.796 (SD=±4.93) μg·m−3, respectively. The final model for O_3 included four predictor variables: ADHHOLD_300, SQRALT, GREEN_5000 and DPOP_5000. The adjusted R^2 value was 0.83 and p-value=2.359E-05. The performance evaluated by LOOCV presented R^2=0.74, RMSE=18.26 and MAE=14.26. for SO_2 included three predictor variables: SQRALT, INDUSTRY_100 and PORT_5000. The adjusted R^2 value was 0.91 and p-value=0.002. The performance showed R^2=0.52, RMSE=3.60 and MAE=2.73.

CONCLUSIONS: It was possible to elaborate a model applicable to areas where there is no air quality monitoring. The model allows an evaluation of the impact on the health of exposed populations, serving to support decision-making and the development of public policies and investments, in the medium and long term.

KEYWORDS: Ozone, Sulfur dioxide, Air pollution.

P-0126 Changes in the short-term relationship between air pollution and mortality over thirty years (1990-2019) in New York City

Rebecca Goldberg[1], Ariel Spira-Cohen[1], Masha Pitiranggon[1], Sarah Johnson[1], Kazuhiko Ito[1]
[1]*New York City Dept. of Health and Mental Hygiene, New York, USA*

BACKGROUND AND AIM: The short-term impacts of air quality on health have long been established, but prior studies evaluating their connection have limited study periods. We aim to characterize changes in the relationships between the Environmental Protection Agency's (EPA's) criteria air pollutants and natural-cause mortality in New York City (NYC) over three decades (1990-2019).

METHODS: Using daily city-wide average concentrations from EPA's Air Quality System of carbon monoxide (CO), sulfur dioxide (SO_2), fine particulate matter ($PM_{2.5}$), nitrogen dioxide (NO_2), and ozone (O_3) and mortality counts from NYC Vital Statistics, we ran quasi-Poisson distributed lag models for each pollutant, considering up to three lag days and adjusting for temperature and seasonal trends. Change in each pollutant's effect estimate over time was examined by (1) five-year rolling segments in the time-series model, and (2) case-crossover analysis with an interaction term based on air quality trends splitting the 30 years.

RESULTS: One lagged day conferred the highest percent excess risk (PER) (95% CI) – CO: 0.5 (0.2, 0.7); $PM_{2.5}$: 0.7 (0.4, 1.1); SO_2: 2.3 (1.5, 3.2); NO_2: 1.2 (0.8, 1.7) per EPA's standard increments (0.75 ppm, 10 μg/m³, 40 ppb, and 30 ppb, respectively). Seasonal stratification did not greatly alter the magnitude of associations. PER from warm-season O_3 was 0.8 (0.3, 1.3) per 30 ppb and sustained for three lag days. Seasonality patterns for O_3 and NO_2 changed around 2005 and $PM_{2.5}$ in 2008. Segmented estimates from years prior to and after these changes indicate an increase in post-period warm-season PER from NO_2 and O_3. Interaction terms, though, did not suggest changes in risk over time.

CONCLUSIONS: Evidence from the analyses conducted reinforce previously known risks from $PM_{2.5}$ and O_3 exposure, and elevate risk of NO_2. Because observed change in risk depends on model specifications, further research is warranted.

KEYWORDS: Air pollution, Mortality

P-0127 Triggering of cardiovascular hospitalization by short-term increases in PM2.5 in New York adults: changes following Tier 3 vehicle introduction

Xinlei Deng[1], Shao Lin[1], Philip K. Hopke[2,3], Sally W. Thurston[2], Mark Utell[2], Yunle Chen[2], Catherine Yount[2], David Q. Rich[2]

[1]University at Albany, State University of New York, Albany, USA, [2]University of Rochester, Rochester, USA, [3]Clarkson University, Potsdam, USA

BACKGROUND and AIM: Previously, increased hospitalizations for cardiovascular disease (CVD) were associated with PM2.5 concentrations in New York State (NYS) adults from 2005-2016, with higher rates after air quality policies and a recession reduced PM2.5 concentrations (2014-2016), suggesting PM had become more toxic. Following introduction of Tier 3 light duty vehicles in 2017, which should produce less secondary organic carbon than previous vehicles likely making PM less toxic, we hypothesized that there would be a lower relative rate in 2017-2019 than 2014-2016.

METHODS: From the SPARCS database (~95% of hospital admissions in NYS), we included hospitalizations with a primary diagnosis of CVD from 2014-2019 to adults living within 15 miles of PM2.5 monitoring stations in Buffalo, Rochester, Albany, Bronx, Queens, and Manhattan. Using daily PM2.5 concentrations from these sites, a case-crossover design, and conditional-logistic regression, we separately estimated the rate of CVD hospitalizations associated with increased PM2.5 concentrations in 2014-2016 and 2017-2019.

RESULTS: Interquartile range (IQR) increases in PM2.5 were associated with increased excess rates of ischemic heart disease hospitalizations in 2014-2016 (lag days 0-3: 2.0%, 95% CI = 0.9%, 3.2%), but not 2017-2019 (-0.8%, 95% CI = -2.3%, 0.6%). However, IQR increases in PM2.5 were associated with larger excess rates of heart failure hospitalizations in 2017-2019 (lag day 0: 4.4%; 95% CI = 1.3%, 7.7%) than 2014-2016 (1.1%; 95% CI = -0.1%, 2.2%), with a similar pattern for hypertension hospitalizations.

CONCLUSIONS: We did not find consistent differences in rates of cause-specific CVD hospitalizations associated with increased PM2.5 concentrations in the previous 1-7 days in NYS adults, before and after Tier 3 vehicles were introduced. However, there may need to be more time for more Tier 3 vehicles to be in the vehicle fleet, and for greater retirement of the older more polluting vehicles.

P-0130 Examining associations between long-term exposures to PM components and arterial stiffness using a Bayesian kernel machine regression approach

Adjani Peralta[1], Heresh Amini[1,2], Diane R. Gold[1,3], Mahdieh Danesh Yazdi[1], Yaguang Wei[1], Joel Schwartz[1,4]
[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [3]Channing Division of Network Medicine, Department of Medicine; Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [4]Department of Epidemiology; Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUNDS AND AIMS: While many studies have found adverse health effects to ambient air pollution exposure, the combined effects of particulate matter (PM) components on measures of arterial stiffness (central augmentation index and central pulse pressure) have not been evaluated. We aimed to model central augmentation index and pulse pressure and the individual and joint associations of long-term exposure to PM components using a Bayesian Kernel machine regression (BKMR) approach and compare the results to those from individual linear mixed-effects regressions.

METHODS: Central Augmentation index (%) and pulse pressure (mmHg) were measured among 398 participants in the Normative Aging Study (NAS) in Eastern Massachusetts between 2007 and 2013 with radial artery applanation tonometry for pulse wave analysis. Fifteen PM components at a 50m x 50m spatial resolution assigned to participants based on residential address from a well-validated ensemble weighted averaging model. BKMR was utilized to assess the overall joint and individual effect of the PM components (bromine, calcium, copper, elemental carbon, iron, potassium, ammonium, nickel, nitrate, organic carbon, lead, silicon, sulfate, vanadium, and zinc).

RESULTS: In the BKMR analysis, the overall joint effect of the PM components was associated with an increase in central augmentation pressure, particularly when the exposures were above their 60th percentile. for example, the joint effect of the PM components at the 80th percentile (compared to the median) was a 0.33SD (95% CI: -0.13, 0.78) change in augmentation index. However, 95% credible intervals around all the joint effect estimates contained the null value. From the mixture, calcium and elemental carbon were the most influential PM components on central augmentation pressure.

CONCLUSIONS: From this mixture analysis, we find suggestive adverse effects of long-term joint exposure to PM components on cardiovascular health in an elderly population.

P-0131 Long-term Exposure to Ambient Ozone and Mortality in a population-based cohort of South Korea

Garam Byun[1], Jong-Tae Lee[1]
[1]*Interdisciplinary Program in Precision Public Health, Korea University, Seoul, Republic of Korea*

BACKGROUND AND AIM: Compared to robust evidence from studies on short-term exposure, the health effects of long-term ozone exposure have been less studied, and the results are mixed. One of the potential sources of inconsistency is the difference in exposure metrics. This study aimed to investigate the association between long-term exposure to ambient ozone and mortality in South Korea, using different exposure metrics. We also examined sources of heterogeneity between previous studies.

METHODS: The study population comprised 179,806 subjects from the National Health Insurance Service-National Sample Cohort (2002-2015) residing in 7 major cities in South Korea. Several ozone exposure metrics (year-round 24-h, year-round 8-h, warm-season 24-h, and warm-season 8-h) were calculated for each district. Time-varying Cox proportional hazards models were adopted to estimate the association between ozone and all-cause and cause-specific mortality. Random-effects meta-analysis and meta-regression analysis were performed to pool the effect estimates of previous studies and examined whether selected study characteristics can explain between-study heterogeneity.

RESULTS: The HRs per 10 ppb increment in year-round 24-h ozone for all-cause (HR, 1.18; 95% CI, 1.07-1.29) and circulatory (HR, 1.52; 95% CI, 1.25-1.84) mortality were higher than that of other exposure metrics. for respiratory mortality, year-round 8-h ozone showed the largest associations (HR per 10 ppb, 4.13; 95% CI, 1.04-1.96). The meta-analysis of 26 previous studies and the present study showed a positive association between long-term ozone exposure and all-cause mortality, with the largest HR from warm-season 8-h ozone (HR, 1.042; 95% CI, 1.015-1.071). The exposure metric was significantly associated with the effect estimates in the multivariable meta-regression model.

CONCLUSIONS: In the population-based cohort of South Korea, we found positive associations between several long-term ozone exposure metrics and mortality. Different ozone exposure metrics could be an important source of heterogeneity between studies.

KEYWORDS: ozone, mortality, long-term exposure, cohort study, meta-analysis

P-0132 Air pollution and Venous Thromboembolism in the Malmö Diet and Cancer cohort

Mehjar Azzouz[1], Yiyi Xu[1], Lars Barregård[1], Bengt Zöller[2], Peter Molnar[1,3], Anna Oudin[4,5], Mårten Spanne[6], Gunnar Engström[2], Leonard Stockfelt[1,3]

[1]Occupational and Environmental Medicine, School of Public Health and Community Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [2]Center for Primary Health Care Research, Lund University/Region Skåne, Malmö, Sweden, [3]Department of Occupational and Environmental Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden, [4]Occupational and Environmental Medicine, Department for Laboratory Medicine, Lund University, Lund, Sweden, [5]Division of Sustainable Health, Umeå University,, Sweden, [6]Division of Ergonomics and Aerosol Technology, Department of Industrial Engineering, Lund University, Lund, Sweden, [7]Department of Clinical Sciences in Malmö, CRC, Lund University and Skåne University Hospital, Malmö, Sweden

BACKGROUND: Air pollution is a major contributor to the global burden of disease and has been linked to several diseases and conditions. The mechanisms are related to inflammation and increased coagulability, factors that play an important role in the pathogenesis of venous thromboembolism (VTE). We investigated if long-term exposure to air pollution was associated with increased VTE incidence.

METHODS: The study followed 29,408 participants from the Malmö Diet and Cancer (MDC) cohort. The population-based cohort recruited adults aged 44-74 from Malmö, Sweden between 1991-1996. Participants were assigned annual mean residential exposure to particulate matter <2.5µg (PM2.5) and <10µg (PM10), nitrogen oxides (NOx) and black carbon (BC) from enrollment up to 2016. Those with previous VTE events or VTE occurring close to a malignancy diagnosis were excluded from main analysis. Analyses were done using Cox proportional hazard models for air pollution in the year of VTE event (lag0) and the mean of 1-10 years before VTE event (lag1-10). VTE was defined as deep vein thrombosis (DVT) of the legs and pulmonary embolism (PE).

RESULTS: The means of annual air pollution exposure during the observation period were 15.8µg/m3 for PM10, 10.8µg/m3 for PM2.5, 27.7µg/m3 for NOx, and 0.96µg/m3 for BC. The mean follow-up period was 19.5 years, with 1418 VTE events recorded during this period. Exposure to lag1-10 PM2.5 was associated with increased risk of VTE (HR 1.17(95%CI 1.01–1.37) per 0.75µg/m3(IQR) increase in PM2.5 exposure) when adjusting for likely confounders. No association was found with lag0 air pollution exposure. Similar results were found for DVT, but no association was observed with PE. Results persisted in sensitivity analyses.
CONCLUSION: Long-term exposure to moderate levels of ambient air pollution was associated with increased risks of VTE in the general population in Sweden.

KEYWORDS:
PM25, air pollution sources, exposure

BACKGROUND AND AIM: The quantification of the contributions of sources of air pollutants, especially PM2.5, can be used for the improvement of our understanding of PM2.5 health effects. Three-dimensional chemical transport models are well suited to address this problem, since they simulate all the major processes that impact PM2.5 concentrations and transport.
In this work, we quantified the changes in the concentration, exposure, composition, and sources of PM2.5 in the US. Significant reductions of emissions of SO2, NOx, VOCs and primary PM have taken place.
METHODS: We evaluate our understanding of the links between these emissions concentration and exposure changes combining a chemical transport model (PMCAMx) with the Particle Source Apportionment Algorithm.
RESULTS: Results for 1990, 2001 and 2010 are presented. The 63% reduction in PM2.5 sulfate concentrations from electrical generation units during these 20 years has led to a 60% reduction in PM2.5 sulfate exposure. Also, the reductions in elemental carbon (EC) concentrations from road transport by 72% have led to a reduction of PM2.5 EC exposure of 70%.
CONCLUSIONS: In 1990 90% of the US population was exposed to PM2.5 concentrations to equal and higher than the suggested annual mean by the WHO, but this reduced to 70% in 2010. These results are the basis for an epidemiological study linking PM2.5 sources in the US and their health effect (Pond et al., 2021).

BACKGROUND/AIM: Globally, 3 billion people rely on solid fuels for cooking and heating, which generates household air pollution (HAP), contributing to preventable morbidity and mortality. The Household Air Pollution Intervention Network (HAPIN) trial was designed to assess the effect of a liquid petroleum gas (LPG) stove intervention on HAP exposure and maternal-child health outcomes. We conducted a sub-study to explore the breastmilk metabolomes among women in the rural Guatemala HAPIN site.

METHODS: Participants were excluded if they delivered by cesarean section, did not intend to breastfeed, or experienced mastitis or antibiotic use in the previous 48-hours. Breastmilk samples were collected from 75 women at six months postpartum using a standardized protocol, transported on dry ice, and processed using high-resolution mass spectrometry. Metabolic features were enhanced, and batch corrected with high quality control methods. Annotated features were quantile normalized, log transformed and analyzed using MetaboAnalyst 5.0.

RESULTS: Thirty-eight breastmilk samples were collected from women in the LPG intervention arm; 37 samples were collected from women in the control arm exposed to solid biomass fuels. The two-sample t-test with equal variances identified 262 significant features with one remaining significant after controlling for the false discovery rate. The fold change analysis (threshold of 2.0) revealed twenty-five up-regulated and four down-regulated features in the LPG group, compared to control ($p<0.05$). Pathway enrichment analysis identified significant pathway disruption in the carnitine shuttle, arginine and proline metabolism, aminosugar metabolism and lysine metabolism when comparing breastmilk from participants using LPG versus solid biomass (all $p<0.05$).

CONCLUSIONS: Minimal significant features were identified among breastmilk samples from participants in the study based on study arm assignment, but several variations were seen among metabolic pathways. Further exploration of maternal nutrition in concurrence with environmental exposures may provide additional differences in the breastmilk metabolome.

[1]Section of Environmental Health, Department of Public Health, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, [2]Section of Social Medicine, Department of Public Health, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, [3]Center for Healthy Aging, University of Copenhagen, Copenhagen, Denmark, [4]Department of Clinical Immunology, Rigshospitalet, University Hospital of Copenhagen, Copenhagen, Denmark, [5]Department of Environmental Science, Aarhus University, Roskilde, Denmark, [6]Global Centre for Clean Air Research (GCARE), University of Surrey, Guildford, UK, [7]iClimate – interdisciplinary Centre for Climate Change, Aarhus University, Roskilde, Denmark, [8]Section of Epidemiology, Department of Public Health, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark

BACKGROUND AND AIM: Ambient air pollution causes a range of adverse health effects, whereas effects of indoor sources of air pollution are not well described in high-income countries. We compared hazards of ambient air pollution and indoor combustion sources with respect to respiratory events and preceding lung function and inflammatory response in the blood in a middle-aged Danish cohort.

METHODS: Our cohort comprised 4,812 men and women aged 49 to 63 years at the recruitment in 2009-11, with information on exposure to second-hand smoke (SHS) and use of candles and wood stove, as well relevant covariates. Ambient air pollution exposure was assessed as 2-year mean nitrogen dioxide (NO2) at the address. Lung function was assessed as % predicted forced expiratory volume in the first second (FEV1) and inflammatory markers comprised interleukin-6 (IL-6) and tumor necrosis factor alpha (TNF-α) at baseline. We followed the cohort up for the first hospital contact for respiratory events [asthma, chronic obstructive pulmonary disease (COPD), pneumonia] until 2018. We used regression and Cox proportional hazard models for biomarkers and respiratory events, respectively, associated with indoor and ambient air pollution exposure after controlling for potential confounders.

RESULTS: We observed a decrease in FEV1 and increased IL-6 and TNF-α associated with exposure to SHS and NO2, but not with use of candles or wood burning. Respiratory events, including COPD incidence, showed positive associations with SHS, but not with other indoor combustion sources (candle use or wood burning) or ambient air pollution.

CONCLUSIONS: These results suggest that the levels of exposure to SHS and ambient air pollution are more harmful for lung function and inflammatory response in the blood than the levels of exposure to indoor combustion sources from candles and wood stoves in a high-income setting.

P-0141 Source apportionment of particulate matter (PM2.5) using Positive Matrix Factorisation in Thohoyandou, South Africa

Adewale Adeyemi[1], Peter Molnar[2], Johan Boman[2], Janine Wichmann[1]
[1]University of Pretoria South Africa, Pretoria, South Africa, [2]University of Gothenburg, Gothenburg, Sweden

BACKGROUND AND AIM: Human health, visibility degradation, and global climate change are all influenced by airborne particles. The study of chemical compositions and sources of particulate matter (PM2.5) is crucial due to the health problems associated to its exposure and the impact on climate change. Investigating the contribution of natural and anthropogenic sources to PM levels and their spatial gradient, particularly in inhabited areas, as well as the information about their origin and source of emission revealed by their composition is key to this study.

METHODS: 24-h fine aerosol particles were collected in Thohoyandou, a rural area of Limpopo province of South Africa sharing boarder with Mozambique and Zimbabwe, every third day from 17 April 2017 to 18 April 2018 and analysed for their elemental composition using an XEPOS 5 energy-dispersive X-ray fluorescence (EDXRF) spectrometer (SPECTRO Analytical Instruments, Germany). The USEPA 5.0 positive matrix factorization program was used to perform source apportionment analysis on this dataset. Six sources were identified and their contributions to the total PM2.5 mass were calculated.

RESULTS: The mean average for PM2.5 (10.8 µg/m3) in Thohoyandou was lower than the yearly WHO guideline (5 µg/m3) and the South African standard (20 µg/m3). S, Si, K, Fe, Ca, Cl had the highest concentrations with C greater than 1µg/m3. The identified sources include secondary sulphur, vehicle exhaust, coal combustion, road/soil dust, biomass burning, and industry/metal processing. It was observed that PM2.5 levels in Thohoyandou were significantly influenced by local anthropogenic sources.
CONCLUSION: Emission reduction strategies aim at reducing coal burning, secondary sulphur, biomass burning etc. are important in combatting the effect of air pollution. Lastly, the finding of the study will support the reviewing and drafting the air quality management plan for the country.

P-0142 Particulate matter (PM2.5) characterization and air quality level in an urban background in Pretoria

Adewale Adeyemi[1], Peter Molnar[2], Johan Boman[2], Janine Wichmann[1]
[1]*University of Pretoria South Africa, Pretoria, South Africa,* [2]*University of Gothenburg, Gothenburg, Sweden*

BACKGROUND: More than ever before, air pollution has become a great importance to the world because of it deleterious effect on human and the environment coupled with the effect of global warming. The presence of PM2.5 in the ambient air have showed strong association of adverse health outcomes for morbidity and mortality such as respiratory problems, cardiovascular diseases, asthma. Chemical characteristics and sources of trace elements in PM2.5, as well as the air quality index, were investigated.
METHOD: 24-h fine aerosol particles were collected in an urban area in Pretoria, South Africa, from 17 April 2017 - 18 April 2018. Eighteen trace elements were determined using an XEPOS 5 energy-dispersive X-ray fluorescence (EDXRF) spectrometer (SPECTRO Analytical Instruments, Germany), while black and organic carbon were estimated using an optical transmissometer from the samples collected. The HYPLIT model (version 4.9) was used to estimate air mass trajectories. Potential health risk was calculated by comparing it to the World Health Organization's air quality index (AQI).
RESULT: The overall mean PM2.5 concentration of the collected sample equals 21µg/m3, this value exceeds WHO air quality limit but below the European Union annual air quality standards. Among these constituents C and S had the highest, greater than 1µg/m3. Ni, Se, Br and Sb showed they were extremely enriched, (EF>10) and suggestive of anthropogenic or non-crustal origin. The 24-h PM, soot, BC and OC were significantly different by the geographical origin of air masses ($p<0.05$). The AQI showed that 70% of the samples showed levels above the AQI range of good and healthy air.
CONCLUSION: The findings include details on the concentration, composition, and potential sources of fine PM2.5, which is essential for policy formulation and mitigation strategies in South Africa's fight against air pollution.

KEYWORDS: Air pollution, transport cluster, particulate matter, trace elements, biomass burning, South Africa.

P-0143 Associations between pre-natal exposures to fine particulate matter (PM2.5), carbon monoxide, and black carbon and birthweight in the multi-country Household Air Pollution Intervention Network (HAPIN) trial

Kalpana Balakrishnan[1], Kyle Steenland[2], Thomas Clasen[2], Howard Chang[2], Michael Johnson[3], Ajay Pillarisetti[4], Luke Naeher[5], Ghislaine Rosa[6], Miles Kirby[7], Anaite Diaz-Artiga[8], John McCracken[5], Lisa Thompson[2], Gurusamy Thangavel[1], Sankar Sambandam[1], Krishnendu Mukhopadhyay[1], Naveen Puttaswamy[1], Vigneswari Aravindalochanan[1], Sarada Garg[1], Stella Hartinger[13], Lindsay Underhill[11], Florien Ndagijimana[14], Katherine Kearns[5], Devan Campbell[5], Jacob Kremer[5], Lance Waller[2], Shirin Jabbarzadeh[2], Jean Wang[2], Yunyun Chen[2], Aris Papageorghiou[10], Penelope Howards[2], Usha Ramakrishnan[2], Joshua Rosenthal[9], William Checkley[11], Jennifer Peel[12]
[1]Sri Ramachandra Institute for Higher Education and Research, Porur, Chennai, India, [2]Emory University, Atlanta, USA, [3]Berkeley Air, Berkeley, USA, [4]University of California, Berkeley, USA, [5]University of Georgia, Athens, USA, [6]London School of Hygiene and Tropical Medicine, London, UK, [7]Harvard University, Boston, USA, [8]Universidad del Valle de Guatemala, Guatemala City, Guatemala, [9]National Institutes of Health, Bethesda, USA, [10]University of Oxford, Oxford, UK, [11]Johns Hopkins University, Baltimore, USA, [12]University of Colorado, Fort Collins, USA, [13]PRISMA, Puno, Peru, [14]DelAgua Health Rwanda (Implementation) Limited, Kigali City, Rwanda

BACKGROUND AND AIM: Low birth-weight is a leading contributor to the burden of disease in low- and middle-income countries (LMICs). Household air pollution (HAP) has been reported to impact birth-weight, but evidence of quantitative exposure-response relationships is limited. As part of the multi-country Household Air Pollution Intervention Network (HAPIN) trial, we examined associations between prenatal exposure to HAP and birth-weight, as well as weight-for-age z-scores, among 3200 pregnant women (recruited between 9 to <20 weeks of gestation). Women randomized to the intervention arm received an LPG stove and free fuel while women in the control arm continued using biomass for cooking.

METHODS: We measured pre-natal 24-hour personal exposures to $PM_{2.5}$, CO, and BC at baseline (pre-intervention), 24-28 and 32-36 weeks of gestation. Gestational age was determined by ultrasound examination in all women and birthweight was measured within 24-hours of birth using standardized procedures. We developed multiple regression models to examine the association of estimated average exposure during gestation with birthweight and weight-for-age z-scores, adjusting for confounders.

RESULTS: Exposure-response models included live births (n=3,060) with valid birth weight (n=3,002) and pollution measurements ($PM_{2.5}$; n=2717), (CO; n=2560), and (BC; n=2772). In adjusted linear models, an inter-quartile increase in average pre-natal exposure to BC (7.3 µg/m³) was associated with a 22.8g reduction in birthweight (95% confidence interval [CI]:-39.5g,-5.8g) and with reduced weight for age Z-scores of -0.05 standard deviations (95%CI: -0.08, -0.01 standard deviations). The associations between $PM_{2.5}$ and birth-weight were in the same direction, but less robust. Relationships between CO exposures and birth-weight were consistent with a null association.

CONCLUSIONS: While modest, the observed associations between HAP exposure during pregnancy and birth-weight, particularly for BC, provide support for continuing efforts to address exposure to HAP alongside other drivers of low birth-weight in LMICs.

P-0144 Solid fuel combustion exposure and respiratory health in children and adults in Europe, USA, Canada, Australia and New Zealand: a systematic review and meta-analysis

Valentina Guercio[1], Karen Exley[1,2]
[1]Air Quality and Public Health Group, Environmental Hazards and Emergencies Department, Radiation, Chemical and Environmental Hazards, UK Health Security Agency, UK., Didcot, UK, [2]Department of Health Sciences, University of Leicester, UK., Leicester, UK

BACKGROUND/AIM: Epidemiological studies in low- and middle-income countries have shown a positive association between solid fuel (SF) burning exposure and adverse effects in children and adults. However, as the evidence is less clear in other countries, we investigated the associations between indoor and outdoor SF combustion (biomass and coal) and respiratory health in children and adults in studies conducted in Europe, North America, Australia, and New Zealand.

METHODS: We performed 2 systematic reviews of epidemiological studies for children and adults. A meta-analysis was performed on the association between indoor wood burning exposure and respiratory outcomes in children only. Pooled relative risks (RRs) and 95% confidence intervals (CI) were calculated using random-effects models.

RESULTS: We identified 74 articles conducted in children. The RR for indoor wood exposure was 0.90 (95%CI 0.77-1.05) for asthma, 1.11 (95%CI 0.88, 1.41) for lower respiratory infection and 1.11 (95%CI 0.85, 1.44) for upper respiratory infection. No association was found with wheeze and cough risk. Inconsistent and limited results were found considering other respiratory outcomes. Results from studies evaluating exposure to outdoor emissions derived from indoor SF combustion were limited. Among 34 articles identified in adults, positive associations were found between indoor SF combustion exposure and lung cancer and COPD risk, although based on limited studies. Inconsistent results were found considering other respiratory outcomes. Exposure to residential coal burning was associated with an increased risk of adverse respiratory effects. The introduction of measures to reduce SF use showed an improvement in air quality resulting in a reduction of adverse respiratory effects.

CONCLUSIONS: Exposure to SF burning was associated with some adverse respiratory effects in children and adults. However, due to limited number of studies for each outcome and several limitations, additional and better studies in high-income countries are needed.

P-0147 Burden of disease due to PM2.5 and NO2 emissions from coal-fired power plants in Germany

Vanessa Jana Soppa[1], Lina Neunhäuserer[2], Jeroen Kuenen[3], Richard Kranenburg[3], Ruud Janssen[3], Peter Coenen[3], Volker Diegmann[2], Claudia Hornberg[4], Barbara Hoffmann[1], Michaela Liebig-Gonglach[4]
[1]Heinrich Heine University of Düsseldorf, Institute for Occupational, Social and Environmental Medicine, Düsseldorf, Germany, [2]IVU Umwelt GmbH, Environmental Planning and Information Systems, Germany, [3]TNO Utrecht, Dept. of Climate, Air and Sustainability, Netherlands, [4]University of Bielefeld, Medical School OWL, Germany

BACKGROUND:
Coal combustion emits pollutants that affect human health. We aimed to quantify the environmental burden of disease (EBD) due to PM2.5 and NO2 emissions from coal-fired power-plants (CFPPs) in Germany.

METHODS: Emissions from CFPPs and other sources were extracted from official German and European inventories. The contribution of CFPPs to AP in Germany was calculated with the chemical transport model REM-CALGRID on a grid of 2x2 km2 for 2015. Mean annual PM2.5 and NO2 exposure was assessed by intersecting the contribution of CFPPs to AP with the population distribution in Germany for 2015. Age- and sex-stratified mortality data and life-expectancy were extracted from the Federal Health Monitoring. The attributable EBD, expressed as Years of Life Lost (YLL), was calculated based on relative risk estimates for natural cause mortality from single- and multi-pollutant models for PM2.5 and NO2 from the ELAPSE (Effects of Low-Level Air Pollution: A Study in Europe) study. for disease-specific endpoints, we calculated YLL using relative risk estimates for PM2.5 from the Global Burden of Disease 2019 study and for NO2 from the ELAPSE study.

RESULTS: The mean (min; max) calculated contributions of CFPPs to ambient PM2.5 and NO2 concentrations in Germany in 2015 were 0.25 µg/m3 (0.05 µg/m3; 3.11 µg/m3) and 0.48 µg/m3 (0.03 µg/m3; 14.95 µg/m3), respectively. The combined attributable EBD for natural cause mortality was 71,912 YLL (95% CI 52,818; 91,510). The sum of YLL for disease specific endpoints was 12,483 YLL for PM2.5 (coronary heart disease 49.7% of YLL, lung cancer 29.5%, COPD 8.9%, stroke 8.6% and diabetes mellitus type 2 3.3%) and 18,380 YLL for NO2 (cardiovascular mortality 96.8%, COPD mortality 3.2%).
CONCLUSION:
In 2015, disease burden due to PM2.5 and NO2 emissions from CFPPs in Germany was substantial and dominated by coronary heart disease and cardiovascular mortality.

P-0149 Effect of long-term exposure to UFP on birth outcomes around Schiphol airport, the Netherlands

José Jacobs[1], Alina Nicolaie[1], Jurriaan Hoekstra[1], Maciek Strak[1], Danny Houthuijs[1], Nicole Janssen[1]
[1]*National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands*

BACKGROUND AND AIM: people who live near airports are exposed to higher concentrations of ultrafine particles (UFP) from aviation. Pregnant women and the fetus in particular are considered to be highly susceptible to environmental exposures. We investigate associations between birth outcomes and exposure to UFP from aviation at the residential address during pregnancy.

METHODS: We identified approximately 286,000 singleton birth records (2006-2018) from mothers that lived at least 6 months during pregnancy in a 45x50 km area around Schiphol Airport. This information was linked to modelled monthly averaged UFP concentrations from aviation at the residential address during pregnancy. We modelled the association between exposure to UFP from aviation during pregnancy and pregnancy outcomes through logistic regression adjusting for individual and neighbourhood-level covariates. We performed a number of sensitivity analyses to investigate the robustness of the results, including adjustment for other air pollutants and noise. Effect estimates were expressed per 3,500 #/cm3 (~p5-p95 difference).

RESULTS: Effect estimates were generally positive, but statistically non-significant in the main model for preterm birth (PTB: OR 1.02 (95%CI 0.96-1.07), small for gestational age (SGA: OR 1.02 (95%CI 0.98-1.07)) and congenital anomalies (any CA: OR 1.05 (95%CI 0.98-1.07)). Associations with UFP reached (borderline) statistical significance in some of the sensitivity analyses, such as when the 4 municipalities with the lowest exposure were excluded (for PTB, SGA, CA), when the population was restricted to mothers with a Dutch background (PTB), after non-linear adjustment for NO2 and EC (PTB), after including municipality as random effect (CA) and in some specific strata of the population. No associations were found with infant mortality, low Apgar score and low birth weight.

CONCLUSIONS: We found suggestive evidence for associations between exposure to UFP from aviation during pregnancy and pregnancy outcomes.

KEYWORDS: ultrafine particles, aviation, airport, air pollution, birth outcomes

P-0151 Associations between air pollution and multimorbidity: results from the population-based UK Biobank study

Amy Ronaldson[1], Jorge Arias de la Torre[1,2,3], Mark Ashworth[4], Anna Hansell[5], Stephani L Hatch[6,7], Matthew Hotopf[6,8], Ian Mudway[9], Rob Stewart[6,8], Alex Dregan[6], Ioannis Bakolis[1,10]

[1]Centre for Implementation Science, Health Service and Population Research Department, Institute of Psychiatry, Psychology and Neuroscience (IoPPN), King's College London, London, UK, [2]CIBER Epidemiology and Public Health (CIBERESP), Madrid, Spain, [3]Institute of Biomedicine (IBIOMED), University of Leon, Leon, Spain, [4]School of Life Course and Population Sciences, King's College London, London, UK, [5]Centre for Environmental Health and Sustainability, University of Leicester, Leicester, UK, [6]Department of Psychological Medicine, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UK, [7]ESRC Centre for Society and Mental Health, King's College London, London, UK., [8]South London and Maudsley NHS Foundation Trust, London, UK., [9]Environmental Research Group, School of Public Health, Faculty of Medicine, Imperial College London; and MRC Centre for Environment and Health, Imperial College London, London, UK., [10]Department of Biostatistics and Health Informatics, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UK

BACKGROUND AND AIMS:
Long and short-term air pollution exposures are well established to be associated with single conditions, but its role in multimorbidity (MM) has not been investigated. We aimed to assess associations between air pollution exposure and MM status and severity, as well MM patterns using the UK Biobank cohort.

METHODS: MM status was calculated based on 41 physical and mental conditions We assessed cross-sectional associations between particulate matter (PM)2.5, PM10, nitrogen dioxide (NO2), and total nitrogen oxides (NOx) in µg/m3 and MM status at the baseline assessment (2006-2010) in 364,144 people (mean age: 52.2±8.1 years, 52.6% female) who had complete data for all study variables. Air pollutants were categorised into quartiles to assess dose response associations. Among those with MM (≥2 conditions; n=156,395) we assessed associations between air pollutants and MM severity. We used factor analysis to identify MM patterns. Potential associations were explored using generalised linear models adjusted for socioeconomic and neighbourhood-level indicators.

RESULTS: Higher exposures to PM2.5, NO2, and NOx was associated with MM status in a clear dose response manner (PM2.5 quartile 1 vs quartile 4: adjusted odds ratio (aOR)=1.21; 95% CI=1.18, 1.24; NO2 quartile 1 vs quartile 4: aOR=1.19; 95 % CI=1.16, 1.23). Among people with MM, higher exposure to air pollutants was linked with increased MM severity. We identified 11 MM patterns. Air pollution was associated with multiple MM patterns with strongest associations observed for neurological (stroke, epilepsy) (PM2.5: aOR=1.31; 95% CI=1.14, 1.51; NO2: aOR=1.33; 95% CI=1.11, 1.60) and respiratory patterns (COPD, asthma) (PM2.5: aOR=1.24; 95% CI=1.16, 1.33; NO2: aOR=1.26; 95% CI=1.15, 1.38).

CONCLUSIONS: This cross-sectional study suggests that exposure to air pollution might be associated with the accumulation of long-term, multi-organ conditions. Prospective studies are needed to investigate associations between air pollution and multimorbidity trajectories.

P-0152 Air pollution exposure in mid-life and cognition over 25 years later: a prospective longitudinal cohort study

Jorge Arias-de la Torre[1,2,3], Marcus Richards[4], Anna Hansell[5], John Gulliver[5], Rebecca Hardy[6,7], Stephani L Hatch[8,9], Amy Ronaldson[1], Helen Fisher[9,10], Ian Mudway[11], Thomas Canning[12], Ioannis Bakolis[1,12]

[1]Centre for Implementation Science, Health Service and Population Research Department, Institute of Psychiatry, Psychology and Neuroscience, London, UK, [2]CIBER Epidemiology and Public Health (CIBERESP), Madrid, Spain, [3]Institute of Biomedicine (IBIOMED), Leon, Spain, [4]MRC Unit for Lifelong Health and Ageing at UCL,University College London, London, UK, [5]Centre for Environmental Health and Sustainability, University of Leicester, Leicester, UK, [6]CLOSER, Social Research Institute, University College London, London, UK, [7]School of Sport, Exercise and Health Sciences, Loughborough University, London, UK, [8]Department of Psychological Medicine, Institute of Psychiatry, Psychology and Neuroscience, London, UK, [9]ESRC Centre for Society and Mental Health, King's College London, London, UK, [10]Social, Genetic & Developmental Psychiatry Centre, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, UK, [11]Environmental Research Group, School of Public Health, Faculty of Medicine, Imperial College London; and MRC Centre for Environment and Health, London, UK, [12]Department of Biostatistics and Health Informatics, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UK

BACKGROUND AND AIM: Existing evidence of the association between air pollution and cognition uses cross-sectional or longitudinal studies with short observation periods. The objective of this research was to investigate this association over a 25-year period.

METHODS: Data were obtained from the MRC National Survey of Health and Development comprising 2125 participants at age 68-70. Annual average sulphur dioxide (SO2), nitrogen dioxide (NO2), and black smoke (BS) air pollution measurement units were obtained from land use regression models and were assigned to place of residence for 1989 and 2010-2011 (only for NO2) when participants were 43- and 64/65-year-old. Cognition was assessed at ages 68-70 using the Addenbrooke's cognitive examination III (ACE-III), which includes measures of attention, memory, verbal fluency, visuospatial skills, and language. Prospective associations between air pollution and cognition over this ~25-year period was investigated using linear regression models adjusted for socioeconomic and neighbourhood-related indicators.

RESULTS: The median (IQR) µg/m3 levels of pollutants in which participants were exposed at age 43 were 28.2 (8.1) for SO2, 29.8 (10.2) for NO2, 11.4 (5.9) for BS and 22.5 (9.1) for NO2 at age 64/65. No associations were observed between pollutants at ages 43 and 64/65 and total score of ACE-III. We found evidence of increases in NO2 and BS at age 43 to be associated with a reduction in total scores for attention (NO2: mean difference (MD) across the interquartile range: -0.27; 95% CI: -0.45 to -0.08; BS: MD: -0.23; 95% CI: -0.36 to -0.10) and memory (BS; MD: -0.23; 95% CI: -0.36 to -0.10).

CONCLUSIONS: The findings suggest that outdoor air pollution in mid-adulthood could potentially affect cognition in later life. Whilst causation cannot be proved, this work suggests decreases in cognitive ability in later life may be avoided with improved air quality.

KEYWORDS: Air pollution, birth cohorts, cognition

P-0153 Fatal unintentional non-fire related carbon monoxide poisoning: Data from Narrative Verdicts, England and Wales, 1998-2019

Rebecca Close[1], Neelam Iqbal[1], Sarah Jones[2], Andrew Kibble[2,3], Robert Flanagan[4], Helen Crabbe[1], Giovanni Leonardi[1,5]

[1]Environmental Epidemiology Group, Radiation, Chemicals and Environment Directorate, UK Health Security Agency, Harwell Campus, Chilton, UK, [2]Environmental Public Health Team, Health Protection Division, Public Health Wales, Cardiff, Wales, [3]Radiation, Chemicals and Environment Directorate, UK Health Security Agency, Cardiff, Wales, [4]Precision Medicine, King's College Hospital NHS Foundation Trust, London, England, [5]Department of Public Health, Environments and Society, London School of Hygiene and Tropical Medicine, London, England

BACKGROUND AND AIM: Unintentional non-fire-related (UNFR) carbon monoxide (CO) poisoning continues to cause fatalities. Coroners' narrative verdicts concerning fatal UNFR CO poisoning in England and Wales, 1998-2019, were collated by the Office for National Statistics.

METHODS: Search terms related to CO exposure were used to obtain information regarding the circumstances of death. Findings were grouped by location of death, source of CO, and reason or behaviour underlying the exposure.

RESULTS: There were 750 deaths (77% male). Annual numbers of deaths decreased over the period studied. Two-thirds (68%) of the deaths occurred in the autumn/winter. of records with information, 59% of deaths occurred in a dwelling (67% male). Males also predominated in deaths in vehicles (91%) and garages/outbuildings (95%). of deaths with information, domestic piped gas was the most common source of CO (36%), and the most frequent underlying factor was inadequate ventilation of exhaust gases (39%, 91% male).
CONCLUSION: Despite the decrease in the annual numbers of deaths over the study period, there remains a clear need for measures to raise awareness of the dangers of CO poisoning, especially amongst men working alone in garages/outhouses. Education campaigns and fitting and maintaining CO alarms in high-risk areas should be encouraged.

KEYWORDS: carbon monoxide, CO, unintentional poisoning, environmental epidemiology, environmental public health, unintentional death, preventing CO poisoning

P-0154 Pathways associated with air pollution exposure and cognitive outcomes: a systematic review of the epidemiological studies

Mohammad Javad Zare Sakhvidi[1], Emilie Burte[2], AmirHoushang Mehrparvar[3], Marion Mortamais[4], Noémie Letellier[5], Claudine Berr[4], Bénédicte Jacquemin[2]

[1]Occupational Health Department, School of Public Health, Shahid Sadoughi University of Medical Sciences, Yazd, Islamic Republic of Iran, [2]Univ Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) – UMR_S 1085, F-35000, Rennes, France, [3]Industrial diseases research center, Shahid Sadoughi University of Medical Sciences, Yazd, Iran, [4]INM, Univ Montpellier, Inserm, Montpellier, France, [5]Herbert Wertheim School of Public Health and Human Longevity Science & Scripps Institution of Oceanography, UC San Diego, 8885 Biological Grade, La Jolla, La Jolla, USA

BACKGROUND AND AIM: Air pollution is a modifiable risk factor for dementia, however the pathways through which air pollution affects cognition in the elderly are not well-understood. We reviewed the epidemiological evidence on the factors mediating this association.

METHODS: We systematically searched three databases (Medline, Scopus, Web of Science) for observational studies about the mediators of the association between outdoor air pollution and cognition in older adults until February 2022. The risk of bias (ROB), and mediation reporting quality were assessed by Navigation Guide, and AGReMA Statement respectively.

RESULTS: Through 1229 items, nine reported mediation analyses. Six had "yes/probably yes", and three "no/probably no" ROB. The average quality of reporting of mediation analysis was good (20 out of 25). Reported exposures were PM2.5, NO2, NOX, PM10, and black carbon (BC). The reported outcomes were episodic memory, cognitive processing time (CPT), visuo-construction performance (VCP), global cognitive performance, dementia, and non-dementia cognitive impairment. Totally 41 exposure-mediator-outcome associations were reported, with six classes of mediators: mental health, lung function, cardiovascular factors, systemic inflammation, type-2 diabetes, and brain anatomic changes. Evidence suggests a mediating role of mental health, particularly of depression. Lung function was found as a mediator for the association between PM2.5, BC, and CPT but not VCP. Type-2 diabetes was found as a mediator for NOX-cognitive impairment and dementia association. Stroke mediated the PM2.5- dementia association; no evidence of mediation was found for cardiovascular factors. Grey matter atrophies mediated PM2.5-associated decline in episodic memory. Systemic inflammation was not suggestive for mediation.

CONCLUSIONS: The available evidence on mediators of the association between air pollution and cognition is very limited. Furthermore, results are not always consistent according to the pollutant and the cognitive outcome. Mediation pathways especially for depression need to be further explored.

P-0155 A knowledge transfer approach to improve maps of long-term air pollution concentrations using short-term mobile measurements

Zhendong Yuan[1], Jules Kerckhoffs[1], Gerard Hoek[1], Roel Vermeulen[1,2]
[1]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, [2]Julius Centre for Health Sciences and Primary Care, University Medical Centre, University of Utrecht, Utrecht, Netherlands

BACKGROUND AND AIM: Mobile measurements are increasingly used to train empirical land-use regression models (LUR) to produce spatially resolved (hyperlocal) air quality maps. However, most mobile monitoring campaigns only measure short-term and on-road air pollution during the daytime on weekdays. We hypothesize that LUR models trained with mobile measurements are not optimized for estimating residential long-term exposure. The association between mobile measurements and land-use covariates (mobile knowledge) may differ from the actual association between long-term residential concentrations and the corresponding covariates (long-term knowledge). To bridge this gap, we propose transfer-learning techniques to improve LUR models trained with mobile measurements by explicitly incorporating long-term knowledge.

METHODS: We implemented a boosting-based transfer-learning algorithm (TrAdaBoost) and a random-forest-based domain adaptation method (Prior_RF) as transfer-learning LUR models. They were trained with mobile measurements and long-term knowledge. Mobile measurements of Nitrogen Dioxide (NO2) and Ultrafine Particles (UFP) were measured on every street in Amsterdam by two Google Street View cars equipped with high-quality instruments (1 Hz for 10 months). The performance of two transfer-learning LUR models tested was compared with two popular LUR models trained exclusively with mobile measurements, namely the random-forest-based LUR model (RF_LUR) and the stepwise linear regression LUR model (LSR).

RESULTS: Our proposed transfer-learning LUR models performed 55% better than RF_LUR and 32% better than LSR, evaluated by normalized mean absolute error against external long-term validation data of NO2. for UFP, the improvements were 27% and 14%, respectively. The predictions of transfer-learning LUR models retained the detailed hyperlocal spatial variations.

CONCLUSIONS: Transfer-learning LUR models improve the assessment of long-term residential (near-road) air pollution exposures, as opposed to LUR models trained with short-term on-road mobile monitoring only.

P-0158 Biomonitoring cadmium and nickel using native mosses in Leicester, UK

Przemysław Sitkowski[1], Florette Nya[1], Titilayo Adenike[1], Manuel Higueras[2], Tiziana Sgamma[1], Gurminderjeet Singh Jagdev[1], Mark Evans[1], Antonio Peña-Fernández[1]

[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, UK, [2]Scientific Computation & Technological Innovation Center (SCoTIC), Universidad de La Rioja, Logroño, Spain

BACKGROUND AND AIM: Mosses provide information about atmospheric contamination by metals and their local spatial distribution. The aim was to conduct a preliminary analysis of cadmium (Cd) and nickel (Ni) in mosses collected from rural and urban environments in Leicester, UK.

METHODS: Native mosses were sampled from green spaces across Leicester/rural surroundings. Species identification was performed by DNA barcoding using bryophyte-specific primers on DNA extracted from 100 mg of frozen, homogenised, ground moss using Isolate II Plant DNA Kit®. After processing (soil removal, drying and homogenising), forty [31 urban; 9 rural] samples were mineralised with HNO3/H2O2. Cd and Ni were determined by atomic absorption spectroscopy; limits of detection were 0.0008 and 0.0072 µg/g, respectively.

RESULTS: Four moss species were identified: Ceratodon purpureus, Brachythecium spp., Hypnum cupressiforme, Kindbergia praelonga; H. cupressiforme is a useful, well recognised biomonitor. Cd was not detected in any of the samples, which agrees with recent work from Poland. Ni was observed in 13 samples, which were processed using maximum likelihood estimation method available in 'NADA' for the software R. Concentrations of Ni for the urban and rural areas (median and interquartile limits; µg/g): 0.0057 (0.0039-0.0084), and 0.0024 (0.0009-0.0064), respectively. Although slightly higher concentrations of Ni were found in the native mosses collected in the urban areas, perhaps reflecting different sources of pollution within Leicester city, the means did not show statistical difference (p-value, 0.626). The level of Ni was within the same range but lower than the medians described in larger biomonitoring studies performed in Germany (1.6 µg/g) and Moscow (2.87 µg/g), suggesting lower emission of this metal in Leicester.

CONCLUSIONS: Undetectable Cd suggests environmental pollution with this toxic metal is minimal in Leicester, whereas Ni pollution may be more prevalent, however in both cases, analysis of more samples are needed to confirm these preliminary observations.

P-0159 Using naturally growing mosses as passive biomonitors of cobalt and zinc in Leicester, UK

Antonio Peña-Fernández[1], Manuel Higueras[2], Florette Nya[1], Tiziana Sgamma[1], Gurminderjeet Singh Jagdev[1], Mark Evans[1]

[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, UK, [2]Scientific Computation & Technological Innovation Center (SCoTIC), Universidad de La Rioja, Logroño, Spain

BACKGROUND AND AIM: Mosses can be used to assess the impact of metal pollution in urban areas. A study was performed to assess cobalt (Co) and zinc (Zn) contamination in the urban and rural atmospheres of Leicestershire, UK.

METHODS: Forty (31 urban; 9 rural) naturally growing mosses were collected from green spaces across Leicester/rural surroundings. Species identification was performed by DNA barcoding using bryophyte-specific primers on DNA extracted from 100 mg of frozen, homogenised, ground moss using Isolate II Plant DNA Kit®. Metals were monitored by atomic absorption spectroscopy after mineralising each sample with HNO3/H2O2. Data was processed using maximum likelihood estimation method available in 'NADA' for the software R.

RESULTS: Different moss species were identified, which have been suggested as good biomonitors: Ceratodon purpureus, Brachythecium spp., Hypnum cupressiforme, Kindbergia praelonga. In contrast to Co, which was not detected (LoD=0.0141 µg/g) in any of the moss samples, Zn was observed in 9 samples, specifically in mosses sampled in the urban area (7 samples). Moreover, these mosses also showed higher contents of Zn than those from rural locations (median and interquartile limits; µg/g): 0.0071 (0.00494-0.01012), and 0.003516 (0.001342-0.00921). Zn is strongly related to car exhaust, as it is present in fuels, lubricants, oils and engines. However, the levels of Zn found were much lower than those reported in similar studies, suggesting minimal contamination in the atmosphere in Leicester city. The ranges of Zn (µg/g) found in Norway's largest city Oslo (18.5-106), were much higher than the found in Leicester city (0.011-0.020), perhaps because Oslo has more inhabitants, industry and traffic density.

CONCLUSIONS: Although our results should be considered as preliminary, the fine atmospheric dust present in urban and rural areas from Leicestershire might not be notably contaminated by either element, especially cobalt, although a more comprehensive biomonitoring study is needed.

P-0160 Household's heating type and energy sources and cause-specific mortality: a census-based cohort study in urban Belgium

Lucia Rodriguez Loureiro[1], Sylvie Gadeyne[1], Lidia Casas[2,3]

[1]Interface Demography, Department of Sociology, Vrije Universiteit Brussel, Brussels, Belgium, [2]Social Epidemiology and Health Policy, Department of Family Medicine and Population Health, University of Antwerp, Wilrijk, Belgium, [3]Institute for Environment and Sustainable Development (IMDO), University of Antwerp, Antwerp, Belgium

BACKGROUND/AIM: In high-income countries, individuals spend most time indoors. Low-income urban dwellers may have inadequate heating while overexposed to environmental hazards. We aimed to investigate the associations between household's heating type and energy sources and cause-specific mortality among Belgian urban dwellers.

METHODS: Data from the 2001 Belgian census was linked to register mortality data for the follow-up period 2001-2014. Our study population included all individuals aged ≥30 years and residing in the largest Belgian urban areas (Brussels, Antwerp, Ghent, Charleroi, and Liège) in 2001. Using information on household heating (type and energy used) from the census, we categorised individuals as: having central heating (CH) (reference category); no CH and using safe energies for heating (butane, electricity, or natural gas); and no CH and using solid fuels (charcoal or wood). We used Cox proportional hazards models to investigate the associations between household's heating type and energy and cause-specific mortality (from natural causes, cardiovascular and respiratory diseases, dementia, and lung cancer), controlling for baseline sociodemographic and building characteristics, and outdoor particulate matter concentrations.

RESULTS: 2,595,266 individuals were included at baseline, from which 423,843 (16.3%) had no CH and used safe energies for heating, and 192,463 (7.4%) had no CH and used solid fuels. Associations generally attenuated with increasing covariate adjustment, especially with educational level. Relative to having CH, no CH and using safe energies increased between 9-12% the mortality risk from most studied causes after complete adjustment. No CH and using solid fuels increased around 23% the risk of dying from natural causes and lung cancer, 29% from CVDs (95%CI: 1.26, 1.31), and 34% from respiratory diseases (95%CI: 1.30, 1.38). No associations were found with dementia mortality.

CONCLUSIONS: Not having central heating was independently associated with increased mortality rates, especially for individuals using solid fuels.

KEYWORDS: Household air pollution, Solid fuels, Coal, Wood, Mortality, Socioeconomic position.

P-0162 The short-term effects of fine dust on suicide death in Korea

Tae-Hwa Go[1], Youn-Young Choi[2], Jae Hyun Han[3], Min-Hyuk Kim[3], Changsoo Kim[4], Dae Ryong Kang[1]
[1]Department of Biostatistics, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea, [2]Artificial Intelligence BigData Medical Center, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea, [3]Department of Psychiatry, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea, [4]Departmentof Preventive Medicine, Yonsei University, Seodaemun-gu, Republic of Korea

Air pollution can cause various respiratory and neurological diseases and lead to death if continuously exposed. Previous studies have reported that fine dust increases the risk of mental illness such as stress, depression, suicidal ideation, and physical health problems. This study aims to identify the relationship between air pollution and suicide deaths.

Fine dust data from the Korea Environment Corporation, autopsy data from the National Police Agency, and death statistics database from the National Statistical Office were used. Additionally, meteorological data and claim data were used. The study design was time series analysis, and we confirmed the effect of single lag, cumulative lag, and moving average of the amount of fine dust from day 0 to day 7 using a distributed non-linear model.

We analyzed 64,150 people who died by suicide from 2013 to 2017 and confirmed the statistically significant result that as the PM_{10} concentration increased, the risk of suicide death increased. Also, as the cumulative number of days increased from 1 to 7 days, the dose-response effect of increasing the risk of suicide was confirmed. Stratified analysis was performed according to gender, age, presence of a suicide note, presence of mental illness, and presence of warning signs before suicide. In particular, in subjects with psychiatric disorders, when the cumulative concentration of $PM_{2.5}$ until 3 days and 5 days before suicide death increased by 10μg/m³, the risk of suicide death increased by 3.1% and 3.2%, respectively.

These results show an association between short-term exposure to fine dust and suicide deaths. It can be suggested that more attention should be paid to fine dust exposure, especially in the group with a vulnerable mental illness.

P-0163 Traffic and air pollution impacts of Low Traffic Neighbourhoods (LTNs)

Xiuleng Yang[1], Katherine Hough[1], Emma McCoy[1], Audrey de Nazelle[1]
[1]*Imperial College London, London, UK*

BACKGROUND AND AIM: Measures to reduce traffic flows through neighbourhoods have gained popularity as means of creating safe, attractive and healthy places for community members. Their relatively rapid expansion during post-COVID times, however, has been controversial. Detractors' main arguments have centred on the potential for traffic, and hence air pollution, to be displaced to surrounding streets. Our aim is to assess impacts of Low Traffic Neighbourhoods (LTNs) on air pollution and traffic flows in and around intervention areas.
METHODS: We obtained monthly traffic count and monthly nitrogen dioxide (NO2) concentration data from the London Borough of Islington where three LTNs were implemented in 2021. The local council regularly measures nitrogen dioxide (NO2) around the borough using passive samplers, but with no systematic approach to monitoring campaigns for evaluation purposes. We identified for each LTN the pre-and post-intervention monitoring periods and eligible monitoring sites to represent conditions: 1) within LTNs, 2) at the boundary of LTNs (less than 500m away), 3) in control areas unaffected by the LTNs. A generalised difference in difference approach was then developed to evaluate whether LTN implementation had a significant causal effect on NO2 and traffic volumes, accounting for road type and time period.
RESULTS: 697 monthly NO2 and 108 monthly traffic counts were usable as pre- and post-intervention observations for the evaluation. LTN implementation led to statistically significant reductions in NO2 both within the intervention areas (5.7%) and in boundary areas (8.9%), compared to the external control sites. Large and statistically significant traffic volumes reductions were found within LTNs (58.2%), and more moderate but not statistically significant reductions at LTN boundary sites (13.4%).
CONCLUSIONS: Neighbourhood traffic reductions measures have the potential to reduce air pollution and traffic in target areas, without necessarily causing displacements in surrounding streets.

P-0164 Temporal and spatial distribution of PM2.5 pollution in Taipei City and its association with traffic flows assessed by microsensor data

Tzu-Hsuen Yuan[1], Master Pei-Cen Wu[2], Jui-Huan Lee[2], Assistant Charlene Wu[2], Chang-Chuan Chan[2]
[1]Department of Health and Welfare, College of City Management, University of Taipei, Taipei, Taiwan, [2]Institute of Environmental and Occupational Health Sciences, National Taiwan University, Taipei, Taiwan

BACKGROUND AND AIM: Due to the insufficient number and distribution of air monitoring stations, we can't represent and estimate the more accurate PM2.5 pollution situation and its association with important exposure sources within the district of Taipei City. This study tries to apply the two datasets of micro sensors and vehicle detectors to further explore the relationship between PM2.5 concentration and traffic flow in Taipei City.

METHODS: We collected PM2.5 data from 90 micro sensors (Airbox) and traffic flow data from 934 vehicle detectors from August 2020 to July 2021 in Taipei City. We used simple linear regression to quantify the relationship between annual average of hourly PM2.5 concentration and traffic flow in each administrative district of Taipei City. and we further develop hourly PM2.5 land-use regression models by combing the traffic flow and land-use data.
RESULTS: It showed significant correlation between traffic flow and PM2.5 concentrations with the R2 of 12 districts from 0.72 to 0.89. An increase of 10,000 vehicles per hour in the total traffic flow could increase the PM2.5 concentrations in each district of Taipei City from 0.36μg/m3 to 1.64μg/m3. In advanced, we developed the land-use regression model in Shilin District and Zhongshan District. The R2 of the hourly PM2.5 land-use regression model in the Shilin District and Zhongshan District is 0.87 and 0.66. The models could reflect the impacts of traffic flow and land-use variables.
CONCLUSIONS: This study used the data of Airbox with large sample size and high density in a small area after combining the hourly traffic flow and land-use data, we successfully established the PM2.5 land-use regression models with the characteristics of different administrative districts. In accordance with this model, the Taipei City hourly model will be further established.

P-0165 Spatio-temporal modeling of airborne pollen concentrations

Behzad Valipour Shokouhi[1,2], Kees de Hoogh[1,2], Marloes Eeftens[1,2]
[1]*Department of Epidemiology and Public Health, Swiss Tropical and Public Health Institute, Basel, Switzerland,* [2]*University of Basel, Basel, Switzerland*

KEYWORDS: Pollen, Machine Learning, Allergic Disease

Abstract

BACKGROUND AND AIM: High concentrations of airborne pollen trigger seasonal allergies and possibly severe adverse respiratory and cardiovascular health events. Predicting pollen concentration accurately is valuable for epidemiological studies to determine the effects on cardiovascular, respiratory, and cognitive health. We aimed to develop a spatiotemporal land-use regression model for pollen, predicting daily concentrations at a fine spatial resolution of 1x1km across Switzerland between 2003 and 2020.

METHODS: Daily pollen concentrations for hazel, alder, ash, birch, and grasses were available from 14 sites. We considered a range of spatial (elevation, tree type), temporal (date, season, month, week and day of the year, national daily pollen concentration) and spatiotemporal predictors (wind speed, wind direction, temperature, precipitation, relative humidity, satellite-observed Normalized Difference Vegetation Index (NDVI), and land-use (CLC, Landsat satellite) to explain variation in total pollen concentration for five specific pollen species. We applied a range of feature engineering techniques to encode categorical variables (land-use) and fill in missing values (Landsat). We applied a random forest model with 5-fold cross-validation.

RESULTS: The median grass pollen concentration was 24 pollen/m3 (P5-P95 range 0-187 pollen/m3) during the main grass pollen season (May-July for all years). Preliminary results of a model predicting grass pollen concentration achieved an overall R2 of 0.74 and a root mean squared error (RMSE) of 24.12 pollen/m3 (cross-validation). Temperature, humidity, wind speed, NDVI, Landsat, average national daily pollen concentration and date features were the most important predictors for grass pollen concentration.

CONCLUSIONS: Building upon national observed pollen concentrations and using random forest machine learning, these spatiotemporal pollen models will serve to estimate individual residential pollen exposure. Resulting estimates will enable us to study respiratory and cardiovascular mortality and hospital admissions using historical data from the Swiss National Cohort and the Swiss Federal Office of Statistics.

P-0166 Impact of short-term ambient PM2.5 exposure on the all-cause and cause-specific mortality among rural population in North India

Harshal Ramesh Salve[1], Abhishek Jaiswal[1], Sagnik Dey[2], Anand Krishnan[1], Shashi Kant[1]
[1]All India Institute of Medical Sciences (AIIMS), New Delhi, New Delhi, India, [2]Indian Institute of Technology (IIT), Delhi, India

BACKGROUND AND AIM: Air pollution due to ambient fine particulate matter (PM2.5) is an environmental hazard. There is dearth of evidence linking PM 2.5 exposure to mortality among rural population in India. We aimed to assess impact PM2.5 exposure on non-trauma all-cause and diseases specific mortality in villages of district Faridabad in north India using eleven years data.

METHODS: Study site was health and demographic surveillance site with yearly approximately 500 deaths where all deaths were recorded by trained field staff. Cause of death was ascertained by verbal autopsy using validated tool. Daily PM 2.5 exposure at village level was assessed using satellite-based PM2.5 (1-km) exposure that was calibrated against the ground-based measurements. Surface PM2.5 concentrations were estimated by converting aerosol optical depth (AOD) from Moderate Resolution Imaging Spectroradiometer (MODIS). Multivariable analysis were done including information on demographic variables, meteorology, Normalised Difference Vegetation Index, Land Surface Temperature using a generalised linear model with Poisson's distribution.
RESULT: Mean daily average PM 2.5 level was 99.97 microgram/m3 with range (15.7 to 968.8) in the study area. We have observed 0.3% rise in the Incidence Rate Ratio (IIR) of non-trauma mortality (IRR 1.003, 95% CI: 0.998-1.007) every 10 units increase of daily PM 2.5. Two days Lag model analysis showed significant relationship between PM 2.5 level and daily mortality with IRR of 1.006 (95% CI: 1.0001-1.011) for every 10 unit rise in the monthly average ambient PM2.5 level, there was 10.5% increase monthly deaths. Impact of ambient PM 2.5 was more among elderly population. No statistically significant association of PM 2.5 exposure on cardiovascular or respiratory diseases related deaths was observed in multivariate analysis.
CONCLUSION: Short-term ambient exposure of PM 2.5 was highly correlated with increase in mortality among rural population in north India. Elderly population reported higher vulnerability to PM 2.5 exposure.

P-0169 An Evaluation of the Cardiovascular Impacts of the Closure of a Coking Operation - An Interrupted Time Series Analysis

Wuyue Yu[1], George D. Thurston[1]
[1]*New York University School of Medicine, New York, USA*

BACKGROUND AND AIM: Coke plant operations are known to generate high emissions of particulate matter, SO_2, heavy metals and volatile compounds, which likely induce oxidative stress and inflammation, and thus increase the cardiovascular disease risk in the local community. Inducing a distinctive alteration of the air pollution profile, the shutdown of the Shenango, Inc. coke plant in Pennsylvania, US, in January 2016 has become an ideal case to evaluate the impacts of air pollution improvements from emission reductions. To better understand the results of this 'natural experiment', our study investigated the changes in local air pollution and constituents associated in time with the closure of the coke plant, followed by a test as to whether there is also a coincident reduction in cardiovascular hospitalizations in the community.

METHODS: Air pollution data were obtained from Allegheny County Health Department Air Monitoring Network and the EPA Chemical Speciation Network. Quarterly inpatient hospitalization data were obtained from the Pennsylvania Health Care Cost Containment Council. Data from 2013 to 2018 were assessed and compared for potential changes in trends before and after the closure of the coke plant using the interrupted time series method.

RESULTS: We found statistically significant local reductions in ambient SO_2, particulate matter sulfate and heavy metal concentrations at air quality monitoring sites near the plant after the shutdown. A statistically significant immediate decrease and a downward trend of total cardiovascular inpatient hospitalization cases were observed in areas near the plant after the closure, whereas no significant change was observed in control populations. We also found a significant decrease in ischemic heart disease and cerebrovascular diseases inpatient cases in areas near the coke plant.

CONCLUSIONS: Our study provides new evidence that interventions eliminating air pollution sources improve the air quality and health of the local community.

KEYWORDS: air pollution, cardiovascular health

P-0170 Associations between short and long-term $PM_{2.5}$ exposure and blood lipid concentrations in myocardial infarction survivors

Samantha Catalano[1], Joshua Moyer[2], Qian Di[3], Joel Schwartz[4], Cavin Ward-Caviness[2]
[1]ORISE Research Participation Program, US Environmental Protection Agency, Chapel Hill, USA, [2]Center for Public Health and Environmental Assessment, US Environmental Protection Agency, Chapel Hill, USA, [3]Research Center for Public Health, School of Medicine, Tsinghua University, Beijing, China, [4]Harvard TH Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Ambient particulate matter ($PM_{2.5}$) increases morbidity and mortality, particularly for those with underlying chronic disease. Examining disease risk factors such as blood lipids can reveal the early stages of the pathophysiologic processes triggered by $PM_{2.5}$.
METHODS: We examined associations between short-term $PM_{2.5}$ and blood concentrations of total cholesterol, high-density lipoprotein cholesterol (HDL), and low-density lipoprotein cholesterol (LDL) among myocardial infarction (MI) survivors (N = 8,740) seen at a University of North Carolina Healthcare System facility between January 1, 2004 and December 31, 2016. Lipid measurements were extracted from electronic health records along with geocoded residential address, patient demographics, and disease history. Daily $PM_{2.5}$ was estimated at 1x1 km resolution using an ensemble machine learning model. We used linear mixed-effects models with a random intercept for each individual to model the associations while adjusting for age, sex, race, temperature, relative humidity, socioeconomic status, and a natural spline for time since study start. We also examined annual average $PM_{2.5}$ in separate models adjusted for age, race, sex and socioeconomic status. Results are presented as the regression coefficient (β, per 1 μg/m³ higher $PM_{2.5}$) and associated 95% confidence interval (CI).
RESULTS: For short-term $PM_{2.5}$, exposure associations were seen between 5-day average $PM_{2.5}$ and HDL (β = -0.06; CI= -0.10, -0.02) and total cholesterol (β = -0.18; CI= -0.37, 0.01). Annual average $PM_{2.5}$ was associated with total cholesterol (β = 1.57; CI= 1.05, 2.12), HDL (β = 0.57; CI= 0.42, 0.72), and LDL (β = -0.95; CI= -1.95, 0.05).
CONCLUSIONS: Short and long-term $PM_{2.5}$ exposures are associated with changes in blood lipids among MI survivors, however with opposite directions of associations for HDL and total cholesterol. Further evaluation of these associations may reveal important insights into the actions of $PM_{2.5}$ for clinically vulnerable individuals.

P-0172 Short-term mortality risks associated with sulfur dioxide: a multi-country analysis in 399 cities

Antonio Gasparrini[1], Edward O'Brien[1], Pierre Masselot[1], Haidong Kan[2]
[1]London School of Hygiene & Tropical Medicine, London, UK, [2]Fudan University, Shanghai, China

BACKGROUND AND AIM: Epidemiological evidence on the health effects of ambient sulfur dioxide (SO2) is limited compared to other pollutants, and doubts remain on aspects such as the nature of the dose-response relationship and the potential role of co-pollutants, as well as the actual risk at low concentrations. Here we assess the short-term association between exposure to ambient SO2 and daily mortality in a large multi-city multi-country dataset, using advanced study designs and statistical techniques.

METHODS: The analysis included 43,780,911 deaths that occurred in 399 cities within 31 countries between 1979 and 2018. A two-stage design was applied to assess the association between the daily concentration of SO2 and mortality counts, including first-stage time series regressions with distributed lag models and second-stage multilevel random-effects meta-analyses. The associations were reported as relative risks (RRs) and as numbers/fractions of excess deaths computed at different geographical aggregation levels.

RESULTS: On average, a 10 µg/m3 increase in daily SO2 level was associated with a RR of mortality of 1.0044 (95%CI: 1.0019 to 1.0070) with substantial heterogeneity between countries. Short-term exposure to SO2 was associated with an average 16,134 (95%eCI: 13,836 to 18,418) excess deaths per year in the 399 cities, corresponding to 0.50% (95%eCI: 0.43% to 0.57%) of mortality. Levels above the WHO guidelines for SO2 (>40 µg/m3 average over 24 hours) occurred on average in 4.6% of days, although predominantly in selected locations, and were associated only with 2,980 (95%CI: 1,498 to 4,358) yearly excess deaths. Significant positive associations remained after controlling for other pollutants.

CONCLUSIONS: The analysis indicates an independent short-term effect of exposure to SO2, with no evidence of a threshold. Levels below the current WHO guidelines for 24-hour averages are still associated with substantial excess mortality, indicating the potential benefits of stricter air quality standards.

KEYWORDS: pollution; time series.

P-0175 Investigating the Regional Concentrations-Response Relations between PM2.5 and daily mortality in Japan

Satbyul Estella Kim[1], Yasushi Honda[1], Masahiro Hashizume[2], Chris Fook Sheng Ng[2], Kazutaka Oka[3], Tatsuya Nagashima[3], Yasuaki Hijioka[3]

[1]University of Tsukuba, Tsukuba, Japan, [2]The University of Tokyo, Tokyo, Japan, [3]National Institute for Environment Studies, Tsukuba, Japan

BACKGROUND: The concentration-response (CR) functions of PM2.5 are sensitive to various local factors, such as meteorological conditions, PM sources and components, and population sensitivity to PM. However, the shape of local CR functions remains unclear in many regions in Japan. This research investigates the association between PM2.5 and cause-, age-, and location-specific mortality to identify susceptible subpopulations and regions using a nationwide dataset.

METHODS: A two-stage analysis was performed to quantify the associations of PM2.5 with mortality. In the first stage, regional differences in the effects of PM were investigated. A time-series quasi-Poisson model, combined with a distributed lag non-linear model and a flexible functional form of splines, was applied to evaluate the location-specific associations between PM2.5 and mortality. Various covariates were controlled, including weather variables, day of the week, and seasonal and long-term time trends. Stratified analyses were performed by age groups and death cause categories. We used a random-effects meta-analytic model to estimate the pooled cumulative association in the second stage. Potential reasons for the regional heterogeneity of PM2.5 effects were further explored through random-effects meta-regression analyses, separately carried out for multiple variables as meta-predictors.

RESULTS: Geographic variations in the concentration of PM2.5 were observed in Japan. An increase in PM2.5 concentration was associated with an increase in excess risk of mortality, and the magnitude of the corresponding associations appeared to vary by region in Japan.

CONCLUSIONS: The regional risks of premature mortality from exposure to PM2.5 were investigated. We identified vulnerable regions and susceptible subpopulations. The disparity in the association of mortality risks and PM2.5 was apparent between geographical regions, indicating the importance of developing area-specific strategies and local risk prevention plans that can serve as a basis for policymaking to reduce the corresponding health effects.

P-0176 Long-term exposure to low level air pollution and the relationship with lung and bladder cancer in older men, in Perth, Western Australia

Elizabeth Lim[1], Peter Franklin[1], Michelle Trevenen[1], Jane Heyworth[1]
[1]*University of Western Australia, Perth, Australia*

BACKGROUND AND AIM: Ambient air pollution has been classified as a human carcinogen for lung cancer and possible carcinogen for bladder cancer. However, the evidence remains sparse in regions with low ambient pollution. We examined the associations between long-term low level exposure to fine particulate matter (PM2.5), nitrogen dioxide (NO_2) and black carbon (BC), and both lung and bladder cancer.

METHODS: 12 203 men ≥65 years old were recruited (1996-1999) from the Health in Men Study. Air pollutant concentrations at baseline and for the follow-up period were estimated at participants' residential addresses using land use regression models. Lung and bladder cancer cases up until 2018 were identified through the Western Australian Cancer Registry. We used Cox proportional hazard models, and adjusted for age, smoking, socioeconomic status, and other pollutants.

RESULTS: Lung cancer was associated with annual average follow-up concentrations of: PM2.5 (HR:1.86 per 5 $\mu g/m^3$; 95%CI: 1.42-2.45), NO_2 (HR:1.48 per 10 $\mu g/m^3$; 95%CI:1.25-1.77) and BC (HR:1.49 per 0.5x10-5m-1; 95%CI: 1.30-1.72), increase respectively. Bladder cancer was associated with annual average follow-up concentrations of NO_2 (HR:1.56; 95%CI: 1.15-2.12) and BC (HR:1.47; 95%CI: 1.15-1.88). Two-pollutant models indicated that BC but not NO_2 was associated with increased lung and bladder cancer. Neither NO_2 nor BC attenuated the findings for PM2.5. Baseline concentrations of air pollution was not associated with lung or bladder cancer. In our lung histological subtype analysis, squamous cell carcinoma was associated with PM2.5 (HR:2.09; 95%CI: 1.11-3.91), NO_2 (HR:1.61, 95%CI: 1.09-2.38) and BC (HR:1.68; 95%CI: 1.23-2.30). Adenocarcinoma was also associated with BC (HR:1.40, 95%CI: 1.08-1.82).

CONCLUSIONS: Long-term exposure to low annual concentrations of PM2.5, NO_2 and BC were associated with both lung cancer and bladder cancer incidence among older men. This supports the literature that there is no known safe threshold for air pollution.

KEYWORDS: ambient air pollution, lung cancer, bladder cancer

P-0181 Air pollution and bone mineral density among Women's Health Initiative participants: A mixture analysis

Diddier Prada[1], Carolyn J. Crandall, Yike Shen, Allison Kupsco, Duanping Liao, James D. Stewart, Jeff D. Yanosky, Jean Wactawski-Wende, Nicole C. Wright, Nelson B. Watts, Longjian Liu, Aladdin H. Shadyab, Andrea Baccarelli, Eric Whitsel

[1]*Mailman School of Public Health - Columbia University, New York City, USA*

BACKGROUND AND AIM: Ambient air pollution has been associated with bone damage, but no studies have examined the role of mixtures (i.e., biological effective components) on bone mineral density (BMD) in postmenopausal women.

METHODS: We conducted a prospective study using data from the Women's Health Initiative (WHI, N=9,041 at baseline, postmenopausal women aged 50 to 79 years from 1993 to 1998). We included participants in both the Clinical Trials (CT) and Observational Study (OS), but only those with BMD and air pollution data were included. We used log-normal, ordinary kriging to estimate daily mean PM10 concentrations, NOx, NO2, and SO2 at geocoded participant addresses. We averaged the mean concentrations over 1-, 3-, and 5-year periods before BMD assessments (and T-scores) at the whole-body, total hip, femoral neck, and spine using dual-energy X-ray absorptiometry. After multiple imputation of missing covariates data, we estimated air pollutant-BMD associations in multivariable linear and linear mixed-effects models controlling for correlation of repeated measures and adjusting for several covariates. We also estimated air pollutant mixture-BMD associations using Bayesian kernel machine regression (BKMR).

RESULTS: at baseline, women were on average 63.29 years old (SD: 7.39 years). In cross-sectional analyses, 1-, 3-, and 5-year mean PM10, NOx, NO2, and SO2 were inversely associated with all BMD sites as well as T-scores. In longitudinal analyses, 1- and 5-year mean PM10, NOx, NO2, and SO2 were associated with whole-body BMD. These results suggest that, for example, lumbar spine BMD decreased 0.023 (95%CI: 0.017, 0.028) g/cm2/year per 10% increase in 5-year mean NO2 concentration. Similar associations were observed at other BMD sites. BKMR suggested that only NO2 was inversely associated with BMD at all sites.

CONCLUSIONS: Our findings suggest air pollution, particularly NO2, has clinically relevant effects on BMD and potentially fracture risk in postmenopausal women.

KEYWORDS: Air pollution, bone, osteoporosis.

P-0182 Application of a hierarchical Bayesian model for air pollution prediction in Poland and its association with neurodevelopmental outcomes in children

University of Girona., Girona, Spain, [3]CIBER of Epidemiology and Public Health (CIBERESP), Madrid, Spain, [4]Nofer Institute of Occupational Medicine (NIOM), Lodz, Poland

BACKGROUND/AIM: Air pollution has been associated to adverse health effects. Poland is one of the most polluted countries in Europe in terms of air quality, with levels exceeding the maximum values established by the UE for several pollutants, including PM10 and PM2.5. This study aims to assess whether air pollution exposures during vulnerable periods (pregnancy, early childhood) affects cognitive/psychomotor development of school-age children.

METHODS: Hourly levels from air pollutants (PM10, PM2.5, NO2, O3) for the prenatal period (2006-2008) was obtained from both the European air quality database (EEA) and Polish institutions. Health data was collected from the Polish Mother and Child Cohort prospective study conducted in Poland since 2007, with around 400 pregnant women and their children followed up until the age of 7 years. Neurodevelopmental outcomes were assessed through the Strengths and Difficulties Questionnaire and the Intelligence and Development Scales. Spatial prediction of air pollution levels in a 100km radius around the geolocation where pregnant women lived during a 3-years period was performed using a hierarchical Bayesian spatiotemporal model. Afterwards, multivariate regression models between the predicted air pollution levels and neurodevelopmental outcomes in 7-year old children were applied, including different approaches to account for sex-specific effects.

RESULTS: Median predicted concentrations of PM10, PM2.5, NO2 and O3 at 91 different locations were 19.6 µg/m3, 16.1 µg/m3, 8.4 µg/m3 and 71.7 µg/m3, respectively. Prenatal exposures to O3 were associated with poorer scores on Hyperactivity/Inattention, specifically in boys. Conversely, PMs and NO2 were associated with poorer scores on Fluid IQ and Total Cognition, specially in girls.

CONCLUSIONS: The present study suggests that air pollution exposures during the prenatal period might have an impact on children's development. Due to the diversity of mechanisms involved in child's neurodevelopment, further studies are required in order to elucidate which are the most critical periods of exposure.

P-0183 Exposure to ambient air pollution and oxidative stress biomarkers in the NYU CHES cohort

Deniz Cataltepe[1], Bo Gu[2], Yelena Afanasyeva[2], Mengling Liu[2], Leonardo Trasande[2], Akhgar Ghassabian[2]
[1]University of Massachusetts Chan Medical School, Worcester, USA, [2]New York University Grossman School of Medicine, New York City, USA

BACKGROUND AND AIM: Emerging evidence suggests associations between air pollution exposure and adverse fetal growth, yet the exact mechanisms behind the impaired growth have yet to be elucidated. One possible linkage can be through oxidative stress mechanisms. This study investigates the extent to which exposure to the traffic-related air pollutants NO2 and PM2.5 is associated with urinary concentrations of Oxidative Stress Biomarkers (OSBs) in pregnant women.

METHODS: Participants were 626 pregnant women enrolled in the New York University Children's Health and Environment Study (2016-present). We used a tree-based machine learning method to predict daily NO2 and PM2.5 at residential addresses. Average NO2 and PM2.5 exposures during the first trimester of pregnancy were calculated using daily exposure. OSBs were measured in spot urine samples provided by women at <18, 18-25, and >25 weeks of gestation. Seven OSBs were measured: MDA (malondialdehyde), 8-PGF2α (8−isoprostaglandin F2α), 11−PGF2α (11β−isoprostaglandin F2α), 15−PGF2α (15(R)-prostaglandin F2α), 8,15−PGF2α (8-iso-15(R)-prostaglandin F2α), 8-OHdG (8-hydroxy-2'-deoxy guanosine), and diY (o,o'-Dityrosine). We examined the associations of exposures to air pollutants with OSB levels using linear regression models. We included averaged concentrations of OSBs, adjusted for urinary creatinine levels, and log-transformed for normality. Models were adjusted for sociodemographic characteristics and health-related factors such as body mass index.

RESULTS: In the first trimester, average NO2 exposure was 19.71 ppb and average PM2.5 exposure was 7.81 µg/m3. OSBs were detected in 88.98% of total urine samples. Higher exposure to NO2 in the first trimester was associated with higher MDA (β=0.02 per ppb, 95% CI: 0.01, 0.03, p=0.003) and diY (β=0.02 per ppb, 95% CI: 0.01, 0.03, p=<0.0001). First trimester PM2.5 exposure was associated with higher 15-PGF2α (β=0.13 per µg/m3, 95% CI: 0.04, 0.22, p=0.01).

CONCLUSIONS: Exposure to NO2 and PM2.5 during early pregnancy may influence maternal oxidative stress.

KEYWORDS: Air pollution, pregnancy, oxidative stress biomarkers

P-0185 Examination of effect modification of the relationship between PM2.5 and cardiovascular mortality by particle oxidative potential within two Canadian cities

Susannah Ripley[1], Scott Weichenthal[1]
[1]*McGill University, Montreal, Canada*

BACKGROUND AND AIM: There is evidence that particle oxidative potential modifies effects of fine particulate matter air pollution (PM2.5) on health outcomes in between-cities studies in Canada. Additionally, previous work shows that oxidative potential of PM2.5 varies considerably at the within-city spatial scale. The aim of the present study was to determine if differences in the oxidative potential of PM2.5 at the within-city spatial scale modify the relationship between PM2.5 and cardiovascular mortality.
METHODS: We conducted a cohort study in the Canadian Census Health and Environment Cohort, a population-based cohort based on the Canadian longform Census. We followed participants who lived in the cities of Toronto or Montreal, Canada, at least 2 years in the period 2001-2016 (approximately 12 271 100 person-years in 1 101 000 individuals, rounded for confidentiality). Annual estimates of PM2.5 exposures were assigned from satellite data calibrated with ground-based observations, and oxidative potential was measured on samples of PM2.5 taken at 234 sites across the study area. We used time-varying Cox proportional hazards models to estimate hazard ratios for the effect of PM2.5 on cardiovascular mortality within strata of PM2.5 oxidative potential. Additionally, we estimated hazard ratios for oxidative burden (the product of oxidative potential and PM2.5 exposures).
RESULTS: We did not find evidence that oxidative potential modifies the effect of PM2.5 on mortality from cardiovascular causes (N = approximately 6100 events). The overall relationship between PM2.5 exposures and cardiovascular mortality was not significantly different from the null, and the same was true for oxidative burden measures.
CONCLUSIONS: Spatial variability in PM2.5 and the oxidative potential of PM2.5 may be insufficient for OP to act as a modifier of the effect of PM2.5 on cardiovascular mortality within the cities of Toronto and Montreal.

KEYWORDS: fine particulate matter, oxidative potential, outdoor air pollution, cardiovascular disease

P-0186 Association between long-term exposure to ultrafine particles and ischemic heart disease mortality in Montreal, Canada: an open cohort study

Martin Resua Rojas[1], Julien Vachon[1], Stéphane Buteau[2], Elhadji Anassour Laouan-Sidib[2], Marianne Hatzopoulouc[3], Scott Weichenthal[4], Audrey Smargiassi[1,2,5]

[1]Department of Environmental and Occupational Health, School of Public Health, University of Montreal, Montreal, Canada, [2]Institut national de santé publique du Quebec (INSPQ), Montreal, Canada, [3]Department of Civil and Mineral Engineering, University of Toronto, Toronto, Canada, [4]Department of Epidemiology, Biostatistics, and Occupational Health, McGill University, Montreal, Canada, [5]Public Health Research Institute, University of Montreal, Montreal, Canada

BACKGROUND AND AIM: Ischemic heart disease (IHD) is the leading cause of death globally and its incidence is expected to increase worldwide due to the ongoing epidemiological transition observed worldwide and aging populations. Long-term exposure to ambient fine particles is associated with cardiovascular mortality. Exposure to ultrafine particles (UFPs) may explain part of this association, but evidence remains scarce. We investigated the association between long-term exposure to UFPs and IHD mortality using a population-based cohort in Montreal, Canada.

METHODS: The open cohort was constructed from health administrative databases and included all adults 45 years and older who were residents of Montreal between 2001-2015. IHD deaths were identified with codes from the International Classification of Diseases nine and tenth revisions. Annual UFP concentrations were estimated with a land use regression model developed for Montreal. Time-varying exposure was assigned to participants using their residential postal codes throughout the follow-up. The association between annual mean concentration of UFPs and IHD mortality was estimated with a Cox proportional hazard model stratified for sex, calendar year and material deprivation.

RESULTS: The cohort included 572,883 adults, with 52,327 IHD mortality cases over the follow-up. Annual average UFP exposure was 24,388 particles/cm3 with an interquartile range (IQR) of 3,448 particles/cm3. Annual mean UFP exposure was positively associated with IHD mortality in both the crude model (HR per IQR: 1.03, 95% CI: 1.03-1.04) and the fully adjusted model (HR per IQR: 1.02, 95% CI: 1.01-1.02).

CONCLUSIONS: In this population-based cohort, we found a small positive association between annual UFP exposure and IHD mortality. Further studies with additional adjustments are needed to improve the current evidence.

P-0189 Short-term exposure to ultrafine particles and mortality in Copenhagen, Denmark

Marie Bergmann[1], Zorana J. Andersen[1], Heresh Amini[1], Andreas Massling[2], Paula A. Kindler[3], Steffen Loft[1], Rina So[1], Jiawei Zhang[1], Matija Maric[1], Tom Cole-Hunter[1], Youn-Hee Lim[1]

[1]Section of Environmental Health, Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [2]Department of Environmental Science, iClimate, Aarhus University, Denmark, [3]RM Umweltkonsulenten ZT GmbH, Salzburg, Austria

BACKGROUND&AIM: Ultrafine particles (UFP; particulate matter <100 nm in diameter) may be more harmful to human health than larger particles, but epidemiological evidence on their health effects is still limited. In this study, we examined the association between short-term exposure to UFP and mortality in Copenhagen, Denmark.

METHODS: Daily levels of size-aggregated ultrafine, accumulation mode and combined ultrafine and accumulation mode particles (10-110, 110-700, 10-700 nm), expressed as particle number (PNC), surface area (PSC) and volume concentration (PVC) together with meteorological factors were monitored at an urban background station in central Copenhagen during 2004 - 2015. Daily counts of all-cause natural, cardiovascular, and respiratory mortality in Copenhagen were obtained from the Danish Register of Causes of Death. Odds ratios (OR) with 95% confidence intervals (CI) of mortality associated with interquartile range (IQR) increases in exposure on the day of death and up to four days before were estimated using case-crossover design, accounting for temperature and relative humidity.

RESULTS: We observed 98,929 all-cause natural, 28,876 cardiovascular, and 11,642 respiratory deaths. for all-cause natural mortality, we found significant associations mainly with exposure to larger, accumulation mode particles, lagged by one day: an IQR increase in PNC (110-700 nm) was associated with an increase in mortality [OR: 1.02 (95% CI: 1.00, 1.03)]. The strongest association was observed with respiratory mortality, with an OR of 1.08 (95% CI: 1.02, 1.14) per IQR increase in PNC in the ultrafine range (10-110 nm) on the same day. We detected null associations with cardiovascular mortality.
CONCLUSION: We present novel findings that short-term exposure to UFP may be associated with mortality in Copenhagen. Particles in the accumulation mode were most strongly associated with all-cause natural mortality, while particles in the ultrafine size range seemed most relevant for respiratory mortality.

KEYWORDS: Air pollution, Epidemiology, Mortality, Particulate Matter

P-0190 Characterizing Impacts of Smoke Exposure from Prescribed Burns on Adverse Respiratory Health Outcomes in Georgia, USA, 2015-2018

Ambarish Vaidyanathan[1], Talat Odman[2], Antonio Gasparrini[3], Yongtao Hu[2], Joy Hsu[1], Shubhayu Saha[4], Jennifer Stowell[5], Pierre Masselot[3], Gregory Wellenius[5], Armistead (Ted) Russell[2]

[1]Centers for Disease Control and Prevention (cdc), Atlanta, USA, [2]Georgia Institute of Technology , Atlanta, USA, [3]London School of Hygiene and Tropical Medicine, London, UK, [4]Office of Climate Change and Health Equity, Washington, USA, [5]Boston University, Boston, USA

As the frequency and intensity of wildfires have been increasing, the use of prescribed fire as a strategy to reduce wildfire risk and keep the forest ecosystems healthier has also increased. Our objective was to evaluate associations between fine particulate matter concentrations from prescribed fires (fire PM2.5) and adverse respiratory health outcomes, using spatiotemporal exposure models and regression techniques.

Our assessment examined employer-based health insurance claims for adverse respiratory health outcomes for a period between January 1 and April 30 2015-2018, in the state of Georgia, USA. We examined medication fills, emergency room (ER) visits, and hospitalizations for asthma and other respiratory health conditions. We linked these outcomes with fire and non-fire-related concentrations of air pollutants, using a data fusion approach combining source-apportioned chemical transport model output with measurements. A conditional quasi-Poisson regression with year/month/day/place strata, in combination with a distributed lag non-linear model, was used to measure the effect of fire PM2.5 exposure on adverse health outcomes. This regression framework accounted for a multi-day lag period and included additional predictors, such as nitrogen dioxide, non-fire related PM2.5, temperature, and an index for influenza-like illness activity levels.

Health risks associated with fire PM2.5 exposure for adverse respiratory hospitalizations and ER visits were not statistically significant. However, the estimated risk ratio associated with a 10 µg/m3 increase in fire PM2.5 exposure for asthma medication fills was 1.077 (95% confidence interval: 1.030–1.127). Delayed effects of initial fire PM2.5 exposure persisted for 3-5 days, and effect sizes varied depending on the type of medication (quick-relief vs. long-term controller).

Our results increase understanding of health effects associated with prescribed burns. A comprehensive strategy to mitigate adverse health impacts associated with wildland fires should also account for fire PM2.5 exposure resulting from land management practices, particularly for populations residing close to prescribed burn sites.

P-0191 Exploring 50-years of fungal spore counts and GP consultation rates for asthma to explore their potential association

Samuel Anees-Hill[1], Philippa Douglas[2], Catherine Pashley[3], Emma Marczylo[4], Anna Hansell[1]
[1]Centre for Environmental Health and Sustainability - University of Leicester, Leicester, UK, [2]Environmental Hazards and Emergencies Department, UK Health Security Agency, UK, [3]Department of Respiratory Sciences, University of Leicester, Leicester, UK, [4]Toxicology Department, UK Health Security Agency, UK

BACKGROUND AND AIM: High concentrations of outdoor airborne fungal spores have been associated with allergic sensitisation and exacerbation of asthma. In the UK, both fungal spore prevalence and episodic asthma display strong, overlapping seasonal characteristics, yet little research has been performed on their association. Counts for 50-years of UK-based, outdoor fungal spores and general practitioner (GP) consultations for asthmatic episodes will be analysed to investigate their association in a multivariate context.

METHODS: Airborne fungal spore and pollen counts were performed in Derby/Leicester. These counts, along with publicly available data for air quality (DEFRA) and meteorological (Met Office) variables were aggregated to weekly sums or averages to match the resolution of national counts for GP consultations for asthma (Royal College of General Practitioners). Weekly counts for respiratory viral infections (UKHSA) and bank/school-holiday dates were also obtained for consideration as potential confounding effects. Time-series analyses will be used to explore a causal pathway between fungal spore counts and the rate of GP consultations for asthma.

RESULTS: Descriptive analyses reveal varying seasonal trends for all counted variables. Peak asthma consultations in September, commonly known as 'back to school asthma', coincide with high airborne fungal spore concentrations for many allergenic taxa. Sharp peaks for varying fungal taxa are shown to occur at varying points across a year and may be related to spikes in asthma consultations.

CONCLUSIONS: This analysis will utilise perhaps the longest-running aerobiological sampling dataset within the UK. The temporal range of this data may be required to account for long-term fluctuations in fungal spore counts which can span multiple decades. It is hoped this ongoing analysis will help to understand the role of fungal spores in healthcare-seeking behaviour for asthma.

KEYWORDS: Fungi, asthma, outdoor

P-0194 Exposure to Air Pollution and the Nasal Microbiome in Children

Joanne Sordillo[1], Dong-Binh Tran[2], George Weinstock[2], Sheryl Rifas-Shiman[1], Brent Coull[3], Heike Luttmann-Gibson[3], Joel Schwartz[3], Itai Kloog[3], Emily Oken[1], Diane Gold[3,4]

[1]Harvard Pilgrim Health Care Institute, Boston, USA, [2]The Jackson Laboratory, Farmington, USA, [3]Harvard TH Chan School of Public Health, Boston, USA, [4]Channing Division of Network Medicine, Boston, USA

BACKGROUND AND AIM: Pollution induced damage to the respiratory epithelium may shift its resident microbial community. We examined associations of air pollution with the nasal microbiome in children.

METHODS: We collected nasal microbiome samples in early adolescence (mean age 12.9 years) from the anterior nares of 286 participants in Project Viva, a pre-birth cohort. Participants were white (66%), Black (15%), Hispanic (4%), Asian (3%) and more than one race/ethnicity (12%). We considered three PM2.5 exposure windows (mean ± SD, µg/m3) prior to nasal sampling (1 day (7.4± 3.0), 1 week (7.4± 2.0), 1 month (7.3± 1.5)). We sequenced the bacterial microbiome by 16S (V1-V3) and summarized OTUs by genus. We modeled both abundance of individual taxa (log-transformed) and PAM derived cluster states (Jensen-Shannon Distance) as outcomes, using MaAsLin2 linear models and multinomial regression, respectively. We adjusted models for age, race/ethnicity, sex, BMI, maternal education, sine and cosine of season, and household smoking.Effect estimates are for a 1-unit PM2.5 increase.

RESULTS: Past week PM2.5 exposure was nominally associated with increased Propionibacterium (Beta=0.02, p=0.046). Past month PM2.5 was associated with increased Neisseriaceae (unclassified genera) (Beta=0.018, p=0.006) and Porphyromonas (Beta=0.002, p=0.02). Six cluster states were identified in participants (Propionibacterium dominant (N=26%), Neisseriaceae dominant (N=10%), Staphylococcus dominant (N=18%), Streptococcus dominant (N=13%), Corynebacterium dominant (N=28%), and Moraxella dominant (N=5%)). for past month PM2.5, odds of Neisseriaceae cluster membership were increased (OR=1.53, 95% CI 1.19 to 1.99), while odds of Moraxella cluster membership were decreased (OR=0.68, 95% CI 0.58 to 0.78) as compared to the Corynebacterium cluster. Prior day PM2.5 was not associated with the microbiome.

CONCLUSIONS: Short term PM2.5 exposure may alter nasal microbiome community cluster states in children. The potential health implications of air pollution associated changes in the host microbiome have yet to be explored but represent a new avenue for research.

P-0196 Physical and Mental Health Symptoms After a Hydrogen Sulfide Disaster in Southern Los Angeles County, CA, USA

Arbor Quist[1], Jill Johnston[1], Brandi Williams-Murdock[2]
[1]University of Southern California, Los Angeles, USA, [2]Murdock Community and Care Services, Inc, Carson, USA

BACKGROUND: In October 2021, over 4,000 complaints of noxious odor, headaches, and breathing problems were reported among residents living near the Dominguez Channel—a flood control waterway in Southern Los Angeles County. Hydrogen sulfide (H2S), a toxic odorous gas, was measured along the Channel at concentrations up to 230 times the state acute air quality standard. High H2S concentrations lasted for six weeks before returning to below-standard levels. Because residents continue to experience odors and health symptoms, we aimed to assess the acute and intermediate-term physical and mental health symptoms related to this disaster.

METHODS: We partnered with two community organizations to educate residents on H2S and to design a health survey. We used the Impact of Event Scale-Revised to assess post-traumatic stress disorder-related (PTSD) symptoms. We recruited participants in high- and low- exposed areas through social media, door-to-door outreach, community events, and postcards.

RESULTS: of the 86 current respondents, 66% noted that the odor worsened their physical health and 57% indicated worse mental health. Among respondents with asthma, 60% noted that asthma was worse during the event. The proportion of high exposed respondents (<2 km from Dominguez Channel) reporting difficulty breathing, headaches, and anxiety during the first week of the odor was 1.5, 1.3, 1.6 times higher, respectively, than among low exposed (>2 km) residents. Although a smaller percent of high exposed respondents reported burning eyes and runny nose than low exposed respondents, overall, 31% and 42% of respondents reported these symptoms, respectively. The percent of high exposed respondents with a probable PTSD diagnosis was 1.3 times higher than the percent of low exposed residents.

CONCLUSIONS: Malodors are often under-prioritized in environmental justice communities. The Dominguez Channel H2S incident harmed the mental and physical health of nearby residents.

KEYWORDS: respiratory outcomes, asthma, mental health outcomes, environmental justice, community outreach

P-0198 Associations of outdoor fine particulate matter (PM2.5) air pollution and symptoms of depression in the Prospective Urban Rural Epidemiology (PURE) study

Svetlana Zdero[1], Michael Brauer[1,4], Perry Hystad[2,4], Selina Rajan[3,4], The PURE team[4]

[1]School of Population and Public Health, University of British Columbia, Vancouver, Canada, [2]College of Public Health and Human Sciences, Oregon State University, Corvallis, USA, [3]Department of Health Services Research and Policy, London School of Hygiene & Tropical Medicine, Tavistock Place, UK, [4]Population Health Research Institute, McMaster University and Hamilton Health Sciences, Hamilton, Canada

BACKGROUND/AIM: Emerging evidence suggests that outdoor fine particulate matter (PM2.5) exposure may be a risk factor for major depressive disorder (MDD). The Prospective Urban Rural Epidemiology (PURE) study provides the opportunity to assess this association using a large global cohort with comprehensive covariate data. Within this cohort, long-term PM2.5 exposure has been linked to cardiovascular disease, and increased risk of cardiovascular disease has been linked to having depressive symptoms. We built on this work by evaluating associations between outdoor PM2.5 and depressive symptoms at cohort baseline, across countries of different levels of economic development.

METHODS: In the PURE study, adults aged 35-70 from 21 high-, middle-, and low-income countries were assigned 3-year rolling mean outdoor PM2.5 estimates, based on their community of residence. Estimates were derived from ground monitoring, satellite retrievals, and chemical transport models. Participants completed the Short-Form Composite International Diagnostic Interview (CIDI-SF), for which validation studies indicate that reporting ≥ 4 of 7 symptoms is predictive of MDD. Multivariate regression models will be used to estimate associations between PM2.5 concentrations and CIDI-SF scores.

RESULTS: of 202,131 participants that enrolled in the PURE study (01/2003 – 07/2018), 155,447 had complete information on exposures, covariates, and depressive symptoms. The mean (SD) age was 50.9 (9.7) years, and 59.1% participants were female. The mean (SD) 3-year outdoor PM2.5 concentration at baseline was 47.5 µg/m³ (32.6), ranging from 6 µg/m³ in Vancouver, Canada to 140 µg/m³ in Jaipur, India. 19.5% of participants reported feeling sad, blue, or depressed for two weeks or longer in the past year, and 12.2% reported ≥ 4 depressive symptoms.

CONCLUSIONS: The findings of this project can help evaluate the association between outdoor PM2.5 exposure and MDD on a multinational scale, and further establish the roles of related risk factors.

KEYWORDS: Ambient air pollution, mental health, depression

P-0199 Long-term exposure to air pollution and incidence of 922 health outcomes in a phenome-wide association study: Danish nationwide administrative cohort

Zorana Jovanovic Andersen[1], Emilie Hegelund[1,2], Youn Hee Lim[1], Steffen Loft[1], Rudi Westendorp[1,3], Bert Brunekreef[4], Gerard Hoek[4], Kees de Hoogh[5], Laust Hvas Mortensen[1,2]

[1]University of Copenhagen, Copenhagen, Denmark, [2]Statistics Denmark, Copenhagen, Denmark, [3]Center for Healthy Aging, Copenhagen, Denmark, [4]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, [5]Swiss Tropical and Public Health Institute, Basel, Switzerland

BACKGROUND: Air pollution poses substantial burden on human health, but typically, epidemiological studies address only a single, or several related diseases at the time. The aim of this study was to investigate the associations of long-term exposure to PM2.5 and NO2 with incidence of all health conditions among adults aged 30 years or older in Denmark 2000-2017.

METHODS: We included 3,323,612 Danish residents aged ≥30 years on 1.1.2000. Annual average for PM2.5 and NO2 in 2010 were estimated from European-wide hybrid LUR models (100x100m resolution) at the individuals' baseline residential address. Incidence of 922 health outcomes defined using entire ICD-10 chapter were extracted from the Danish National Patient Register and the Register of Causes of Death until 31.12.2017. The associations of PM2.5 and NO2 with health were estimated by use of Cox regression models accounting for age, sex, country of origin, cohabitation status, education, occupational status, income, and municipality.

RESULTS: Long-term exposure to PM2.5 and NO2 were positively associated with >700 (>80%) and inversely with 12-19% of the 922 health conditions. Considering the most common diseases, strongest associations were detected with chronic obstructive pulmonary disease, type 2 diabetes mellitus, ischaemic heart disease, heart failure, pneumonia, and myocardial infarction, and strongest inverse association with inguinal hernia. We also detected associations with a number of novel outcomes, such as cough, abnormal findings in specimen from respiratory organs and thorax and imaging of the lung, anaemia, tuberculosis, diseases of the liver and eye, mental and behavioural problems, among others.
CONCLUSONS: Using a novel, nationwide phenome-wide association type of approach, we showed that long-term exposure to PM2.5 and NO2 have adverse effects on more than 80% (>700) of all health conditions defined by ICD-10 chapter, illustrating the profound adverse effects of air pollution may have on human health.

KEYWORDS: Air pollution; PM2.5; NO2; PheWAS

P-0201 Short-term effects of exposure to particulate matter concentrations originating from desert dust on mortality in Athens, Greece

Victor Levis[1], Konstantina Dimakopoulou[1], Evangelia Samoli[1], Klea Katsouyanni[1,2]
[1]Department of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, [2]MRC Centre for Environment and Health, Environmental Research Group, Imperial College London, UK NIHR HPRU in Environmental Exposures and Health, Imperial College London, London, UK

BACKGROUND & AIM: Evidence on the independent associations of source-specific particulate matter (PM) exposures with health outcomes is limited. Our aim was to investigate the effects of short-term exposure to PM≤ 10μm (PM10) concentrations originating from windblown desert dust and local sources on mortality.

METHODS: We investigated the effect of exposure to total PM10 concentrations, as well as estimated concentrations originating from desert dust and other sources on total mortality, between the years 2010-2019. We used Poisson regression models to estimate the association between PM10 from different sources, also controlling for possible confounding by season, meteorology, day of the week and holiday effect.

RESULTS: During the 10-year study period, 35% of days were affected by desert dust (desert dust PM10> 0μg/m3). An increment of 10μg/m3 in total PM10 concentrations was associated with a 0.52% (lag 0–1, 95% confidence interval (CI): 0.21, 0.83%) increase in natural mortality. When mutually adjusting non-desert and desert dust PM10 concentrations, a 10μg/m3 increase in non-desert was associated with a 0.45% (95% CI: 0.07% to 0.84%) increase in natural mortality. On the other hand, the effect of desert PM10 (lag 0-1 days) concentrations was non-significant (0.59%; 95% CI: -0.53% to 1.72%).

CONCLUSIONS: Our findings support the hypothesis that daily exposure to traffic-related particles have more toxic effects, compared to ones originating from windblown desert dust, in Athens, Greece leading to increased mortality.

P-0204 The Association of Visibility and Adenocarcinoma Lung Cancer in Southern Taiwan

Wei-chi Lin[1], Ruei-Hao Shie[2], Chi-Hsin S. Chen[3], Tzu-Hsuen Yuan[4], Chang-Chuan Chan[5]
[1]Institute of Environmental and Occupational Health Sciences, National Taiwan University, Taipei, Taiwan, [2]Green Energy and Environment Research Laboratories, Industrial Technology Research Institute, Hsinchu, Taiwan, [3]College of Public Health, National Taiwan University, Taipei, Taiwan, [4]Department of Health and Welfare, University of Taipei, Taipei, Taiwan, [5]College of Public Health, National Taiwan University, Taipei, Taiwan

BACKGROUND/AIM:
Studies on association between lung cancer and long-term exposure to air pollution are limited due to the unavailability of air pollution data. The study aims to assess association of visibility, a proxy indicator of long-term air pollution exposure, with adenocarcinoma lung cancer.

METHODS: Our study area is in southern Taiwan, an industrial area with 2.7 million people in 5.7 thousand km². Annual lung cancer incidence data with the ICD-O-3 codes from C34.0-C34.9 were obtained from Taiwan Cancer Registry (TCR) from 1997 to 2018. Age-adjusted incidence of lung cancers were standardized by the WHO 2000 world standard population. Hourly atmospheric visibility data from 1961 to 2022 were obtained from Taiwan Central Weather Bureau. 30-years moving averages were then calculated from 1967 onward to represent long-term visibility in the study area. Linear regression models were employed to estimate associations of 30-years averaging visibility annual age-adjusted lung cancers incidence for both adenocarcinoma and non-adenocarcinoma from 1997 to 2018.

RESULTS: From 1997 to 2018, southern Taiwan's adenocarcinoma lung cancer incidence increased from 8.93 to 25.81 per 100,000 population, while non-adenocarcinoma incidence decreased from 14.61 to 10.41 per 100,000 population. The 30-years averaged visibility in the study area declined from 14.90 km to 7.65 km in the same period. Reducing visibility is significantly associated adenocarcinoma lung cancer, with a 2.43% (95% confidence interval [CI]: 2.77-2.11, adjusted R2 value: 0.92) increase in incidence by 1 km decrease in visibility during this period. Such associations exist for both females and males with increasing incidence of 2.57% (95% CI: 2.92-2.22, adj R2: 0.92) and 2.32% (95% CI: 2.69-1.95, adj R2: 0.89) by 1 km visibility reduction, respectively. By contrast, visibility reduction was not associated with increased in non-adenocarcinoma incidence.

CONCLUSIONS: Long-term visibility reduction is associated with increase in adenocarcinoma lung cancer incidence but not with non-adnocarcinoma.

P-0205 Association between short-term exposure to fine particulate matter components and cause-specific mortality in Korea: a multi-city time-series study

Kyungpil Kim[1], Jong-Tae Lee[1,2]

[1]Interdisciplinary Program in Precision Public Health, Department of Public Health Sciences, Graduate School of Korea University, Seoul, Republic of Korea, [2]School of Health Policy and Management, College of Health Sciences, Korea Universit, Seoul, Republic of Korea

BACKGROUND/AIM:
Many studies have reported fine particulate matter (PM2.5) has various health effects. The effects of PM2.5 have been shown to vary in space and time. One of the underlying explanations was the variability in the distribution of chemical components in PM2.5. Therefore, identifying whether the health effects of each component of PM2.5 differ can provide evidence for the heterogeneous mortality risk of PM2.5. Our study aims to estimate the associations between short-term exposure to components and cause-specific mortality across six major cities in Korea.

METHODS: Daily mass concentration of PM2.5 and 25 components of PM2.5 were obtained from the National Institute of Environmental Research for 2012-2019. We used six intensive air monitoring stations in each of the six major cities: Seoul, Incheon, Daejeon, Gwangju, Ulsan, and Jeju. We employed a two-stage analysis. In the first stage, we conducted generalized additive model with quasi-Poisson regression to estimate city-specific associations of mortality with PM2.5 and its components on the same day. We excluded Asian dust days and adjusted the model for temperature, relative humidity, and time trend. In the second stage, we used fixed-effects meta-analysis to pool the city-specific estimates.

RESULTS: We could not find statistically significant association of PM2.5 and all components with all-cause mortality. Potassium was associated with 2.2% increment (95% CI:0.4%, 4.0%) in cardiovascular mortality per IQR increase (0.24μg/m3). Magnesium ion was associated with 0.7% increment (95% CI: 0.1%, 1.4%) in respiratory mortality per IQR increase (0.01μg/m3).
CONCLUSION: This study suggests potential adverse health effects of particles produced by dust, salt, or traffic. In contrast to previous studies, our results showed no association of elemental carbon or nitrate with any mortality. Further study would be needed to account for the joint and lagged effect of components and meteorological variables.

P-0208 A randomized crossover trial of portable in-home air purifiers for highway PM and cardiovascular risk: HAFTRAP study update

Doug Brugge[1], Neelakshi Hudda[2], Anil Gurcan[1], Amy Mertl[1], Teresa Vazquez-Dodero[1], Shir Ginzburg[1], Chermaine Morson[3], Warren Goldstein-Gelb[4], Francesca Majluf[5], John Durant[2], Mohan Thanikachalam[2], Scott Hersey[5], Wig Zamore[6], Linda Sprague Martinez[7], Misha Eliasziw[2]

[1]University of Connecticut, Farmington, USA, [2]Tufts University, Boston, USA, [3]Mass Mobile Phlebotomy, Boston, USA, [4]The Welcome Project, Somerville, USA, [5]Olin College, Needham, USA, [6]Somerville Transportation Equity Partnership, Somerville, USA, [7]Boston University, Boston, USA

BACKGROUND AND AIM: We have shown previously that cardiovascular biomarkers are associated with traffic-related air pollution (TRAP) near highways and that reducing particulate exposure improves blood pressure (BP) in controlled settings. Our aim here is to assess the efficacy of portable in-home high-efficiency particle arrestance (HEPA) air purifiers to reduce indoor concentrations of TRAP and therefore reduce BP and systemic inflammation in a real world, lived-in setting.

METHODS: We are conducting a randomized crossover trial of air purifiers in homes <200m from a major highway. Participants receive real or sham filtration for one month each separated by a one-month wash out period. We collect peripheral and central BP, as well as blood samples for inflammatory biomarker analysis before and after each one-month period. We also conduct air monitoring and satisfaction interviews with a subset of homes and participants.

RESULTS: A sample of 57 participants has been enrolled with recruitment ongoing. Thirty-three percent live within 100m of the highway. The average age of participants is 44 years (range: 30-78 years), 68% are female, and 37% are racial/ethnic minorities. The mean (SD) baseline peripheral and central systolic BP are 123 (14) mmHg and 113 (13) mmHg, respectively. Indoor and outdoor PNC measurements indicate that median concentrations were 40-60% lower during HEPA than SHAM and during HEPA use indoor concentrations were 60-70% lower than outdoors. Data on electricity use and quantitative and qualitative feedback suggest air purifiers were on the medium setting most of the time.

CONCLUSIONS: Approximately one-third of the way to our recruitment goal we have good acceptance and compliance with the intervention, quality data and indications that the air purifiers are reducing TRAP as intended. An interim analysis of health outcomes should be possible in a year.

P-0209 Demand for environmental health technologies: a clean cookstove experiment in Northern Ghana to investigate effects of prices and peers

Katherine Dickinson[1], Zachary Brown[2], Maxwell Dalaba[3]
[1]Colorado School of Public Health, Aurora, USA, [2]North Carolina State University, Raleigh, USA, [3]University of Health and Allied Sciences, Ho, Ghana

BACKGROUND AND AIMS: Across a wide range of environmental health issues, understanding the drivers of technology adoption and behavior change is key to achieving exposure reductions. In areas reliant on biomass for cooking, reducing exposure to household air pollution requires shifts toward cleaner cooking technologies. We conducted an experiment in Northern Ghana to assess how prices and peer effects shape demand for two models of improved cookstoves.

METHODS: Our experiment involved offering stoves at randomized prices to peers and non-peers of households who received free stoves during a prior study. This experimental design allows us fully estimate a two-good demand system for the high- and low-end stoves, and to econometrically identify complex changes in demand for these goods owing to peers' adoption of the stoves.

RESULTS: The peer treatment only affected demand for the less familiar and more expensive stove, making users less price-sensitive while leaving aggregate willingness to pay unchanged. We also find evidence that users found the two stoves offered to be complements: users preferred purchasing one of each stove over purchasing two of either stove. Estimated price elasticity effects translate into substantial positive or negative impacts to the predicted cost-effectiveness of subsidies for these technologies, depending on marketing costs and the relative performance of the two stoves.

CONCLUSIONS: Programs and policies that seek to expand use of health-improving technologies must examine how social context and prior experiences with similar technologies among peers shape households' decision. "Market spoilage" is a risk when low-quality products are distributed in free trials, and these risks should be considered in the design of environmental health promotion strategies.

KEYWORDS: Peer effects, social learning, environmental health, cookstoves, demand modeling

P-0210 Acceptability of air purifiers to reduce traffic-related particulate exposure near a highway

Doug Brugge[1], Anil Gurcan[1], Teresa Vazquez-Dodero[1], Neelakshi Hudda[2], Amy Mertl[1], Shir Ginzburg[1], Wig Zamore[3], Warren Goldstein-Gelb[4], Misha Eliasziw[2], Linda Sprague Martinez[5]
[1]University of Connecticut, Watertown, USA, [2]Tufts University, Boston, USA, [3]Somerville Transportation Equity Project, Somerville, USA, [4]The Welcome Project, Somerville, USA, [5]Boston University, Boston, USA

BACKGROUND AND AIM: Traffic-related ultrafine particle pollution near highways has been associated with adverse health. Reducing exposure by use of portable air purifiers in homes is one way to try to reduce this risk. However, acceptability of having air purifiers in homes is not well studied.

METHODS: We collected data via questionnaires (N=43 surveys at the end of the first month of the intervention), interviews (N=19) and HOBO monitors on air purifiers (N=14) from participants in our randomized crossover trial of air purifiers in homes near a major highway.

RESULTS: From survey questions, only 17% and 12% were bothered by noise of the air purifier in the living room and bedroom, respectively. Most survey respondents, 75% and 68%, again for living room and bedroom, reported they set the air purifier to medium air flow. In qualitative interviews, Seventy-four percent (74%) reported that they did not move their air purifiers, but 63% changed the fan speed, many to reduce noise or air flow. Only 21% said that they ever turned it off. Space, noise, airflow and energy consumption were the main concerns from interviews, while cleaner air, improved symptoms and white noise were positives. Data on electricity use indicates >95% compliance of use on a consistent setting (majority choose medium) during our intervention. We have had few participants drop out after their first home data collection visit, with 36 completing the entire intervention, 20 still actively in the intervention and only one lost to follow-up.

CONCLUSIONS: Evidence from surveys, interviews and HOBO monitors suggests that a small minority of participants were bothered by noise, space issues or air movement from the air purifiers and that they are largely accepted and used by residents near a highway, albeit on settings below maximal air flow.

P-0211 Historical Concentration Estimates for Air Pollutants for the Purpose of Health RiskAssessment and Epidemiological Studies of Chronic Diseases in Relation to Long-Term orLifetime Exposures

Jiri Michalik[1,2], Ondrej Machaczka[1], Vitezslav Jirik[1,3]

[1]Centre for Epidemiological Research, Faculty of Medicine, University of Ostrava, OSTRAVA, Czech Republic, [2]Public Health Institute Ostrava, OSTRAVA, Czech Republic, [3]Department of Epidemiology and Public Health, Faculty of Medicine, University of Ostrava, OSTRAVA, Czech Republic

BACKGROUND AND AIM: Estimates of historical concentrations are necessary when epidemiological studies on chronic
diseases, especially oncological diseases, need to relate to lifetime exposure to air pollutants. The aim was to develop a methodology to obtain the most reliable estimates of annual average historical pollutant concentrations, which are further applied to the evaluation of long-term exposure.
METHODS: A combination of air quality monitoring data, a modelled of five-year average pollutant concentrations in a grid 1x1 km and a number of spatial and time correlations of PM10, PM2.5, NO2, SO2, benzene, and B(a)P concentrations have been used. Subsequently, the data were corrected for residential areas and for emissions balances.
RESULTS: In the period 1997-2019, the result accuracy is mainly influenced by the number and territorial distribution of air quality monitoring stations in the respective district. for the period 1980-1995 concentration estimates are directly related to the 1997 and uses correlations with emission balance data, so is burdened with more uncertainty. The resulting annual concentration data represents six pollutants for 13 evaluated districts for the period 1980 - 2019.
CONCLUSIONS: This work is an original contribution to the interdisciplinary field of environmental epidemiology, dealing with the relationship between long-term or lifetime exposure to air pollutants and the incidence of chronic diseases. The methodology tries to solve the insufficient or different availability of historical input data from pollutant monitoring as effectively as possible.

P-0215 Incidence of medication related to emissions from a large steel plant

Danny Houthuijs[1], Wilco de Vries[1], Jurriaan Hoekstra[1], Ronald Hoogerbrugge[1]
[1]*National Institute for Public Health and The Environment, Bilthoven, Netherlands*

BACKGROUND AND AIM: This study was initiated in 2011 in response to concerns about the risks of emissions from a large steel plant in the Netherlands, as follow-up of a study into lung cancer (Breugelmans et al., 2013). The aim of the study was to assess the relation between the contribution of the steel plant site to local air pollution levels and the incidence of medication in the period 2008-2019.

METHODS: The administrative cohort study included all residents of 18 municipalities around the industrial site (~0.75 million inhabitants). We collected information about the annually incidence of medication for heart diseases, high blood pressure, diabetes, Parkinson's disease in adults and for respiratory diseases in children and adults. The contribution of the site to the concentration of primary PM2.5 (PPM2.5) was modelled annually for the period 2005-2019. We carried out discrete survival analyses with a random effect for district. Effect estimates were adjusted for individual and neighborhood-level covariates and the air pollution from other sources (PM2.5 and nitrogen oxides) and expressed as percentage increase per 0.84 μg/m³ (corresponding to the contrast between low and high exposed areas over time).

RESULTS: The increase in RR for the PPM2.5 contribution from the site was for women and men 13% [6-20] and 11% [5-17] for hypertension medication, 16% [6-28] and 15% [4-27] for diabetes medication, 16% [7-26] and 14% 14 [7-22] for heart disease medication, and 5% [-4 ; 14] and 10% [2 ; 19] for respiratory disease medication, respectively. No positive associations were found for medication for respiratory diseases in persons under the age of 20 and for Parkinson's disease.

CONCLUSIONS: Exposure to airborne emissions from a large steel plant site was associated with the incidence of medication for cardiovascular, metabolic and respiratory diseases in adults.

KEYWORDS: air pollution, medication, steel plant

P-0219 Satellite-derived local air pollution impacts of the household 'coal-to-clean energy' program in Beijing

Martha Lee[1], Mark Goldberg[1], Alexandra Schmidt[1], Guofeng Shen[2], Shu Tao[2], Jill Baumgartner[1,3]
[1]Department of Epidemiology, Biostatistics, and Occupational Health, McGill University, Montreal, Canada, [2]Laboratory for Earth Surface Processes, Sino-French Institute for Earth System Science, College of Urban and Environmental Sciences, Peking University, Beijing, China, [3]Institute for Health and Social Policy, McGill University, Montreal, Canada

BACKGROUND:
In 2015 Beijing started a coal-to-clean energy program that banned coal stoves and subsidized electric- or gas-powered heaters and electricity costs in thousands of peri-urban villages. Our objective was to estimate the effect of this program on satellite-derived $PM_{2.5}$.
METHOD:
We geolocated villages in Beijing and assigned participation status in the program between 2015 and 2018. Average monthly outdoor $PM_{2.5}$ data at a spatial resolution of 0.01°x0.01° grid cell were obtained for heating months (Dec-Feb) from Dec. 2014 to Dec. 2018. We estimated the number of households in each grid cell participating in the program ('treated') for each study month. We used a Bayesian spatiotemporal model to estimate the local effect of household participation in the program on satellite-derived $PM_{2.5}$, adjusting for meteorological conditions (temperature/RH, precipitation, and wind vectors), elevation, imperious surface, presence of villages, and eligibility to participate in the program. We assessed linearity using linear splines.

RESULTS: In the 1768 grid cells with at least one village participating in the program by the end of 2018 (out of 17353 grid cells total), the number of treated households ranged from 1-5290 (median: 155). We observed a small but consistent effect of participating in the coal-to-clean energy program on decreases in local $PM_{2.5}$ whereby for every 10 households treated there was an accompanying 0.03μg/m³ decrease [95%CI:-0.04,-0.02] in grid-cell $PM_{2.5}$ up to 155 households. There was no effect of treatment on $PM_{2.5}$ in grid cells with over 155 treated households.
CONCLUSION: In less-populated areas, we observed modest reductions in satellite-derived outdoor $PM_{2.5}$ at the grid cell level in Beijing after participation in the program. The lack of effect in areas with households is likely due to the presence of other sources of local outdoor $PM_{2.5}$ that masks any $PM_{2.5}$ benefit of the program.

KEYWORDS: Outdoor air pollution; residential coal burning

P-0223 The impact of coal and oil power plants retirements on air pollution and cardiorespiratory health in California: an application of generalized synthetic control design

Chen Chen[1], Sindana Ilango[2], Lucas Henneman[3], Joan Casey[4], Tarik Benmarhnia[1]
[1]University of California San Diego, La Jolla, USA, [2]Department of Epidemiology, University of Washington, Seattle, USA, [3]Department of Civil, Environmental, and Infrastructure Engineering, George mason University, Fairfax, USA, [4]Columbia University Mailman School of Public Health, New York, USA

BACKGROUND AND AIM: Evidence documenting the harmful consequences of ambient air pollution can be advanced by examining the effect of well-defined interventions on air pollution and possible benefits on health outcomes. This study aims to evaluate the effect of coal and oil facility retirements, on fine particulate matter (PM2.5) and cardiorespiratory hospitalizations in California.

METHODS: We identified 15 coal and oil facilities in California that retired between January 1st, 2006 and December 31st, 2013 and estimated the effect of facility retirements with a generalized synthetic control design. We classified California zip codes as exposed or unexposed to a facility retirement using emissions information and a dispersion model. We then estimated the difference in weekly average PM2.5 concentrations and cardiorespiratory hospitalization rate after each facility retirement between the exposed zip codes and the synthetic control generated based on all unexposed zip codes (i.e., the average treatment effect among the exposed [ATE]). Time-fixed (e.g., age distribution) confounding are controlled by study design while time-varying confounders like temperature were adjusted for in the model. We pooled ATEs across facilities using meta-regressions.

RESULTS: The generalized synthetic control performed well with overlapping trends pre-retirement between the exposed zip codes and synthetic controls. The pooled ATE was 0.02 µg/m3 (95% confidence interval (CI): -0.25 to 0.29 µg/m3) for weekly PM2.5. The pooled ATE across all facility retirements was 0.34 per 10,000 person-time (95% CI: -0.08 to 0.75 per 10,000 person-time) for weekly cardiorespiratory hospitalization rates.

CONCLUSIONS: We did not identify reductions in PM2.5 or cardiorespiratory hospitalization rates after oil and coal facility closures in California. The declining contribution of industrial emissions to ambient air pollution in California may explain this observation. We encourage future research to replicate this work in regions with different amounts of industrial activity.

KEYWORDS: Quasi-experimental, natural experiment, air pollution, industrial facility

P-0225 Effect of historical redlining and current-day segregation on air pollution disparities across 143 cities in the USA

Abas Shkembi[1], Lauren Smith[1], Richard L. Neitzel[1]
[1]*University of Michigan, Ann Arbor, USA*

BACKGROUND AND AIM: Systematic racial/ethnic segregation via historical redlining has been identified as a potential contributor to environmental injustices in the US today, particularly air pollution. However, no studies have examined how the effect of current-day racial/ethnic segregation has modified this association. This study examined this hypothesized effect modification on current levels of air pollution (i.e., PM2.5 and diesel PM) across the USA.

METHODS: Current-day demographics and air pollution levels were estimated for USA census tracts using the EPA EJSCREEN. Census-tract-level HOLC grade was assessed using 2010 Historical Redlining Scores, and current-day segregation from the dissimilarity index. We examined differences in air pollution by HOLC grades using city-adjusted, intra-urban air pollution levels from mixed-effects linear regression models using cities as a random intercept to account for city-to-city differences in air pollution levels. We examined our hypothesized effect by investigating the joint effects of redlining (comparing A- and D-grade census tracts) and current-day segregation (comparing low and moderate/high levels of dissimilarity) on log-transformed, population-weighted average diesel PM and PM2.5 levels.

RESULTS: Overall, D-grade air pollution levels are 28% (95% CI: 25% to 31%) and 1.2% (1% to 1.4%) higher than A-grade census tracts for diesel PM and PM2.5, respectively. Moderately/highly segregated, D-grade census tracts have 70% (49% to 95%) times higher diesel PM levels and 5% (0%, 11%) times higher PM2.5 levels compared to lowly segregated, A-grade census tracts. Estimates indicate significant departures from additive (RERI: 24%; 14% to 34%) and multiplicative joint effects (percent change of interaction term: 10%; 3% to 17%) for diesel PM, and similarly for PM2.5 (RERI: 1%, 1% to 2%; percent change of interaction term: 1%, 1% to 2%).

CONCLUSIONS: Current-day segregation modifies the association between historical redlining and air pollution in the USA.

KEYWORDS: environmental justice; redlining; air pollution; effect modification; RERI

P-0227 Air Pollution Exposure and Public Transport in Addis Ababa: Vulnerability Scoping Study

Abel Weldetinsae Kidane[1]
[1]*Ethiopian Public Health Institute, Addis Ababa, Ethiopia*

The effects of air pollution on human health are well documented in a range of epidemiological studies; exposure increases the risk of lung cancer, heart disease, bronchitis and other cardiorespiratory conditions. Whilst, air pollution is considered to impact on all groups, particularly when exposed over prolonged periods of time, some groups are considered to be more susceptible than others. This scoping study explores the vulnerability of commuters, bus drivers and street vendors who are exposed to poor air quality on buses or at bus stations via the deployment of low-cost PM sensors in both indoor and outdoor settings. The study also probed perceptions of commuters, street vendors and bus drivers regarding air pollution. Findings underscore the vulnerability of these groups to air pollution and suggest that those from low socioeconomic backgrounds are likely to face a triple burden of exposure both at home, in work or during commutes. The air pollution levels at both bus station (outdoor) and bus (indoor) settings regularly exceed World Health Organization (WHO) guideline amounts. Bus station PM2.5 were measured to be on average 113 ± 99 µg/m3 and peaked at 323 ± 203 µg/m31. Further to this, air pollution levels tend to peak during early morning and late evening hours, consistently reaching unhealthy levels throughout the day. Measured levels of PM2.5 on buses ranged between PM2.5 49 ± 19 µg/m3 and 105 ± 45 µg/m3 on journeys measured. Survey findings suggest that survey respondents are relatively cognizant of their inherent vulnerability to air pollution, perceiving their vulnerability on a scale of 1-5 at an average of 3.87/5 (five indicating extreme levels of vulnerability). Respondents demonstrated a mixed understanding of the potential sources of air pollution, though this is to be expected given the relative lack of knowledge regarding air pollution in many societies.

P-0232 Particle surface area, ultrafine particle number concentration, and cardiovascular hospitalizations

Shao Lin[1,2], Ian Ryan[1], Sanchita Paul[3], Xinlei Deng[1], Wangjian Zhang[4], Gan Luo[5], Guanghui Dong[4], Arshad Nair[5], Fangqun Yu[5]

[1]Department of Environmental Health Sciences, State University of New York at Albany, Rensselaer, USA, [2]Department of Epidemiology and Biostatistics, State University of New York at Albany, Rensselaer, USA, [3]Department of Environmental & Sustainable Engineering, State University of New York at Albany, Albany, USA, [4]Department of Medical Statistics, School of Public Health, Sun Yat-sen University, Guangzhou, China, [5]Atmospheric Sciences Research Center, State University of New York at Albany, Albany, USA

BACKGROUND AND AIM: While the human health impacts of larger particulate matter, such as PM10 and PM2.5, have been studied extensively, research regarding ultrafine particles (UFPs or PM0.1) and particle surface area is lacking. This case-crossover study assessed the associations between exposure to particle surface area concentration (PSC) and UFP particle number concentration (UFPnc) and hospital admissions for cardiovascular diseases (CVDs) in New York State (NYS), 2013-2018.

METHODS: We used a time-stratified case-crossover design to compare the PSC and UFPnc levels between hospitalization days and control days (similar days without admissions) for each CVD case. We utilized NYS hospital discharge data to identify all CVD cases who resided in NYS. We used UFP simulation data from GEOS-Chem, a state-of-the-art chemical transport model, to define PSC and UFPnc. Using a multi-pollutant model and conditional logistic regression, we assessed CVD risk per inter-quartile change of PSC and UFPnc after controlling for meteorological factors, co-pollutants, and time-varying variables.

RESULTS: Our results indicate an immediate and robust positive association between PSC and overall CVDs (lag0–lag0-1: 1.0%) and a delayed, lasting effect between UFPnc and CVDs (lag0-3–lag0-6: 0.4%). Exposure to larger PSC was associated with immediate increases in stroke, hypertension, and ischemic heart diseases (0.7%, 0.8%, 0.8%, respectively). The adverse effects of PSC on CVDs were highest among youngest children (0-4 years old), in fall and winter, and during cold temperature days (2.0%, 1.4%, 1.3%, 1.5%, respectively) compared to those on other days.
CONCLUSION: We found an immediate, positive effect of PSC on overall CVDs and a delayed, lasting impact of UFPnc. PSC was a more sensitive indicator than UFPnc. The PSC-related effects were higher among certain CVD subtypes, in the youngest children, in certain seasons, and during cold days.

P-0235 Association between long-term and short-term PM2.5 exposure and hospitalizations among a cohort of COPD patients, North Carolina, 2002-2015

Kristen Cowan[2], Lauren Wyatt, Tom Luben, Jason Sacks, Kristen Rappazzo
[1]University of North Carolina at Chapel Hill Department of Epidemiology, Carrboro, USA, [2]Environmental Protection Agency (EPA), Chapel Hill, USA

BACKGROUND: Approximately nine million adults in the USA are living with Chronic Obstructive Pulmonary Disease (COPD). Previous research has reported associations between short-term air pollution exposures and increased risk of hospitalization for COPD in older adults. This study examined associations individually between short-term and long-term PM2.5 exposure and hospitalizations, and whether the association between short-term PM2.5 exposure is modified by long-term PM2.5 exposure in a cohort of individuals with COPD.

METHODS: The study population consists of a cohort of randomly selected individuals with electronic health records from the University of North Carolina Healthcare System that had a COPD diagnosis from 2002-2015 (n=1,429). Estimated ambient PM2.5 concentrations are from a previously validated ensemble model. Poisson regression was used to estimate the Risk Ratios (RR (95%CI)) of cardiovascular disease (CVD) and all-cause hospitalizations with 0-2 day lags of PM2.5, annual average PM2.5 concentrations, and their interactions. Models were adjusted for individual race, and area-level urbanicity, education, unemployment, and proportion on public assistance.

RESULTS: Among the 1,429 COPD patients in our cohort there were 4,302 inpatient hospital visits recorded, including 3,559 CVD-related visits. The mean short-term PM2.5 concentration was 9.62 µg/m3 (IQR 6.77-11.45); the mean long-term PM2.5 concentration was 9.83 µg/m3 (IQR 8.73-10.34). We observed a null association with CVD (RR=1.01 (1.00, 1.02) and a small association with all-cause (RR=1.03 (1.02, 1.04)) hospitalizations per unit increase of short-term PM2.5. There were positive associations between long-term exposure and CVD hospitalizations (RR=1.12 (1.09, 1.16) and all-cause hospitalizations (RR=1.20 (1.17, 1.23)). There was no evidence of interaction between long- and short-term PM2.5 exposures with CVD hospitalizations (RR=1.19 (1.07, 1.32), ICR 0.06) and all-cause hospitalizations (RR=1.21 (1.14, 1.29), ICR -0.02)

CONCLUSIONS: Our preliminary results show associations between short- and long-term PM2.5 and CVD and all-cause hospitalizations among COPD patients, but no evidence of interaction between exposure periods.

P-0236 Chronic Exposure to Fine Particles and Mortality in Chile

Luis Abdón Cifuentes[1], Pablo Busch[2], Camila Cabrera[1]
[1]Pontificia Universidad Católica De Chile, Santiago, Chile, [2]UC at Davis, USA

BACKGROUND and AIM: Cities in the center-south of Chile have high air pollution from industrial, mobile, and residential wood burning sources. Several studies have linked PM2.5 air pollution exposure to higher mortality risk due to cardiovascular, pulmonary, and lung cancer causes. Due to the ambient PM2.5 standard, Chile has developed an extensive monitoring that, along with public access databases for population characteristics and socioeconomic conditions, allows this relationship to be studied. Confirming this relationship in a Latin-American country is important for supporting public policies for pollution abatement.

METHODS: a negative binomial regression model, with data at the municipality level, was used to study the impact of 3-year average PM2.5 exposures on age-adjusted mortality rates, controlling by multiple confounding variables. Models were adjusted for all, cardiopulmonary, cardiovascular, pulmonary, cancer, and lung cancer causes of death.

RESULTS: We found evidence of higher mortality risk for cardiopulmonary (1.06; 95% CI: 1.00, 1.13), pulmonary (1.11; 95% CI: 1.02, 1.20) and cardiovascular (1.06; 95% CI: 0.99, 1.13) causes of death (all for an increase of 10 µg/m3 of PM2.5). The positive associations remained even when controlling for multiple confounding factors, and when considering different methods for exposure characterization. These estimates are in line with previous results from US and European studies.

CONCLUSIONS: PM2.5 pollution exposure, as well as demographic and socioeconomic factors, are associated with age-adjusted mortality rates in Chile, for cardiovascular and pulmonary causes. This result reinforces the need to reduce fine particulate matter air pollution in Chile and other Latin-American countries

KEYWORDS: fine particulate matter; PM2.5; Latinamerica; Cardiopulmonary disease; Age-adjusted mortality rates; Ecological study; negative binomial

P-0238 Prediction of health effects of Asian dust in Japan

Kazunari Onishi[1], Masanori Nojima[2], Tsuyoshi Thomas Sekiyama[4], Yasunori Kurosaki[3], Teruya Maki[5], Youichi Kurozawa[6], Zentaro Yamagata[7]

[1]Division of Environmental Health, Graduate School of Public Health, St. Luke's International University, Chuo-ku, Japan, [2]Center for Translational Research, The Institute of Medical Science Hospital, The University of Tokyo, Tokyo, Japan, [3]Arid Land Research Center, Tottori University, Hamasaka, Japan, [4]Metrological Research Institute, Tsukuba, Japan, [5]Department of Life Science, Faculty of Science and Engineering, Kindai University, Higashiosaka, Japan, [6]Division of Health Administration and Promotion, Department of Social Medicine, Faculty of Medicine, Tottori University, Yonago, Japan, [7]Department of Health Sciences, School of Medicine, University of Yamanashi, Chuo, Japan

BACKGROUND AND AIM: The health effects of cross-border air pollutants and Asian dust are of significant concern in Japan. Currently, models predicting the arrival of aerosols have not investigated the association between arrival predictions and health effects. We investigated the association between subjective health symptoms and data acquired from the Japan Meteorological Agency's (JMA's) Model of Aerosol Species in the Global Atmosphere (MASINGAR) aerosol model with the objective of ascertaining if the data could be applied for predicting health effects.

METHODS: Subjective symptom scores were collected using self-administered questionnaires and used with the JMA model's surface concentration data to conduct a risk evaluation using a multiple linear mixed model, from 2013 to 2015. Altogether, 160 individuals provided 16226 responses. Data regarding climate (temperature, humidity, and atmospheric pressure) and environmental factors (NO2, SO2, and Ox) were used as covariates. We calculated the association between the surface dust concentration and symptoms.

RESULTS: A strong association was also observed for nasal and cough symptoms (P for trend < 0.001). The differences in scores of nasal symptoms (sneezing and runny) of the highest quartile [Q4] vs. the lowest [Q1] were 0.039 (95% confidence interval (CI): 0.02–0.01, $p < 0.05$) and 0.046 (95% CI: 0.002–0.02, $p < 0.05$), respectively. The differences in scores of cough symptoms were 0.036 (95% confidence interval (CI): 0.002–0.01, $p < 0.05$).

CONCLUSIONS: This study suggests that predictive models for pollutants' arrival can be used to capability to foresee and possibly prevent the health impact of long-range transport of air pollutants, recommending the potential role of aerosol forecast models in health care. MASINGAR is the Global Spectral Model (GSM), this has the potential that can contribute to health predictions all over the world.

P-0241 Use of wildfire smoke indicators in health exposure research: high spatial resolution mapping of wildfire-related PM2.5 in California

Nathan Pavlovic[1], Lianfa Li[2], Frederick Lurmann[1], Crystal McClure[1], Jun Wu[4], Rima Habre[2,3]
[1]Sonoma Technology, Inc, Petaluma, USA, [2]Spatial Sciences Institute, University of Southern California, Los Angeles, USA, [3]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, USA, [4]Program in Public Health, Susan and Henry Samueli College of Health Sciences, University of California, Irvine, USA

BACKGROUND: Wildfire smoke is a leading driver of acute exposure to PM2.5 in the American West and a significant contributor to chronic pollution exposure in immediately impacted and further downwind areas. Exposure to wildfire smoke is linked to acute respiratory morbidity and all-cause mortality, yet little is known about chronic effects of repeated, elevated exposures. Inclusion of wildfire smoke in air quality models for health effects research is important for improving accuracy of the overall models and understanding the specific and independent effects of wildfire smoke relative to the entire pollution mixture. However, the nature of smoke, including high spatial variability and the three-dimensional structure of smoke plumes, presents challenges for the accurate representation of wildfire smoke in health research applications. In this presentation, we will discuss exposure and health research applications that use explicit representations of wildfire smoke to improve exposure estimates.

METHODS: We used dispersion modeling of wildfire smoke to predict ground-level concentrations and support a deep learning ensemble model of PM2.5 over California for 2008-2017. Smoke emissions were modeled using satellite detections of wildfires and a database of emissions related to fire radiative energy. Emissions were dispersed using a fine-scale meteorological data set. We assessed the ability of the model to reproduce spatial and temporal patterns of wildfire smoke using visual satellite imagery of smoke and correlations with ground-based monitoring, respectively.

RESULTS: Our results show that the inclusion of smoke dispersion surfaces produces accurate predictions of PM2.5 concentrations in wildfire smoke conditions.

CONCLUSIONS: This work highlights the importance of incorporating wildfire smoke data sources into exposure assessments, and it indicates new directions for use of wildfire smoke data in health research. The extension of our smoke modeling through the high-smoke years between 2018 and 2021 will support important additional research on wildfire smoke exposure health impacts.

P-0243 The NASA TEMPO Mission: Revolutionary Satellite Observations for Community-Scale Air Quality Monitoring and Improved Health Studies

Aaron Naeger[1]
[1]*University of Alabama In Huntsville, Huntsville, USA*

In December 2022, NASA plans to launch the Tropospheric Emissions: Monitoring of Pollution (TEMPO) instrument, a geostationary ultraviolet/visible grating spectrometer, which will observe trace gases and aerosols, including nitrogen dioxide (NO2), sulfur dioxide (SO2), formaldehyde (HCHO), ozone (O3), and aerosol optical depth (AOD), at high spatial resolution (~2 x 4.75 km2) every daylight hour over a Field of Regard (FoR) covering greater North America. An O3 profile product from TEMPO will provide information on O3 in the 0-2 km layer where people live and breathe. TEMPO will also enable observations at even higher frequency (e.g., <= 10 minutes) over smaller regions during special non-standard scan operations. During the pre-launch era of the TEMPO mission, a large diversity of stakeholders and end-users have participated in workshops, data tutorials, and focus sessions hosted by the TEMPO Early Adopters Program, supported by the NASA Applied Sciences Program (ASP), which aims to maximize the societal benefit of the mission data after launch. These user engagement activities have led to a comprehensive understanding of the unprecedented air quality and health applications that can be achieved through use of the highly anticipated data products. In particular, the TEMPO mission will provide multi-pollutant data at high spatiotemporal resolution for enabling more robust and accurate health studies and exposure assessments. This presentation will provide details on the current status of the TEMPO mission, Early Adopter Program activities, and science applications and demonstrations relevant to the epidemiology community.

P-0245 Evaluation of the effects of particulate matter forecasting system on behavior patterns in Seoul, Korea

Yongsoo Choi[1], Garam Byun[1], Jong-Tae Lee[1]
[1]*Korea University, Seoul, Republic of Korea*

BACKGROUND AND AIM: The particulate matter (PM) forecasting system is one of the most prominent political options that can help to reduce the risk of PM. Its goal is to urge people to take avoidance behaviors for upcoming pollution by issuing warnings. In Korea, the national PM10 forecasting system was launched on February 6, 2014. We aimed to estimate the effectiveness of the PM forecasting system in relation to the number of visitors to the Children's Grand Park in Seoul, Korea.

METHODS: We used regression discontinuity design to estimate the effectiveness of the policy from 2014 to 2019. Since the PM forecasting results were not available, the measured PM10 concentration of Seoul was used as a proxy for treatment variable. The cut-off point of the intervention was set to 80ug/m3, the starting point for a "Bad" rating, and the bandwidth was set to 10ug/m3. We further adjusted the daily mean temperature.

RESULTS: When the PM10 concentration exceeds 80ug/m3, the number of visitors to the park decreased by about 15,000. In addition, there was a negative relationship between PM10 concentration and the number of park visitors where pollution levels were over 80ug/m3. The results were statistically significant at the 10% significance level.

CONCLUSIONS: Our result indicates that the PM10 forecasting system seems effective in Korea. According to previous studies in Korea, the risk of PM10 on various health outcomes decreased in recent years. The introduction of the forecasting system and increment in awareness of PM might be possible causes for that change in the PM10 risk.

P-0246 Impact of traffic congestion on near-road black carbon particulate matter and nitric oxide levels

Tamunosai Cookey[1], Donna Spiegelman[1], Linda A. George[3]

[1]Department of Biostatistics, Yale School of Public Health, New Haven, USA, [2]Department of Environmental Science and Management, School of the Environment, Portland State University, Portland, USA, [3]Department of Environmental Science and Management, School of the Environment, Portland State University, Portland, USA

BACKGROUND AND AIM: Most health studies related to traffic-related air pollution (TRAP) link proxies of traffic levels (annual average daily traffic (AADT), distance from roadway, etc.) to health outcomes. These proxies overlook intermittent elevated pollution emissions arising from congested traffic periods. With data from under-pavement vehicle sensor systems, we developed models of traffic behavior and near road air pollution.

METHODS: A suite of air pollutants and meteorological parameters were monitored nearly continuously for one year, between October, 2020-September, 2021, 15 meters from a heavily trafficked freeway. Vehicle speed, % heavy-duty vehicle and vehicle counts were monitored by under pavement sensors near the monitoring station. These data were used to predict black carbon (BC) and nitric oxide (NO) concentrations as a function of the traffic and meteorological parameters using Generalized Additive Models (GAM) with the default convergence criteria. We also compared our NO measurements with C-Line, an emission and dispersion roadway pollution model supported by EPA.

RESULTS: As expected, TRAP levels increased with greater traffic volume and speeds, with an additional super-linear increase observed under high volume, low speed congestive conditions. Fifteen-minute averaged BC data (n=1739) was split into 80% training/20 % test datasets. The BC model using the training dataset explained 43% of the variation in the test data with all predictors significant. GAM predictions of near road NO concentrations were within 20% of the monitored levels while C-Line overpredicted NO by two-fold.
CONCLUSION: Exposure to roadway air pollution can be significantly impacted by traffic behavior, compared with annual averages and/or models based upon proxy roadway variables. U.S. Blacks and Hispanics are twice as likely to live in high traffic density census tracts. Linked to health outcomes, these data may help identify further causes of health disparities, and provide future paths towards the attainment of U.S. environmental justice.

THEMATIC 05: Chemical Exposures

P-0319 Ecological and health risks assessment of lead in environmental and plants in an artisanal mining area in Nigeria

Temitope Laniyan[1], A. J Adewumi[2]
[1]Department of Environmental Health Sciences Faculty of Public Health COllege of Medicine University of Ibadan, IBADAN, Nigeria, [2]Department of Geological Sciences, Achievers University, Owo, Nigeria, IBADAN, Nigeria

BACKGROUND AND AIM: The emission of persistent toxic metals into the environment from artisanal mining remains a major challenge to the environment and risk to public health. Thereby causing severe diseases and eventual death amongst adults and children. The study determined the ecological and health risk assessment of lead emission from gold mining in Arufu, Northeast, Nigeria.

METHODS: Fifty-sixty (56) samples, comprising 30 soils, 10 stream sediments, 6 rocks, 5 mine tailings and 5 plants were collected in areas close to mining excavation. All samples were air-dried and pulverized while rock samples was crushed and pulverized. Samples were analysed for Lead (Pb) using High Performance Liquid Chromatography-Inductively Coupled Plasma-Mass Spectrometry. Statistical evaluations of rate of bioaccumulation of metals in plant and health risk assessment for carcinogenic and non-carcinogenic effect were also assessed.

RESULTS: Mean concentration of Pb in soils, sediments, tailings, rocks and plants are: 1,100 mg/kg, 15,800 mg/kg, 110 mg/kg, 12,756 mg/kg, 7,105 mg/kg and 50 mg/kg, respectively. Bioaccumulation factor showed metal mobility from soil to plant. Ecological risk assessment revealed that Pb poses threat to the environment and metals in all the media pose high carcinogenic and non-carcinogenic health risk especially in children. Pollution load index (PLI) revealed all samples to be highly polluted with Pb due to mining.
CONCLUSION: Mining and geogenic activities contributes significantly to the contamination of media in the area. Lead in the samples poses both carcinogenic and non-carcinogenic health diseases. It is recommended from this study that artisanal mining in the area should be regularly monitored to forestall future epidemic.

P-0322 Systematic Evidence Map of the Epidemiological Evidence for Health Effects of Ethylbenzene

Rachel Shaffer[1], Rebecca Nachman[1], Whitney Fies[2], Courtney Lemeris[2], Alexandra Goldstone[2], Paul Reinhart[1], Laura Dishaw[1]
[1]U.S. Environmental Protection Agency, Washington, USA, [2]ICF, Fairfax, USA

BACKGROUND & AIM: Ethylbenzene is an aromatic hydrocarbon widely used in consumer and industrial applications, including as styrene feedstock and in paints, glues, and fuels. Given that ethylbenzene is one of the most highly emitted hazardous air pollutants, it is relevant to survey the available literature to understand potential adverse health effects. Here, we utilize a systematic evidence map (SEM) approach to identify epidemiological studies of ethylbenzene exposure and characterize aspects of the evidence base that may support human health hazard identification.

METHODS: We developed a Populations, Exposures, Comparators, and Outcomes (PECO) statement to guide our SEM. Searches were conducted in PubMed, Web of Science, and selected grey literature sources. DistillerSR was used to identify PECO-relevant human studies and extract study details. The results are displayed in interactive Tableau® dashboards.

RESULTS: Over 40 epidemiological studies, including cross-sectional, case-control, cohort, and controlled trials, met the PECO criteria. Study participants included samples of the general population (adults), occupational populations, and children/infants. Most studies evaluated exposure to ethylbenzene through air monitoring or modeling, while fewer studies characterized exposure using biomarkers. Immune and respiratory outcomes were the two most commonly evaluated health effects across all study types. Other commonly assessed health effects included sensory, ocular, hematology, and developmental effects.

CONCLUSIONS: Through the SEM, we identified and categorized numerous studies documenting a total of >10 organ systems potentially adversely affected by ethylbenzene exposure. The epidemiological data for ethylbenzene are suitable to inform human health hazard identification. Data gaps can be used to prioritize future research needs.

P-0323 Mixture Toxicity of Perfluoroalkyl Substances to the Kidney in the Elderly: the Application of the Bayesian Kernel Machine Regression to the 2003-2018 US National Health and Nutrition Examination Survey Datasets

Jinyoung Moon[1], Shinhee Ye[2], Hwan-Cheol Kim[1]
[1]Inha University Hospital, Incheon, Republic of Korea, [2]Occupational Safety and Health Research Institue, Incheon, Republic of Korea

INTRODUCTION: Previous studies focused on the independent toxicity of each Perfluoroalkyl Substance (PFAS) on the kidney and did not consider the mixture toxicity of PFASs. In a mixture toxicity study, complex interaction effects among multiple PFASs and a non-linear relationship between PFAS mixture exposure and kidney damage should be considered sufficiently. This study will analyze the mixture toxicity of PFASs for the aging kidney at ≥ 65 years of age, using the Bayesian Kernel Machine Regression (BKMR) method.

METHODS: The 2003-2018 US National Health and Nutrition Examination Survey (NHANES) datasets were used.

RESULTS: A total of 2832 subjects ≥ 65 years of age were included. for the univariate exposure-response relationship, the estimated glomerular filtration rate (eGFR) decreased about -15, -10, -5, and -2 ml/min/1.73 m² when ln PFOA, ln PFOS, ln PFHxS, and ln PFNA increased from 1.0 to 4.3, from 0 to 6.0, from 1.5 to 3.9, and from -2.8 to 3.0 ng/mL respectively. for the bivariate exposure-response relationship, PFHxS showed a protective interaction effect (by about 5-10 mL/min/1.73 m² of eGFR change) when independently mixed with each of the other 3 PFASs. PFOS showed an aggravating interaction effect (by about 7-10 mL/min/1.73 m² of eGFR change) when independently mixed with each of the other 3 PFASs. for the interaction effects, when the serum concentrations of other 3 PFASs were increased from the 25 th percentile to the 75 th percentile, the eGFR decrease for PFOA, PFOS, PFHxS, and PFNA (the 99 th percentile vs. the 50 th percentile) was alleviated by 0.29, 0.77, 2.57, and 0.05 ml/min/1.73 m², respectively.
DISCUSSION: Several interesting conclusions can be inferred from the study results. Biologic plausibility and the possibility of reverse causation were discussed based on previous literature.

P-0325 Prenatal exposure to POPs mixtures and DNA methylation alterations in multiple tissues at birth

Ashley Song[1], Jason Feinberg[1], Kristen Lyall[2], Craig Newschaffer[3], Lisa Croen[4], Irva Hertz-Picciotto[5], Rebecca Schmidt[5], Daniele Fallin[1], Christine Ladd-Acosta[1], Heather Volk[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, Baltimore, USA, [2]Drexel University, Philadelphia, USA, [3]Penn State University, State College, USA, [4]Kaiser Permanente North California, Oakland, USA, [5]University of California, Davis, Sacramento, USA

BACKGROUND/AIM: Prenatal exposure to persistent organic pollutants (POPs) has been linked to adverse health conditions in the offspring. However, little is known about the underlying mechanisms. Growing literature suggests epigenetics may play a role. We aimed to evaluate the associations of prenatal exposure to individual POPs exposure and POP mixtures with global and site-specific DNA methylation (DNAm) changes in cord blood and placenta in the Early Autism Risk Longitudinal Investigation (EARLI) study.

METHODS: We leveraged existing data on maternal serum POPs collected during early pregnancy and cord blood (n=122) and placenta DNAm (n=80) measured on the Illumina 450K platform at birth. Concentrations of 11 polychlorinated biphenyls (PCBs), 4 polybrominated diphenyls (PBDEs), and 2 persistent pesticides were measured. We examined global DNAm in 5 genomic regions (genome wide, open sea, shelf, shore, and island regions) and site-specific DNAm at 261 loci previously identified to be associated with POPs. Linear regression and quantile g-computation models were performed to evaluate the single pollutant effect and joint effect of POP mixtures on DNAm adjusted for surrogate variables and confounders.

RESULTS: Prenatal exposure to PCB 28 was associated with decreased placental DNAm levels at sites located in shelf regions (p=0.04). There was an inverse linear relationship observed between POP mixtures and placental DNAm in open sea regions. POP mixtures were associated with a decrease in methylation levels at 5 sites in cord blood and 14 sites in placenta and an increase in methylation levels at 4 sites in cord blood at nominal level. None of these associations was significant after FDR adjustment.

CONCLUSIONS: We observed global DNAm changes in placenta associated with prenatal exposure to PCB 28 and POP mixtures. The findings suggest DNAm involvement in response to prenatal environmental exposures in developmentally relevant tissues.

P-0327 Sources of children's exposure to phthalates and phthalate replacements

Michael Bloom[1], Juliana Clark[1], John Pearce[2], Pamela Ferguson[2], Roger Newman[2], Kelly Garcia[1], John Vena[2], Kelly Hunt[2], for the ECHO-FGS Study Group
[1]George Mason University, Fairfax, USA, [2]Medical University of South Carolina, Charleston, USA

BACKGROUND AND AIM: Phthalates and their replacements are endocrine disrupting chemicals; children may be exposed when using personal care products (PCPs). Our aim was to identify PCPs associated with phthalates/replacements exposure in children.

METHODS: Children (4-8 years) enrolled in the ECHO-FGS study provided urine from 2017-2019 (n=951). We queried parents about children's PCP-use during the preceding 24-hours. Concentrations of 16 urinary phthalate/replacement metabolites were determined by liquid chromatography tandem-mass spectrometry (n=630). Based on reported product use, we operationalized 15 PCP-use variables by product type (e.g., lotions, oils) and 4 PCP-use variables by product ingredients (e.g., "phthalate-free," "organic"). Multiple linear regression models estimated PCP-use variables as individual predictors of natural log-transformed urinary phthalates/replacements, adjusted for specific gravity, age, gender, BMI, race/ethnicity, maternal education, and season as confounders. We also used self-organizing maps (SOM) to identify 8 exposure "profiles" that classified joint patterns of the 19 PCP-use variables, and were employed as predictors of natural log-transformed urinary phthalates/replacements.

RESULTS: Children applied lotions (45.2%) frequently, but "2-in-1" hair-care products (7.2%), sunscreens (6.4%), and hair/skin oils (4.3%) infrequently. Lotions predicted higher MBzP (β=0.17, 95%CI: 0.03,0.31), oils predicted higher MEP (β=1.03, 95%CI: 0.62,1.45) and MBP (β=0.35, 95%CI: 0.07,0.63), and sunscreens predicted higher MCPP (β=0.15, 95%CI: 0.01,0.29) and MiBP (β=0.26, 95%CI: 0.02,0.49). However, 2-in-1s predicted lower MCPP (β=-0.15, 95%CI: -0.29,-0.01). Race/ethnicity modified the association of lotions with the sum of MEP, MBP, and MiBP. SOM exposure profiles predicted greater MBzP (β=0.35, 95%CI: 0.08,0.61) and MCiNP (β=0.08, 95%CI: 0.02,0.15 and β=0.07, 95%CI: 0.01,0.14), but lower MCOCH (β=-0.15, 95%CI: -0.29,-0.01), MCPP (β=-0.24, 95%CI: -0.45,-0.02; β=-0.13, 95%CI:-0.26,-0.005; and β=-0.13, 95%CI: -0.26,-0.01), and DINCH (β=-0.01, 95%CI: -0.01,-0.0001) relative to a reference profile.

CONCLUSIONS: Recent PCP-use was associated with urinary phthalate/replacement metabolites among children. These results may inform stakeholders to help limit children's exposure to endocrine disrupting chemicals.

KEYWORDS: Exposure, Phthalates

P-0328 Per- and polyfluoroalkyl substances (PFAS) in serum of 2- to 5-year-old children: temporal trends, determinants, and correlations with maternal PFAS concentrations

Jiwon Oh[1], Hyeong-Moo Shin[2], Rebecca Schmidt[1,3], Hertz-Picciotto Irva[1,3], Deborah Bennett[1]
[1]University of California, Davis, Davis, USA, [2]Department of Environmental Science, Baylor University, Waco TX, USA, [3]UC Davis MIND (Medical Investigations of Neurodevelopmental Disorders) Institute, Sacramento, USA

BACKGROUND/AIM: Early-life exposure to per- and polyfluoroalkyl substances (PFAS) occurs through placental and lactational transfers and ingestion of contaminated food, drinking water, and dust. However, little is known about temporal trends of PFAS in children's serum, especially since the phase-out of certain long-chain PFAS in the early 2000s. We investigated temporal trends and determinants of child serum PFAS concentrations and assessed their correlations with maternal PFAS concentrations.

METHODS: We included 551 children age 2 to 5 years from the CHildhood Autism Risks from Genetics and Environment (CHARGE) study. We quantified 14 PFAS in their serum samples collected during 2009-2017. for 9 PFAS detected in greater than 74% of the samples, we performed multiple regression with adjustment of potential determinants to calculate least square geometric means of PFAS concentrations for each sampling year and to estimate their average annual percent changes. for a subset of 354 children, we quantified 9 PFAS in their mother's serum collected at the same study visit and computed Spearman's correlation coefficients between maternal and child PFAS concentrations.

RESULTS: During the study period, child serum concentrations of 9 PFAS significantly decreased (range of annual percent changes: 6-12%). Child PFAS concentrations were positively associated with longer breastfeeding duration. Non-Hispanic white children had higher PFAS concentrations compared to Black, Asian, and multiracial children. for 354 mother-child pairs, the correlation coefficients between maternal and child PFAS concentrations ranged from 0.15 to 0.36, depending on the compound.

CONCLUSIONS: Our results showed that childhood body burdens of PFAS decreased from 2009 to 2017. Breastfeeding appears to contribute to higher child PFAS concentrations and lower maternal PFAS concentrations, resulting in relatively low correlation coefficients between maternal and child PFAS concentrations for samples collected in early childhood.

KEYWORDS: PFAS, child serum, temporal trends, determinants, breastfeeding

P-0334 Determinants of urinary phthalate biomarker concentrations in pre- and perimenopausal women with consideration for race

Brad Ryva[1,2,3], Diana Haggerty[4], Diana Pacyga[3,4], Tamarra James-Todd[5], Jodi Flaws[6], Zhong Li[7], Rita Strakovsky[3,4]
[1]Department of Pharmacology and Toxicology, Michigan State University, East Lansing, USA, [2]College of Osteopathic Medicine, Michigan State University, East Lansing, USA, [3]Institute for Integrative Toxicology, Michigan State University, East Lansing, USA, [4]Department of Food Science and Human Nutrition, Michigan State University, East Lansing, USA, [5]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [6]The Department of Comparative Biosciences, University of Illinois Urbana-Champaign, Urbana, USA, [7]Roy J. Carver Biotechnology Center, University of Illinois, Urbana-Champaign, Urbana, USA

BACKGROUND: Phthalates are endocrine disruptors in consumer plastics and personal care products. Our objectives were to identify determinants of phthalate biomarkers in women during the hormonally-sensitive midlife period, and to consider differences between non-Hispanic white and black women.

METHODS: We used information from the Midlife Women's Health Study of pre- and peri-menopausal women from Baltimore, Maryland (enrolled 2006-2015). We collected sociodemographic/health information via baseline questionnaires or during clinic visits and measured nine phthalate metabolites in pools of 2-4 urines collected across one menstrual cycle. We calculated molar sums of metabolites to approximate exposure to di(2-ethylhexyl) phthalate (ΣDEHP), personal care product phthalates (ΣPCPs), and phthalates in plastics (ΣPlastics). Accounting for meaningful predictors from bivariable analyses, our multivariable linear regression models evaluated determinants of phthalate biomarkers in all women (n=689), non-Hispanic white women only (n=467), or non-Hispanic black women only (n=195).

RESULTS: In multivariable analyses of all women, those who were perimenopausal, widowed/divorced, non-Hispanic black, with higher family income, with lower BMI, or who reported more frequent nausea had higher monoethyl phthalate (MEP) and ΣPCP. Non-Hispanic white women who were perimenopausal had lower mono-(3-carboxypropyl) phthalate (MCPP) and monobutyl phthalate (MBP), those who consume alcohol had higher mono-isobutyl phthalate (MiBP), and those with higher BMI had lower MEP and higher MCPP. Alternatively, widowed/divorced black women had higher ΣDEHP, monobenzyl phthalate (MBzP), and ΣPlastics, whereas black women with higher income had higher MEP and ΣPCP. Black women who described themselves as having "as much" physical activity as others or who reported a skin condition had lower MBzP and MCPP, respectively.
CONCLUSION: We identified important determinants of phthalate biomarkers in midlife women and observed some differences by race. Future studies could consider reasons for these differences when considering interventions to reduce phthalate disparities and related health effects.

P-0337 Aerosols in 3D Printing - Measurement of Emissions and Estimation of Body Deposition

Chungsik Yoon[1], Jihoon Park[2], Ohhun Kwon[3], Mijin Park[4], Haejoon Jeon[5]

[1]Graduate School of Public Health, Seoul National University, Seoul, Republic of Korea, [2]Chemical Safety Management Department, Nakdong River Basin Environmental Office, Ministry of Environment, Changwon, Republic of Korea, [3]Environment, Health & Safety Team Gwacheon/Magok, R&D Campus Magok, LG Energy Solution, Seoul, Republic of Korea, [4]Wonjin Institute for Occupational and Environmental Health, Seoul, Republic of Korea, [5]Division of climate & Environmental Research, Seoul Institute of Technology, Republic of Korea

As 3d printers become more and more popular, there have been many concerns about the hazards. We aimed to evaluate the emission of ultrafine particles (UFP) during fused deposition modeling (FDM) 3D printing according to the filament types and temperature and to estimate the dose of UFP in the respiratory tract.

The emission rates of UFP during 3D printing was evaluated using a direct-reading instrument (scanning mobility particle sizers and optical particle spectrometer) in a well-designed dynamic chamber. A total of six filament materials (ABS, PLA, PVA, Laywood, HIPS, and Nylon) were tested at the manufacturer-recommended temperature and gradual increasing conditions. The deposited dose at the head air way (HA), the tracheobronchial region (TB), and the alveolar region (AL), was estimated using the International Commission on Radiological Protection (ICRP) model

The filaments were classified as high emitter (>1011 #/min) which included HIPS and nylon, medium emitters (109#/min −1011 #/min) included ABS 1 and ABS2, and low emitters (<109 #/min) included PVA and PLA based on UFP emissions. The emission rate increased gradually as the temperature increased. Both filament type and temperature were the key factors affecting the emission rate.

For all filament types, the particles between 10 nm and 1um occupied a large portion and the proportion of UFP was dominated. The deposited particles in the alveolar region had larger proportions from 23 to 44% to total inhaled doses than in other regions. More than 5.8x108 particles/kgbw/g (about 40%) released from the high emitter were estimated to be deposited, while about 2.0x106 particles/kgbw/g (27% of inhaled dose) from the low emitter can be deposited at alveolar region. The emission rate of UFP were different between printing materials and temperature. Modeled estimates of UFP smaller than 1 μm had a large proportion to deposited dose at each respiratory region.

P-0338 Associations between per- and polyfluoroalkyl substances (PFAS) and diabetes in two population-based cohort studies from Sweden

Linda Dunder[1], Samira Salihovic[2], Sölve Elmståhl[3], Lars Lind[4], Monica Lind[1]

[1]Department of Medical Sciences and Occupational and Environmental Medicine, Uppsala University, Uppsala, Sweden, [2]Inflammatory Response and Infection Susceptibility Centre, School of Medical Sciences, Örebro University, Örebro, Sweden, [3]Division of Geriatric Medicine, Department of Clinical Sciences in Malmö, Lund University, Malmö, Sweden, [4]Department of Medical Sciences, Cardiovascular Epidemiology, Uppsala University, Uppsala, Sweden

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) have been put forward as metabolism disrupting chemicals with the potential to contribute to the development of many metabolic diseases such as obesity and diabetes. However, evidence from epidemiological studies remain divergent. The aim was to investigate associations between PFAS concentrations and prevalent diabetes in a cross-sectional analysis and fasting glucose in a longitudinal analysis in two population-based cohort studies in Sweden.

METHODS: In 2,373 subjects aged 45-75 years from the EpiHealth study, three PFAS; PFHxS, PFOA and PFOS were analyzed in plasma together with information on prevalent diabetes. Participants in the PIVUS study (n=1016 at baseline, all aged 70 years) were followed over 10 years regarding changes in plasma levels of six PFAS; PFHxS, PFOA, PFOS, PFNA, PFDA, and PFUnDA and changes in plasma levels of fasting glucose.

RESULTS: In the EpiHealth study, no overall associations could be observed between the levels of PFOA, PFOS or PFHxS and prevalent diabetes. However, there was a significant sex-interaction for PFOA, and an inverse association could be seen between PFOA and prevalent diabetes in women only (β: -0.40, p = 0.02). This association showed a non-monotonic dose-response curve. In the PIVUS study, inverse relationships could be observed between the changes in levels of PFOA and PFUnDA vs the change in fasting glucose levels over 10 years (p = 0.04 and p = 0.02). As in EpiHealth, these inverse associations were only significant in women (PFOA: β: -0.03, p = 0.02, PFUnDA: β: -0.03, p = 0.03).

CONCLUSIONS: Some PFAS were inversely related to prevalent diabetes and fasting glucose levels. These associations were observed in women only, clearly demonstrating a sex-difference regarding the relationship between PFAS exposure and diabetes outcomes.

KEYWORDS: Per-and polyfluoroalkyl substances (PFAS), diabetes, glucose levels, cross sectional, longitudinal

P-0339 Changes in adipose tissue and circulating concentrations of persistent organic pollutants: the Study of Women's Health Across the Nation

Amelia Grant-Alfieri[1], Amila Devasurendra[1], Stuart Batterman[1], Carrie Karvonen-Gutierrez[1], Sung Kyun Park[1]
[1]*University of Michigan, Ann Arbor, USA*

BACKGROUND: Polychlorinated biphenyls (PCBs) and organochlorine pesticides (OCPs) are persistent organic pollutants (POPs) that bioaccumulate in adipose tissue and can negatively impact health often via endocrine system disruption. In the U.S., regulations on the industrial production or commercial use of POPs have reduced external exposure. Nevertheless, POPs can be released from adipose tissue and constitute a continued internal source of exposure.
Objective: We investigated the relationship between a change in central adiposity and changes in circulating concentrations of POPs.

METHODS: We measured serum concentrations of 34 PCBs and 19 OCPs at four timepoints in a longitudinal cohort of midlife women within the Study of Women's Health Across the Nation. for PCBs, 65 women with at least two serum measurements were included, for a total of 181 observations. for OCPs, 59 women with at least two serum measurements were included, for a total of 151 observations. Linear mixed models were used to test the association between an increase in waist circumference and a change in serum POPs concentrations.

RESULTS: After adjustment for confounding variables, as the difference in waist circumference between visits increased by one inch, the difference in the serum concentration of PCB-194 decreased by 4.8% (95% CI: -7.9, -1.6). No significant associations were found for other PCB congeners or OCPs. of all the POPs analyzed, PCB-194 has the greatest lipophilicity.

CONCLUSIONS: POPs may be released from adipose tissue into the blood or conversely sequestered in adipose tissue following adiposity loss or gain, respectively. The dynamics and distribution of POPs may be influenced by a compound's lipophilicity. Further research is warranted on intra-person variation in serum POPs concentrations as well as other factors that may affect trends in serum concentrations.

P-0341 Associations between co-exposure of metals and the renal tubular damage of the residents in the metal contaminated smelter area

Dahee Han[1,4], Yong Min Cho[1], Kyung Hwa Choi[2], Young Seoub Hong[3], Eunil Lee[4]
[1]Seokyeong University, Seoul, Republic of Korea, [2]Dankook University, Cheonan, Republic of Korea, [3]Dong-A University, Busan, Republic of Korea, [4]Korea University, Seoul, Republic of Korea

BACKGROUND AND AIM: The effects of metals to renal tubular damage have been mostly reported for individual metals. We investigated non-linear effects of multiple metals for renal tubular damage and interactions among metals of the real population living near the metal contaminated smelter area.

METHODS: A total of 120 individuals were included for urine sampling and survey in the Forensic Research via Omics Markers(FROM) study. Nine metals(V, Cr, Mn, Ni, Mo, Cd, Sb, Pb, and Hg) in urine were analyzed by inductively coupled plasma-mass spectroscopy and mercury analyzer. Beta-2-microglobulin(β2-MG) and N-acetyl-β-D-glucosaminidase(NAG) were applied as renal tubular damage markers. We compared the difference between the single-metal models and the multiple-metal models. and Bayesian kernel machine regression(BKMR) was conducted to examine the joint effects of multiple metals on renal tubular damage, interactions among metals and non-linear dose-response effects.

RESULTS: V for β2-MG, and Hg and Cd for NAG were consistently significant in both simple and multiple linear regression, though Ni for β2-MG was significant only in the multiple linear regression model. Mn for NAG was significant only in the single linear regression model. The BKMR analysis showed that the co-exposure of metals was significantly increased only NAG and Hg contributed the most to the NAG(PIP, posterior inclusion probability=0.608). β2-MG was increased by co-exposure of metals but not statistically significant and V contributed the most to the β2-MG(PIP=0.704).

CONCLUSIONS: This study suggests that co-exposure of metals was significantly associated with NAG. The interaction among metals for renal tubular damage was not shown but further study is needed.

KEYWORDS: Metals, Co-exposure, Kidney damage, BKMR, Metal exposure

P-0342 The chemical exposome in brain cancer: an exploratory study

Rubén Gil-Solsona[1], Albert Pons-Escoda[2], Sergi Díez[1], Daniel Gutierrez-Martin[1], Noemí Vidal-Sarro[2], Jordi Bruna[2], Payam Dadvand[3], Carles Majós[2], Pablo Gago-Ferrero[1]

[1]Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Barcelona, Spain, [2]Bellvitge University Hospital - Bellvitge Biomedical Research Institute (HUB-IDIBELL), Barcelona, Spain, [3]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain

Diffuse gliomas are a highly heterogeneous and aggressive brain tumours with poor prognosis and survival and few established risk factors. Environmental exposures are suspected in the pathogenesis of these tumours; however, results of existing studies are limited and inconsistent, particularly for exogenous organic chemicals, with no available characterization of the chemical exposome of these tumours. Also, better understanding of phenotypic differences in tumour types is needed in order to improve clinical decision making and provision of personalised treatment recommendations. In this proof of concept study we analysed 33 glioblastoma samples (Bellvitge Glioma Cohort (BGC), Spain, 2005-present), including 16 methylated and 17 non-methylated tumours combining HRMS-based wide-scope target and suspect strategies. Forty-six exogenous chemicals were identified in the tumour tissue samples (31 confirmed with standard) including a variety of industrial chemicals (e.g. plastic additives or perfluorinated compounds), personal care products and pharmaceuticals. Our findings provide novel evidence on the presence of these chemicals in brain tissue, highlighting the need for comprehensive evaluations of their potential effects in the tumour pathogenesis. Finally, after applying metabolomics methods we observed clear differences in the profiles of endogenous chemicals among the studied glioma subtypes, and identified possible biomarkers. These chemicals have potential to be determined in a non-invasive manner, either by LC-HRMS-based blood analysis or using complementary techniques (proton magnetic resonance (1H-MRS)). These are inspiring results since methylation is a strong independent predictor of survival as well as tumour response to chemotherapy for glioblastoma. Indeed, its non-invasive and pre-surgical determination would have a major impact on patient management. Our preliminary data is suggestive for the potential of nontargeted exposome methods to find new valuable biomarkers for diffuse gliomas diagnostic and prognostic stratification.

Chemicals are part of our daily lives and we are exposed to numerous chemicals through multiple pathways. Relevant scientific evidence contributing to the regulation of hazardous chemicals require a holistic approach to assess simultaneous exposure to multiple compounds. Currently, the main way to obtain data on the exposure to organic chemicals is through human biomonitoring, that requires very complex and costly sampling campaigns. Finding efficient proxies to predict the risk of chemical exposure in humans is an urgent need to cover large areas and populations at a reasonable cost. We conducted an exploratory study to characterize the human chemical exposome in maternal blood and placenta samples of a population-based birth cohort in Barcelona (2018-2021). Ultimate HRMS-based approaches were applied including wide-scope target, suspect (for >2300 and >10000 chemicals, respectively) and non-target screening. Forty-two chemicals were identified including pesticides, personal care products or industrial compounds, among others, in the range of ng/mL and ng/g. In parallel, sewage sludge from the wastewater treatment plants serving the residence areas of the studied population were also screened, showing correlations with the type and concentrations of chemicals found in humans. Our findings were suggestive for the potential use of sewage sludge as a proxy of the human exposure and its application in early-warning systems to prevent chemical threats.

P-0344 Demographic differences in chemical mixture exposure and associated determinants among Swedish adolescents

Sebastian Pineda[1], Anders Glynn[1], Erik Lampa[2], Irina Gyllenhammar[3], Jon Benskin[4], Thomas Lundh[5], Christian Lindh[5], Kiviranta Hannu[6], Sanna Lignell[3]

[1]SLU - Swedish University of Agricultural Sciences, Uppsala, Sweden, [2]Uppsala University, Uppsala, Sweden, [3]Swedish Food Agency, Uppsala, Sweden, [4]Stockholm University, Stockholm, Sweden, [5]Lund University, Lund, Sweden, [6]Finnish Institute for Health and Welfare, Helsinki, Finland

BACKGROUND AND AIM: Few population-based studies of adolescents have investigated the relation between socio-demographic factors and the wider chemical exposome. Adolescents are likely going through a sensitive developmental window were negative exposure-induced health effects can manifest into adulthood. We aim to identify associations of social demographic factors with the chemical exposome of Swedish adolescents as well as to identify demographic groups more at risk of higher exposure to specific substances.

METHODS: Using the Riksmaten Adolescents 2016-17 cohort (RMU) we analysed several social-demographic factors: gender, participant/maternal (P/M) birth country income level, parental education levels, and geographic location (longitude/latitude), and their relation to blood/serum/urine concentrations of a large range of toxic substances (N=64) across multiple chemical groups (heavy metals, chlorinated pesticides, PCBs, BFRs, PFASs, phthalates, phenols, pesticides, PAHs). Association analysis was conducted using ordinal regression models due to its robustness to handle highly skewed data.

RESULTS: P/M birth country was the most frequent determinant of toxic substance concentrations, being significantly associated with concentrations of 45 substances, followed by gender (N=41), and longitude (N=37). P/M birth country also showed the largest fold-differences in concentrations, with subjects born in high-income countries having several-fold higher estimated adjusted mean (EAM) concentrations of PCBs, BFRs and PFASs than those born in low-income countries. In contrast, adolescents born in low-income countries had higher EAM levels of heavy metals, chlorinated pesticides, and phthalates. Substances belonging to the same chemical group tended to have the same determinants. Interesting north to south or west to east gradients of substance concentrations were identified in Sweden, suggesting geographical inequalities of exposure.

CONCLUSIONS: P/M birth country is an important confounder and should be included in future toxicology population-based studies. Exposure associations with latitude/longitude should be further investigated.

KEYWORDS: Adolescents, RMU, ordinal regression, exposome, metals, PCB, BFR, PFAS, pesticides, phthalates, phenols, epidemiology, birth country income

P-0345 Endocrine disruptors and Gestational Diabetes Mellitus: A pilot study of INSULIN cohort (Catalonia, Spain)

Montse Marquès[1,2], Pablo Gago-Ferrero[3], Elena Sánchez-Resino[1], Ruben Gil-Solsona[3], Daniel Gutiérrez-Martín[3], Núria Taltavull[4], Montserrat Ingés[5], Raquel Gómez[5], Ana Megía[6], Adrian Covaci[2], José Luis Domingo[1]

[1]Laboratory of Toxicology and Environmental Health, Universitat Rovira i Virgili / Pere Virgili Health Research Insitute, Reus, Spain, [2]Toxicological Center, University of Antwerp, Wilrijk, Belgium, [3]Institute of Environmental Assessment and Water Research – Severo Ochoa Excellence Center (IDAEA),Spanish Council of Scientific Research (CSIC), Barcelona, Spain, [4]Diabetes and Metabolic Associated diseases Research group (DIAMET), Pere Virgili Health Research Institute, Tarragona, Spain, [5]Department of Obstetrics and Gynecology, University Hospital of Tarragona Joan XXIII, Pere Virgili Health Research Institute, Tarragona, Spain, [6]Department of Endocrinology and Nutrition, Research Unit, University Hospital of Tarragona Joan XXIII, Institut d´Investigació Sanitària Pere Virgili, Tarragona, Spain

BACKGROUND AND AIM: The incidence of Gestational Diabetes Mellitus (GDM) has increased in the past 20 years, and it is now diagnosed in up to 10% of all pregnancies. GDM is associated with adverse consequences like preeclampsia, birth complications, as well as with cardiometabolic diseases for both the mother and child. Many environmental factors can cause beta-cell stress, including the developmental exposure to Endocrine-Disrupting Chemicals (EDCs). The present pilot study was aimed at assessing the exposure to EDCs of pregnant women of INSULIN, a cohort of GDM built at Hospital Joan XXIII (Tarragona, Spain).

METHODS: Sociodemographic, dietary and life-style determinants were linked to the occurrence of the EDCs and clinical data, including the development of GDM during pregnancy. The occurrence of BPA and 10 BPA analogues (BPF, BPS, BPAF, BPAP, BPB, BPE, BPG, BPM, BPP, BPZ), phthalates metabolites (mono-ethyl, mono-butyl and mono-methyl); parabens and their metabolites (methyl-, ethyl-, propyl- and butyl-); and flame-retardants (HBCD, TBBPA, TBP) were assessed in urine (12-week and delivery), mother serum (delivery), cord serum and/or placenta of 25 pregnant women by means of LC-QTOF.

RESULTS: High detection rates of BPs, phthalate and parabens were found in urine and mother serum, but also their detection in placenta and cord serum, might be slightly related to the use of plastic and personal care products, along with the consumption of canned foodstuffs according to the results of the individual questionnaire.

CONCLUSIONS: The premature state of the results does not allow identifying a potential role of a target EDC (or a mixture of EDCs) on the development of GDM. However, we can confirm the widespread presence of these EDCs in our daily life, which might become a hazard for the health of vulnerable population groups, such as pregnant women and their newborns.

P-0347 Metabolic signatures of youth exposure to mixtures of lipophilic persistent organic pollutants

Jesse Goodrich[1], Brittney Baumert[1], Hongxu Wang[1], Douglas Walker[2], Jingxuan He[1], Xiangping Lin[2], Xin Hu[3], Tanya Alderete[4], Zhanghua Chen[1], Damaskini Valvi[2], Sarah Rock[1], Kiros Berhane[5], Frank Gilliland[1], Michael Goran[6], Dean Jones[3], David Conti[1], Leda Chatzi[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [2]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Clinical Biomarkers Laboratory, Division of Pulmonary, Allergy, Critical Care and Sleep Medicine, Emory University, Atlanta, USA, [4]Department of Integrative Physiology, University of Colorado Boulder, Boulder, USA, [5]Department of Biostatistics, Columbia University, New York, USA, [6]Department of Pediatrics, Children's Hospital Los Angeles, The Saban Research Institute, Los Angeles, USA

BACKGROUND AND AIM: Exposure to lipophilic persistent organic pollutants (POPs), including organochlorine compounds (OCs), polychlorinated biphenyls (PCBs), and polybrominated diphenyl ethers (PBDEs), is ubiquitous and may increase risk of metabolic disorders in children. We examined the associations of OC, PCB, and PBDE mixtures with metabolic pathways in two independent cohorts.

METHODS: 301 overweight/obese adolescents from the Study of Latino Adolescents at Risk (SOLAR, 2001-2012; age: 8-15 years) and 135 young adults from the Southern California Children's Health Study (CHS, 2014-2018; age 17-22 years) were included in analysis. Measurements of the metabolome along with 11 lipophilic POPs, including 2 OCs (4,4'-dichlorodiphenyldichloroethylene, hexachlorobenzene), 4 PCBs (PCBs-153, 138, 118, 180) and 5 PBDEs (PBDEs-154, 153, 100, 85, 47) were determined in plasma. for each chemical class, we performed a metabolome wide association study using quantile g-computation to assess the associations of exposure to the chemical mixture with each of the 23,166 untargeted metabolite features. Pathway enrichment analysis was performed using mummichog. Significant pathways were determined with an α=0.05.

RESULTS: In the SOLAR cohort, OCs, PCBs, and PBDEs were associated with 12%, 6%, and 14% of metabolites, respectively. for the CHS cohort, OCs, PCBs, and PBDEs were associated with 4%, 5%, and 4% of metabolites, respectively. for the OC and PCB mixtures, 9 and 12 metabolic pathways were enriched in both cohorts, respectively. for OCs, 7 pathways were related to amino acid metabolism, including alanine, aspartate, and asparagine metabolism. for PCBs, 8 pathways were related to amino acid metabolism, including valine, leucine, and isoleucine metabolism. for PBDEs, only 1 pathway (linoleate metabolism) was enriched in both cohorts.

CONCLUSIONS: Exposure to chlorinated lipophilic POPs is associated with alterations in amino acid metabolism in children and young adults. These associations may link exposure to POPs with risk of metabolic disease.

P-0351 The combined associations of mercury exposure and DNA methylation with sustained attention in children

Jessa Ehlinger[1], Jaclyn Goodrich[1], Dana Dolinoy[1,2], Deborah Watkins[1], Alejandra Cantoral[3], Adriana Mercado-García[4], Niladri Basu[5], Martha Maria Tellez-Rojo[4], Karen Peterson[2]

[1]Environmental Health Sciences, University of Michigan, Ann Arbor, USA, [2]Nutritional Sciences, University of Michigan, Ann Arbor, USA, [3]Iberoamerican University, México City, México, [4]National Institute of Public Health, Cuernavaca, México, [5]Agriculture and Environmental Sciences, McGill University, Montreal, Canada

BACKGROUND AND AIM: Attention deficit disorder (ADHD) is one of the world's most common neurodevelopmental disorders, yet the etiology is not well-understood. Childhood DNA methylation (DNAm) patterns and exposure to methylmercury have both been implicated in the development of ADHD, though simultaneous assessments of these factors are rare. This study leverages the ELEMENT (Early Life Exposures in Mexico to Environmental Toxicants) cohort to identify the associations of childhood mercury exposure and DNAm with sustained attention in adolescence, and how these associations differ by sex.

METHODS: Total mercury was measured in hair and urine from ELEMENT participants aged 6-12, reflecting organic and inorganic sources respectively. Children were followed on average 5.6 years, when adolescent DNAm was quantified in blood leukocytes via the Infinium EPIC array. Conners Continuous Performance Test (CPT3) was used to quantify measures of inattention, impulsivity, sustained attention, and vigilance. Linear regression was used to assess relationships between mercury biomarkers and CPT3 outcomes (N=399). In an epigenome-wide association study, we examined associations between adolescent DNAm and CPT3 performance (N=517). All analyses were adjusted for age, sex, socioeconomic status, and response style in adolescence.

RESULTS: Childhood hair and specific gravity-adjusted urine mercury averaged 0.62±0.03 µg/g and 1.09±0.14 µg/L, respectively. Relationships between mercury levels and attention varied by mercury biomarker and CPT3 variable. Hair mercury, for instance, was associated with reduced inattentiveness (β=-0.021(SE=0.0095), p=0.027); urine mercury was not (β=-0.0045(SE=0.0078), p=0.57). Sex modified associations; for instance, urine mercury exposure was related to decreased vigilance in males (β=1.31(SE=0.65), p=0.045), but not in females (β=-0.20(SE=0.81), p=0.80). Lastly, DNAm at certain genes was associated with CPT3 scores. for example, DNAm at a loci in ZNF814 (Zinc Finger Protein-814) was related to increased sustained attention (β=0.97(SE=0.17), q=0.012).

CONCLUSIONS: Both DNAm and mercury exposure are associated with adolescent CPT3 performance.

KEYWORDS: mercury, sustained attention, DNA methylation, ADHD

P-0355 Exposure to melamine and its derivatives and aromatic amines among pregnant women in the USA: The ECHO Program

Lee Institute for Health Policy Studies, University of California San Francisco, San Francisco, USA

BACKGROUND: Melamine, melamine derivatives, and aromatic amines are nitrogen-containing compounds with known toxicity and widespread commercial uses. Nevertheless, biomonitoring of these chemicals is lacking, particularly during pregnancy, a period of increased susceptibility to adverse health effects. We aimed to measure melamine, melamine derivatives, and aromatic amine exposure in pregnant women across the USA (U.S.) and evaluate associations with participant and urine sample collection characteristics.

METHODS: We measured melamine, cyanuric acid, ammelide, ammeline, and 41 aromatic amines in urine from pregnant women in nine diverse ECHO cohorts during 2008-2020 (N=171). To assess relations with participant and urine sample collection characteristics, we used generalized estimating equations to estimate prevalence ratios (PRs) for biomarkers dichotomized at the detection limit, % differences (%Δ) for continuous biomarkers, and 95% confidence intervals. Multivariable models included age, race/ethnicity, marital status, cotinine, and year of sample collection.

RESULTS: Twelve chemicals were detected in >60% of samples, with near ubiquitous detection of cyanuric acid, melamine, aniline, 4,4'-methylenedianiline, and a composite of o-toluidine and m-toluidine. In multivariable models, concentrations of 3,4-dichloroaniline were higher among Hispanic (%Δ: 149, 95% CI: 17, 431) and non-Hispanic Black (%Δ: 136, 95% CI: 35, 311) women compared with non-Hispanic White women. We observed similar results for ammelide, o-/m-toluidine, 4,4'-methylenedianiline, and 4-chloroaniline. Most chemicals were positively associated with the tobacco biomarker cotinine, with strongest associations observed for o-/m-toluidine (%Δ: 23; 95% CI: 16, 31) and 3,4-dichloroaniline (%Δ: 25; 95% CI: 17, 33). Some chemicals exhibited annual trends (e.g., %Δ in melamine per year: -11; 95% CI: -19, -1) or within-day, seasonal, and geographic variability.

DISCUSSION: Exposure to melamine, cyanuric acid, and some aromatic amines was ubiquitous in this first investigation of these analytes in pregnant women. Future research should expand biomonitoring, identify sources of exposure disparities by race/ethnicity, and evaluate potential adverse health effects.

P-0356 Associations between prenatal exposure to endocrine disrupting chemicals and play behavior in 7-year-old children in the SELMA study

Fatih Özel[1,2,3], Marlene Stratmann[3], Joëlle Rüegg[1,3], Carl-Gustaf Bornehag[3,4]

[1]Department of Organismal Biology, Uppsala University, Uppsala, Sweden, [2]Centre for Women's Mental Health during the Reproductive Lifespan – WOMHER, Uppsala University, Uppsala, Sweden, [3]Department of Health Sciences, Karlstad University, Karlstad, Sweden, [4]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: A growing body of evidence shows that exposure to some commonly used chemicals affects child development through altered endocrine function. These so-called endocrine disrupting chemicals (EDCs) include a spectrum of substances; since many EDCs have been shown to affect sex hormone signaling, they may affect sexual development of the brain. Indeed, a few studies report the effects of prenatal EDC exposure and sex-atypical play behavior. However, these were conducted on single chemicals while human exposure entails mixtures of EDCs. In this study, we aimed to investigate the associations between prenatal exposure to single chemicals as well as chemical mixtures and play behavior.

METHODS: A total of 618 mother-child pairs from the Swedish Environmental Longitudinal, Mother and Child, Asthma and Allergy (SELMA) study were included. In the median week 10 of pregnancy, prenatal exposure to 26 EDCs was measured in urine and blood samples. Play behavior was measured with Preschool Activities Inventory at the age of 7 years. Linear and weighted quantile sum (WQS) regressions were used for single compound and mixture analyses, respectively; data stratification by sex was performed. Models were adjusted for child and maternal age, maternal education, parental attitudes towards play behavior and urinary creatinine concentration.

RESULTS: Higher urinary concentrations of diisononyl phthalate (DINP) metabolites were shown to be associated with decreased masculinity among boys (β=-1.35; 95%CI=-2.62,-0.08). Also, higher prenatal exposure to a mixture of 7 chemicals - among the 26 compounds measured - was demonstrated to be associated with decreased masculinity among boys (β=-0.91; 95%CI=-1.45,-0.36).

CONCLUSIONS: Our findings indicate an association between prenatal EDCs exposure and alterations in play behavior, in part confirming earlier findings.

KEYWORDS: Prenatal exposure, endocrine disrupting chemicals, phthalates, chemical mixture, play behavior

P-0361 Fluoride exposure via public drinking water supplies and associated health outcomes: an ecological study in England

Hannah Emmett[1,2], Neville Q Verlander[3], Tony Fletcher[2,4], Giovanni S Leonardi[2,4]
[1]Field Epidemiology Training Programme, UK Health Security Agency, Chilton, UK, [2]Environmental Epidemiology, Radiation, Chemical, and Environmental Hazards Directorate, UK Health Security Agency, Chilton, UK, [3]Statistics Unit, Statistics, Modelling, and Economics Department, UK Health Security Agency, London, UK, [4]Department of Public Health, Environments and Society, London School of Hygiene and Tropical Medicine, London, UK

BACKGROUND AND AIM: The protective effect of drinking water fluoridation on dental caries is established. While adverse effects are known for fluoride concentrations above 1.5mg/L, the evidence is less clear for effects at lower concentrations. In new updated analyses, we aimed to estimate the association between fluoride exposure and dental health outcomes and hip fractures.
METHODS: Exposure was defined as mean public drinking water fluoride concentrations, assigned to geographical areas, over time periods of interest. Concentrations were categorised: <0.1, 0.1-<0.2, 0.2-<0.4, 0.4-<0.7, ≥0.7mg/L. Area-level health outcomes, deprivation scores, and age- and sex-specific denominators were obtained from hospital data, oral health surveys, and routine data sources. Binomial models with logit link were used to determine the association (adjusted odds ratios) between fluoride and dental caries prevalence. Negative binomial models were used to determine the association (adjusted incidence rate ratios) with dental extractions and hip fractures.
RESULTS: The association between fluoride and dental outcomes varied by deprivation. Odds of caries decreased in each fluoride concentration category relative to the lowest, with the greatest reduction in the most deprived quintile (ORs 0.61-0.80, composite p<0.001). Incidence of hospital admissions for carious tooth extractions decreased similarly (IRRs 0.37-0.66, composite p<0.001). The association with hip fracture varied by age (p<0.001), with evidence of a protective association in those aged under 50 (IRRs 0.83-0.97, composite p<0.001) and an adverse association in those aged over 80 (IRRs 0.98-1.08, composite p<0.01) at some individual concentration categories. There was no evidence of a dose response.
CONCLUSION:
Exposure to fluoride in drinking water, at concentrations <1.5mg/L, was associated with reduced dental caries and extractions. The most deprived populations benefited the most. There was no clear evidence of an association with hip fractures. The findings support adoption of water fluoridation as an equitable dental public health intervention.

Fluoride; oral health; fractures

P-0363 Perfluoroalkyl chemicals and mortality: an exploratory analysis using NHANES 1999-2014

Ram Siwakoti[1], Sung Kyun Park[1], John Meeker[1]
[1]*University of Michigan, Ann Arbor, USA*

BACKGROUND: Per- and Polyfluoroalkyl Substances (PFAS) are ubiquitous synthetic chemicals that have been widely used in industrial and consumer products, and are detected in the blood of more than 98% of Americans. PFAS have been linked to increased risks of multiple health outcomes such as cardiovascular disease (CVD) and cancer.
Aim: To examine the associations of PFAS exposures with all-cause, CVD, and cancer mortality in the general US population using the most up-to-date publicly available data.

METHODS: The current study included participant-level data for 5,839 adults aged 45 years or older from the National Health and Nutrition Examination Survey (NHANES) 1999-2000 and 2003-2014 that were eligible for linkage to the public-use National Death Index (NDI) Mortality Files. The associations between 5 individual PFAS, including perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), perfluorononanoic acid (PFNA), perfluorohexane sulfonic acid (PFHxS), and perfluorodecanoic acid (PFDA) and mortality were examined using survey-weighted Cox-Proportional Hazards model with the age as the time scale. Hazard ratios (HR) were calculated to compare the mortality HR of participants per interquartile range (IQR) increase in log-transformed serum PFAS concentrations.

RESULTS: After adjusting for sex, race, education, BMI, hypertension, cholesterol level, and survey cycle, most PFAS were not statistically significantly associated with increased risk of CVD or cancer mortality. While higher PFOS and all PFAS were inversely associated with CVD and all-cause mortality risks, respectively ($p < 0.05$), the observed associations became null when analyses were restricted to participants without chronic kidney disease (CKD).

CONCLUSIONS: Based on the most available data from NHANES, there was no evidence of increased risks of CVD or cancer mortality due to elevated PFAS concentrations. Further studies are needed to fully understand the inverse associations observed in this study as well as the role of CKD in PFAS related health effects.

P-0364 Relations of urinary volatile organic compound metabolites with inflammation and immune response

Clara Sears[1,2], Marina Malovichko[1,2], Daniel Riggs[1,2], Israel Sithu[1,2], Breandon Taylor[1,2], Hong Gao[1,2], Zhengzhi Xie[1,2], Rachel Keith[1,2], Aruni Bhatnagar[1,2], Sanjay Srivastava[1,2]

[1]Christina Lee Brown Envirome Institute, Department of Medicine, University of Louisville, Louisville, USA, [2]Superfund Research Center, University of Louisville, Louisville, USA

BACKGROUND AND AIM: Volatile organic compounds (VOCs) are ubiquitous environmental pollutants that are generated by combustion, industrial solvents, and household items. VOCs are also detected at several hazardous waste sites. Exposure to VOCs is associated with insulin resistance, diabetes, and cardiovascular disease. However, the effects of VOCs on systemic inflammation are unclear. We evaluated the relation of urinary VOC metabolites, individually and in mixtures, with circulating cytokines and immune cells in a cross-sectional study of 625 participants (ages 25-70 years) from Louisville, Kentucky, USA.

METHODS: We quantified a) concentrations of 16 urinary metabolites corresponding to 12 parent VOCs by liquid chromatography-mass spectrometry; b) blood immune cells by blood analyzer; and c) plasma cytokines by multiplex array. Using linear regression models, we estimated covariate-adjusted relations of individual VOC metabolites with ln-transformed cytokine concentrations and immune cells. We used quantile-based g-computation to estimate covariate-adjusted relations of urinary VOC metabolite mixtures with inflammation biomarkers.

RESULTS: We found weak to moderate positive correlations between cytokines, correlation coefficients ranged from 0.03 to 0.59. In separate models, interquartile range (IQR) increases in the urinary metabolites of crotonaldehyde, acrylonitrile, 1,3-butadiene, and acrolein were associated with 4.0 to 10% higher concentrations of several pro-inflammatory cytokines, including IL-6, IL-8, or MCP1. Higher concentrations of the propylene oxide metabolite were associated with lower IL-9 (-1.0% per IQR; 95%CI=-1.1, -0.1). In mixture analyses, a quartile increase in all VOC metabolites was associated with 8.6% (-15, -2.0%) lower IL-10, an anti-inflammatory cytokine, and 5.1% (95% CI= 1.0, 11%) higher white blood cell count. These associations were largely driven by acrylonitrile and 1,3 butadiene, respectively. We did not find strong evidence of a joint VOC mixture effect on IL-6, IL-8, or MCP1.

CONCLUSIONS: VOC exposure could promote systemic inflammation thereby increasing susceptibility to cardiometabolic disease.

P-0367 Breast Cancer Incidence is Associated with Uranium Exposure in a Population Living Near a Uranium Refinery

Susan Pinney[1], Cecily Shimp Fassler[1], Jeanette M. Buckholz[1], Elizabeth Shaughnessy[1], Changchun Xie[1]
[1]*University of Cincinnati College of Medicine, CINCINNATI, USA*

BACKGROUND AND AIM: s: Ionizing radiation is recognized as a risk factor for breast cancer in humans, but recent studies of rodents and mammary cell lines have noted that the heavy metal uranium exhibits estrogenic activity. We examined data from a large longitudinal cohort to determine if breast cancer incidence was related to exposure to uranium and radiation in a population residing around the Feed Materials Production Center, a uranium refinery in Fernald, Ohio. The FMPC was part of the US Department of Energy nuclear weapons complex, and produced uranium metal products from 1952-1989, with releases of soluble and insoluble uranium dusts. The US Centers for Disease Control and Prevention (CDC) developed dose estimation models for exposures to individuals who lived within a 5-mile radius from the perimeter of the plant.

METHODS: We used the CDC algorithms to estimate exposure for 4832 women enrolled in the Fernald Community Cohort, of whom 324 were diagnosed with breast cancer during 31 years of follow-up (1990–2021), and conducted proportional hazards analyses, with appropriate covariates (age, family history of breast cancer, alcohol consumption, age at menarche, parity), to determine the association of uranium/radiation exposure and breast cancer incidence.

RESULTS: The mean value of the uranium particulate exposure (ug/m3-years) for women in the three exposure groups was 0.086, 0.354, 1.596, and for cases was 0.35 vs. 0.19 for controls. The risk of breast cancer in the highest exposure group compared to baseline was significantly elevated (HR=1.53, 95% CI 1.20, 1.95). In the subgroup with age at first exposure ≤13.75 years the HR for the highest exposure group compared to baseline was higher.

CONCLUSIONS: for women living within five miles of a uranium processing plant, degree of exposure to uranium particulates was related to risk of incident breast cancer.

KEYWORDS: uranium, breast cancer

P-0371 Prenatal Exposure to organochlorine compounds (OCs) and puberty-related hormones in boys and girls at 11 years of age; findings from the Rhea birth cohort, Crete, Greece

Katerina Margetaki[1], Vicky Bempi[1], Theano Roumeliotaki[1], Marianna Karachaliou[2], Manolis Kogevinas[2], Leda Chatzi[3], Marina Vafeiadi[1]

[1]University of Crete, Herakion, Greece, [2]ISGlobal, Barcelona, Spain, [3]Keck School of Medicine, LA, USA

BACKGROUND AND AIM: Puberty is a period of major hormonal changes and prenatal exposure to endocrine disruptors such as organochlorine compounds (OCs) might impair normal development. However, only a few studies have investigated relationships between OCs and pubertal development with mixed findings. The aim of the current study was to examine the role of in utero exposure to OCs on pubertal development in 11-years old children (n=137 boys and n=107 girls) from the Rhea birth cohort in Greece.

METHODS: Concentrations of 6 polychlorinated biphenyls (PCBs), dichlorodiphenyldichloroethene (DDE), and hexachlorobenzene (HCB) were determined in 1st trimester maternal serum. at 11 years of age, we measured dehydroepiandrosterone sulfate (DHEA-S), luteinizing hormone (LH) and follicle-stimulating hormone (FSH). Associations between OCs and puberty-related hormones were assessed using multivariable linear regression separately in boys and girls. Further, the hierarchical version of Bayesian Kernel Machine Regression (BKMR) was employed to investigate exposure mixtures as well as possible interactions between exposures.

RESULTS: In boys, the sum of prenatal PCBs was positively associated with DHEA-S (for a doubling of exposure, β= 25.5 μg/mL, 95% CI: 1.5, 48.5) and HCB was positively associated with FSH (β= 0.2 mUI/mL, 95% CI: 0.1, 0.5). In BKMR the OCs mixture showed a trend for a positive association with DHEA-S and the PCBs ranked higher according to their group Posterior Inclusion Probabilities (PIPs) with PCB-170 and PCB-180 ranking higher according to their conditional PIPs. Also, the OCs mixture showed a positive association with FSH with HCB ranking higher according to the conditional PIPs. No sign for an interaction between compounds was detected. Among girls the associations were null.
CONCLUSION: Prenatal exposure to OCs was associated with puberty-related hormones in boys but not in girls. The implications on future reproductive function in puberty and adulthood should be determined.

KEYWORDS: endocrine disruptors, puberty, prenatal

P-0372 Transfer of perfluoroalkyl substances (PFAS) from serum to breastmilk and breastmilk concentrations over the course of lactation: a study in the highly-exposed Ronneby Mother-Child Cohort

Annelise Blomberg[1,2], Erika Norén[1], Line S. Haug[3], Christian Lindh[1], Azemira Sabaredzovic[3], Daniela Pineda[1], Kristina Jakobsson[4,5], Christel Nielsen[1]

[1]Division of Occupational and Environmental Medicine, Department of Laboratory Medicine, Lund University, Lund, Sweden, [2]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [3]Department of Food Safety, Norwegian Institute of Public Health, Oslo, Norway, [4]School of Public Health and Community Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [5]Department of Occupational and Environmental Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden

BACKGROUND: PFAS are detectable in human breastmilk, and breastfeeding may be a significant source of infancy exposures. The magnitude of exposure is determined by the transfer efficiency (TE) of PFAS from maternal serum into breastmilk. However, there are no studies of PFAS concentrations in the breastmilk of highly-exposed mothers.
OBJECTIVES: To estimate the transfer of PFAS from maternal serum into breastmilk and changes in concentrations over the course of lactation in a cohort of women with a wide range of PFAS exposures.

METHODS: We conducted this study in the prospective Ronneby Mother-Child birth cohort, which was established in 2015 after PFAS contamination was discovered in the public drinking water of Ronneby, Sweden. We measured seven PFAS in matched samples of colostrum, breastmilk, and maternal serum at delivery. We calculated the TE (%) as the ratio of PFAS in colostrum or breastmilk to serum and evaluated whether TE varied by PFAS, lactation stage, or exposure level using linear mixed-effects models. We also measured PFAS in repeated breastmilk samples collected over a period of nine months from a subset of 15 mothers.

RESULTS: This study included 126 women. While all seven PFAS were quantifiable in serum, only PFNA, PFHxS, PFOA and PFOS were above the LOQ in >50% of colostrum and breastmilk samples. Median overall TE varied from 0.8% to 2.7%. TEs were generally higher for PFNA and PFOA than PFOS and PFHxS, and were of a similar magnitude across exposure categories. While PFOA concentrations decreased over the course of lactation, PFOS and PFHxS concentrations remained relatively consistent.
DISCUSSION: PFAS concentrations in colostrum and breastmilk of highly-exposed women were higher than concentrations in background-exposed women. This suggests that breastfeeding may be an important route of PFAS exposure for breastfeeding infants with highly-exposed mothers.

P-0374 Do nutrients modify the risk of cadmium on acute myocardial infarction among never smokers in the Danish Diet, Cancer and Health cohort?

Victoria Fruh[1], Tesleem Babalola[2], Gregory Wellenius[1], Thomas Webster[1], James Harrington[3], Clara Sears[4], Ole Raaschou-Nielsen[5], Birgit Claus Henn[1], Jaymie Meliker[2]

[1]Boston University, Boston, USA, [2]Stony Brook University, Stony Brook, USA, [3]RTI International (Research Triangle Institute), Research Triangle Park, USA, [4]University of Louisville, Louisville, USA, [5]Danish Cancer Society Research Center, Copenhagen, Denmark

BACKGROUND/AIM: Urine cadmium (U-Cd) is an established biomarker of long-term Cd exposure. U-Cd may be associated with risk of acute myocardial infarction (AMI), but results are equivocal at low biomarker levels. Nutrients including calcium (Ca), magnesium (Mg), and potassium (K) may play an important role in slowing atherosclerosis progression, though research findings with AMI have been inconsistent, and studies are limited in examining whether Cd-AMI associations are modified by these nutrients.

METHODS: We analyzed data from a never smoking subgroup of the Danish Diet, Cancer, and Health (DCH) cohort, a prospective study of 50–64-year-old participants recruited between 1993-1997. Using a case-cohort design, with complete case analysis, we identified 1135 members of the randomly selected subcohort and 776 AMI cases through 2015. We quantified Cd (µg/g) and Ca (mg/g) concentrations in baseline urine samples. We calculated combined nutrient dietary intake scores (3-12 points) from Ca, K, and Mg food frequency questionnaires. We estimated adjusted hazard ratios (HRs) and 95% confidence intervals (95% CIs) using Cox proportional hazard models, adjusted for sex, education, passive smoking, alcohol, waist circumference, exercise and healthy diet. We stratified by median cutpoints and defined as high and low urine Ca (U-Ca) concentrations (median: 117.5 µg/g) or dietary intake scores (median: 8 points).

RESULTS: Results were not materially different when stratified. Among high and low U-Ca groups, HRs for AMI were 1.27 (95% CI: 0.81, 1.98) and 0.93 (95% CI: 0.62, 1.41), respectively, when comparing highest vs. lowest U-Cd quartiles. HRs among high and low dietary intake scores were 0.96 (95% CI: 0.62, 1.49) and 1.25 (95% CI: 0.80, 1.95), respectively, when comparing highest vs. lowest U-Cd quartiles.

CONCLUSIONS: We did not find evidence that nutrient levels modified the association between low-level Cd and AMI among never smokers.

KEYWORDS: metals, nutrients, cadmium, myocardial infarction, cardiovascular health

P-0375 Tampons as a source of exposure to metals among reproductive-aged Black women

Jenni Shearston[1], Ruth Geller[2], Quaker Harmon[3], Kristen Upson[4], Lauren Wise[2], Amelia Wesselink[2], Ganesa Wegienka[5], Donna Baird[3], Marianthi-Anna Kioumourtzoglou[1]

[1]Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [2]Department of Epidemiology, Boston University School of Public Health, Boston, USA, [3]National Institute of Environmental Health Sciences, Durham, USA, [4]Department of Epidemiology and Biostatistics, Michigan State University, East Lansing, USA, [5]Department of Public Health Sciences, Henry Ford Health System, Detroit, USA

BACKGROUND/AIM: Tampons are cotton/rayon plugs commonly used to manage menstrual bleeding. Tampons may become contaminated by environmental chemicals during manufacturing and through cotton production; cotton is a high-pesticide crop and can uptake metals. Retention of the tampon in the vagina for several hours and saturation with menstrual fluid may allow for chemicals to be released from the tampon and efficiently absorbed through the vaginal mucosa into systemic circulation. We evaluated whether tampon use was associated with blood metal concentrations in menstruators.

METHODS: We performed a cross-sectional analysis of baseline data from the Study of Environment, Lifestyle and Fibroids (SELF) in Detroit, Michigan (2010-2012; n=1,664 participants). Tampon use was defined as reporting use of ≥1 tampon on the day of heaviest bleeding during the participant's last menstrual period. We analyzed whole blood metal concentrations using ICP-MS (Al, As, Ba, Cd, Co, Cr, Cs, Cu, Mg, Mn, Mo, Ni, Pb, Sb, Se, Sn, Tl, V, Zn) and Direct Mercury Analysis (Hg). We used linear regression models to calculate mean differences and 95% confidence intervals (CIs) for associations between tampon use and log-transformed metal concentrations, adjusting for potential confounders.

RESULTS: Tampon use was associated with lower concentrations of Zn (-0.02 µg/L, 95% CI: -0.04, -0.00) and Co (-0.06 µg/L, 95% CI: -0.10, -0.01). Associations with other metals were null. In a sensitivity analysis restricted to participants currently menstruating during biospecimen collection (n=401), tampon use was associated with greater Cr concentrations (0.15 µg/L, 95% CI: 0.01, 0.29)

CONCLUSIONS: We observed weak and inverse associations of Zn and Co with tampon use, and a positive association of Cr with tampon use among participants currently menstruating. Future research is needed to evaluate the presence of contaminants in tampons and determine absorption rates of such chemicals across vaginal mucosa.

P-0376 Assessing the role of the Gut Microbiome in the interface between Environmental Chemicals Exposure and Human Health

Anna Maria Campana[1], Hannah E. Laue[2], Yike Shen[1], Martha J. Shrubsole[3], Andrea A. Baccarelli[1]
[1]Department of Environmental Health Sciences, Columbia University, Mailman School of Public Health, New York, USA, [2]Department of Epidemiology, Geisel School of Medicine at Dartmouth, Hanover, USA, [3]Division of Epidemiology, Department of Medicine, Vanderbilt Epidemiology Center, School of Medicine, Vanderbilt University, Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, USA

BACKGROUND:
Since the explosion of microbiome research over the last ten years, findings have shed light on multiple ways through which factors can interact with the human microbiome and drive health and disease. Evidence showed that the microbiome may be an early response system to environmental toxins and a biological mediator of their adverse effects on human health. However, only a few reviews provided a framework for research and translation on the role of the gut microbiome in environmental health science.

METHODS: We summarized the up-to-date published evidence on environmental compounds and their effect on the gut microbiome, the subsequent metabolic pathways, and the long-term outcomes on host health. The PubMed database was queried for the following keywords: “gut microbiota”, “microbiome”, “chemicals”, “xenobiotics”, “human diseases”, “obesity”, “diabetes”, “cardiovascular diseases”, “neurologic disorders”, “biological pathways”, “metabolomics”, and “metagenomics”. Studies related to the subject of our review and written in English, which were published between 2004 and 2022 and available in the English language were included.

RESULTS: We concluded that the evidence supports the gut microbiota as a crucial factor that may mediate and modulate the human health effects of environmental chemicals. However, there are still challenges in understanding the microbiome’s role in pollutants’ toxicity. for example, since environmental chemicals are omnipresent contaminants, they can act consecutively or synchronously as a mixture. It is also critical to elucidate the dynamic interactions between the heterogeneous and individual “omics” datasets. Lastly, more shotgun metagenomics-oriented approaches would help in exploring a larger range of microorganisms present in the human gut microbiome ecosystem like fungi, viruses, and small eukaryotes.
CONCLUSION: Future research in this field is required to build on our limited knowledge of interactions between the intestinal microbiota and environmental pollutants and further elucidate the human health effects.

P-0378 Childhood exposure to non-persistent endocrine disrupting chemicals and multi-omic markers in a population-based child cohort

BACKGROUND AND AIM: Individuals are exposed to multiple environmental pollutants with endocrine disrupting activity (endocrine disruptors, EDCs). The early stages of life are recognized to be particularly susceptible to these stressors. Previous studies have focused on identifying molecular signatures associated with EDCs to elucidate potential mechanisms, however few have integrated multiple omics layers. We aimed to identify multi-omic signatures associated with childhood exposure to non-persistent EDCs using an integrative network approach.

METHODS: We relied on the HELIX Child Panel, which includes roughly 150 children aged 6 to 11 and with no serious health problems. Multi-omic profiles (serum and urinary metabolome, proteome, methylome) were measured in blood and urine samples collected at two time points, 6 months apart. Similarly, 22 non-persistent EDCs (10 phenols, 5 phthalate metabolites, 7 organophosphate pesticide metabolites) were measured at each time point in weekly pooled urine samples, to account for their intra-individual variability. We used Gaussian Graphical Models (GGMs) based on shrinkage estimates of pairwise partial correlations between covariates-adjusted molecular features and EDCs. The networks for the two time points were merged based on the intersection of their significant edges in order to identify reproducible associations.

RESULTS: The time-specific networks included associations of comparable strength and statistical significance. The merged network consisted of 950 edges, 462 nodes, 7 connected components, and included less than 3% of mixed omics-exposure edges. Inter-omic connections represented known biochemical pathways such as insulin, blood hexose and citrate. The reproducible inter-layer associations were corroborated with data from the literature. Among the most significant, we found associations between mono benzyl phthalate and N-acetyl neuraminic, triclosan and serotonin, and diethyl phosphate and serotonin.

CONCLUSIONS: Through partial correlation network analyses, repeat time points and weekly EDC exposure assessment, we identified several biologically relevant molecular signatures related to EDC exposure in childhood.

P-0381 PFAS exposures and the human metabolome: a systematic review of epidemiological studies

Sandra India-Aldana[1], Meizhen Yao[1], Vishal Midya[1], Elena Colicino[1], Leda Chatzi[2], Jaime Chu[1], Chris Gennings[1], Dean Jones[3], Ruth Loos[1,4], Veronica Setiawan[2], Angela Slitt[5], Ryan Smith[3,6], Ryan Walker[1], Dinesh Barupal[1], Douglas Walker[1], Damaskini Valvi[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [3]Clinical Biomarkers Laboratory, Division of Pulmonary, Allergy, Critical Care and Sleep Medicine, Emory University, Atlanta, USA, [4]Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, USA, [5]Department of Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, USA, [6]Veterans Affairs Medical Center, Decatur, USA

BACKGROUND/AIM:
There is growing interest in understanding the health effects of exposure to per-/polyfluoroalkyl substances (PFAS) through the study of the human metabolome. We conducted a systematic review of epidemiologic studies evaluating the association between PFAS and metabolomics.

METHODS: Following PRISMA guidelines, we searched two databases (EMBASE/PubMed) through February 28, 2022 and identified 27 eligible observational studies. We summarized the evidence for PFAS associations reported with individual metabolites or metabolic pathways to identify consistent findings and research gaps.

RESULTS: Effects of twenty-six PFAS exposures have been evaluated using human metabolomic studies, with the most common exposure being legacy long-chain PFAS. Most studies measured exposures during adulthood (n=15), followed by prenatally/perinatally (n=9) and/or in childhood (n=6). Sample sizes ranged from 40 to 1,105 participants. A total of 18 studies used a non-targeted metabolomics approach, 7 studies used targeted approaches, and 2 studies included both. Metabolomics were measured in serum (n=16), plasma (n=9), urine (n=2), or semen samples (n=1). Only two studies integrated repeated metabolomics measures in plasma or urine. The majority of studies were cross-sectional (n=24), including four with prospective analyses of PFAS measured prior to metabolomics. Consistent associations (either up- or down-regulated) were reported between PFAS and amino acids, fatty acids, glycerophosphocholines, glycerolipids, sphingomyelins, bile acids, ceramides, and carnitines. Common enriched metabolic pathways included lipid metabolism, amino acid metabolism, carbohydrate metabolism, purine and urea cycle metabolism. Results for other pathways were less consistent across studies.
CONCLUSION:
A growing body of literature has identified alterations in several metabolites and metabolic pathways that could underlie PFAS-associated metabolic disease in humans. Future studies should consider prospective designs optimizing methods for exposure-metabolomics analyses with longitudinal measures, tissue-specific effects, additional confounder adjustment, or assessment of emerging PFAS and mixture effects to address existing limitations in this field.

KEYWORDS: PFAS, metabolomics, endocrine disrupting chemicals, systematic review.

P-0382 Liver and Plasma concentrations of Per- and Polyfluoroalkyl Substances in Adolescents from the Teen-Longitudinal Assessment of Bariatric Surgery (Teen-LABS) Study

Brittney Baumert[1], Nikos Stratakis[2], Jesse Goodrich[1], Douglas Walker[3], Sandrah Eckel[1], Xiangping Lin[3], Scott Bartell[4], Yinqi Zhao[1], Damaskini Valvi[3], Thomas Inge[5], Todd Jenkins[6], Justin Ryder[7], Rohit Kohli[8], Stephanie Sisley[9], Stavra Xanthakos[6], Zoe Coates Fuentes[3], Sarah Rock[1], Michele Andrea La Merrill[10], Flemming Nielsen[11], Philippe Grandjean[11,12], Rob McConnnell[1], David Conti[1], Leda Chatzi[1]

Lurie Children's Hospital of Chicago, Chicago, USA, [6]Cincinnati Children's Hospital Medical Center, Department of Pediatrics, University of Cincinnati College of Medicine, Cincinnati, USA, [7]Center for Pediatric Obesity Medicine, University of Minnesota Medical School, Minneapolis, USA, [8]Division of Gastroenterology, Hepatology and Nutrition, Children's Hospital Los Angeles, Los Angeles, USA, [9]Department of Pediatrics, Baylor College of Medicine, Houston, USA, [10]Department of Environmental Toxicology, University of California, Davis, Davis, USA, [11]Institute of Public Health, University of Southern Denmark, Odense, Denmark, [12]Department of Environmental Health, T.H. Chan School of Public Health, Harvard University, Boston, USA

BACKGROUND AND AIM: Exposure to per- and poly-fluoroalkyl substances (PFAS) is ubiquitous due to their persistence in the environment and in humans. Extreme weight loss has been shown to influence concentrations of circulating persistent organic pollutants (POPs). Using data from the multi-center perspective Teen-Longitudinal Assessment of Bariatric Surgery (Teen-LABS) cohort, we compared concentrations of liver and plasma-PFAS and investigated changes in plasma-PFAS in adolescents after bariatric surgery.

METHODS: Adolescents (Mean age = 17.1 years, SD = 1.5 years) undergoing bariatric surgery were enrolled in the Teen-LABS study. Plasma-PFAS were measured at the time of surgery and then 6-, 12-, and 36 months post-surgery. PFAS was measured in liver tissue from biopsies collected at the time of bariatric surgery. Concentrations of liver and plasma-PFAS were compared using Spearman's rank correlation coefficients. Linear mixed effect models were used to evaluate longitudinal changes in plasma-PFAS after the time of bariatric surgery.

RESULTS: This study included 186 adolescents at baseline with severe obesity who underwent bariatric surgery between 2007 and 2012. Baseline plasma and liver-PFAS concentrations were found to be strongly positively correlated (ρ = 0.76-0.91). Models of longitudinal changes in plasma-PFAS after bariatric surgery revealed an increase in plasma-PFAS concentrations from the time of surgery to 6 months ($p<0.05$ for all plasma-PFAS except PFHxS) and a decline in PFAS concentrations from 6 months to 36 months ($p<0.05$ for all plasma-PFAS).

CONCLUSIONS: Bariatric surgery in adolescents was associated with an initial increase in circulating PFAS at 6 months following surgery, followed by continuing decline in concentration to 36 months following bariatric surgery. High correlations between liver and plasma-PFAS concentrations suggest that measurements in plasma are a good proxy for PFAS accumulation in the liver and potential liver-specific PFAS effects.

P-0383 Replacement Phthalates are Associated with Adverse Pregnancy Outcomes in an Ethnically Diverse Nulliparous Pregnancy Cohort in the USA, 2010-2015

Autumn Clemons[1], Pam Factor-Litvak, Shabnaz Siddiq[1], Susannah Leisher[1], Chris Gennings[2], John Meeker[3], Nancy Mervish[4], Virginia Rauh[5], Ronald Wapner[5]

[1]Columbia University Mailman School of Public Health, NY, US, [2]Environmental Medicine and Public Health Mount Sinai, NY, US, [3]Michigan School of Public Health, Ann Arbor, US, [4]Icahn School of Medicine at Mount Sinai, NY, US, [5]Columbia University Irving Medical Center, NY, US

BACKGROUND: Preterm birth and preeclampsia are leading causes of pregnancy-related morbidity and mortality. We examined associations between prenatal exposure to phthalate metabolites (PMs) and the risk of these outcomes in an ethnically diverse cohort.

METHODS: 1,020 cases of preeclampsia (PE), new-onset antenatal hypertension (aHTN), or spontaneous preterm birth (sPTB) and 1,020 matched controls from the Nulliparous Mothers To Be Study cohort were included. Urine specimens in each trimester (total = 5,789) were analyzed for 14 PMs including four di-2-ethylhexyl (DEHP) PPMs with concentrations below the limit of detection (LOD) values were replaced with LOD/√2 and PMs with under 70% detection were not analyzed. Exposure was defined as the geometric mean of each PM in each trimester, adjusted for specific gravity, and divided into quartiles. Multivariate conditional logistic regression analyses were performed to examine associations between PMs and outcomes, adjusting for confounders. Race and infant sex were considered a priori effect modifiers.

RESULTS: 59.1% of women were white, and 40.9% were non-white. PE: Overall odds of PE were increased two-fold for 2 PMs of di-2-ethylhexyl terephthalate (DEHTP), a replacement plasticizer for DEHP. These associations were held for both white and non-white mothers and for mothers of girls. Several non-DEHP PMs were also associated with increased odds of PE. aHTN: Odds of aHTN were increased at lower concentrations of several DEHP metabolites. These associations were held for mothers of boys and girls, but only for non-white mothers. sPTB: Overall, the odds of sPTB were decreased for DEHP PMs, regardless of infant sex. for boys and non-white mothers, non-DEHP PMs were associated with increased odds of sPTB.
CONCLUSION: Associations between PMs and adverse pregnancy outcomes differed by infant sex and maternal race, suggesting that interventions to reduce exposure be tailored to specific groups.

P-0384 Exposure to PFAS in Australian communities impacted by environmental contamination; the PFAS Health Study, 2016-2020

Kayla Smurthwaite[1], Nina Lazarevic[1], Jennifer Bräunig[1], Sandra Nilsson[1], Jochen Mueller[1], Catherine D'Este[1], Robyn Lucas[1], Bruce Armstrong[1], Aparna Lal[1], Susan Trevenar[1], Hsei-Di Law[1], Rose Hosking[1], Imogen Gad[1], Archie Clements[1], Jo Lane[1], Philip Batterham[1], Cathy Banwell[1], Adrian Miller[1], Deborah Randall[1], Rosemary Korda[1], Martyn Kirk[1]

[1]Australian National University, Canberra, Australia, [2]University of Queensland, Brisbane, Australia, [3]University of Sydney, Sydney, Australia, [4]Curtin University, Perth, Australia, [5]Central Queensland University, Rockhampton, Australia

BACKGROUND:
Communities impacted by environmental contamination may have higher exposure to per- and polyfluoroalkyl substances (PFAS), which has the potential for both immediate and latent impacts on human health. We investigated PFAS exposure in children and adults who had lived or worked in three Australian communities affected by environmental contamination associated with the historic use of Aqueous Film Forming Foams (AFFF) at military bases.

METHODS: From 2016 to 2019, the Australian Government conducted the Voluntary Blood Testing Program for PFAS. We recruited 2,587 participants into the PFAS Health Study, in addition to 702 randomly sampled residents of three comparison communities not known to be affected by environmental contamination. Comparison communities were selected based on area-level sociodemographic characteristics, in accordance with the three exposed communities. We measured concentrations of nine PFAS blood serum samples from each participant using Liquid Chromatography Tandem Mass Spectrometry.

RESULTS: Geometric means of serum PFAS concentrations across exposed communities ranged from 4.9–6.6 nanograms per millilitre (ng/mL) for perfluorooctane sulfonic acid (PFOS), from 2.9–3.7 ng/mL for perfluorohexane sulfonic acid (PFHxS) and from 1.3–1.8 ng/mL for perfluorooctanoic acid (PFOA). Geometric means of PFAS concentrations were higher in older participants and males. In total, 29–42% of participants from exposed communities had an elevated serum PFOS concentration (above the 95th percentile of the comparison population) and 48–55% had an elevated serum PFHxS concentration.

CONCLUSIONS: Evidence of higher serum PFOS and PFHxS concentrations in these Australian communities is consistent with the nature of the environmental contamination and the main constituents of the AFFF used in the areas. Serum PFAS concentrations across the exposed communities were comparable to those reported for communities in the USA affected by environmental PFAS contamination from firefighting foam use on military bases, though lower than in a community in Sweden.

P-0387 Current exposure levels and endocrine related outcomes of five non-phthalate plasticizers in humans: A systematic review

Joeun Jung[1], Yoojin Cho[1], Yura Lee[1], Kyungho Choi[1]
[1]*Graduate school of Public Health, Seoul National University, Seoul, 08826, Republic of Korea*

Several substitutes such as DEHA, DINCH, DEHTP, ATBC, and TOTM are widelyused in commercial products in replacement of phthalates. Consequently, their human exposure and related health outcomes are increasingly reported. In the present study, we reviewed and synthesized the current knowledge on biomonitoring and endocrine related epidemiological studies on the five alternative plasticizers. A systematic literature search was conducted on PubMed and Scopus, for the articles published since January 2000 up to November 2021. The total number of literatures identified was 56 and 11 for biomonitoring and epidemiological studies, respectively. Major metabolites of the alternative plasticizers were reported in human urines of 17 countries, and the detection frequency was the highest in Europe, and the lowest in Asia. Among the substances detected over 60%, DINCH metabolites were most frequently detected, followed by those of DEHTP, DEHA, and TOTM. ATBC exposure has not been evaluated in urine but in plasma. Urinary DINCH and DEHTP metabolites showed androgenic associations in the US women. Both chemicals were associated with increased uterine fibroid prevalence in premenopausal women of Korea. Urinary DINCH metabolites increased the risk of preterm birth in the US infants and mothers, and thyroid hormones in Swedish pregnant women. ATBC in plasma showed positive association with breast cancer risk in French women. Positive associations between urinary DINCH metabolites and sperm DMRs were observed in the US men, suggesting potential epigenetic changes on the male gamete. Lack of reliable urinary biomarkers of exposure and limited observations on the association on susceptible populations were identified as research gaps that require further investigations.

KEYWORDS: Alternative plasticizers, urinary phthalate metabolites, endocrine disruption, systematic review

P-0389 Hypothetical interventions on dietary intakes to mitigate lead and cadmium induced mortality in US adults

Nasser Laouali[1,2,3], Tarik Benmarhnia[3], Youssef Oulhote[2]
[1]CESP UMR1018, Université Paris-Saclay, UVSQ, Inserm, Gustave Roussy, Villejuif, France, [2]Department of Biostatistics and Epidemiology, School of Public Health and Health Sciences, University of Massachusetts at Amherst, Amherst, USA, [3]Scripps Institution of Oceanography, University of California, San Diego, San Diego, USA

CONTEXT: In the recent decades, lead and cadmium exposure have declined sharply, although they are ranked second and seventh most significant potential threat to human health through increasing oxidative stress and inflammation. In parallel, high diet quality may prevent from chronic inflammation. Therefore, we sought to estimate the effects of a joint hypothetical intervention on metals exposures levels and adherence to an anti-inflammatory diet or fruits and vegetables (FV) intake on the expected all-cause and specific causes of mortality distributions.

METHODS: We used data on 14,311 adults aged ≥20 years enrolled in the NHANES-III between 1988 and 1994 and followed up through Dec 31, 2015. at baseline, daily FV servings and adherence to the dietary inflammatory index (DII) were assessed using 24-hour dietary recalls. Mortality was determined from the National Death Index records. We used the parametric g-formula with pooled logistic regression models to estimate the absolute risk of all-cause, cardiovascular, and cancer mortality under the different interventions while controlling for risk factors.

RESULTS: Median follow-up was 22.5 years, 5,167 (36%) participants died; 1,550 were attributable to cardiovascular disease and 1,135 to cancer. Compared to the natural course (no intervention), the joint intervention to lower BLLs and increase the adherence to the DII had the strongest impact on cancer mortality risk with a RD of -1.77% (-2.73% to -1.01%). for UCd, the corresponding RD was -3.10% (-9.50 to -0.47) for cancer and -6.97% (-12.39 to -1.52) for all-cause mortality. Intervening on BLLs and FV servings/days was associated to lower risk of all-cause and cancer mortality. Any of the joint intervention was associated to cardiovascular disease mortality.
CONCLUSION: These results suggest that higher diet quality may constitute an complementary approach to the interventions to reduce exposures to cadmium and lead to further minimize their effects on mortality, specially from cancer.

P-0391 Psychological distress in three Australian communities living with chronic environmental per- and polyfluoroalkyl substances contamination

Nina Lazarevic[1], Kayla Smurthwaite[1], Philip Batterham[1], Jo Lane[1], Susan Trevenar[1], Catherine D'Este[1,2], Archie Clements[3], Amelia Joshy[1], Rose Hosking[1], Imogen Gad[1], Aparna Lal[1], Hsei Di Law[1], Deborah Randall[4], Adrian Miller[5], Rosemary Korda[1], Martyn Kirk[1]

[1]Australian National University, Canberra, Australia, [2]The University of Newcastle, Newcastle, Australia, [3]Curtin University, Perth, Australia, [4]The University of Sydney, Sydney, Australia, [5]CQUniversity, Townsville, Australia

BACKGROUND AND AIM: Chronic environmental contamination is a recognised risk factor for psychological distress. Psychological distress has been seldom studied in the context of per- and polyfluoroalkyl substances (PFAS) contamination, despite the existence of numerous and widespread contamination sites globally. We examined psychological distress in Australian communities exposed to PFAS from the historical use of aqueous film-forming foam in firefighting activities.

METHODS: We conducted a cross-sectional study of 881 adults in three exposed communities and 801 adults in three comparison communities. Participants provided blood samples and completed a survey on their exposure history, sociodemographic characteristics, and measures of psychological distress (Kessler-6, Distress Questionnaire-5), somatisation (Patient Health Questionnaire-15), and anxiety (Generalised Anxiety Disorder-7). We estimated prevalence ratios (PR) of clinically-significant psychological distress scores and differences in mean scores: (1) between exposed and comparison communities; (2) per doubling in PFAS serum concentrations in exposed communities; (3) for factors that affect the perceived risk of living or working in a community exposed to PFAS; and (4) in relation to self-reported concerns about health.

RESULTS: We observed higher levels of self-reported psychological distress in exposed communities than in comparison communities (e.g., in Katherine compared to Alice Springs, Northern Territory: clinically-significant anxiety scores, adjusted PR=2.82, 95%CI 1.16–6.89). We found little evidence to suggest that psychological distress was associated with PFAS serum concentrations (e.g., in Katherine, PFOS and anxiety, adjusted PR=0.85, 95%CI 0.65–1.10). Psychological distress was higher among participants who were occupationally exposed to firefighting foam, used bore water on their properties, or were concerned about their health.
CONCLUSION: Psychological distress was substantially more prevalent in exposed communities than in comparison communities. Our findings suggest that the perception of risks to health, rather than direct PFAS exposure, contribute to psychological distress in communities with PFAS contamination.

P-0393 Lipid Metabolites and Arsenic Methylation in the Strong Heart Family Study: An Untargeted Metabolomics Approach

Ahlam Abuawad[1], Jinying Zhao[2], Arce Domingo-Relloso[1], Jeff Goldsmith[3], Sandra Albrecht[4], Shelley Cole[5], Miranda Spratlen[1], Walter Goessler[6], Jason Umans[7,8], Vrinda Kalia[1], Mary Gamble[1], Tiffany Sanchez[1], Ana Navas-Acien[1]
[1]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA, [2]Department of Epidemiology, College of Public Health and Health Professions & College of Medicine, Gainesville, USA, [3]Department of Biostatistics, Mailman School of Public Health, Columbia University, New York, USA, [4]4Department of Epidemiology, Mailman School of Public Health, Columbia University, New York, USA, [5]Department of Population Health, Texas Biomedical Institute, San Antonio, USA, [6]Institute of Chemistry – Analytical Chemistry, Karl-Franzens University Graz, Graz, Austria, [7]MedStar Health Research Institute, Hyattsville, USA, [8]Georgetown-Howard Universities Center for Clinical and Translational Science, Washington, USA

BACKGROUND AND AIM: There are no safe levels of arsenic (As) exposure. Inorganic As (iAs) is methylated into mono-methyl (MMA) and dimethyl (DMA) arsenicals; methylation to DMA facilitates urinary As elimination and potentially reduces As-related toxicity. Our goal is to identify metabolites associated with As methylation patterns, as measured by the As species (iAs%, MMA%, and DMA%), and As methylation indices (primary methylation index (PMI:MMA/iAs) and secondary methylation index (SMI:DMA/MMA) which are less influenced by As exposure levels.

METHODS: This study leveraged urinary As and untargeted lipid metabolite data from 1,838 participants in the Strong Heart Family Study, which recruited adult participants from 12 American Indian communities in Arizona, Oklahoma, and North/South Dakota in 2001–2003. Metabolite data was performed on plasma samples using a quadrupole time-of-flight mass spectrometer. We used linear regression models to evaluate the cross-sectional associations between lipid metabolites and As methylation patterns and Mummichog for metabolic pathways analysis.

RESULTS: 1543 (543 identified, 1000 unidentified) lipid metabolic features were included. From 1,088 lipid metabolites that were significantly associated (pFDR<0.05) with at least one As species in linear regression models, 531 were associated with all three species, and 541 overlapped with MMA%, DMA% and SMI. Pathway enrichment analyses of associated metabolites (p<0.1) with ≥3 significant lipid metabolites in the pathway showed effects in 12 pathways that were associated with As methylation markers. Although there were only 3 pathways that were associated with PMI, (lineolate, fatty acid activation, and carnitine shuttle metabolism), these same pathways were associated with all 5 measures of As methylation.

CONCLUSIONS: We found that associations between As methylation indices and lipid metabolites predominantly affect the secondary methylation of As, from MMA to DMA along fatty acid metabolism pathways. Future work will investigate if these metabolites are also associated with adverse health outcomes.

P-0394 Using geographic information systems to estimate potential pesticide exposure in Belgium

Sarah Habran[1], Christelle Philippart[1], Suzanne Remy[1]
[1]*ISSeP, Liège, Belgium*

BACKGROUND AND AIM: The assessment of residential exposure to agricultural pesticides is a major issue for public health, regulatory and management purposes. In that context, geographic information systems (GIS) approaches for mapping estimates of agricultural pesticide exposure were developed in this study.
METHODS: Data on pesticide application rates, high-resolution annual datasets of the geographic distribution of crops, and the 100x100m grid population dataset were used to complete this analysis in Wallonia (Belgium) over the period 2015-2019. Pesticide exposure metrics were estimated using a buffer-based exposure model by neighborhood analysis in ArcGIS. The model takes into account both proximity to crops, estimated amount of pesticides and acreage treated. The weighting factors established for Harmonized Risk Indicators under Directive 2009/128/EC were applied to the estimated amounts of actives ingredients in order to align with the European approach. Then, a population weighted method was used to 'up-scale' the exposure data to administrative levels to match up with public health datasets.
RESULTS: The results provide the first map of modeling residential exposure to agricultural pesticides for the entire region of Wallonia. The northern part of the Sambre-Meuse axis shows more intensive agriculture and the highest pesticide weighted exposure indices. Such GIS approaches help to characterize pesticide exposure for residents living close to agricultural lands but also in non-domestic environments such as schools, nurseries, etc.
CONCLUSIONS: This research work on exposure characterization to agricultural pesticides using GIS models gives a valuable basis for research and environmental health actions in Belgium. Maps highlight areas where human biomonitoring and epidemiological studies should be implemented to investigate the impact of potential environmental exposure to pesticides. Using this information, policymakers will able to detect potential priority zones and take action to check and reduce agricultural pesticide loads in the environment.

P-0396 Dose reconstruction of four alternative plasticizers from urinary biomarkers of exposure

Jinhyun Kwon[1], Jeong Weon Choi[1], Hyojoo Choi[1], Dongmin Song[1], Eukyung Jo[1], Yehoon Jo[1], Younglim Kho[2], Sungkyoon Kim[1]

[1]Seoul National University, Seoul, Republic of Korea, [2]Eulji University, Seongnam, Republic of Korea

BACKGROUND AND AIM: As alternative plasticizers (APs) are widely being used, more and more studies reported detection of urinary metabolites of APs including Di-2-ethylhexyl terephthalate (DEHTP), disononyl phthalate (DiNP), di(2-ehtylhexyl) adipate(DEHA), diisononyl-cyclohexane-1,2-dicarboxylate (DINCH). This study aimed to estimate the external exposure of above four APs using urinary excretion fraction (Fue)s and simple pharmacokinetic (PK) models for humans.

METHODS: The Fue and time-concentration profiles (PK-profiles) were obtained from the published articles, where the study APs were administered in humans. Three metabolites, mainly monoesters and secondary oxidative metabolites were selected for each APs. A compartment-model for each APs was constructed to describe the elimination of parent compound and the metabolites. Then, exposure-conversion factors (ECFs) were calculated from PK model simulation showing the relationship between daily intake and urinary biomarkers. Regarding dose-reconstruction, synthetic biomarker measurements were used for typical body weight, urinary creatinine values in Korean children, adolescents and adults.

RESULTS: The exposure estimates from PK/ECF corresponding to 10 ug/L were as follow: 5OH-MEHTP (4.8 ~ 5.5 μg/kg/d) for DEHTP; 5OH-MEHA (127 ~ 166 μg/kg/d) for DEHA; 5OH-MINCH (0.67 ~ 0.87 μg/kg/d) for DINCH; OH-MINP (0.43 ~ 0.56 μg/kg/d) for DiNP. Those from Fues were comparable with 1.1 to 4 folds.

CONCLUSIONS: Reverse dosimetry was successfully performed with simple human PK models for urinary biomarkers of exposure to APs, which were close or comparable to those from popular Fue methods. for future investigations, we believe the PK technique will be more effective in exposure modeling.

P-0397 Association between prenatal exposure to organophosphate flame retardants and thyroid hormone levels in diverse pregnancy cohorts

Jessica Trowbridge[1], Stephanie, M. Eick[2], Dana Going[1], Erin DeMicco[1], Susan Schantz[3], Tracey Woodruff[1], Rachel Morello-Frosch[4]

[1]University of California, San Francisco, San Francisco, USA, [2]Emory University, Atlanta, USA, [3]University of Illinois, Urbana-Champaign, Urbana-Campaign, USA, [4]University of California, Berkeley, Berkeley, USA

BACKGROUND: Organophosphate flame retardants (OPFR) are rarely measured in pregnant people. Prenatal exposure to organophosphate pesticides (structurally similar to OPFRs) is linked to thyroid hormone (TH) disruption. Prenatal TH disruption has been associated with adverse pregnancy-related outcomes and poor neurodevelopment in the offspring. We aim to characterize prenatal OPFR exposures and assess their relationship with thyroid-stimulating hormone (TSH), thyroxine in free and total forms (TT4 and fT4, respectively).

METHODS: We analyzed nine OPFR metabolites in 2nd-trimester urine, as well as fT4, TT4, and TSH in 2nd-trimester blood collected from 287 pregnant participants from a combined and demographically diverse pregnancy cohort from the University of California San Francisco and the University of Illinois Urbana-Champaign (N= 110 and N = 177 respectively). We used linear regression models to assess relationships between prenatal OPFR levels and each of the measured thyroid hormones. Linear models were adjusted for gestational age at sample collection, maternal age, and cohort. We calculated the percent change in TH for a 10-fold increase in OPFR level.

RESULTS: OPFRs were modestly associated with TH disruption, however, confidence intervals were imprecise. DBUP was associated with 8% decrease in TSH (95% CI: (-24.5, 11.0), while BCPP with a 10% increase in TSH levels (0.9, 21.0), neither chemical was associated with changes in TT4 or fT4. DPHP and BDCPP were associated with changes in fT4 (2% (-4.7, 1.2) decrease and 1% (-1.4,2.7) increase, respectively). BCETP was associated with an increase in both fT4 (1% (-0.7, 2.5)) and TT4 (1.5% (-0.4, 3.6)). BBOEP showed a 3% (-0.9, 7.7) increase in TT4. The remaining OPFRs did not have evidence for change in TSH, fT4 or TT4 levels.

CONCLUSIONS: Prenatal OPFR exposures may influence levels of TSH, free and total T4 in pregnant women.

KEYWORDS: Thyroid hormone, flame retardants, infant neurodevelopment, prenatal exposures

P-0398 Human health risks of gadolinium contamination in urban and rural soils across Leicestershire (UK)

Antonio Peña-Fernández[1], Manuel Higueras[2], G. S. Jagdev[1], M.D. Evans[1], M. Carmen Lobo Bedmar[3]
[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, LE1 9BH, UK, [2]Scientific Computation & Technological Innovation Center (SCoTIC), Universidad de La Rioja, Logroño, Spain, [3]IMIDRA, Alcalá de Henares (Madrid), Spain

BACKGROUND AND AIM: Gadolinium (Gd) is widely used in industrial and household applications, including compact discs, microwaves, fibre optics and flat screen displays. The aim was to determine the presence, distribution and risks to this element in urban/rural topsoils from Leicestershire (UK).

METHODS: A total of 850 soil samples were collected (2017-18); 26 composite samples were appropriately prepared after mixing topsoil samples collected per park/location (18 urban, 8 rural), which were further processed in duplicate. Gd was measured in triplicates in each of the 52 composite samples by ICP-MS. Noncarcinogenic risks were characterised following US EPA methodologies.

RESULTS: Slightly higher levels of Gd were found in rural area, although without significance (data presented as median and interquartile ranges, in mg/kg): 3.312 (2.174, 3.862) vs. 3.094 (2.763, 3.418). Fertilisers, a major diffuse source of rare earth elements in topsoils, might explain the lack of statistical significance between both main areas. The urban/rural regions were subdivided into the four ordinal directions to study the Gd distribution. Significant differences were detected for the Gd monitored in the composite samples monitored throughout Leicester city ($p=0.017$) and rural areas ($p=0.007$), which revealed different concentration patterns NE>SW>SE>NW and SE>NE>SW>NW for each area, respectively, reflecting the Gd wide distribution. Noncarcinogenic risks quotients for ingestion (2.98E-03) and dermal contact (1.06E-04) were lower than the threshold.

CONCLUSIONS: Our results would suggest a minimal risk through the ingestion/dermal contact of Gd present in topsoils in Leicester city. However, the risk characterisation is incomplete as the specific risks derived through the inhalation of resuspended soils would require for further and unknown toxicological data. Moreover, understanding the fate processes Gd undergoes in the environment is critical to perform environmental risk assessments, which is increasing in relevance owing to the myriad of anthropic applications of Gd.

KEYWORDS: Gadolinium, HREEs, Leicester, topsoils, distribution, risks.

P-0399 Calcium and body mass index modify the associations between prenatal phthalate exposure and ultrasound measures of bone metabolism among pregnant women in Mexico City

Amber Cathey[1], Marcela Tamayo-Ortiz[2], Juan Tamayo-Orozco[3], John Meeker[1], Karen Peterson[1], Belem Trejo-Valdivia[4], Martha Maria Téllez-Rojo[4], Deborah Watkins[1]

[1]University of Michigan School of Public Health, Ann Arbor, USA, [2]Mexican Social Security Institute, Mexico City, Mexico, [3]Mexican Committee for the Prevention of Osteoporosis, Mexico City, Mexico, [4]National Institute of Public Health, Cuernavaca, Mexico

BACKGROUND AND AIM: Phthalates are used in numerous consumer products, resulting in ubiquitous human exposure. As phthalates have demonstrated endocrine and peroxisome proliferator-activated receptor activity, we hypothesize that exposure may interfere with bone remodeling, particularly if exposure occurs during periods of increased bone activity, like pregnancy. We evaluated associations between prenatal phthalate exposure and bone remodeling during pregnancy and one year postpartum among 289 mothers from the ELEMENT birth cohort.

METHODS: Urine samples were collected at up to three points during pregnancy (3, 6, 8 months) and assayed for 9 phthalate metabolites. Geometric means of specific gravity-corrected phthalate concentrations were used as overall measures of prenatal phthalate exposure. Bone remodeling was assessed utilizing quantitative ultrasound speed of sound (SOS) of the phalange (cortical bone) and distal radius (trabecular bone) at each prenatal visit and 1, 3, 7, and 12 months postpartum. Participants were randomized to receive calcium supplementation or placebo throughout pregnancy. Linear mixed effect models were used to estimate associations between phthalate exposure and repeated SOS z-scores, with separate models for prenatal and postnatal measurements. Final models adjusted for maternal age, pre-pregnancy BMI, education, parity, calcium supplementation, and study visit. We also explored effect modification by calcium supplementation and BMI.

RESULTS: We observed higher prenatal phalange SOS z-scores with interquartile range increases in MEP (β=0.11; 95%CI: 0.003,0.31) and MiBP (β=0.15; 95%CI: 0,0.42). Several phthalates were associated with lower SOS among women who received calcium compared to the placebo group, particularly for postpartum phalange measures. Prenatal and postpartum phalange SOS measures were positively associated with phthalate exposure among women with a BMI≥25 compared to those with a BMI<25.

CONCLUSIONS: Our findings suggest that phthalate exposure may interfere with bone remodeling during pregnancy, and that consideration of effect modifiers is paramount to understand the effects of environmental exposures on bone health.

P-0406 Prenatal Exposure to Organophosphate Insecticides and Measurements of Fetal Growth and Length of Gestation in the Study of Asian Women and their Offspring's Development and Environmental Exposures (SAWASDEE)

Brittney Baumert[1], Nancy Fiedler[2], Tippawan Prapamontol[3], Panrapee Suttiwan[4], Todd Everson[1], Parinya Panuwet[1], Warangkana Naksen[5], Chayada Dokjunyam[3], Supattra Sittiwang[4], Sureewan Pingwong[4], Carmen J. Marsit[1], P. Barry Ryan[1], Dana Boyd Barr[1]

[1]Emory University, Atlanta, USA, [2]Rutgers University, Environmental and Occupational Health Science Institute, Piscataway, USA, [3]Chiang Mai University, Research Institute for Health Sciences, Chiang Mai, TH, [4]Chulalongkorn University, Faculty of Psychology, Bangkok, TH, [5]Chiang Mai University, Faculty of Public Health, Chiang Mai, TH

BACKGROUND AND AIM: Experimental studies have shown associations between organophosphate pesticides (OPs) and fetal growth measurements, but these associations have been inconsistent in epidemiological studies. We aimed to evaluate associations between prenatal exposure to OPs and birth outcomes by including trimester specific measures of OPs.

METHODS: We recruited pregnant farmworker women in Chom Thong and Fang, two districts of Chiang Mai province in Thailand (N = 330) into the Study of Asian Women and their Offspring's Development and Environmental Exposures (SAWASDEE). We collected up to 6 serial urine samples per participant during gestation and composited the samples to represent early, mid, and late pregnancy. Spearman correlation coefficients of concentrations of dialkyl phosphates (DAPs) across pregnancy were calculated. Windows of vulnerability to OP exposure were assessed by modeling urinary DAPs measured in early, middle, and late pregnancy with outcomes of growth measurements at birth.

RESULTS: DAP metabolite concentrations in serial composite samples were weakly to moderately correlated. We observed significant differences between participants from Fang compared to Chom Thong, both in demographic and exposure characteristics. We were unable to demonstrate an adverse relationship between in utero exposure to OPs and measurement of fetal growth (birth length, weight, and head circumference). Among participants from Fang, we observed increases in gestational duration associated with early pregnancy exposure to ∑DEAP (βadjusted = 0.80 weeks per log10 unit increase; 95% CI (0.34, 1.2), $p<0.01$) and its individual metabolites (DETP, DEDTP, DEP) as well as with late pregnancy exposure to ∑DEAP (βadjusted = 0.69 weeks per log10 unit increase; 95% CI (0.18, 1.2), $p<0.01$) and its individual metabolites (DETP, DEDTP, DEP).

CONCLUSIONS: Maternal concentrations of urinary DAPs were not associated with fetal growth measurements at birth; however, we did observe associations with length of gestation.

KEYWORDS: pesticides, birth outcomes, exposure assessment

P-0408 Urinary Concentrations of Oxidative Stress Biomarkers Across Pregnancy: Variability of Measures in Two Birth Cohorts

Mrudula Naidu[1,3], Bo Gu[2], Yelena Afanasyeva[2], Mengling Liu[2,3], Leonardo Trasande[1,2,3], Akhgar Ghassabian[1,2,3]
[1]Department of Pediatrics, NYU Grossman School of Medicine, New York, USA, [2]Department of Population Health, NYU Grossman School of Medicine, New York, USA, [3]Department of Environmental Medicine, NYU Grossman School of Medicine, New York, USA

BACKGROUND AND AIM: Measurement of urinary levels of oxidative stress biomarkers (OSB) is often used to infer about the biological mechanisms associated with exogenous environmental exposures, particularly in pregnancy. Yet, it is unclear if a single measure of OBS in pregnancy can be used an indicator of oxidative status in pregnant women. Here, we examined the stability of repeated measures of OSBs across pregnancy, accounting for sociodemographic, health-related and life style factors, and identified patterns in variability in urinary OSBs.

METHODS: Seven Oxidative stress biomarkers including MDA, F2-isoprostanes, 8-OHdG, and diY were analyzed using urine samples that were collected at <18, 18-25 and >25 weeks of gestation in two birth cohorts, NYU CHES (n=679) and TIDES (n=240) using Solid Phase Extraction and High-Performance Liquid Chromatography coupled with Tandem Mass Spectrometry. After replacing values below levels of detection(LOD)with LOD/√2, urinary levels were divided by creatinine to account for dilution and log-transformed for normality. We estimated the intraclass correlation coefficients (ICCs) of repeatedly measured OSBs using a 2-way mixed-effects model with absolute agreement, adjusted for covariates. We used latent class linear mixed model (LCLMM) to identify classes of women with similar patterns in variability of biomarkers.

RESULTS: OSBs were detected in more than 80% of samples, except F2-isoprostanes, for which percent below LOD was close to 30%. ICCs varied between 0.17 and 0.40 for a single measurement and 0.43 and 0.67 for average measurements. The results of LCLMM suggested that, for most OSBs, three latent classes well characterize distinct variability patterns of repeated measured biomarkers in pregnant women.

CONCLUSIONS: Urinary measures of OSB showed within-individual variability across the course of pregnancy. Future studies of OSB measures in pregnant women are recommended to rely on more than one measurement to infer about oxidative status in pregnancy.

KEYWORDS: Pregnancy, Environmental Exposure, Oxidative Stress

P-0409 Why Indoor Chemistry Matters: A National Academies Consensus Study

Megan Harries[3], Rima Habre[1], Jonathan Abbatt[4], William Bahnfleth[5], Ellison Carter[6], Delphine Farmer[6], Gillian Gawne-Mittelstaedt[7], Allen Goldstein[8], Vicky Grassian[9], Glenn Morrison[10], Jordan Peccia[11], Dustin Poppendieck[12], Kimberly Prather[9], Manabu Shiraiwa[13], Heather Stapleton[14], Meredith Williams[15], David Dorman[2]

[1]University of Southern California, Los Angeles, USA, [2]North Carolina State University, Raleigh, USA, [3]The National Academies of Sciences, Engineering, and Medicine, Washington, USA, [4]University of Toronto, Canada, [5]Pennsylvania State University, USA, [6]Colorado State University, USA, [7]Tribal Healthy Homes Network, USA, [8]University of California, Berkeley, USA, [9]University of California, San Diego, USA, [10]University of North Carolina, Chapel Hill, USA, [11]Yale University, USA, [12]National Institute of Standards and Technology, USA, [13]University of California, Irvine, USA, [14]Duke University, USA, [15]California Department of Toxic Substances Control, USA

BACKGROUND AND AIM: The indoor environment is a significant contributor to human chemical exposures and health risks, and indoor chemistry plays an important role in driving and modifying exposure to many indoor pollutants. Despite recent developments, much of the chemical complexity and variability of indoor environments remains poorly understood.

METHODS: The National Academies of Sciences, Engineering, and Medicine (the National Academies) convened an ad hoc committee of 16 experts to conduct a consensus study examining the state of the science regarding chemicals in non-industrial indoor environments.

RESULTS: This presentation will summarize findings and emerging discoveries related to indoor chemistry and sources, chemical partitioning and reactions, and links between chemical exposure, air quality, and human health. Briefly, thousands of chemicals are found indoors in air, particles, dust, and surfaces, and they partition across phases. Humans can modify indoor chemistry and act as primary sources. Indoor chemicals undergo oxidation, photolysis, hydrolysis, acid-base, and other reactions and can form reaction products with differing properties. Improved knowledge of molecular reaction rates, kinetics, emission rates, building and environmental factors, and human behaviors and time activity patterns along with their uncertainties are needed to refine exposure and health risk models. This presentation will also summarize recommendations regarding: 1) key implications of recent scientific research, including potential near-term opportunities for translating research findings into practice, and 2) opportunities for new scientific research in several priority areas critical to achieving a better understanding of the chemistry of the indoor environment and resulting adverse exposures and health risks.

CONCLUSIONS: The committee noted opportunities for advancing this field of study by enhancing interdisciplinary collaboration and addressing methodological or technological barriers to research. This scientific foundation will further our understanding of indoor chemistry and its impacts on health and the environment and support regulatory action and guidelines.

THEMATIC 17: Non-communicable diseases including cancer, cardio-metabolic and neurological

P-1036 Prevalence of overweight and obesity and associated risk factors among pupils in primary schools in northern Iraq: a cross-sectional study

Ahmed Al-Delaimy[1]
[1]*University of Anbar, Medical College, Baghdad, Iraq*

BACKGROUND:
The prevalence of overweight and obesity among school children in the Eastern Mediterranean region is increasing. Childhood obesity can cause several health problems. The aim of this study is to find the prevalence and the associated risk factors of increasing weight among primary school pupils.

METHODS: This is cross-sectional descriptive study was carried out during the school year 2019. A total of 450 pupils primary school children of both sexes (222 male and 228 female) were involved in this study aged 7 to 13 years old. Children were categorized into 4 BMI categories: Thin < 5th percentile or normal ≥ 5-84th percentile or overweight 85-97th percentile or obese ≥ 97th. All students were weighted with light clothes and were barefooted.

RESULTS: The prevalence of obese in this study was 12%, and overweight was 18.4%. It was found that most food taken to school were sugar and carbohydrates (Chips and Juice were 25%, Biscuit and Nestle were 28.1%). Class level (second and third) of pupils (p value=0.0001) of schoolchildren and mother education risk factors (p value=0.025) shows significant difference with BMI percentile. Other risk factors such as father education, family monthly income, type of feeding and time of weaning show no significant difference. Also our results show significant difference with BMI percentile and risk factors (type of food taken to school (p value: 0.048), taking money to buy from school canteen (0.005), soft drinking (0.038), and eating snacks (0.001).
CONCLUSION: In this survey an increase of prevalence of weight among primary schoolchildren was found. Several factors contribute in this epidemiological result including absence of health educated programs delivered to the pupils by schools. A mandatory education program should established to both the pupils and their families to prevent obesity among pupils.

P-1037 Clinical-environment characteristics among Brazilian women diagnosed with benign breast disease

Marla Schilling[1], Rafaela Soares Senra Costa[1], Ilce Ferreira Da Silva[1]
[1]*National School of Public Health - Oswaldo Cruz Foundation, Rio de Janeiro, Brazil*

INTRODUCTION: Although benign breast disease (BBD) is one of the main breast cancer risk factors, its natural history is still unclear. The breast development, maturation, and differentiation suffer hormones and growth factors influence that may modulate BBD development. Thus, clinical-environment risk factors could influence BBD histological type. Aim: To evaluate the distribution of selected environmental, clinical, sociodemographic, and reproductive factors in cohorts of Brazilian women diagnosed with benign breast disease, according to histopathology group. Methodology: Cross-sectional study conducted with women with BBD diagnose referred to two hospitals in Rio de Janeiro (IFF/Fiocruz and HFL/Ministry of Health) from 2013 and 2018. A standardized questionnaire was applied by trained interviewers. Crude and adjusted odds ratios and 95% respective confidence interval were estimated using multinomial logistic regression.

RESULTS: From 353 women included, 62.9% had non-proliferative diseases, 27.8% had proliferative diseases without atypia, and 9.3% had proliferative diseases with atypia or lobular carcinoma in situ. About 30% were either current or former smokers, and reported alcohol consumption. Women exposed to hair dyes and hair straightening products (81.8%) were statistically higher in the proliferative lesion with atypia/lobular carcinoma in situ compared with non-proliferative and proliferative without atypia lesions. Compared to women with non-proliferative diseases, those with proliferative diseases with atypia or lobular carcinoma in situ were more likely to be older at diagnosis (OR =1.05;95%CI:1.01-1.09); to have 3+ histological types in biopsied lesion (OR=26.74;95%CI: 9.79-73.01); and to have regular menstrual cycles (OR=2.98; 95%CI: 1.03-8.66).
CONCLUSION: Findings suggest that age at diagnosis, increased histological types found in biopsied tissue, and having presented regular menstrual cycles throughout the reproductive period may be associated with benign lesions with a high risk of breast cancer.

P-1039 Phthalates/replacements are associated with maternal second-trimester glucose homeostasis and lipid-related metabolic factors

Diana Pacyga[1], Antonia Calafat[2], Joseph Braun[3], Susan Schantz[4], Rita Strakovsky[1]
[1]Department of Food Science and Human Nutrition and Institute for Integrative Toxicology, Michigan State University, East Lansing, USA, [2]Division of Laboratory Sciences, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA, [3]Department of Epidemiology, Brown University, Providence, USA, [4]Department of Comparative Biosciences and Beckman Institute, University of Illinois, Urbana-Champaign, USA

BACKGROUND AND AIM: Pregnant women are widely exposed to metabolic disruptors, including phthalates and their replacements, but their metabolic targets are not well-characterized. We evaluated associations of phthalates/replacements with a broad panel of maternal metabolic biomarkers.

METHODS: Illinois women (n=300) provided five first-morning urines (median 13, 17, 23, 28, 34 weeks gestation), which we pooled to quantify 19 phthalate/replacement metabolites. Women provided a fasting blood sample at median 17 weeks gestation, in which we quantified plasma total and high-density lipoprotein (HDL) cholesterols, glucose, insulin, C-peptide, leptin, triglycerides, and free fatty acids. We calculated low-density lipoprotein (LDL) and very-low-density lipoprotein (VLDL) using published equations. Using principal component analysis (PCA), we reduced ten maternal metabolic factors into three uncorrelated principal components (PCs), which we evaluated in relation to phthalates/replacements using multivariable linear regression.

RESULTS: These predominately non-Hispanic white, high-income, college-educated women had similar phthalate/replacement concentrations to U.S. women. Using PCA, three PCs explained 73% of the variability in metabolic factors (each $r > 0.40$): cholesterol PC (loaded strongly on total, HDL, and LDL cholesterols); glucose homeostasis PC (loaded strongly on glucose, insulin, C-peptide, leptin); and lipids PC (loaded strongly on triglycerides, VLDL, free fatty acids). Using linear regression models, two-fold increases in molar sums of metabolites of di-isononyl phthalate and of di(2-ethylhexyl) terephthalate (DEHTP) were associated with 0.08 (95%CI: -0.01, 0.17) and 0.10 (95%CI: 0.03, 0.17) higher glucose homeostasis PC scores, respectively. Additionally, each two-fold increase in the molar sum of di(2-ethylhexyl) phthalate metabolites was associated with higher lipids PC scores (β: 0.14; 95%CI: 0.02, 0.26), whereas monoethyl phthalate was associated with lower lipids PC scores (β: -0.13; 95%CI: -0.22, -0.04).

CONCLUSIONS: Our results suggest concentrations of select phthalate biomarkers measured across pregnancy, including plasticizer replacement DEHTP, are associated with disrupted second-trimester maternal glucose and lipid homeostasis.

P-1040 A Nested Case-Control Study of Serum Per- and Polyfluoroalkyl Substances and Testicular Germ Cell Tumor Risk in U.S. Air Force Personnel

Mark Purdue[1], Jongeun Rhee[1], Hristina Denic-Roberts[2,3], Katherine McGlynn[1], Celia Byrne[2], Joshua Sampson[1], Julianne Cook Botelho[4], Antonia Calafat[4], Jennifer Rusiecki[2]

[1]National Cancer Institute, Rockville, USA, [2]Uniformed University of the Health Sciences, Bethesda, USA, [3]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, USA, [4]Centers for Disease Control and Prevention, Atlanta, USA

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) are a component of aqueous-film-forming-foam fire suppressants used at military installations. However, PFAS-related cancer risks among military personnel are unclear. We investigated serum PFAS associations with testicular germ cell tumors (TGCTs) among U.S. Air Force servicemen within the Department of Defense Serum Repository (DoDSR).

METHODS: We conducted a nested case-control study involving 530 cases and 530 controls individually matched to cases on date of birth, race/ethnicity, year entered the service and year of sample collection, selected from among active-duty personnel with pre-diagnostic DoDSR sera collected between 1988 and 2017. A subset of 187 case-control pairs had a second pre-diagnostic sample collected on average five years after the baseline sample. Perfluorooctanesulfonate (PFOS), perfluorooctanoate, perfluorohexanesulfonate and other PFAS were quantified using isotope-dilution tandem mass spectrometry. Odds ratios (ORs) and 95% confidence intervals (CIs) relating PFAS concentrations (categorized using quartiles among controls) and TGCT were computed using conditional logistic regression adjusting for rank, with tests of trend across exposure categories.

RESULTS: Case-control analyses of the baseline PFAS concentrations were null. In the later samples, however, increasing PFOS concentrations were associated with TGCT (Q2: OR 1.1, 95% CI 0.6-2.0; Q3: OR 1.8, 95% CI 0.9-3.8; Q4: OR 2.7, 95% CI 1.1-6.4; p-trend = 0.02).

CONCLUSIONS: Our findings provide limited evidence of an association between serum PFOS concentrations and TGCT risk which warrants further investigation.
Disclaimer: The views presented here are those of the authors and are not to be construed as official or reflecting the views of the Uniformed University of the Health Sciences, the Centers for Disease Control and Prevention, the Department of Defense or the National Institutes of Health.

P-1041 Associations Between First Trimester Particulate Matter Exposure and Blood Pressure During Pregnancy

Miatta Buxton[1], Safa Heydarzadeh[1], Marie O'Neill[1]
[1]*University of Michigan, Ann Arbor, USA*

BACKGROUND AND AIM: Higher blood pressure (BP) is a risk factor for hypertensive disorders of pregnancy (HDP), a major cause of adverse maternal outcomes. Air pollution is associated with severe forms of HDP including preeclampsia; therefore, examining associations between air pollution and BP during early pregnancy may be helpful for understanding pathways. We evaluated associations between first trimester particulate matter (PM) less than 2.5 and 10 microns (PM2.5 and PM10) exposure and systolic (SBP) and diastolic (DBP) blood pressure at points during pregnancy.
METHODS: We utilized data from 814 women enrolled in the Pregnancy Research on Inflammation, Nutrition, & City Environment: Systematic Analyses (PRINCESA) Study in Mexico City, 2009-2014. Generalized linear models controlling for age, secondhand smoke exposure, gestational age at enrollment and pre-pregnancy body mass index were used to evaluate associations.
RESULTS: The mean age of participants was 25.2 years, and mean gestational age at enrollment was 14.6 weeks, range 2.6 – 26.3 weeks. Mean PM2.5 concentration was 25.1 µg/m3, range 12.5 – 36.1 while mean PM10 was 57.3 µg/m3 (range 29.8 – 105.6). Marginally significant associations were found between PM2.5 and SBP at visit 1 (β = 0.22, p-value = 0.1) and visit 2 (β = 0.20, p-value = 0.1), while PM2.5 was marginally and significantly associated with DBP at visit 1(β = 0.22, p-value = 0.1) and visit 2 (β = 0.42 p-value = 0.0006), respectively. for PM10, significant associations were found only for DBP for visit 1 (β = 0.08, p-value = 0.04) and visit 2 (β = 0.13, p-value = 0.007).
CONCLUSIONS: PM2.5 and PM10 exposure in early pregnancy was associated with higher SBP and DBP. This work provides additional support for PM's role in HDP and suggests minimizing prenatal exposure may reduce risk of adverse outcomes.

KEYWORDS: Air pollution, pregnancy, blood pressure, cardio-metabolic health

P-1042 Lung cancer and annual mean exposure to outdoor air pollution in Crete, Greece. Reflections from a two decades big-database

Dimitra Sifaki-Pistolla[3], Christos Lionis[3], Filippos Koinis[1], Dimitrios Mavroudis[1], Nikos Tzanakis[2]
[1]Department of Medical Oncology, University General Hospital of Heraklion, Heraklion, Greece, [2]Department of Pneumonology, University General Hospital of Heraklion, Heraklion, Greece, [3]Clinic of Social and Family Medicine, Department of Social Medicine, School of Medicine, University of Crete, Heraklion, Greece

BACKGROUND: The increasing burden of lung cancer (LC) in Crete, Greece, has raised certain concerns about the potential association of environmental risk factors with LC.
Aim: The aim of this study was to assess outdoor air pollution (OAP) and the risk for LC mortality for the first time in Crete using LC primary data.

METHODS: 5057 LC cases (diagnosed from 1992 to 2013) were obtained from the Cancer Registry of Crete (http://www.crc.uoc.gr) and followed up until 2014. The age-standardized incidence and mortality rates (ASIR) were calculated. Data on OAP indicators [particulate matter (PM)2.5, between 2.5 and 10 μm (PM2.5-10), PM10, PM2.5 absorbance (black carbon measure), nitrogen dioxide (NO2), and nitrogen oxides (NOx)] were collected. Spatial statistics were calculated and the binary logistic regression model was constructed at α=0.05 in IBM SPSS 24 and ArcMap 10.3.1.

RESULTS: LC in Crete accounts for 40.2 new cases/100 000/year for both sexes (ASIRmales=73.1 new cases/100 000/year; ASIRfemales=11.8 new cases/100 000/year). Annual median estimates of environmental concentrations in Crete were as follows: PM2.5=20.7 (±1.5) μg/m, PM10=38.9 (±2.5) μg/m, PM2.5-10=59.6 (±3.7) μg/m, PM2.5 absorbance=1.2 (±0.3)×10/m, NO2=15.2 (±3.8) μg/m, and NOx=20.1 (±4.9) μg/m. A statistically significant association was observed between OAP and LC mortality (mean correlation coefficient=0.75; P<0.05). The highest risk for 5-year LC mortality was found in the major urban centers and several south-east and north-west rural regions of Crete (relative risk=3.2, 95% confidence interval=1.6-4.7).

CONCLUSIONS: OAP seems to be an important determinant of LC mortality. Targeted interventions should be performed in the high-risk areas.

P-1043 Environmental Exposures Associated with Amyotrophic Lateral Sclerosis (ALS)

Paul Mehta[1], Jaime Raymond[1], Theodore Larson[1], Greg Zarus[1], D. Kevin Horton[1]
[1]*CDC/ATSDR - National ALS Registry, Atlanta, USA*

BACKGROUND AND AIM: ALS is a devastating neuromuscular disease with no cure, and most patients only survive 2– 5 years post-diagnosis. Since the etiology of ALS is largely unknown, it has been hypothesized that environmental exposures may increase risk and susceptibility to the disease. Our aim is to examine the role of environmental exposures in ALS from research studies funded by the USA National ALS Registry.

METHODS: To identify possible environmental exposures linked to ALS, the Registry funds academic institutions and conducts intramural research on Registry data. The former has been accomplished by funding investigator initiated R01 grants that allow institutions to explore etiologies. Intermural research explores data from several sources, including survey data collected from patients.

RESULTS: Since 2013, the Registry has funded over 20 grants. Key findings from the program-funded research include statistically increased risks for ALS from exposures to pesticide, lead, mercury, and several polychlorinated biphenyls congeners. Hobbies involving lead were strongly associated with ALS risk as were occupations with potential environmental exposures.
Additional program-study results that can inform additional exposure studies include:
1) Exposures to lead 20 or more years prior to diagnosis had larger effects than those occurring more recently.
2) Estrogen-related factors in women suggest the role of endogenous estrogen exposure and early-onset ALS.
3) Specific metabolism alterations associated with ALS are also impacted by substance exposures.
4) Living near water bodies with blooms of cyanobacteria increases ALS risk, with many blooms being associated with fertilizer runoff.

CONCLUSIONS: Research funded by the National ALS Registry has resulted in increased understanding of the etiologic role of environmental exposures and ALS. This research supports the development of mitigation strategies to limit or reduce risk in the future.

KEYWORDS: Amyotrophic lateral sclerosis, ALS, environmental exposure

P-1044 Effects of low-level environmental mercury on thyroid cancer risk and red blood cell indices among residents living near national industrial complexes in South Korea: A population-based cohort study

Seyoung Kim[1], Sang-Hwan Song[4], Chul-Woo Lee[4], Jung-Taek Kwon[4], Eun Young Park[1], Jin-Kyoung Oh[2], Hyun-Jin Kim[2,3], Eunjung Park[2], Byungmi Kim[1,2]

[1]Division of Cancer Prevention, National Cancer Control Institute, National Cancer Center, Goyang-si, Republic of Korea, [2]Department of Cancer Control and Population Health, Graduate School of Cancer Science and Policy, National Cancer Center, Goyang-si, Republic of Korea, [3]Cancer Big Data Center, National Cancer Control Institute, National Cancer Center, Goyang-si, Republic of Korea, [4]Environmental Health Research Division, National Institute of Environmental Research, Incheon, Republic of Korea

BACKGROUND AND AIM: Previous studies suggested that mercury may be linked to thyroid cancer due to its bioaccumulation in the thyroid gland, but no studies have been evaluated the association between mercury exposure and thyroid cancer. We examined the effect of mercury exposure on the thyroid cancer, and the potential modification of hematological parameters.

METHODS: We conducted a prospective cohort study using data from South Korean “Monitoring Project for Exposure to Environmental Pollutants and Health Effects among Residents Living near Industrial Complexes” survey during 2003 to 2011. The incidence of thyroid cancer cases (C73, ICD-10 code) were identified from the National Cancer Registry and Statistics Korea. Urinary mercury concentrations were measured using thermal decomposition amalgamation atomic absorption spectrometry (TDA-AAS). Cox proportional hazards regression models were used to estimate the hazard ratio (HR) and 95% confidence interval (CI) between mercury exposure and thyroid cancer risk.

RESULTS: During the follow-up (median 8.7 years), we documented 69 cases of thyroid cancer in a total of 5213 participants. The geometric mean of urinary mercury concentration was 1.8 μg/L for thyroid cancer cases and 1.2 μg/L for non-cases. After adjusting for potential confounders, those in the highest tertile of urinary mercury levels had a two-fold higher incidence risk of thyroid cancer (HR=1.97, 95% CI 1.03−3.80 in the highest tertile vs. the lowest tertile, p for trend=0.043). This association was stronger for those with lower mean corpuscular volume and mean corpuscular hemoglobin status.

CONCLUSIONS: Urinary mercury concentration was positively associated with the risk of thyroid cancer among residents living near national industrial complexes, and this association was influenced by red blood cell indices status. These results provide further evidence for the adverse effects of environmental metal pollution in the development of thyroid cancer.

KEYWORDS: Mercury (Hg), Metal pollutant, Environmental pollutant, Thyroid cancer, Red blood cell

P-1045 Machine learning to evaluate mixtures of circulating levels of 42 environmental contaminants to predict incident diabetes

Lars Lind[1], Samira Salihovic[2], Monica Lind[1]
[1]Uppsala University, Uppsala, Sweden, [2]Örebro University, Örebro, Sweden

BACKGROUND AND AIM: Many studies have been published on the relationships between different environmental contaminants and diabetes. In these studies, the environmental contaminants have most often been evaluated one by one, but in real life we are exposed to a mixture of contaminants that interact with each other. The major aim of this study was to see if a mixture of contaminants could improve the prediction of incident diabetes, using machine learning.
METHODS: In the Prospective Investigation of the Vasculature in Uppsala (PIVUS) study (988 men and women aged 70 years), circulating levels of 42 contaminants from several chemical classes were measured at baseline. Incident diabetes was followed for 15 years. Six different machine-learning models were used to predict prevalent diabetes (n=115). The variables with top importance were thereafter used to predict incident diabetes (n=83).
RESULTS: Boosted regression trees performed best regarding prediction of prevalent diabetes (area under the ROC-curve= 0.70). Following removal of correlated contaminants, addition of nine selected contaminants (Cd, Pb, Trans-nonachlor the phthalate MiBP, Hg, Ni, PCB126, PCB169 and PFOS) resulted in a significant improvement of 6.0% of the ROC curve (from 0.66 to 0.72, p=0.018) regarding incident diabetes (n=51) compared with a baseline model including age, sex and BMI when the first 5 years of the follow-up was used. No such improvement in prediction was seen over 15 years follow-up. The single contaminant being most closely related to incident diabetes over 5 years was Nickel (odds ratio 1.44 for a SD change, 95%CI 1.05-1.95, p=0.022).
CONCLUSIONS: This study supports the view that machine learning was useful in finding a mixture of important contaminants that improved prediction of incident diabetes. This improvement in prediction was only seen during the first 5 years of follow-up.

KEYWORDS:
Diabetes, machine learning, contaminants, epidemiology, prediction.

P-1046 Multiple environmental contaminants and diabetes - Results from two population based studies

Monica Lind[1], Linda Dunder[2], Samira Salihovic[3], Lars Lind[2]
[1]Department of Medical Sciences, Occupational and Environmental Medicine, Uppsala University, Sweden, Uppsala, Sweden, [2]Department of Medical Sciences, Cardiovascular Epidemiology, Uppsala University, Uppsala, Sweden, [3]Inflammatory Response and Infection Susceptibility Centre, School of Medical Sciences, Örebro University, Örebro, Sweden

BACKGROUND AND AIM: In previous studies on environmental contaminants and diabetes only a limited number of contaminants have been evaluated. The aim with the present study is therefore to obtain a comprehensive picture of the relationships between a large number of environmental contaminants and prevalent diabetes.
METHODS: In 10 examination cycles in The National Health and Nutrition Examination Survey (NHANES) (1999-2017) altogether 116 different environmental contaminants were evaluated in the circulation or urine in relation to prevalent diabetes. Similar analyses were also performed in the Prospective Investigation of Vasculature in Uppsala Seniors (PIVUS) study (n=1016, all aged 70 years, 50% women, 42 contaminants). The logistic regression models were adjusted for age, sex, race, education, BMI, alcohol intake, smoking and lipids.
RESULTS: In a meta-analysis of the 10 NHANES examinations, thirty-six contaminants were significantly related to prevalent diabetes. Those contaminants represent a number of different classes, such as metals, PCBs, dioxins, furans, pesticides, PFAS, phthalates, and phenols.
Some of these relationships were inverse, such as lead, cadmium, mercury, barium, cesium and strontium, some PFAS and furans, as well as benzophenone-3. In the smaller PIVUS study (119 prevalent diabetes cases), significant relationships similar to NHANES were seen for some PCBs, p,p´-DDE and lead. PFHxS and PFOA, showed inverse relationships also in PIVUS. The same was seen for mercury and cadmium.
CONCLUSIONS: Many environmental contaminants were related to diabetes in the NHANES study. Some of these relationships, mainly some metals and PFAS, were negative. Many of these results were similar in the smaller PIVUS study. These findings need be evaluated in prospective studies.

Diabetes, contaminants, epidemiology, metals, organic pollutants.

P-1047 The Causal Relationship Between Radiofrequency-Electromagnetic Radiation from Wireless Phones and Brain Tumor, Part 1: A Systematic Review for Possible Biases and Confounding

Jinyoung Moon[1], HyeKyoung Yoo[2], Hwan-Cheol Kim[1]
[1]Inha University Hospital, Incheon, Republic of Korea, [2]Seoul National University Graduate School of Public Health, Seoul, Republic of Korea

INTRODUCTION: The hypothesis of this study is that RF-EMR exposure from wireless phones causes brain tumors and that this causal relationship can be accurately validated only when accurate exposure assessment methods are applied. As a starting point of this series article, a systematic review of published literature for possible biases and confounding in previous studies will be conducted in the first part.

METHODS: The medical librarian searched MEDLINE: PubMed, EMBASE, and the Cochrane Central Register of Controlled Trials (CENTRAL) in the Cochrane Library (until 24 December 2020).

RESULTS: AND DISCUSSION: of the total of 13 studies included, 8 studies concluded that the risk estimates in original studies were underestimated. The other 2 studies concluded that the risk estimates in original studies were underestimated in most scenarios except for a limited number of low possibility scenarios. The other 2 studies concluded the risk estimates might be under- or over-estimated equivocally, and another 1 study concluded the risk estimates might be fair. One study insisted the accurate assessment of RF-EMR exposure should be based on (ⅰ) site-specific, (ⅱ) time integral of (ⅲ) specific absorption rate (SAR). As for the 'site specific' component, the fact that the widespread Bluetooth technology is making the distance between the head and wireless phones farther than before should be considered. As for the 'time-integral' component, almost all people in modern society are using their mobile phones every day, every minute, even when they are sleeping (as a morning-alarm device), for various purposes other than mere calling. As for the 'SAR' component, the fluctuating output power range according to various conditions should be considered in the exposure assessment.

CONCLUSION: Overall, the risk estimates were underestimated in previous literature. However, a more important point is that accurate exposure assessment is required for valid epidemiologic studies.

P-1048 The Causal Relationship Between Radiofrequency-Electromagnetic Radiation From Wireless Phones and Brain Tumor, Part 2: A Meta-Analysis of Current Literature Using Crude Proxies for RF-EMR Exposure Assessment

Jinyoung Moon[1], HyeKyoung Yoo[2], Hwan-Cheol Kim[1]
[1]Inha University Hospital, Incheon, Republic of Korea, [2]Seoul National University Graduate School of Public Health, Seoul, Republic of Korea

INTRODUCTION: Considering the imprecise characteristic of the currently used exposure classification categories discussed in the first part of this series article, in this second part, the authors will conduct a series of meta-analyses and subgroup analyses using various exposure classification categories from crude ones to more precise ones.

METHODS: The medical librarian searched MEDLINE (PubMed), EMBASE, and the Cochrane Library until 16 December 2020.

RESULTS: AND DISCUSSION: As for the separate analysis stratified by each tumor type, the odds ratio for meningioma for regular users was statistically significantly decreased, 0.86 (95% CI 0.77-0.95). for ipsilateral users, the pooled odds ratio for meningioma (1.20 (95% CI 1.04-1.39)), glioma (1.45 (95% CI 1.16-1.82)), and malignant tumors (1.93 (95% CI 1.55-2.39)) showed a statistically significant increased estimate. for years of use, the pooled odds ratio for glioma for > 10 years of use group showed a statistically significant increased estimate (1.32 (95% CI 1.01-1.71)). To sum up, these results stratified by each tumor type, glioma, and malignant tumors were strong candidate tumor types of the possible tumorigenic effect of RF-EMR from wireless phones. In the meta-analysis for the total cumulative hours of use > 867 hours, the pooled odds ratio was 1.56 (95% CI 1.27-1.91). This statistically significant increased pooled odds ratio indicates that a rather moderate amount of cumulative exposure to RF-EMR from wireless phones could induce brain tumors.
CONCLUSION: The study hypothesis, 'the causal relationship between RF-EMR exposure and brain tumor incidence can be clearly validated only when accurate exposure assessment methods are applied,' was validated by the increasing pattern of estimated odds ratios from the use of rather crude exposure categories to more precise exposure categories.

P-1049 The Causal Relationship Between Radiofrequency-Electromagnetic Radiation From Wireless Phones and Brain Tumor, Part 3: The Brain Tumor Incidence Trends in South Korea and a Systematic Review of Nationwide Natural Experiment

RESULTS: Jinyoung Moon[1], HyeKyoung Yoo[2], Hwan-Cheol Kim[1]
[1]Inha University Hospital, Incheon, Republic of Korea, [2]Seoul National University Graduate School of Public Health, Seoul, Republic of Korea

INTRODUCTION: We will (i) briefly look over the incidence trend of various types of brain tumors in South Korea and will (ii) conduct a systematic review of the literature reporting a nationwide or regional brain tumor incidence trend.

METHODS: for the brain tumor incidence trend in South Korea, the brain tumor incidence data from 1999 to 2018 provided by Korea Central Cancer Registry, National Cancer Center were used. for a systematic review, the medical librarian searched MEDLINE (PubMed), EMBASE, and the Cochrane Central Register of Controlled Trials (CENTRAL) in the Cochrane Library (until 24 December 2020).

RESULTS: AND DISCUSSION: In South Korea, the subscription rate increased from 0 per 100 persons in 1989 to 135 per 100 persons in 2019. From 1999 to 2018, the average annual percentage change (AAPC) for benign meningioma, benign brain tumors, malignant tumors in the CNS except for the brain, malignant tumors in the frontal lobe, and malignant tumors in the temporal lobe were 3.6 (95% CI 3.3-3.9), 11.3 (95% CI 9.7-12.9), 0.2 (95% CI 0-0.5), 1.5 (95% CI 1.2-1.9), and 0.6 (95% CI 0.5-0.8), respectively. In a systematic review of literature reporting brain tumor incidence trends in each country (or region), 22 articles reporting annual percentage change (APC) (or AAPC) and 15 articles reporting age-standardized incidence rate (ASIR) were analyzed. When the collected data were analyzed using the subscription changes as the independent variable, the results of all 8 analyses were statistically non-significant. These results could be different if a more precise RF-EMR exposure assessment is used in future studies (for example, a site-specific, time-integral of SAR for the brain). Other 4 possible causal factors for the increasing incidence of brain tumors were provided.
CONCLUSION: Future analysis using data with a more precise exposure assessment could indicate a more valid picture for this topic.

P-1051 Systematic review and meta-analysis of studies of exposure to wood smoke from cooking or heating and lung cancer

Elizabeth Hodgson[2], Suril Mehta[1], Whitney Arroyave[2], Ruth Lunn[1]
[1]NIEHS, Research Triangle Park, USA, [2]Integrated Laboratory Systems LLC, an Inotiv Company, Morrisville, USA

BACKGROUND AND AIM: Worldwide, about 2 billion people use biomass fuels for home heating and cooking. In low- and middle-income countries, wood is often burned in open hearths or inefficient stoves, exposing people to hazardous pollutants. Over 2 million U.S. households use wood as their primary source of heating. In the U.S., wood is often perceived as safe because it is a natural substance.
To inform a cancer hazard evaluation for possible listing of wood smoke in the Report on Carcinogens, we conducted a systematic review and meta-analysis of studies of wood use and lung cancer.

METHODS: We searched three bibliographic databases for studies of wood smoke exposure and lung cancer and selected studies providing risk estimates explicitly for wood use. Using a structured protocol, we evaluated study informativeness (risk of bias and study sensitivity) and pooled the least biased, most relevant risk estimates from each study, employing random-effect models to calculate meta-ORs.

RESULTS: Of the ten studies meeting our inclusion criteria, two-thirds were informative based on study evaluation guidelines. All queried wood use for fuel, potentially leading to non-differential exposure misclassification as fuel may be an imperfect surrogate for wood smoke levels. Most studies addressed the major potential confounders (e.g., smoking, socioeconomic status, [SES]/education); however, in some studies, it was unclear if wood users also used coal. Residual confounding by SES is also possible. The meta-ORs and 95% confidence intervals for using wood as fuel were 1.49 (1.22–1.82) for all studies, 1.35 (1.16–1.58) for never smokers, and 1.39 (1.21–1.58) for women. The meta-OR for informative studies was higher than that for less informative studies. Never smoker studies were the least consistent.

CONCLUSIONS: Globally, wood smoke was associated with lung cancer risk and robust in subgroup analyses. Additional analyses are ongoing.

KEYWORDS: Wood smoke, lung cancer, meta-analysis, systematic review

P-1052 Noise-induced hearing loss and obesity: a bidirectional Mendelian randomisation study

Yiyan He[1], Ville Karhunen[1], Anna Pulakka[1,2], Marko Kantomaa[1], Sylvain Sebert[1]
[1]University of Oulu, Oulu, Finland, [2]Finnish Institute for Health and Welfare (THL), Helsinki, Finland

BACKGROUND AND AIM: Exposure to environmental noise causes both auditory and non-auditory health effects. Noise-induced hearing loss (NIHL) might play a vital role in the relationship between noise exposure and obesity. While observational studies have demonstrated an association between hearing loss and obesity, the causal nature of these relationships remains unestablished. We aimed to infer the causality between NIHL and obesity-related traits (obesity-RT) from a genetic perspective and gain insight into the noise-obesity relationship.

METHODS: We used publicly available genetic summary statistics of genome-wide association studies from four consortia (GIANT, UKBB, FINNGEN, and EGG), including data from European-descent men and women aged 15 and older (number of participants: 36160–681275). Genetic variants used as proxies for NIHL and obesity-RT [BMI, waist-hip-ratio (WHR) and childhood obesity] were derived from the consortia, minimising confounding and sample overlap. We conducted a bidirectional and two sample Mendelian randomisation study to investigate the causal relationships between NIHL and obesity-RT.

RESULTS: We found no evidence to support bi-directional causal associations from NIHL to BMI, WHR and childhood obesity [inverse-variance weighted (IVW): 1-unit increase in log odds of NIHL: 0.00 (beta 95% CI: -0.01–0.01), 0.00 (beta 95% CI: 0.00–0.01), 1.00 (OR 95% CI: 0.98–1.01), respectively] and from obesity-RT to the risk of NIHL [IVW: 1-SD increase in BMI: 1.13 (OR 95% CI: 0.78–1.63), 1-SD increase in WHR: 1.19 (OR 95% CI: 0.74–1.92), 1-unit increase in log odds of childhood obesity: 0.93 (OR 95% CI: 0.78–1.10)].

CONCLUSIONS: No clear evidence of a causal effect was seen between NIHL and obesity-RT, in either direction. However, we can still not rule out a modest or non-linear effect of exposures. Future studies may be designed to understand the relationship between them in more detail. NIHL may be a mediator in the noise-obesity relationship.

P-1053 Exposure to PM2.5 could affect the severity of major depressive disorder: preliminary results from the DeprAir project

Michele Carugno[1,2], Luca Fedrizzi[2], Elisa Borroni[1], Massimiliano Buoli[3,4], Guido Nosari[3,4], Valentina Bollati[1,2], Angela Cecilia Pesatori[1,2]

[1]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy, [2]Occupational Health Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [3]Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy, [4]Department of Neurosciences and Mental Health, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

BACKGROUND AND AIM: Exposure to air pollution increases the risk of many diseases and recent evidence supports a relationship with psychiatric disorders such as depression. Major depressive disorder (MDD) is characterized by a complex pattern of biological alterations thought to be caused by genetic, biological, psychological and environmental factors. The DeprAir project aims to assess the effect of air pollution exposure on MDD severity and to clarify potential underlying biological mechanisms.

METHODS: Since September 2020, we have been recruiting patients accessing the Psychiatry Unit of the Policlinico Hospital (Milan, Italy) for mild, moderate, and severe depression. After collecting informed consent, we administered a questionnaire on personal, lifestyle and clinical characteristics, assessed MDD severity and disability through psychiatry rating scales (MADRS, HAM-D, CGI, DISS, GAF) and collected blood samples (lab analyses will be performed after concluding the recruitment). Multivariate linear regression models were performed to verify the association between MDD severity and average PM2.5 concentration in the month preceding recruitment.

RESULTS: Study population so far consists of 256 patients affected by MDD (median age: 56 years, females: 68%). About 50% of subjects reported family history of psychiatric disorders. We observed a positive association between PM2.5 and both the HAM-D score (more focused on anxiety and somatic symptoms: β=0.26, 95%CI: -0.03; 0.55, p=0.076) and the "working life" domain of the DISS scale (evaluating social dysfunction: β=0.084, 95%CI: -0.005; 0.171, p=0.063). When considering the "social support" domain of the DISS scale, family history of depression appeared to modify the association between PM2.5 and MDD severity (p=0.010).

CONCLUSIONS: Although preliminary, our results suggest a potential role of PM2.5 in influencing MDD severity. The ongoing expansion of our study population, together with finer exposure estimates that are becoming available, will likely allow us to further confirm our findings.

P-1057 Rail traffic noise-induced nocturnal awakenings might lead to depression and anxiety disorder – Results of the Leipzig LIFE cohort study

Andreas Seidler[1], Steffi Riedel-Heller[2], Andrea Zülke[2], Julia Gerlach[3], Matthias Reusche[4], Janice Hegewald[1], Hajo Zeeb[5], Pauline Kaboth[1], Karla Romero Starke[1], Melanie Schubert[1]

[1]Institute and Policlinic of Occupational and Social Medicine, Faculty of Medicine, TU Dresden, Dresden, Germany, [2]Institute of Social Medicine, Occupational Health and Public Health, Public Health Research Unit, University of Leipzig, Leipzig, Germany, [3]Institute of Transport Planning and Road Traffic, TU Dresden, Dresden, Germany, [4]Institute for Medical Informatics, Statistics and Epidemiology (IMISE), University of Leipzig, Leipzig, Germany, [5]Leibniz-Institute for Prevention Research and Epidemiology – BIPS GmbH, Department of Prevention and Evaluation, Bremen, Germany

BACKGROUND AND AIM: Recent studies found elevated depression risks for people exposed to traffic noise. In the LIFE cohort-study, we analysed the relationship between “awakenings” induced by maximum railway-traffic noise levels and affective disorders.

METHODS: Based on the 5-year-follow-up of the Leipzig LIFE cohort study (n=5679 participants), we examined the relationship between address-specific rail traffic noise-induced “awakenings” and depression (incidence of 5.3% applying the CES-D scale) as well as anxiety disorder risks (incidence of 4.9% applying the GAD-7 scale). We converted maximum noise pressure levels induced by railroad noise into awakening probabilities according to Möhler et al. (2018), and we summed up the individual awakening probabilities to get the total number of nocturnal awakenings. Thus, for example, if the awakening probability for the passage of a freight train is 5.7%, then approximately 18 train passages would result arithmetically in 1 awakening.

RESULTS: An increase in depression risk for ≥3 nocturnal awakenings was found (incidence rate ratio IRR=1.86; 95% 0.63-5.52, adjusted for gender, age and socioeconomic status) for rail traffic noise. The risk of depression reached statistical significance if people with missing values for depression at baseline were included. The risk of an incident anxiety disorder was increased due to an exposure of ≥3 awakenings due to rail traffic noise (IRR=2.56; 95% CI 1.02-6.43).

CONCLUSIONS: Increased risks for anxiety disorders (and less pronounced for depression) were found for ≥3 nocturnal awakenings due to rail traffic noise. Noise protection measures should take into account the reduction of maximum rail traffic noise levels to in turn reduce nocturnal awakenings.

KEYWORDS: rail traffic noise, maximum noise levels, nocturnal awakenings, depression, anxiety disorder, cohort study

ACKNOWLEDGMENTS: This study was supported by German Environment Agency (UBA).

Navarra 4, 20013 Donostia-San Sebastián, Spain, [6]Faculty of Psychology, University of the Basque Country (UPV/EHU), Av. Tolosa 70, 20018 Donostia-San Sebastian, Spain

BACKGROUND AND AIM: Attention Deficit Hyperactivity Disorder (ADHD) is one of the most common childhood neurodevelopmental disorders, characterized by inattention, hyperactivity, and impulsive behavior.
The objective of this study is to estimate the prevalence of ADHD symptoms during childhood in the INMA (INfancia y Medio Ambiente) population-based cohort (www.proyectoinma.org), as well as to identify differences in the distribution of the symptoms based on sociodemographic (cohort, maternal social class, gender) characteristics of the participants.
METHODS: The present study includes participants from the cohorts of Gipuzkoa, Sabadell, and Valencia. ADHD symptoms were measured at three different time points: 4-5 years (n=1181), 7-8 years (n=1341), and 11-13 years (n=1184). ADHD was measured using ADHD-DSM-IV at 4-5 years, while Conner's Rating Scale Revised short form was used at the 7-8 and 11-13 year measurements.
RESULTS: The overall prevalence of ADHD was 5,17%, 20,81%, and 15,71%, respectively for each time point (4-5, 7-8, and 11-13 years). Remarkably, the ADHD trends through the different time points along the three cohorts show that ADHD is more prevalent at 7-8 years and in children from mothers of lower social class. Concerning gender, at the 4-5 year assessment ADHD prevalence is slightly lower in girls, with 97,39% of healthy girls compared to 92,42% of boys, but this percentage gets balanced in the following measurements. Looking closely at the data of each cohort, the difference in the prevalence of ADHD between Gipuzkoa, Sabadell, and Valencia at 4-5 (2,54%, 5,04%, and 7,32%, respectively), 8-7 (16,37%, 22,11% and 23,24%, respectively) and 11-13 years (12,77%, 19,63%, and 14,21%, respectively) show to be mainly distributed attending the social class of each cohort.
CONCLUSIONS: From an epidemiological perspective, the results could help to better understand the real magnitude and dimension of ADHD in children.

P-1063 Residential exposure to solar ultraviolet radiation and risk of childhood hematological malignancies in Switzerland: a nationwide census-based cohort study

Astrid Coste[1,2,3], Christian Kreis[1], Claudine Backes[4], Jean-Luc Bulliard[4], Christophe Folly[1], Eva Brack[5], Raffaele Renella[6], David Vernez[4], Ben Spycher

[1]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, [2]Département Prévention, Cancer et Environnement, Centre Léon Bérard, Lyon, France, [3]INSERM UMR 1296 Radiation: Defence, Health, Environment, France, [4]Center for Primary Care and Public Health (Unisanté), University of Lausanne, Lausanne, Switzerland, [5]Division of Pediatric Hematology and Oncology, Department of Pediatrics, Inselspital, Bern University Hospital, Bern, Switzerland, [6]Pediatric Hematology-Oncology Unit, Division of Pediatrics, Lausanne University Hospital, Lausanne, Switzerland

BACKGROUND: Childhood hematological malignancies (CHM) are the most frequent pediatric cancers yet their environmental drivers remain largely unknown. Solar ultraviolet radiation (UVR) is a known risk factor for skin, lip, and eye cancers. Results from the few studies on CHM risk from UVR exposure suggest a non-linear negative association for acute lymphoblastic leukemia (ALL). We aimed to investigate this association in Switzerland, a country with varying topography and weather conditions.

METHODS: We included all children aged 0-15 years from the Swiss National Cohort during 1990-2015 and identified incident cancer cases through probabilistic record linkage with the Swiss Childhood Cancer Registry. We used a climatological model of the midday (11am-3pm) UV-Index (UVI) with a spatial resolution of 1.5x1.5 km during 2004-2018 and calculated the overall annual mean and mean levels for the month of July at children's homes at diagnosis. We fitted conditional logistic regression models to case-control data matched by birth year obtained by risk-set sampling (odds ratios can be interpreted as hazard ratios). Analyses were adjusted for sex, neighborhood SES, urbanization, air pollution, and background ionizing radiation.

RESULTS: We included 1,446 cases of CHM. Adjusted hazard ratios per unit UVI increase from linear models including July exposure were 0.76 (95% CI 0.59-0.98) for leukemia and 0.74 (0.55-0.98) for ALL. Corresponding point estimates for annual exposure were similar but CIs wider. Linear models showed no evidence of association for lymphoma (1.14, 0.59-2.19 for annual exposure). In the categorical analyses, there was no evidence of an association overall for any of the diagnostic groups with p-values of likelihood ratio (LR) tests >0.2; nor was there any evidence of a departure from linearity (p-values LR test >0.3).

CONCLUSIONS: Our study provides weak evidence that UVR may protect against childhood ALL.

P-1065 Short-term effects of exposure to ultrafine particles and black carbon on cause-specific morbidities in older adults in New York State

Kexin Zhu[1], Muwu Xu[1], Yifan Wang[2], Qiao Zhu[2], Liuhua Shi[2], Meng Wang[1]
[1]Department of Epidemiology and Environmental Health, School of Public Health and Health Professions, University at Buffalo, The State University of New York, Buffalo, USA, [2]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA

BACKGROUND AND AIM: Ambient fine particulate matter (PM2.5) is known to have adverse health effects, but less is known about the effects of ultrafine particles (UFP, <100 nm) and black carbon (BC). We examined the associations of short-term exposure to UFP, BC, and PM2.5 with cardiovascular disease (CVD), chronic obstructive pulmonary disease (COPD), asthma, depression, and Alzheimer's disease and related dementias (ADRD) among adults aged 65 years and older.

METHODS: We performed a time-stratified case-crossover analysis among Medicare enrollees in New York State (NYS) from 2012 to 2018. Daily air pollution data were obtained from the NYS Department of Environmental Conservation. Cases were limited to those residing in a zip-code within a 30 km-buffer around each monitor site. The control days were chosen bi-directionally and matched on the same day of the week in the same month and year as the case day. We used conditional logistic regression to quantify the associations, adjusting for daily maximum temperature. Effect modification by age, sex, race, and Medicaid eligibility was examined.

RESULTS: Each interquartile range (IQR) increase in UFP exposure was associated with increased odds of overall CVD (OR=1.031, 95% CI: 1.021-1.041), stroke (OR=1.042, 95% CI: 1.026-1.057), ischemic heart disease (IHD, OR=1.034, 95% CI: 1.024-1.045), asthma (OR=1.044, 95% CI: 1.026-1.062), depression (OR=1.037, 95% CI: 1.026-1.048), and ADRD (OR=1.040, 95% CI: 1.027-1.053), but not with COPD. We observed positive associations for BC exposure per IQR change with stroke (OR=1.024, 95% CI: 1.006-1.043), IHD (OR=1.014, 95% CI: 1.001-1.027), and depression (OR=1.014, 95% CI: 1.001-1.028). The associations were stronger among individuals aged 65-75, males, and Non-Whites. No associations for PM2.5 exposure were found.

CONCLUSIONS: Our findings contribute to emerging evidence for positive associations of short-term exposure to UFP and BC with adverse health outcomes among older adults.

KEYWORDS: Black carbon; Ultrafine particles; Short-term exposure; Case-crossover design

P-1067 The influence of air pollution exposure on the association between active mobility and long-term health outcomes: A systematic review

Damian Chandia-Poblete[1], Tom Cole-Hunter[2], Melissa Haswell[1], Kristi Heesch[1]
[1]Queensland University of Technology, School of Public Health and Social Work, Institute of Health and Biomedical Innovation, Brisbane, Australia, [2]Section of Environmental Health, Department of Public Health, University of Copenhagen, Copenhaguen, Denmark

BACKGROUND: Walking and cycling for transportation, namely active mobility (AM), can improve health through increasing individuals' daily physical activity levels. People using AM increase their breathing rate, however, inhaling harmful air pollutants (AP) along with necessary oxygen. The interaction of these complex combined effects can develop slowly and clinically manifested over time.
Purpose: Our study aimed to synthesize the current knowledge on effect modification of AP exposure with AM on long-term health outcomes.

METHODS: A systematic review was conducted using Medline, Embase, Web of Science and Scopus databases. Searches included a wide range of keywords related to AP and AM to identify original articles published in English or Spanish in peer-reviewed journals until September 2021. Effect modification by AP was examined in studies on healthy adults where an interaction term between AM and AP was included in modelling or that presented stratified analyses by AM or AP levels.

RESULTS: 5725 studies were found and 10 were finally included where AP main indicators studied include particulate matter and nitrogen oxides. Health outcomes studied are wide in range but grouped into cardiovascular and respiratory outcomes. Most studies tested an interaction term within models. High NO2 levels do not attenuate the reductions in risk of all- and cause-specific mortality from AM, however, PM2.5 did attenuate these reductions. No significant effect modification was seen by NO2 levels on the association between cycling or walking and cardiovascular or respiratory outcomes.

CONCLUSIONS: Little evidence of interaction between AP and AM on long-term outcomes was found, but pollutant-specific long-term effects need further investigation. Further consideration on study design, interaction testing, and results reporting is needed to advance understanding of this complex relationship to guide future work and decision-making.

P-1071 Air pollution, risk of neurodegenerative disorders and potential mediation pathways

Alessandro Gialluisi[1,2], Simona Costanzo[2], Giovanni Veronesi[1], Gaetano Zazzaro[3], Assuntina Cembalo[3], Marco Ferrario[1], Francesco Gianfagna[1,4], Stefania Massari[5], Licia Iacoviello[1,2]

[1]University of Insubria, Varese, Italy, Varese, Italy, [2]IRCCS NEUROMED, Pozzilli, Italy, Pozzilli, Italy, [3]CIRA-Italian Aerospace Research Centre, Capua, Italy, Capua, Italy, [4]Mediterranea Cardiocentro, Napoli, Italy, Naples, Italy, [5]Italian Workers' Compensation Authority (INAIL), Rome, Italy, Rome, Italy

BACKGROUND AND AIM: Recent studies revealed an implication of air pollution in neurodegenerative disorders. Still, due to the scarcity of studies testing air pollution in a comprehensive manner, including potential mediation pathways, this link remains controversial. Here, we aimed to investigate these aspects by testing multiple pollutants simultaneously.

METHODS: In the Moli-sani cohort (N=24,325; ≥35 years; 51.9% women, baseline 2005-2010), we estimated yearly levels of exposure to nitrogen oxides (NOX, NO, NO2), ozone (O3), particulate matter (PM10) and BTX hydrocarbons (benzene, toluene and xylene) in the period 2006-2018, applying residence geo-localization of participants and Kriging interpolation algorithm to land measurements of air pollutants. We performed a principal component analysis and tested association of the resulting principal components (PCs) with the incident risk of Parkinson (PD) and Alzheimer disease (AD), through multivariable Cox PH regressions adjusted for age, sex and education level completed.

RESULTS: Over 24,308 subjects with pollution data available (51.9% women, 55.8(12.0) years), we extracted three PCs explaining ≥5% of pollution exposure variance: PC1 (38.2%, tagging PM10 exposure), PC2 (19.5%, O3/CO/SO2), PC3 (8.5%, NOx/BTX hydrocarbons). Over a mean follow-up of 10.9(2.1) years, we observed statistically significant associations of PC1 with an increased risk of PD (HR[CI] = 1.04[1.02-1.05]; 405 incident cases) and AD (1.06[1.04-1.08]; 218 cases). These associations were confirmed when we analyzed PM10 levels averaged over follow-up time, in models further adjusted for professional exposures like working class, compartment and toxic compounds and lifestyles like smoking and drinking habits, physical activity and adherence to Mediterranean diet (PD: 1.27 [1.19-1.37]; AD: 1.22[1.16-1.28] per 1 µg/m3 increase of PM10).

CONCLUSIONS: We found evidence supporting an influence of air pollution – especially PM10 – on increased neurodegenerative risk in the Italian population, independent on concurring risk factors. We are now investigating a potential mediation role of circulating inflammation in this link.

P-1072 Household air pollution, polycyclic aromatic hydrocarbons and esophageal cancer risk in Kenya: ESCCAPE case-control study

James Watson[1], Diana Menya[2], Elisa Puzzolo[1], Iva Cukic[1], Edna Sang[2], Craig Sams[3], Daniel Middleton[4], Joachim Schüz[4], Valerie McCormack[4], Daniel Pope[1]

[1]Department of Public Health, Policy and Systems, University of Liverpool, Liverpool, UK, [2]Moi University, School of Public Health, Eldoret, Kenya, [3]Health and Safety Executive Science and Research Centre, Buxton, UK, [4]Environment and Lifestyle Epidemiology Branch, International Agency for Research on Cancer, Lyon, France

BACKGROUND AND AIM: Esophageal squamous cell carcinoma (ESCC) is highly prevalent in Western Kenya. Established risk factors (e.g. smoking and alcohol consumption) are not common in female patients. Exposure to household air pollution (HAP) from solid fuels used for cooking and heating might be relevant in ESCC aetiology. As such, this study aims to examine the relationship between self-reported indicators of exposure to HAP with risk of ESCC in Western Kenya.

METHODS: Six-hundred and four (604) ESCC cases and six-hundred and thirty-one (631) controls were recruited during three phases of the ESCCAPE Kenya case-control study. Surveys on risk factors were conducted with all participants. Surveys included questions on demographic and socio-economic factors, and fuels used in the home currently and during childhood, and their proximity to heating and cooking sources.

RESULTS: When accounting for confounding demographic factors, odds ratios (OR) derived from binomial regression illustrates a significantly increased risk of esophageal cancer among those who use firewood as their primary cooking fuel (OR: 2.187; CI: 1.368-3.557). Women were almost three times as likely to have esophageal cancer when using firewood as the primary cooking fuel (OR: 2.821; CI: 1.255-6.917). Risk of esophageal cancer was significantly greater among participants who cooked in their living room (OR: 1.954; CI: 1.234-3.107). Findings demonstrate greater wood burning exposure is associated with significantly heightened risk of esophageal cancer.

CONCLUSIONS: Findings from the ESCCAPE case-control study indicate the potential role of exposure to smoke from firewood used in cooking and heating, in the complex aetiology of ESCC. Given the increased lifetime exposure to woodsmoke for women due to traditional domestic roles, and their lower exposure to other known risk factors, reliance on solid fuels for domestic energy could be an important potentially preventable risk factor for women in areas when the occurrence of ESCC is high.

P-1075 An examination of vitamin D levels as a mediator in the association of ambient air pollution and incident type 2 diabetes mellitus in India

Suganthi Jaganathan[1,2], Ruby Gupta[2], Siddhartha Mandal[1,2], P A Praveen[3], V Mohan[4], Deepa Mohan[4], KMV Narayan[5], Joel Schwartz[6], Dorairaj Prabhakaran[1,2], MK Ali[5], Nikhil Tandon[3]

[1]Centre for Chronic Disease Control, New Delhi, India, [2]Public Health Foundation of India, Delhi-NCR, India, [3]All India Institute of Medical Sciences, New Delhi, India, [4]Madras Diabetes Research Foundation, Chennai, India, [5]Emory University, Atlanta, USA, [6]Harvard T.H.Chan School of Public Health, Boston, USA

BACKGROUND & AIM:
Recent evidence suggests a role for air pollution and low vitamin D levels in enhancing the risk of diabetes. In India, both air pollution and a high prevalence of vitamin D deficiency exist alongside a high burden of diabetes. Particulate matter also reduces penetration of UVB light into earth's atmosphere resulting in reduced synthesis of cutaneous vitamin D. We hypothesized that air pollution as measured by PM2.5 is associated with vitamin D levels as measured by 25-OHD in the body, which may mediate association between PM2.5 and incident type 2 diabetes mellitus.

METHODS: We used a nested prospective case-control study in the Center for Cardiometabolic Risk Reduction in South Asia cohort study in Delhi and Chennai. Cases (n=506) defined as those with incident diabetes mellitus, were matched with healthy controls/non-diabetics (n=506). Multivariable regression analyses were performed to evaluate the associations between varying lag exposures of PM2.5 and incident diabetes. We estimated the mediating effects of vitamin D levels associated with PM2.5 exposure on incident diabetes through causal mediation analyses and boot strapping.

RESULTS: 92.4% and 89.9% of cases and controls were vitamin D insufficient (< 30 ng/ml), respectively. We observed statistically significant negative correlation [-0.41 95%CI: -0.35, -0.46] between vitamin D levels and PM2.5 for all the lag periods (1-day, 7-day, 30-day, and 90-day) studied. The association between short-term exposure to PM2.5 and incident diabetes were evident among people who were obese, had higher waist-hip-ratio, and elevated triglyceride levels. The mediating role of low vitamin D was not supported by our dataset.

CONCLUSIONS: Air pollution appears to interfere with vitamin D synthesis from natural sources. We, however, did not find evidence to support a mediating role of vitamin D on the association between PM2.5 and incident diabetes.

KEYWORDS: Air pollution, diabetes mellitus, vitamin D, mediation analysis

P-1078 Air pollution and risk of lung cancer within the EAGLE case-control study

Luca Fedrizzi[1], Dario Consonni[1], Elisa Borroni[2], Angela Cecilia Pesatori[1,2], Michele Carugno[1,2]
[1]Occupational Health Unit, Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, Italy, [2]Department of Clinical Sciences and Community Health, Università degli Studi di Milano, Milan, Italy

BACKGROUND AND AIM: In 2013 IARC classified air pollution (AP) as group 1 human carcinogen based on studies documenting that long-term exposure to particulate matter (PM) increases the risk of lung cancer (LC). Within the EAGLE case-control study, we previously reported that exposure to PM ≤10 µm (PM10) in a year (2000) close to diagnosis/enrollment was associated with an increased LC risk. We now aim to evaluate this association considering AP exposures further away in time.

METHODS: From 2002 to 2005, 2,099 incident LC cases were recruited from 13 Lombardy (Italy) hospitals belonging to five areas (Milan, Monza, Varese, Pavia, Brescia) and matched by sex, age, and area to 2,101 controls. Subjects underwent a computer assisted personal interview (CAPI), filled in a self-administrated questionnaire and donated blood samples. Annual means of PM10 for the year 1990 were estimated with a resolution of 3x3 km through an Eulerian chemical transport model. Association between PM10 and LC was assessed applying multivariable unconditional logistic regression models to the entire sample and stratifying by area.

RESULTS: Study sample consists of 3,473 subjects (1,665 cases and 1,808 controls, males: 77%, smokers: 37%) who did not change residence since 1980 and mainly lived in Milan (69.4%). Adenocarcinoma was the most common morphology (males: 38%, females: 55%). In the entire population, we did not observe an association between AP and LC (OR=0.96 per 10 µg/m³ of PM10, 95%CI: 0.86;1.06). When stratifying by area, a positive association was found in Pavia (OR=1.89, 95%CI: 0.66;5.45) and Varese (OR=2.27, 95%CI: 0.77;6.68).

CONCLUSIONS: These preliminary results partially confirm an increased LC risk using AP measured 12-15 years before. Further analyses will aim to assess non-linear associations, analyze gaseous pollutants, evaluate the interplay between different pollutants, and improve the spatial resolution of our exposure data.

KEYWORDS: particulate matter, lung cancer, case-control study

P-1080 Prevalence and determinants of sunburns and sun protection behaviors among children: A nationwide cross-sectional survey in Switzerland

Astrid Coste[1], Claudine Backes[3], Antonella Mazzei[2], Eleftheria Michalopoulou[2], Christian Kreis[2], Christophe Folly[2], David Vernez[3], Jean-Luc Bulliard[3], Ben Spycher[2]

[1]Centre Léon Bérard, INSERM UMR 1296 Radiations: Defence, Health, Environment, Lyon, France, [2]Institute for Social and Preventive Medicine, University of Bern, Bern, Switzerland, [3]Unisanté, University of Lausanne, Lausanne, Switzerland

BACKGROUND: High exposure to solar ultraviolet radiation in early life increases the risk of developing skin cancer later, with increasing risk related to an increasing number of sunburns. Switzerland has high incidence rates of skin cancer compared to surrounding countries. We aimed to estimate the prevalence of sunburns and sun protection behaviors and their potential determinants among children in Switzerland.

METHODS: In February 2019, we sent questionnaires to the parents of a random sample of 8,221 Swiss resident children. The questionnaires of 2,841 children were returned (response rate 35%). In spring and summer of the same year, follow-up questionnaires were sent to these children (response rate ~50%). Parents were asked about their child regarding protection measures, number of sunburns in the previous year, and skin phototype. We calculated the prevalence of sunburns and sun-protective behaviors (wearing a hat, seeking for shade, and use of sunscreen) by season, sociodemographic characteristics and skin phototype.

RESULTS: Among participating children, 39.9% had at least one sunburn in the previous year, of whom 20.5% had a severe sunburn. When outside on a sunny day, 50.3% of the children wore a hat in summer (46.8% in spring), 21.1% (19.8%) sought shade more than half of the time, and 53.6% (43.5%) wore sunscreen. Prevalence of sunburns and of severe sunburns was higher among older children, boys, and children with sensitive skin. Protective measures were more frequent among younger children, girls, and children with sensitive skin. Prevalence of both outcomes varied substantially between regions. Sunburn prevalence was associated with lower use of sun protection.

CONCLUSIONS: Compared to previous regional studies in Switzerland, we found a lower prevalence of sunburns and of protection behaviors, with important regional heterogeneity. Our results should help tailor sun exposure prevention measures to specific age groups and regions.

KEYWORDS: sunburn, children, skin cancer

P-1083 Association between selenium species and hippocampal volume in subjects with mild cognitive impairment

BACKGROUND AND AIM: Selenium is a trace element with nutritional and toxicological properties. Its influence on human health is thought to depend on exposure dose and chemical form. The effects of selenium exposure on medical conditions that involve the central nervous system have been understudied. In a cohort of individuals with mild cognitive impairment, we have previously documented a positive relation between cerebrospinal fluid (CSF) levels of inorganic hexavalent selenium (selenate) and risk of dementia.

METHODS: We assessed the relation between CSF levels of selenium species and volume of the hippocampus among the 33 cohort members aged 43-82 years who had undergone magnetic resonance imaging at baseline (2008-2014) using both linear and spline regression analyses. We also performed a surface-based analysis using SPHARM-PDM to evaluate differences in shape of the hippocampus in addition to its volume in relation to CSF levels of selenium species.

RESULTS: We found an inverse association between selenate and total hippocampal volume (β regression coefficient in multivariable linear regression analysis -3.05, 95% confidence interval -5.74 to -0.37), which was similar for the right and left hippocampus and emerged mainly at the highest exposure levels. We found little association between the other selenium forms and hippocampal volume. In the surface-based analysis, the left hippocampus showed considerably more pronounced shape differences in the ventro-medial region of the head.

CONCLUSIONS: This is the first study to analyze selenium species in relation to hippocampal volume and structure, suggesting that a selenium form with high toxicological potential may adversely affect a key structure involved in dementia onset and progression as the hippocampus, possibly the left one in particular. However, we cannot entirely rule out the influence of reverse causation or unmeasured confounding on these results.

Paris-Sud, Inserm, Gustave Roussy, "Exposome and Heredity" team, CESP, 94807, Villejuif, France, [5]Institut des Neurosciences de Montpellier | Unité 1298 |Inserm/Université de Montpellier, Montpellier, France, [6]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [7]University of Basel, Basel, Switzerland

BACKGROUND AND AIM: Literature is scarce regarding the effect of exposure to outdoor air pollution on frailty. In this longitudinal study, we aimed to assess the association between long-term air pollution exposure and handgrip muscle strength (HGS) change, a marker of frailty.

METHODS: Data from the 45-69 years-old population of the French CONSTANCES cohort with two HGS measurements were used. Annual mean concentrations of PM2.5, black carbon (BC), and NO2 were estimated using 2010 land-use regression models at the residential addresses of the participants at enrolment (2014-2016). Absolute change in maximum HGS (HGSmax) between enrolment and follow-up (around 4.5yrs after) was used as the outcome and decline was defined as a negative absolute change in HGSmax. Sex-stratified multilevel adjusted (including length of follow-up) linear regressions with the center of recruitment as a random effect and sandwich robust error were used (reported as adjusted β, and 95% confidence interval [CI] for an interquartile range increase in exposure).

RESULTS: Among the 4655 included participants, 50% (N=2331) were women, mean age was 57 years old, and 54% had a high educational level. Average HGSmax at baseline was higher among men than women (45.1 vs 27.6 kg). Around 60% had a decline in HGSmax between the two measurements and decline was higher in men (median[Q1;Q3]=-2[-5;2]) than in women (-1[-3.5;1]). Preliminary results showed that exposure to BC was associated with HGS decline in women (β[95%CI]: -0.33[-0.62;-0.05]), but not in men (-0.17[-0.60;0.25]). Further adjusting on urbanity led to similar effect sizes, but results among women were no longer statistically significant. Results for PM2.5 and NO2 were similar to the ones for BC.

CONCLUSIONS: Long-term exposure to ambient air pollution is associated with HGS decline in women, with urbanity as a possible confounding factor.

P-1089 Associations between per- and polyfluoroalkyl substances and liver transient elastography measures in U.S. adults

Ashley Eng[1], Damaskini Valvi[2], Jonathan Huang[3], Nasser Laouali[1], Michael Mascari[1], Youssef Oulhote[1]
[1]University of Massachusetts Amherst, Pelham, Morocco, [2]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Singapore Institute for Clinical Sciences, Singapore, Singapore

BACKGROUND AND AIM: Non-alcoholic fatty liver disease (NAFLD) is increasingly diagnosed in the U.S. and elsewhere and affects approximately one billion individuals worldwide. In the U.S., almost 1 in every 3 adults are estimated to have NAFLD. Exposure to per- and polyfluoroalkyl substances (PFAS) has been linked to liver steatosis and hepatocyte apoptosis in animal studies, but evidence in humans for a link between PFAS and NAFLD is sparse. We investigated the associations between PFAS and liver steatosis and fibrosis using transient elastography (TE) in U.S. adults.

METHODS: We studied 1700 adult participants from the 2017-2018 National Health and Nutrition Examination Survey (NHANES) with available serum PFAS measurements and valid vibration-controlled TE measures of liver steatosis (median controlled attenuation parameter [CAP] in decibels per meter [dB/m]) and liver fibrosis (median stiffness in kilopascals [kPa]). Participants with viral and autoimmune hepatitis and liver cancer were excluded from analyses. We used multivariable regressions to assess the covariate-adjusted associations between six PFAS and median CAP and liver stiffness. We also investigated effect modification by sex and age.

RESULTS: Average CAP was 263.0 dB/m (SD: 62.6) and average median stiffness was 5.7 kPa (SD: 4.3). Concentrations of perfluorooctanoic (PFOA), perfluorodecanoic (PFDA), perfluoroundecanoic (PFUA) acids, perfluorohexane (PFHxS) and perfluorooctane (PFOS) sulfonic acids were significantly negatively associated with CAP and liver stiffness measures. for instance, a twofold increase in PFDA was associated with a decrease of 0.11 SD (95% CI: -0.16, -0.05) and 0.08 SD (95% CI: -0.14, -0.02) in CAP and stiffness measures, respectively. Associations of PFNA and PFUA with both outcomes were modified by sex, whereas associations of PFUA and PFOA with liver stiffness were modified by age.

CONCLUSIONS: This is the first study to assess associations between PFAS and liver TE measures. Results show that PFAS may alter liver measures indicative of NAFLD.

P-1090 Assessing the critical windows and aggregations of air pollution exposure on metabolic biomarkers in atherosclerotic patients

Kexin Zhu[1], Zhihui Hou[2], Conghong Huang[1], Muwu Xu[1], Lina Mu[1], Bin Lu[2], Meng Wang[1]
[1]Department of Epidemiology and Environmental Health, School of Public Health and Health Professions, University at Buffalo, The State University of New York, Buffalo, USA, [2]Department of Radiology, Fuwai Hospital, Chinese Academy of Medical Sciences, Beijing, China

BACKGROUND AND AIM: Air pollution exposure has been associated with metabolic biomarkers, but critical exposure window and appropriate aggregation of exposure duration is less understood. We aim to fill this research gap using air pollution exposure with flexible time intervals.

METHODS: We analyzed ten metabolic biomarkers in 1550 atherosclerotic patients from a cardiovascular cohort. Daily residential exposure to PM2.5 and NO2 was estimated using satellite-based spatiotemporal models and assigned to participants for up to 8 weeks before the blood collection. Distributed lag models were used to examine the single-day lag effects and cumulative effects. Effect modification by sex, smoking, and coronary artery calcium (CAC) score was explored.

RESULTS: In single-day-lag-effect models, apolipoprotein A (Apo A) was negatively associated with NO2 during the first 11 lag days (change range per 10 μg/m3: -0.21 to -0.07%) and with PM2.5 during the first 22 lag days (-0.06 to -0.03% per 10 μg/m3), and the effects peaked on the first lag day; while we observed critical windows for C-reactive protein (CRP) after first few lag days (NO2: lag4 to lag22 days, 0.51-0.78%; PM2.5: lag6 to lag23 days: 0.21-0.25%). In cumulative effect models, the effects became stronger when averaging NO2 exposure over longer periods compared to shorter periods for Apo A (-0.97% over 1-week to -1.59% over 8-week) and CRP (7.05% over 1-week to 15.85% over 8-week), whereas stronger associations appeared in shorter periods for triglycerides with NO2 (1.75 % over 1-week to 0.11% over 8-week) and glucose with PM2.5 (0.21 % over 1-week to -0.05% over 8-week). Association between NO2 and CRP was stronger among females, non-smokers, and individuals without CAC.

CONCLUSIONS: Air pollution impacts on inflammation and lipid and glucose metabolism were differed by critical windows and varying duration of exposure, suggesting different underlying mechanisms.

P-1091 Cardiometabolic, kidney, and thyroid markers and conditions in three Australian communities living with environmental per- and polyfluoroalkyl substances contamination

Nina Lazarevic[1], Kayla Smurthwaite[1], Catherine D'Este[1,2], Bruce Armstrong[3,4], Robyn Lucas[1], Archie Clements[5], Susan Trevenar[1], Imogen Gad[1], Rose Hosking[1], Amelia Joshy[1], Hsei Di Law[1], Jochen Mueller[6], Jennifer Braunig[6], Sandra Nilsson[6], Philip Batterham[1], Jo Lane[1], Aparna Lal[1], Deborah Randall[3], Catherine Banwell[1], Adrian Miller[7], Rosemary Korda[1], Martyn Kirk[1]

[1]Australian National University, Canberra, Australia, [2]The University of Newcastle, Newcastle, Australia, [3]The University of Sydney, Sydney, Australia, [4]The University of Western Australia, Perth, Australia, [5]Curtin University, Perth, Australia, [6]The University of Queensland, Brisbane, Australia, [7]CQUniversity, Townsville, Australia

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) have been associated with altered kidney, thyroid, and cardiometabolic function markers, particularly elevated total cholesterol, but the evidence for specific health conditions has been inconclusive. We quantified the single and combined associations of PFAS on 17 biomarkers and 13 related health conditions in Australian communities with PFAS-contaminated water from the historical use of aqueous film-forming foam in firefighting activities.

METHODS: This was a cross-sectional study of 881 adults in three exposed communities and 801 adults in three comparison communities. Participants self-reported their health and sociodemographic characteristics, and provided blood samples for measurement of nine PFAS and 17 biomarkers. We estimated differences in mean biomarker concentrations for each PFAS (PFOS, PFOA, and PFHxS) using linear regression and for the PFAS-mixture using Bayesian kernel machine regression. We also estimated prevalence ratios of biomarker concentrations above/below the reference limit and self-reported health conditions using modified Poisson regression.

RESULTS: We observed higher mean total cholesterol and uric acid concentrations with higher single and mixture PFAS concentrations in blood serum, with varying certainty across communities and PFAS. PFOA was associated with higher prevalence of self-reported hypercholesterolemia (one community) and gout and kidney disease (two communities), but PFOS and PFHxS were associated with lower prevalence of gout and kidney disease. No clear associations were observed for self-reported cardiovascular disease, and there was less certainty for liver and thyroid function markers and disease due to low prevalence.

CONCLUSIONS: Our study is one of few that simultaneously quantifies the associations of a PFAS-mixture on a large number of biomarkers and underlying health conditions in multiple communities. Our findings for total cholesterol and uric acid were consistent with previous studies; however, few associations were consistent across communities and the cross-sectional design limited causal inference.

P-1097 Comparison of Carcinogenic Risk from Inhalation Exposures in Industrial and Non-Industrial Areas

Vitezslav Jirik[1,2], Ondrej Machaczka[1]
[1]Centre for Epidemiological Research, Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic, [2]Department of Epidemiology and Public Health, Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic

BACKGROUND AND AIM: Cancer of respiratory tract is the world's most common cause of death among all cancer diseases. It's occurrence is influenced by many risk factors including outdoor and indoor air pollution, occupational exposure and other risk factors. The aim was to compare selected significant risk factors for respiratory cancer in two different polluted areas.

METHODS: A combination of a longitudinal cross-section study with a risk assessment methodology was used. Data from a specially developed methodology were used to evaluate lifetime exposures, and in addition, exposures to aerosol fractions $PM_{2.5}$, $PM_{1.0}$ and $PM_{0.25}$ were measured using cascaded personal samplers. The results were expressed as lifetime cancer risks and their proportions to the overall incidence of the disease.

RESULTS: By comparing the risks of benzo[a]pyrene in ambient air and fibrogenic dust in workplaces, much more higher risks have been attributed to indoor radon exposures, while surprisingly a very high proportion of the most biologically effective ultrafine particles in the ambient air aerosol was found (UFP, ie $PM_{0.25}$ was in the ratio 0.43, 0.57 and 0.67 in SPM, $PM_{2.5}$ and $PM_{1.0}$). Proportions of carcinogenic risks in industrial (IA) and non-industrial (NA) areas take on very different values with dominance of other factors (85% for men in IA, especially smoking) or radon (100% for women in NA). The benzo[a]pyrene represents only a proportion of lung cancers below 1%.

CONCLUSIONS: The most significant proportion of respiratory cancers is represented by radon and other risk factors, although UFP mass dominance was found in IA and it is hypothesized as the major carrier of carcinogenic polycyclic aromatic hydrocarbons.

P-1099 Effects of Ambient Air Pollutants on Cardiac Structure and Function in ECHO-SOL

Claire Leiser[1], Daniela Sotres-Alvarez[2], Elizabeth W. Spalt[3], Barry E. Hurwitz[4], Martha L. Daviglus[5], Gregory A. Talavera[6], Robert Kaplan[7], Bonnie E. Shook-Sa[2], Carlos J. Rodriguez[7,8], Joel D. Kaufman[1,2]

[1]Department of Epidemiology, University of Washington, Seattle, USA, [2]Department of Biostatistics, University of North Carolina Chapel Hill, Chapel Hill, USA, [3]Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, USA, [4]Department of Psychology, University of Miami, Miami, USA, [5]Institute for Minority Health Research, University of Illinois Chicago, Chicago, USA, [6]School of Public Health, San Diego State University, San Diego, USA, [7]Department of Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, USA, [8]Department of Medicine, Albert Einstein College of Medicine, Bronx, USA

BACKGROUND AND AIM: The relationship between air pollution (AP) exposure and incident heart failure has been investiagted; less is known about effects of AP on subclinical cardiac structure and function preceding clinical diagnosis. Cross-sectional associations between fine particulate matter (PM2.5) and nitrogen dioxide (NO2) and echocardiographic were assessed among 1,660 participants aged 45-74 years of the Echocardiographic Study of Latinos, an ancillary study to the Hispanic Community Health Study/Study of Latinos (HCHS/SOL).

METHODS: Measures including left ventricular (LV) mass index, relative wall thickness, average global longitudinal strain (GLS), LV ejection fraction, e', left atrial volume index, E/e' ratio, and diastolic function grades were assessed by echocardiogram. AP concentrations were estimated from spatio-temporal models at participant building residence. Primary exposures were interquartile range (IQR) increases in annual average PM2.5 and NO2 prior to clinical visit 1 (2008-2011). Survey linear regression estimated the effect of AP on measures of cardiac structure and function adjusting for age, sex, study site, alcohol use, physical activity, and education. Strain measurements are expressed as negative percentages (more positive numbers indicating worse myocardial strain).

RESULTS: 42.3% were male and 35.4% had no high school diploma. Average concentrations for PM2.5 and NO2 were 10.30 µg/m3 (standard deviation (SD) 1.9) and 17.4 ppb (SD 6.3), respectively. PM2.5 was associated with increased (worse) GLS (2.40%; 95% CI 1.03, 3.76) and decreased LV ejection fraction (-2.36; 95% CI -4.34, -0.38) per IQR increase. NO2 was associated with increased GLS (1.57; 95% CI 0.69, 2.46) and decreased LV ejection fraction (-2.07; 95% CI -3.77, -0.37) per IQR increase. Associations with other measures of cardiac structure and function were not found.

CONCLUSION:

These results provide evidence that in this Hispanic/Latino cohort, AP adversely affects GLS and EF, both known precursors to clinical heart failure.

P-1100 Differential uranium exposure and its association with hypertension and elevated blood pressure in American Indian communities in the Strong Heart Family Study

Abigail Onderwyzer Gold[1], Kevin Patterson[2], Miranda Spratlen[2], Jason Umans[3,7], Amanda Fretts[4], Walter Goessler[5], Ying Zhang[6], Anne Nigra[2], Ana Navas-Acien[2]

[1]Vagelos College of Physicians and Surgeons, Columbia University, New York, USA, [2]Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [3]MedStar Health Research Institute, Washington, USA, [4]Department of Epidemiology, University of Washington, Seattle, USA, [5]Institute of Chemistry - Analytical Chemistry, Karl-Franzens University Graz, Graz, Austria, [6]Center for American Indian Health Research, Department of Biostatistics and Epidemiology, The University of Oklahoma Health Sciences Center, Oklahoma City, USA, [7]Georgetown-Howard Universities Center for Clinical and Translational Science, Washington, USA

BACKGROUND: Urinary uranium (U) is present at higher concentrations in American Indian (AI) participants in the Strong Heart Study compared to the general US population. Cardiovascular disease is the leading cause of death among American Indians, of which hypertension is an important risk factor. We evaluated the association between U exposure and incident hypertension and increased blood pressure (BP) among Strong Heart Family Study (SHFS) participants.

METHODS: We included 1453 SHFS participants with baseline visits in 1998-1999 or 2001–2003, and follow-up visits in 2001-2003 and/or 2006–2009. We estimated the association of urinary U exposure with changes in systolic BP and diastolic BP levels using linear regressions, and hypertension incidence using Poisson regression with robust variance, accounting for family clustering.

RESULTS: Median (IQR) urinary uranium levels were 0.029 (0.013, 0.059) µg/g creatinine. at follow-up, 17.4% of participants developed hypertension. After adjustment for sociodemographic variables, eGFR, pre-diabetes status, and BMI, comparing the highest to lowest urinary uranium quartiles, the RR (95% CI) of incident hypertension was 1.38 (1.00, 1.91) and the mean difference (95% CI) in systolic BP levels between baseline and follow-up was -2.00 (-3.83, -0.16) mmHg. After adjustment for urinary cadmium and arsenic, the corresponding RR (95% CI) was 1.44 (1.04, 1.99) and the mean difference (95% CI) for systolic BP between baseline and follow-up was -1.48 (-3.32, 0.37) mmHg. The association between uranium and blood pressure levels at follow-up was non-linear, with an increased risk at higher urinary uranium levels.

CONCLUSIONS: These findings suggest moderate increased risk for hypertension at urinary uranium levels greater than 0.06 µg/g, typical of the Southwest and Great Plains, furthermore a potential association with higher systolic BP levels and higher uranium exposure levels. Further work is needed to assess the cardiovascular effects of chronic uranium exposure in US populations.

KEYWORDS: Uranium, hypertension, blood pressure

P-1101 Acanthamoeba spp. in public parks' soils in Spain: presence, distribution and risks

Antonio Peña-Fernández[1], Manuel Higueras[2], M. Carmen Lobo Bedmar[3], Lucrecia Acosta[4], Umar Anjum[1]
[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, LE1 9BH, UK, [2]Scientific Computation & Technological Innovation Center (SCoTIC), Universidad de La Rioja, Logroño, Spain, [3]IMIDRA, Alcalá de Henares (Madrid), Spain, [4]Universidad Miguel Hernández, Elche (Alicante), Spain

BACKGROUND AND AIMS: Acanthamoeba spp. is a protozoan that is becoming a public health threat. This parasite has been isolated in stray cats from Madrid (Spain), which could play a role in contaminating urban environments. The aim was to determine the presence/distribution of Acanthamoeba spp. in Alcalá de Henares (a major city in the Madrid Region) to identify potential risks.

METHODS: 227 topsoil samples were collected in July 2017 across urban parks/green areas (155), industrial (60) and a public garden (12). Following extraction of DNA with FastDNA® Spin, a triplex real-time TaqMan PCR assay was performed to detect Acanthamoeba spp., using established methodologies. Organic matter (OM), pH, electric conductivity (EC) and texture (sand, clay and silt percentages) were also determined in soils.

RESULTS: Acanthamoeba spp. was detected in 39 topsoil samples, which suggests a moderate distribution throughout Alcalá. Higher presence in the urban (24) area could be explained by the major presence of urban animals, such as stray cats, in this area. The presence of cysts would have not been affected by the OM, pH or EC, despite variations seen in the levels of OM in the studied soils. In contrast to sand and silt, Acanthamoeba spp. seem to be more present in the areas with lower percentages of clay (13.76 detected vs. 18.38 not detected; p=0.006), association which has also observed within the four sub-areas in which the urban area was divided (p=0.016). Clay has more water holding capacity than sand and silt, so it would have been expected to find Acanthamoeba positively associated with clay, although its lower permeability might affect their survival.

CONCLUSIONS: The low-moderate distribution of Acanthamoeba spp. detected could highlight a risk for the Alcalá population which should be further investigated as this protozoan can affect immunocompromised/immunocompetent individuals.

KEYWORDS: Acanthamoeba, urban soils, human risks

P-1106 Metal mixture mediates associations between socioeconomic indicators and blood pressure outcomes in rural Bangladeshi adults: Evidence from a prospective population study

Juwel Rana[1,2,3], Syed Emdadul Haque[4], Jay S. Kaufman[2], Habibul Ahsan[4,5]
[1]North South University, Bangladesh, Dhaka, Bangladesh, [2]McGill University, Montreal, Canada, [3]South Asian Institute for Social Transformation (SAIST), Dhaka, Bangladesh, [4]UChicago Research Bangladesh, Dhaka, Bangladesh, [5]The University of Chicago, Illinois, USA

BACKGROUND AND AIM: There is limited evidence on the causal mechanism in the socioeconomic differentials in blood pressure (BP) in low and middle-income countries (LMICs). We, therefore, examined the associations of socioeconomic indicators (SEIs) and BP, socioeconomic disparities in metal mixture exposures, and the potential mediation effect of metal mixtures in the associations between SEIs and BP outcomes in rural Bangladeshi adults.

METHODS: This study included 900 rural Bangladeshi adults prospectively followed for six years in the Bangladesh vitamin E and selenium Trial (BEST). Blood pressure was measured at baseline and during three biennial follow-up examinations. Blood levels of arsenic, lead, selenium, and urinary arsenic, including socioeconomic indicators-years of education, and agricultural land ownership (ALO), were measured at baseline. Weighted quantile sum (WQS) regression was used to estimate the joint effects of metal mixture on systolic blood pressure (SBP), diastolic blood pressure (DBP), pulse pressure (PP), and mean arterial pressure (MAP) taken at the third follow-up. Causal mediation effect of the metal mixture was estimated using the parametric g-computation method.

RESULTS: Education was positively, but ALO was inversely associated with BP. Participants with higher SEIs were less likely to be exposed to metal mixtures than their counterparts. Metal mixture mediated the associations of SEIs with SBP, DBP, MAP, and PP. for example, the randomized analogue of total natural direct effect (rRTNDE) was 5.31 (95% CI: 1.91, 8.77) and the pure natural indirect effect (rRPNIE) was -0.67 (95% CI: -1.34, -0.22) for education and SBP. Similarly, the rRTNDE was -2.31 (95% CI: -4.37, -0.33) and the rRPNIE was -0.29 (95% CI: -0.70, -0.03) for ALO and SBP. There was no evidence of the exposure-mediator interaction in the mediation models (Pint>0.20).

CONCLUSIONS: Our study suggests that metal mixture mediates socioeconomic differentials in BP.

KEYWORDS: Blood Pressure; Metals; SES; Mediation; Mixture

P-1107 Association between particle components and inpatient Parkinson's hospitalizations among people ages 40 years and up in the U.S. using Bayesian kernel machine regression (BKMR)

Bryan N. Vu[1], Xinye Qiu[1], Joel Schwartz[1]
[1]*Harvard University, Boston, USA*

BACKGROUND: Recent studies have shown that air pollutants may have adverse effects on neurological disorders. However, few studies have investigated the long-term exposure of particle components in conjunction with PM2.5 and ozone to assess their individual and additive effects on Parkinson's disease.
AIM: We aim to utilize a Bayesian Kernel machine regression (BKMR) to assess the individual and join effects of air pollutants including 15 different particle components such as organic carbon (OC), elemental carbon (EC), copper (Cu), and zinc (Z), along with PM2.5 and ozone, on counts of inpatient Parkinson's hospitalizations for adults ages 40 years and up.

METHODS: Inpatient records were collected from the State Inpatient Databases which included hospitals from 12 U.S. states ranging in years from 2000 through 2016. We also included temperature from Daymet and variables from the U.S. census to control for socio-economic status. All variables were aggregated to the annual level.

RESULTS: We observed a decrease of 0.05 (95%CI: 0.03,-0.14), 0.04 (95%CI: 0.05,-0.14), and an increase of 0.03 (95%CI: -0.07,0.12) in the number of Parkinson's inpatient hospitalizations each year at the 25th, 50th, and 75th percentiles of pollutant mixture, respectively. at the 90th and 95th percentile, there is a significant increase of 0.12 (95%CI: 0.01,0.22) and 0.17 (95%CI: 0.06,0.28) annual Parkinson's cases, respectively.

CONCLUSIONS: Our results contribute to the growing body of literature on air pollution and neurological disorders.

KEYWORDS: Parkinson's Disease, PM Components, PM2.5, Ozone, BKMR

P-1108 Effects of long-term exposure of particle components on inpatient stroke hospitalizations in U.S. adults ages 40 years and up using Bayesian kernel machine regression (BKMR)

Bryan N. Vu[1], Xinye Qiu[1], Joel Schwartz[1]
[1]*Harvard University, Boston, USA*

BACKGROUND: Air pollutants, including PM2.5, have been shown to adversely affect health; however, few studies have investigated the long-term exposure of particle components in conjunction with PM2.5 and ozone to assess their individual and additive effects on cerebrovascular incidents such as stroke.
AIM: We aim to utilize a Bayesian Kernel machine regression (BKMR) to assess the individual and join effects of air pollutants including 15 different particle components such as organic carbon (OC), elemental carbon (EC), copper (Cu), and zinc (Z), along with PM2.5 and ozone, on counts of inpatient Parkinson's hospitalizations for adults ages 40 years and up.

METHODS: Inpatient records were collected from the State Inpatient Databases which included hospitals from 12 U.S. states ranging in years from 2000 through 2016. We also included temperature from Daymet and variables from the U.S. census to control for socio-economic status. All variables were aggregated to the annual level.

RESULTS: We observed a significant increase of 2.00 (95%CI: 1.72,2.29), 5.87 (95%CI: 5.57,6.16), and 9.81 (95%CI: 9.51,10.12) in the number of inpatient stroke hospitalizations each year at the 25th, 50th, and 75th percentiles of pollutant mixture, respectively.

CONCLUSIONS: Our results indicate that the mixture of pollutants greatly contribute to the increase in the number of stroke hospitalizations each year and that the effects of short-term exposures of particle components on stroke hospitalizations should be assessed next.

THEMATIC 18: Occupational Exposures and Health

P-1112 Epidemiologic profile of work-related accidents with biological material in Brazil, 2007-2021

Rafael Buralli[1], Cristiano Barreto de Miranda[1], Klauss Kleydmann Garcia[1]
[1]*General-Coordination of Occupational Health, Ministry of Health of Brazil, Brasília, Brazil*

Accidents with biological material involve contact with body fluids, contamination potential, and mainly occurs among healthcare workers. Notification of WA-BM is mandatory for health services in Brazil. This work aims to describe the epidemiologic profile of work-related accidents with biological material (WA-BM) in Brazil.

METHODS: Data of WA-BM from 2007-2021 was gathered from the Information System of Notifiable Diseases (Sinan). Absolute and relative frequencies, proportional variation, and incidence rates (IR) per 100,000 workers were presented and analyzed by year with sociodemographic and occupation characteristics.

RESULTS: From 2007-2021, 720,076 WA-BM were notified in Sinan, with a sharp upward increase over the years, soaring from 15,735 cases in 2007 to 67,012 cases in 2019 (+325%), followed by a decline to 61,791 cases in 2021 (-8%), what may have happened due to interruption of several clinical cares and non-emergency surgeries because of the Covid-19 pandemic. IR was 17.3 cases x 100,000 workers in 2007, 70.3 in 2019, and 64.8 cases in 2021. Most cases occurred among women (77.1%), white (54.7%) or brown (29.7%), aged 20-34y (56.5%) or 35-49y (31.9%), with completed high school (41.1%) or undergraduate (23.4%). Most WA-BM were needlestick (67.3%) and sharp (6.9%) injuries, and affected nursing technician or assistant (47.2%), followed by nurses (8.0%), students – probably from health courses (6.0%), and clinical physicians (4.0%).

CONCLUSIONS: Unsafe working conditions, lack of training and information on occupational risks, and psychosocial hazards (e.g., time pressure, long working hours, and shift work) are the main drivers of WA-BM in health care facilities, resulting in illness, injuries, absenteeism, and high expenditures for the health sector. Thus, it is urgent to strengthen occupational health and safety programs at national and facility levels, to identify hazards, to promote exposure and incident reporting, and to provide education, training, and immunizations against infectious disease.

P-1114 Assessment of fungal hazards in archives based on nasal swab samples

Marcin Cyprowski[1], Anna Ławniczek-Wałczyk[1], Rafał L. Górny[1]
[1]*Central Institute for Labour Protection - National Research Institute, Warsaw, Poland*

BACKGROUND AND AIM: Scientists are looking for exposure indicators that could accurately describe the impact of bioaerosols on workers' health. Especially useful in this regard seems to be the swabs collected from the nose or nasopharynx, which represent easy to obtain biological samples. The aim of this study was to identify a mycobiota occurring in the upper respiratory tract of archive workers as a result of work shift exposure.
METHODS: Eleven workers from three archives and two libraries participated in this study. Each of them was equipped with a personal measurement set consist of CIS sampler to check the concentration of inhalable dust and, after work shift, the swab samples from nasal cavity were collected. Qualitative mycobiota analysis was performed using culture-based method and isolated pathogens were additionally diagnosed based on MALDI-TOF MS.
RESULTS: The average fungal concentration in swab samples was 43 CFU/ml, (SD=59). In turn, the concentrations of airborne fungi were very variable and depended on the place of measurement (mean value: 2916 CFU/m^3, SD=3051). The qualitative analysis of the samples revealed the presence of 33 fungal species belonging to 17 genera. The swab samples were dominated by the yeast of Candida genus and filamentous fungi from Penicillium and Aspergillus genera. It was shown that 59% of identified fungal strains were simultaneously present in the air at workplaces and in the nasal cavities of employees. Two isolated fungal genera, i.e., Aspergillus and Microsporum, represent human pathogens classified in risk group 2, according to the Commission Directive (EU) 2019/1833.
CONCLUSIONS: As airborne fungi in archives and libraries can colonize the upper respiratory tract of workers, the microbiologcal analysis of nasal swabs can be a precise tool to assess the exposure to biological aerosol in this working environment.

P-1117 Mortality and cancer incidence in British military veterans involved in human experiments at Porton Down: 40-year follow-up

Gemma Archer[1], Thomas Keegan[2], Katherine Venables[3], Lucy Carpenter[4], Nicola Fear[1]
[1]King's College, London, UK, [2]Lancaster University, Lancaster, UK, [3]Nuffield Department of Population Health, University of Oxford, Oxford, UK, [4]Nuffield College, University of Oxford, Oxford, UK

BACKGROUND AND AIM: To investigate whether veterans involved in chemical warfare agents research at Porton Down have increased rates of mortality or cancer incidence.

METHODS: The study is a historical cohort study. Participants are male UK veterans who participated in the 'Service Volunteer Programme', 1941-1989, identified from Porton Down experiment books, and a comparison group of similar 'non-Porton Down' veterans identified from military personnel files. of 19,233 records retrieved for each group, 18,069 (94%) Porton Down and 17,588 (91%) non-Porton Down are included herein our study sample.
The main outcome measures – National Health Service Central Registry Data on mortality and cancer registrations up to December 2019.

RESULTS: Over a median follow-up of 48.1 years, 10,889 Porton Down veterans (60.3%) and 10,657 non-Porton Down veterans (60.6%) died. After adjustment for age, year of birth, and military service characteristics, overall, Porton Down veterans had a 7% higher rate of all-cause mortality compared to non-Porton Down veterans.
Associations with all-cause mortality were stronger for veterans who attended Porton Down between 1960 and 1964 (1.36, 95% CI 1.20 to 1.54), compared to other periods; likelihood-ratio test, p=0.006. for cause-specific mortality, Porton Down veterans had a statistically significantly higher rates of death from infectious and parasitic disease (5%), genitourinary (45%), circulatory diseases (5%), external causes (23%) and deaths attributable to alcohol (48%).
There was no association between attendance at Porton Down and overall cancer incidence (0.99, 0.95 to 1.03). although Porton Down veterans had higher rates of neoplasms of 'uncertain or unknown behaviour' (1.26, 1.04 to 1.53), but lower rates of 'other urinary tract' neoplasms (0.77, 0.60 to 0.98).

CONCLUSIONS: Overall, mortality rates were slightly higher in Porton Down veterans, but there was no difference in cancer incidence. Associations were stronger in Porton Down veterans who attended in the early 1960s.

P-1118 Seroprevalence of Hepatitis B and Hepatitis C Virus Among Inmates and Staff in Lafia Correctional Service, Nasarawa State, Nigeria

Mojisola Owoseni[1], Hamida Usman[1]
[1]*Federal University of Lafia, Lafia, Nigeria*

BACKGROUND AND AIM: Hepatitis infection has remained a reoccurring health challenge in blood transfusion, liver cirrhosis and hepatocellular carcinoma (HCC). This cross-sectional study assessed the seroprevalence of Hepatitis B and Hepatitis C virus among inmates and staff in Lafia correctional service, Nasarawa State, Nigeria.
METHODS: A total of 160 samples comprising 120 inmates within the age range of 20-70 years and 40 staff were collected. Serological blood screening was done using the HBV surface antigen (HBsAg) rapid test Dip-strip and HCVAb plus rapid test strip. The socio-demographic factors in form of a structured questionnaire were conducted among consenting inmates and staff. The significance of risk factors on the prevalence of the hepatitis infection among inmates was analyzed using logistics regression.
RESULTS: A total seroprevalence of 29.16 % HBV and 8.3% HCV among inmates and 5% HBV and 2.5% HCV among staff was determined. A prevalence of 30% HBV and 8.18% HCV male, 20% HBV and 10% HCV female inmates, 7% HBV males and 9% HCV female staff were recorded. The prevalence of hepatitis infection among inmates and staff below 40 years was higher than the prevalence above 40 years although insignificant between the two age groups ($p \leq 0.05$). Married inmates at 48.8% HBV and 16.3% HCV were more infected than 18.18% HBV and 4% HCV single inmates and single staff were more infected than the married staff. Illicit drug use and length of stay above 5 years in the correctional service were risk factors significant for HBV and HCV prevalence among inmates.
CONCLUSIONS: A high seroprevalence of HBV and HCV infections among inmates and staff in Lafia correctional service, Nigeria and the predisposing risk factors reaffirm the need for sensitization and routine screening of inmates and staff before and during incarceration.

KEYWORDS: Hepatitis, seroprevalence, correctional service, Inmates, staff

P-1121 Prevalence and predictors of per- and polyfluoroalkyl substances (PFAS) serum levels among US volunteer firefighters

Katherine Lubina[1], Kaleigh M Hinton[1], Zorimar Rivera-Núñez[1,2], Taylor M Black[1], Robert J Laumbach[1,2], Shou-en Lu[1], Nimit N Shah[1], Zhihua Fan[3], Chang Ho Yu[3], Jefferey L Burgess[4], Alberto J Caban-Martinez[5], Miriam M Calkins[6], Brian S Kubiel[7], Judith M Graber[1,2]

[1]Rutgers University School of Public Health, Piscataway, USA, [2]Rutgers University Environmental and Occupational Health Sciences Institute, Piscataway, USA, [3]New Jersey Department of Health Environmental and Chemical Laboratory Services, Trenton, USA, [4]University of Arizona Mel and Enid Zuckerman College of Public Health, Tucson, USA, [5]University of Miami Leonard M. Miller School of Medicine, Miami, USA, [6]Centers for Disease Control and Prevention National Institute for Occupational Safety and Health, Cincinnati, USA, [7]Toms River Board of Fire Commissioners District 1, Toms River, USA

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) are synthetic persistent compounds of health concern. Firefighters may be exposed to PFAS through firefighting foams, combustion products, and equipment/gear. Studies have shown elevated PFAS levels in paid firefighters. Few studies include volunteer firefighters, who comprise 67% of US firefighters. We assessed seroprevalence and predictors of PFAS levels among US volunteer firefighters enrolled in the Firefighter Cancer Assessment and Prevention Study (CAPS), a research partner of the Fire Fighter Cancer Cohort Study (FFCCS).

METHODS: Consenting firefighters (n=413) enrolled from 34 volunteer departments in four US states - Connecticut (CT), Maine (ME), Maryland (MD), and New Jersey (NJ). Participants completed a survey and provided blood samples, analyzed for PFAS by online solid phase extraction unit and HPLC-MS/MS instrumentation. We calculated prevalence and geometric means by location (a single NJ department (NJ-Dept1), NJ-Other, CT&MD, ME). for select PFAS (prevalence ≥75%), we assessed associations between PFAS (log-transformed) and age, firefighting years, monthly responses, and location in single-PFAS multivariate models.

RESULTS: Most participants were non-Hispanic White (91%), male (92%), with an average age of 45.2 years (sd 15.4) and 20.2 years (sd 15.7) of firefighting. Serum levels of the six PFAS were similar between locations, except perfluorodecanoic acid (PFDeA) was significantly higher in NJ-Dept1 than elsewhere (0.25ug/L, vs 0.08, 0.09, 0.08; $p<0.0001$) and perfluorooctanoic acid (PFOA) was higher in NJ-Other than elsewhere (2.35ug/L vs 1.96, 1.23, 1.29; $p<0.0001$). In multivariate analysis, PFOA and PFDeA were positively associated with age ($p=0.006$, 0.0736, respectively) and location ($p<0.0001$ (for all locations, ref = NJ-Dept1)), controlling for firefighting years and monthly responses.

CONCLUSIONS: We observed spatial differences in volunteer firefighters' serum PFOA and PFDeA levels. Further research is needed to better understand sources of PFAS among volunteer firefighters, including their primary occupations and community exposures.

KEYWORDS: PFAS, firefighters, volunteers

P-1123 Heat stress and incidence of acute kidney injury among agricultural workers in Spain

Cristina O'Callaghan-Gordo[1,2,3,4], Lourdes Arjona[2,3,4], Francisco Brocal[5], Ben Caplin[6], Ana Espinosa[2,3,4], Rocío García[6], Mayte Martín-Bustamante[7], Claudia Malpica[1], Oriana Ramirez-Rubio[2,9], Elena Ronda[5], Neil Pearce[8], Manolis Kogevinas[2,3,4]

[1]ISGlobal, Barcelona, Spain, [2]Universitat Oberta de Catalunya (UOC), Barcelona, Spain, [3]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [4]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [5]Universidad de Alicante, Alicante, Spain, [6]Centre for Nephrology, University College London Medical School, UK, [7]Institut Català de Seguretat i Salut Laboral, Departament d'Empresa i Treball, Generalitat de Catalunya, Spain, [8]Department of Medical Statistics, London School of Hygiene and Tropical Medicine, London, UK, [9]Department of Epidemiology, Boston University School of Public Health, USA

BACKGROUND AND AIM: Heat stress (HS) is associated with adverse health outcomes among agricultural workers, including acute kidney injury (AKI). The aim on this study was to estimate the incidence of AKI over the course of the work shift and the association with HS among agricultural workers in Spain, where summer temperatures are high and heat waves are expected to be more frequent.

METHODS: Male agricultural workers were enrolled in the study in two different periods and provinces: summer harvesting season in Alacant (n=43, September 2018) and winter harvesting season in Tarragona (n=52, November 2018 and January 2019). for each participant we estimated exposure to HS during a work shift based on the wet bulb globe temperature (WBGT) index (ISO 7243:2017) and AKI cross-shift incidence, defined as an increase in post-shift serum creatinine by at least 0.3 mg/ dl or at least 1.5 times the pre-shift serum creatinine levels. We collected information on potential confounders. for a subsample of participants (n=54), we measured neutrophil gelatinase-associated lipocalin (NGAL) levels before and after the working shift. We used regression models to assess if heat stress is a risk factors for AKI and increase in NGAL levels.

RESULTS: Mean WBGT was 24.5 °C (20.2-27.1) during the summer harvesting season and 14.2 °C (8.0-20.7) during the winter harvesting season. Nine percent of workers harvesting during the summer months were exposed to HS. Incidence of AKI was higher during the summer harvesting season (33% versus 4%). HS was associated with cross-shift incidence of AKI [Age adjusted OR (95%CI) =9.6 (1.4, 67.9)]. No differences in NGAL levels were observed between participants exposed to HS.

CONCLUSIONS: Heat stress is a risk factor for AKI among agricultural workers in Spain even when environmental temperatures are not extremely hot.

P-1124 Association between diesel exhaust exposure and mitochondrial DNA methylation

Wei Jie Seow[1], Wei Hu[2], Yu fei Dai[3], Roel Vermeulen[4], Hyang-Min Byun[5], Jason Wong[2], Bryan Bassig[2], Batel Blechter[2], Huawei Duan[3], Yong Niu[3], George Downward[4], Shuguang Leng[6], Bu-Tian Ji[2], Wei Fu[7], Jun Xu[8], Kees Meliefste[4], Jufeng Yang[7], Dianzhi Ren[7], Meng Ye[3], Tao Meng[3], Ping Bin[3], Dean Hosgood[9], Debra Silverman[2], Nathaniel Rothman[2], Yuxin Zheng[3], Qing Lan[2]

[1]National University of Singapore, Singapore, Singapore, [2]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Rockville, MD, USA,, [3]National Institute of Occupational Health and Poison Control, Chinese Center for Disease Control and Prevention, Beijing, China,, [4]Division of Environmental Epidemiology, Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands,, [5]Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, UK,, [6]School of Public Health, Qingdao University, Qingdao, China,, [7]Chaoyang Center for Disease Control and Prevention, Chaoyang, Liaoning, China,, [8]Hong Kong University, Hong Kong, Hong Kong,, [9]Division of Epidemiology, Albert Einstein College of Medicine, New York, NY, USA,

BACKGROUND: Diesel exhaust is an established human carcinogen, however the mechanisms by which it leads to cancer development are not fully understood. Mitochondrial dysfunction is an established contributor to carcinogenesis, and recent studies have improved our understanding of the role played by epigenetic modifications in the mitochondrial genome on tumorigenesis. In light of these developments, we aim to evaluate the association between diesel engine exhaust (DEE) exposure with mitochondrial DNA (mtDNA) methylation levels in workers exposed to DEE.

METHODS: The study population consisted of 53 male workers employed at a diesel engine manufacturing facility in Northern China who were routinely exposed to diesel exhaust in their occupational setting, as well as 55 unexposed male control workers from other unrelated factories in the same geographic area. Exposure to DEE, elemental carbon as a DEE surrogate, organic carbon, and particulate matter (PM2.5) were assessed. mtDNA methylation for CpG sites (CpGs) from seven mitochondrial genes (D-Loop, MT-RNR1, MT-CO2, MT-CO3, MT-ATP6, MT-ATP8, MT-ND5) was measured in blood samples. Linear regression models were used to estimate the associations between DEE and mtDNA methylation levels, adjusting for potential confounders. The associations between elemental carbon, organic carbon, and PM2.5 exposures with mtDNA methylation levels were also assessed.

RESULTS: DEE exposure was associated with decreased MT-ATP6 (difference = -35.6%, p-value = 0.019) and MT-ATP8 methylation (difference = -30%, p-value = 0.029) compared to unexposed controls. Exposures to elemental carbon, organic carbon, and PM2.5 were also significantly and inversely associated with methylation in MT-ATP6 and MT-ATP8 genes (all p-values < 0.05).

CONCLUSIONS: Our findings suggest that DEE exposure perturbs mtDNA methylation, which may be of importance for tumorigenesis.

KEYWORDS: Diesel exhaust, mitochondrial DNA methylation

P-1128 Impact of COVID-19 Pandemic on Military Medical Encounters and Musculoskeletal Injuries

Vy Nguyen[1], LTC Jason Judkins[1], Kathryn Taylor[1]
[1]*U.S. Army Research Institute of Environmental MedicineU.S. Army Research Institute of Environmental Medicine, Natick, USA*

BACKGROUND AND AIM: Musculoskeletal injuries (MSKI) are the leading cause of outpatient medical encounters in the U.S. Army, and trends have remained stable over the past decade. The COVID-19 pandemic has altered healthcare use and workplace and lifestyle patterns, potentially affecting injury trends. We investigated the impact of the pandemic on healthcare use and injuries within the Army.

METHODS: We quantified medical encounters (all, in-person only, telephone consults only) and incident MSKI from electronic medical records among active duty soldiers from April 2016 through March 2021. We compared weekly counts before and after the COVID-19 national emergency declaration on March 13, 2020 in an interrupted time-series analysis using autoregressive integrated moving average models accounting for time and seasonal trends.

RESULTS: From April 2016 to March 2020, the mean (SD) weekly count was 125,953 (20,782) for all medical encounters [in-person: 113,249 (19,139); telephone consults: 17,053 (2,536)] and 11,016 (1,907) for MSKI. Weekly counts for all and in-person medical encounters and MSKI decreased and telephone consults increased in the month following the declaration. All medical encounters gradually returned to levels predicted in the absence of the pandemic, yet the reductions for in-person medical encounters [-13,405 (95% CI: -21,516, -5,294)] and MSKI [-1,933 (95% CI: -2,812, -1,056)] and increases in telephone consults [1,530 (95% CI: 566, 2,496)] were sustained through March 2021.

CONCLUSIONS: Observed trends in healthcare use during the pandemic differed from previous years. All medical encounters appeared to have returned to predicted levels. While activities in the Army have largely resumed, the sustained reduction in MSKI is likely multifactorial and may be due to shifts in healthcare access and use.
The views expressed are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government.

P-1129 Multiple Myeloma in Radiography Testing Worker

Jun Hyeok Choi[1], Sang gil Lee[2]
[1]OSHRI(Occupational Safety and Health Research Institute, Ulsan, Republic of Korea, [2]OSHRI(Occupational Safety and Health Research Institute, Republic of Korea

BACKGROUNDS: Radiography Testing (RT) is a non-destructive testing method mainly using x-ray and γ-rays emitted from Ir192 and Co60 nuclides. X-rays, and γ-rays are reported by International Agency for Research on Cancer (IARC) as carcinogens inducing multiple myeloma in human with limited evidences. In this study, the amount of exposure to radiation and probability of causation (PC) of multiple myeloma were assessed in a 65-year-old of patient who worked as an inspector in shipyards and plumbing works using radiation for 9 years.

METHODS: Cumulative radiation exposure was calculated using the records of past personal dosimeter and previous studies. PC developed by the Occupational Safety and Health Research Institute (OSHRI) and Radiation Health Research Institute was used to assess the causal relationship between radiation exposure and disease under exposure scenarios.

RESULTS: Considering that the patient rarely used the collimator nor shielding equipment during works at shipyard (1983~1988), we calculated the radiation exposure under the scenario assuming collimator was used in half at shipyard work. The radiation exposure dose of workers was estimated to be a minimum of 73.76mSv and a maximum of 1688.34mSv. The PC accounting for attribution of radiation to the cancer was 47.74% applying the upper 95th confidence value.

CONCLUSIONS: The work-relatedness between RT without using protective equipment and shielding in the past and multiple myeloma was approved by the Epidemiological Investigation and Evaluation Committee for this case.

P-1131 Tracking the SARS-CoV-2 Omicron (B. 1.1. 529) health and economic impact by occupational sector

Marcela Tamayo-Ortiz[1], Waldo Vieyra-Romero[1], David Barros-Sierra[1], Rodrigo Zepeda-Tello[1], José Rosa-Parra[1], Hector Gutierrez-Diaz[1], Mauricio Hernandez-Avila[1]
[1]*Mexican Social Security Institute, Mexico City, Mexico*

BACKGROUND: Real-time outbreak patterns during the COVID-19 pandemic have been crucial to provide quick response, prevention and attention programs. Workers reflect a country's population, hence, paid sick leaves (short-term disability claims, STDC) can track epidemics, including the current pandemic. Our aim was to assess the impact of Omicron by occupational sector/subsector among N=19,961,714 private-sector workers affiliated to the Mexican Social Security Institute.

METHODS: We used STDC that had a linked SARS-CoV-19 diagnostic test between January and March 4, 2022. There were n=1,543,730 STDC and n=663,245 of them with a test. We calculated the positivity rate, lost work days (LWD), and relative risks (RR) of Omicron vs the same epidemiological weeks for the first, second and Delta COVID waves by economic sector/subsector.

RESULTS: Workers were 36±10.7 years old and 47% were men. We saw an 85.4% positivity rate, with an average of 6.8±3 LWD, representing 528.3 LWD per 1,000 workers. The RR of Omicron was highest compared to the first wave (RR= 1.84; 95%CI: 1.83, 1.84) with the Accommodation (RR= 3.98; 95%CI: 3.89, 4.07) and Educational Services-arts-entertainment-recreation (RR= 2.41; 95%CI: 2.37, 2.46) sectors having the highest RRs. The RR of Omicron vs Delta was the next highest RR= 1.29; 95%CI: 1.29, 1.29) with Health Care and Social Assistance (RR= 2.15; 95%CI: 2.12, 2.19) and Social and Community Services (RR= 1.79; 95%CI: 1.78, 1.81) having the highest RR. Omicron vs the second wave had a RR of 1.07; 95%CI: 1.07, 1.07, with Accommodation (RR= 1.40; 95%CI: 1.38, 1.41) and Educational Services-arts-entertainment-recreation (RR= 1.60; 95%CI: 1.57, 1.62) sectors having the highest RRs.

CONCLUSIONS: Omicron spread more effectively than the previous COVID-19 and Delta waves in Mexico, affecting the touristic and health care sectors more importantly, reflecting the entrance of the variant to the country through tourism.

KEYWORDS: Omicron impact, occupational sector, Mexico

P-1132 Anxiety, Depression and Post Traumatic Stress Syndrome and their Association with Presenteeism among a COVID-19 Hospital in Mexico City

Eduardo Ignacio-Velázquez[1], Víctor Martínez-Enciso[1], María Toledo-Palacios[1], Marcela Tamayo-Ortiz[1]
[1]*Mexican Social Security Institute, Mexico, Mexico*

BACKGROUND AND AIM: Hospital workers providing care to COVID-19 patients have reported depression, anxiety and post-traumatic stress disorder (PTSD). These pathologies could be related to job presenteeism, decreasing productivity. Our aim was to analyze the association between depression, anxiety and PTSD, and job presenteeism among hospital workers.

METHODS: We applied a sociodemographic questionnaire, the Hospital Anxiety and Depression Scale (HADS), the Global Evaluation of Post-traumatic Stress (EGEP-5) Scale and the Stanford Presenteeism Scale (SPS-6) to n=272 workers of a COVID-dedicated hospital of the Mexican Social Security Institute in Mexico City. We used logistic regression models to analyze the odds of presenteeism associated with depression, anxiety and PTSD separately, adjusted for sex, age, marital status, education, direct contact with COVID patients and previous COVID-related incident (eg. being sick themselves or a relative).

RESULTS: Participants had a mean age of 32 years and 78% were female. 5.5% had depression, 18% anxiety and 19.1% PTSD. Presenteeism in the last month was 45.2%. The odds of presenteeism among those with depression were OR=5.69 (95%CI: 1.44, 22.47), among those with anxiety OR=18.93 (95%CI: 6.80, 52.71) and among those with PTSD OR=4.64, (95%CI: 2.19, 9.80). The odds of presenteeism among those caring directly for COVID patients were: depression OR=3.48 (95%CI: 2.03, 5.96), anxiety OR=4.49 (95%CI: 2.44, 8.24), PTSD OR=3.62 (95%CI: 2.08, 6.29). In the model for depression the odds for those having a previous COVID-related incident was OR=2.04 (95%CI: 1.20, 3.46). Women had larger odds of presenteeism than men in the depression OR=2.03 (95%CI: 1.05, 3.93) and the PTSD OR=2.03 (95%CI: 1.05, 3.93) models.

CONCLUSIONS: Depression, anxiety and PTSD were strongly associated with job presenteeism among hospital workers, pointing at the relevance of providing mental care for workers, especially those directly in contact with COVID patients.

KEYWORDS: Presenteeism, Mental Health, COVID-19 health care workers

P-1135 Lost work days associated with long COVID among healthcare workers

Marcela Tamayo-Ortiz[1], Alejandro Cabello-López[1], Cuauhtémoc Juárez-Pérez[1], Millitéotl Rincón-Rojas[1], Mat Ismael Velázquez-Ramírez[1], Constanza Aguilar-Jiménez[1], Belmar Toledo-Ortiz[1], Gabriel Real-Ornelas[1]
[1]Mexican Social Security Institute, Mexico City, Mexico

BACKGROUND AND AIM: Long COVID among healthcare workers may have an important impact on productivity. Our aim was to analyze lost work days (LWD) related to long COVID among healthcare workers.

METHODS: We analyzed data from n=2,330 healthcare workers from the Mexican Social Security Institute previously diagnosed with SARSCoV-2, that submitted at least one short term disability claim (STDC) for a post-COVID symptom (April 2020-August 2021). Outcome was the sum of LWD for main reported post-COVID symptom for STDC submitted. Post-COVID symptoms included those reported by the literature at the time of the study, and categorized as: circulatory, kidney and liver symptoms (CKL), mental and behavioral disorders (MB), nervous system symptoms (NS) and respiratory symptoms (RS). We used linear regression to model adjusting for age, sex, work category (assistant to COVID attention (REF), direct COVID-patient contact and, administrative/no COVID attention), hospitalization due to SARSCoV-2 infection, having a STDC previous to SARSCoV-2 with the same post-COVID symptom and if the STDC was classified as work-related.

RESULTS: Participants had a mean age of 41±9 years and 70% were women. MB were most frequent (45%), followed by RS (30%), CKL (14%) and NS (11%). LWD were on average of 23±39 and n=312 participants submitted more than one STDC. Compared to RS, all categories were associated with increased LWD, NS: ß= 17.26 (95% CI: 2.46, 14.89), CKL: ß= 8.51 (95% CI: -3.49, 13.53) and MB: ß= 8.08 (95% CI: 4.36, 11.79). Sex was not associated with LWD, whereas all covariates were associated with increasing LWD, with work-related STDC classification having the strongest association (ß= 24.14, 95% CI: 17.42, 30.86).

CONCLUSIONS: LWD due to long COVID among healthcare workers increased the most among those with NS and especially for STDC classified as work-related.

KEYWORDS: long COVID, healthcare workers, lost work days.

P-1137 Epidemiological profile of work-related Covid-19 in Brazil, 2020-2021

Cristiano Miranda[1], Rafael Buralli[1], Klauss Kleydmann Garcia[1]
[1]*General Coordination of Occupational Health, Ministry of Health of Brazil, Brasília, Brazil*

Covid-19 is the newest occupational disease, and its transmission patterns can lead to high rates among workers. This work aims to describe the epidemiological profile of work-related Covid-19 cases in Brazil.

METHODS: Descriptive study using notifications of work accidents by Covid-19 (B34.2) from 2020 and 2021. Data were collected from the Notifiable Diseases Information System (Sinan). Absolute and relative frequencies of sociodemographic characteristics and occupation groups were presented, and Incidence Rates (IR) per 100,000 workers calculated.

RESULTS: In 2020 and 2021, 70,618 cases of work-related Covid-19 were reported, with a mean IR of 37.2 cases per 100,000 workers. Most cases occurred among women (65.1%), brown (36.1%) or white (33.0%), aged between 35-39y (17.4%) and 40-44y (15.4%), with more than 8 years of study (60.2%). The most affected workers were nursing technicians or assistants (25.6%), followed by nurses (10.0%), doctors (5.1%), and administrative agents, assistants or auxiliaries (5.1%). Approximately 70.1% cases progressed clinically to cure, 14.5% to temporary disability and 2.0% to death caused by Covid-19.

CONCLUSIONS: Covid-19 has driven several physical, social and economic impacts to workers globally. In Brazil, frontline workers, particularly healthcare workers, appear to have a high probability of infection. Lack or misuse of protective equipment, workplaces with person-to-person physical contact, inadequate ventilation, shared eating, and accommodation areas, can be considered the main causes of outbreaks of Covid-19 at work. Despite most cases has progressed to cure, the impacts of long Covid-19 are still unknown and must be further investigated.

P-1139 Correlation between per- and polyfluoroalkyl substances (PFAS) in seminal plasma and semen quality parameters in firefighters

Jana Navrátilová[1], Ales Pindur[2], Petr Senk[1],Pavel Cupr[1],Michal Jeseta[3]
[1]Masaryk University, Recetox, Brno, Czech Republic, [2]Masaryk University, Faculty of Sports Studies, Brno, Czech Republic, [3]Center of Assisted Reproduction, Department of Gynecology and Obstetrics, Faculty of Medicine, Masaryk University Brno and University Hospital Brno, Czech Republic, Brno, Czech Republic

BACKGROUND AND AIM: For decades firefighters have used aqueous film-forming foam (AFFF) to extinguish specific types of fires. Some of the AFFF formulations contains per- and polyfluoroalkyl substances (PFASs). PFASs exposure was reported to induce male reproductive toxicity in toxicological studies. Further current epidemiological studies linked increased exposure to PFASs with lowered testosterone and semen quality. As firefighters are exposed during their service to PFASs to a much greater extent than the general population we aim to evaluate the associations between occupational exposure to PFASs and semen quality and spermatozoa DNA damage.
METHODS: We developed an analytical method based on solid phase extraction followed by liquid chromatography tandem mass spectrometry (LC/MSMS) to detect selected PFASs in human seminal plasma. Subsequently, concentrations of PFASs in seminal plasma were determined among 23 firefighters recruited from a local fire-training center. The relationship between PFASs concentrations with semen quality parameters and DNA integrity will be addressed by statistical methods.
RESULTS: We screened in total for 16 PFASs in seminal plasma commonly found in AFFF. The highest detection frequency was observed for perfluorooctanoic acid (PFOA). Associations of PFASs concentrations with semen quality parameters, DNA integrity measures will be assessed by logistic or linear regression models with adjustment for potential confounders.
CONCLUSIONS: Several PFASs were detected in seminal plasma samples of male firefighters. Further we aim to test the potential effect of the substances on semen quality.

P-1140 Effects of heat exposure on occupational injuries in the agricultural sector in Italy

Chiara Di Blasi[1], Francesca de' Donato[1], Michela Bonafede[2], Luca Taiano[2], Claudio Gariazzo[2], Marco Morabito[3], Alessandro Marinaccio[2]

[1]Department of Epidemiology Lazio Regional Health Service, ASL ROMA 1, Rome, Italy, [2]Occupational and Environmental Medicine, Epidemiology and Hygiene Department, Italian Workers' Compensation Authority (INAIL), Rome, Italy, [3]Institute of Bioeconomy, National Research Council (IBE-CNR), Florence, Italy

BACKGROUND AND AIM: – The health effects of extreme temperatures at population level are well known. However, the effects on occupational injuries in different sectors have been scarcely investigated.

METHODS: We collected work-related injuries in the agriculture sector occurring in the 8,090 Italian municipalities from the Italian national workers' compensation authority (INAIL) between 2014-2018. Daily air temperatures from Copernicus ERA5-land were used to define exposure at municipality level. First, we applied distributed lag non-linear models (DLNM) to estimate the association between daily mean air temperature and injuries at regional level; then meta-analysed results to have overall estimates. The relative risk (RR) and attributable cases of agriculture-related injuries for an increase in mean temperature above the 75th percentile were estimated, as well as heatwave effects. Analysis were also stratified by age, duration of leave and professional qualification.

RESULTS: Analysis were conducted on 150,422 agricultural injuries. The overall relative risk of agricultural work-related injuries for an increase in temperatures was 1.13 (95%CI: 1.08; 1.18). The number of injuries attributable to heat is of 2050 cases in the considered period. A higher risk was observed among young workers (1.23 95% CI: 1.14; 1.34) and seasonal workers (1.25 95% CI: 1.03; 1.52). When considering duration of leave, a proxy of severity of heat-related injuries, the greatest risk and frequency was observed for short duration between 0-14 days (1.21 95% CI: 1.10; 1.33) with a decreasing trend. Considering extreme heat wave events, the risk of injuries in the agricultural sector was of 1.04 (95% CI: 1.01; 1.08).

CONCLUSIONS: Occupational exposure to extreme temperatures is a critical issue considering climate change especially among sectors engaged in outdoor and labour-intensive activities such as the agricultural sector. These results can help promote specific prevention actions for workers.

KEYWORDS: Work-related injuries; heat waves; agricultural sector.

P-1142 Deployment-Related Decline in Physical Fitness Increases Risk of Injury in U.S. Army Soldiers

Kathryn Taylor[1], Barry Spiering[1], Vy Nguyen[1]
[1]*U.S. Army Research Institute of Environmental Medicine, Boston, USA*

BACKGROUND AND AIM: Aerobic performance had been shown to decline during military deployment. Low levels of cardiorespiratory and muscular endurance may increase injury risk. We evaluated whether deployment-related declines in cardiorespiratory and muscular endurance increased injury risk.

METHODS: The study population was all U.S. Army Soldiers (N= 6,080) who had completed the Army Physical Fitness Test (APFT) 90 days before and after deployment from 2016-2019. We defined injury as receiving an injury-related lost or limited-duty profile within 1-year post-deployment. We used mixed models to evaluate change in 2 mile-run time, 2-minute repetition maximum for pushups and sit-ups and overall APFT score. We used logistic regression models to evaluate relationships between changes in all scores on injury risk. We adjusted the models for pre-deployment event performance, prior injury, change in BMI, deployment duration, age and sex.

RESULTS: 2-mile run time increased on average 16.6 seconds (95% CI: 12.6, 19.8) and overall APFT score declined 2.15 points (95% CI: -3.35, -0.94) after deployment. Pushups and sit-ups scores did not change after deployment. for every one minute increase in post-deployment run time, one point decrease in overall APFT score and one pushup decrease, the odds of receiving an injury-related profile increased by 6% (95% CI: 1.01, 1.11), 0.3% (95% CI: 0.995, 0.999) and 0.8% (95% CI: 0.986, 0.998), respectively.
CONCLUSIONS: We demonstrated that deployment-related declines in APFT-derived measures of physical fitness increased injury risk within 1-year post-deployment. Our findings suggest that maintaining pre-deployment cardiorespiratory and muscular endurance may be an effective strategy to attenuate injuries and lost duty time post-deployment.

P-1144 Soil, sewage sludge and digestate samples contamination with Gram-negative bacteria from Enterobacteriaceae

Ewelina Farian[1], Angelina Wójcik-Fatla[1], Teresa Kłapeć[1], Jolanta Zdybel[2], Katarzyna Kowalczyk[1], Jacek Sroka[2], Tomasz Cencek[2]

[1]Institute of Rural Health, Lublin, Poland, [2]National Veterinary Research Institute in Puławy, Puławy, Poland

BACKGROUND AND AIM: In Poland, organic fertilizers may be used in agriculture, if no Salmonella are found in 100 g of the sample and the number of Enterobacteriaceae is lower than 1000 cfu/g. However, there are no standards of microbiological contamination methods dedicated directly to sewage sludges or digestate. The aim of the study was to assess the contamination levels of Enterobacteriaceae in sewage sludge, digestate and arable soil samples.

METHODS: The microbiological tests included 82 soil samples, 9 sewage sludge and 9 digestate samples. Due to the lack of applicable standards in the field of microbiological testing of sewage sludge and digestate for the presence of pathogenic bacteria, the tests were based on the procedures used to test soil, feed, and food. Detection of Salmonella, was performed according to the standard PN-Z-19000-1/2001, Escherichia coli - PN-EN ISO 16649-2:2004, the total number of bacteria - PN-EN ISO 4833-2:2013-12/AC, and Enterobacteriaceae - PN-EN ISO 21528-2:2017-08.

RESULTS: The total number of mesophilic bacteria ranged from 1,1 x105 to 1,0 x106 cfu/g, from 0,1 x108 to 9,8 x108 cfu/g, and from 1,6 x103 to 5,7 x108 cfu/g for soil, digestate and sewage sludge samples, respectively. for the soil samples, contamination with Enterobacteriaceae, was estimated at an average level of 1,1 x104 cfu/g, while for sewage sludge and digestate samples these values were 9,4 x105 cfu/g and 5,6 x106 cfu/g, respectively. The presence of Escherichia coli was confirmed in 2 soil, 6 digestate and 4 sewage sludge samples. None of the samples were contaminated with Salmonella, excluding one positive of digestate sample.

CONCLUSIONS: The development of standards for the use of sewage sludge and digestate as fertilizers should take into account microbiological contamination with Enterobacteriaceae.

KEYWORDS: Soil, sewage sludge, digestate, Enterobacteriaceae.
FUNDING: The research was financed by NCBiR (Poland); Project No.: GOSPOSTRATEG-III/0061/2020-00.

P-1145 Species diversity of bacteria isolated from soil, sludge sewage and digestate

Angelina Wójcik-Fatla[1], Katarzyna Kowalczyk[1], Teresa Kłapeć[1], Jolanta Zdybel[2], Ewelina Farian[1], Jacek Sroka[2], Tomasz Cencek[2]

[1]Institute of Rural Health, Lublin, Poland, [2]National Veterinary Research Institute in Puławy, Puławy, Poland

BACKGROUND AND AIM: Scientific research confirms the positive aspects of the using sludge to improve the physical, chemical and biological properties of soil. Organic compounds are well absorbed by plants, and thus the value of their organic matter increases. The one of the main difficulties in the management of sewage sludge or digestate are bacteria, which may cause humans' infections The aim of the study was to species identification of bacteria from the Enterobacteriaceae family and chosen Gram-positive bacteria presented in soil, sewage sludge and digestate.

METHODS: Identification of bacteria isolated from arable soil (82), sewage sludges (9) and digestate (9) samples was based on biochemical (ENTEROtest 24N, NEFERMtest 24N, GEN III MicroLog M System) and genetic methods. Total DNA from bacterial cultures was isolated using Qiamp® DNA Mini Kit. PCR reaction was performed with primers complementary to the conserved ribosomal DNA regions of most bacterial species, including the 16S rRNA genes. Sequencing was performed on ABI Prism 310 Genetic Analyzer (Applied Biosystems, USA).

RESULTS: From the soil samples, Gram-negative bacteria belonging to the genus Serratia, Citrobacter and Enterobacter were identified most frequently. The other identified bacteria species were: Pantoea agglomerans, Escherichia vulneris, E. coli, Hafnia alvei, Aeromonas salmonicida, A. hydrophila, Kluyvera intermedia, Rahnella aquatilis, Raoultella terrigena, Buttiauxella gaviniae, Klebsiella pneumoniae. Bacteria isolated from the sewage sludges and digestate included: Yersinia intermedia, Y. enterolitica, Y. frederiksenii, E. coli, Enterobacter cloacae, Klebsiella oxytoca, K. pneumoniae, Morganella morganii, Aeromonas salmonicida, Proteus mirabilis. Salmonella johannesburg and Listeria monocytogenes have been found in one and in 2 samples, respectively.

CONCLUSIONS: Standards relating to the use of sewage sludge and digestate for fertilization in agriculture should take into pathogenic/potentially pathogenic bacterial species presented in organic additives.

KEYWORDS: Bacteria species, Enterobacteriaceae, soil, sewage sludge, digestate.
FUNDING: The research was financed by NCBiR (Poland); Project No.: GOSPOSTRATEG-III/0061/2020-00.

P-1148 Cholangiocarcinoma and pleural mesothelioma: asbestos exposure as a shared risk factor? A comparison of age-standardized incidence rates in Italy

Mena Gallo[1], Stefano Mattioli[2], Stefania Curti[1]
[1]Department of Medical and Surgical Sciences, University of Bologna, Italy, [2]Department of Medical Sciences, University of Ferrara, Italy

BACKGROUND AND AIM: Cholangiocarcinoma (CC) is the second most common primary liver malignancy. Anatomically, CC is divided into intrahepatic (ICC) and extrahepatic (ECC) forms. A possible causal association between ICC and exposure to asbestos has been hypothesized. To support this, we compared age-standardized incidence rates (ASR) of CC and malignant pleural mesothelioma (MPM) in Italy considering that asbestos is thought one of the major risk factors for MPM.
MATERIALS AND

METHODS: We extracted ASR of ICC, ECC and MPM reported by 36 Italian cancer registries and listed in the last report on Cancer Incidence in Five Continents of the IARC. Data referred to 2008-2012 and covered 29 million population. We used linear regression analysis to evaluate the possible association between ASR of ICC, ECC and MPM. Analyses were stratified by sex.

RESULTS: From 2008 to 2012 ASR per 100,000/years in men ranged: 0.4-2.2 for ICC, 0.5-1.8 for ECC, and 0.0-0.7 for MPM. In women, ASR per 100,000/years ranged: 0.2-1.0 for ICC, 0.1-1.3 for ECC, and 0.0-0.6 for MPM. at regression analysis ICC did not report an association with MPM in men (beta coefficient -0.044, 95%CI -0.980–0.892) and women (beta coefficient -0.093, 95%CI -0.670–0.485). No association was detected for ECC as well.

CONCLUSIONS: This crude analysis does not appear to support the hypothesis that CC could be associated to exposure to asbestos. This could be related to the large amount of known and suspected risk factors for CC that include common liver diseases due to genes, viruses and personal habits. Analyses adjusted for aggregated data might help disentangle this issue.

KEYWORDS: Asbestos, Cholangiocarcinoma, age-standardized incidence rates.

P-1149 Occupational sectors and cancer mortality in a large administrative cohort

Giulia Cesaroni[1], Lisa Bauleo[1], Luca Dei Bardi[1], Nera Agabiti[1], Marina Davoli[1], Sara Maio[2], Massimo Stafoggia[1], Giovanni Viegi[2], Claudio Gariazzo[3], Alessandro Marinaccio[3], Stefania Massari[3]
[1]Department of Epidemiology-Regional Health Service, Rome, Italy, [2]National Research Council, Italy, [3]Italian Workers' Compensation Authority (INAIL), Italy

BACKGROUND AND AIM: The International Labor Organization estimates 2.4 million work-related deaths every year. We aimed to investigate the role of the occupational sector in cancer mortality.

METHODS: We used the 2011 census cohort of Rome, including all residents aged 30+ years. We retrieved the information on occupational sectors from the 70s to 2011 for private-sector workers from the National Social Insurance Agency (INPS) database. We classified the occupational sectors into 23 categories and modeled occupational exposure as ever/never been employed in each sector. We followed the subjects from the census reference day (9 October 2011) to 31 December 2019, investigating cancer mortality overall and site-specific cancers (larynx, lung, pleura, kidney, liver). We used Cox regression models to estimate the age and sex-adjusted hazard ratio (HR) with 95% confidence intervals (CI) of being employed in an occupational sector. In addition, we performed the analyses for males and females separately.

RESULTS: We analyzed a cohort of 910,559 (53% males). We found evidence of a higher cancer mortality risk in workers of the paper and print industry for lung and pleural cancer (HR=1.22 95%CI:1.08-1.38 and HR=2.19 95%CI:1.18-4.05, respectively), food and tobacco for lung cancer (HR=1.34 95%CI:1.15-1.55), building construction industries for liver, lung and pleural cancer (HR=1.44 95%CI:1.21-1.63, HR=1.29 95%CI:1.20-1.39, HR=1.99 95%CI:1.32-3.00, respectively), hotels and restaurants sector for liver and lung cancer (HR=1.30 95%CI:1.05-1.61 and HR=1.27 95%CI:1.15-1.41), hairdressers for liver, larynx and lung cancer (HR=1.65 95%CI:1.30-2.10, HR=1.99 95%CI:1.05-3.80, HR=1.44 95%CI:1.28-1.62), and waste workers for lung cancer (HR=2.04 95%CI:1.34-3.10). The analyses by gender confirmed the results.
CONCLUSION:
The results confirm the well-known associations between occupational exposures (characteristic of specific sectors) and cancer mortality and highlights sectors with elevated cancer risk. Administrative data might be a valuable tool in occupational epidemiology research.

P-1150 Night shift work and altered metabolic profile among hospital female nurses: results from a targeted metabolomic approach

Elisa Borroni[1], Gianfranco Frigerio[2,3], Angela Cecilia Pesatori[1,2], Silvia Fustinoni[1,2], Michele Carugno[1,2]
[1]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy, [2]Occupational Health Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [3]Luxembourg Centre for Systems Biomedicine, University of Luxembourg, Belvaux, Luxembourg

BACKGROUND AND AIM: Shift work, especially including night shift (NSW), has been found associated with several diseases, including obesity, diabetes, cancers, and cardiovascular, mental, gastrointestinal and sleep disorders. Metabolomics (an omics-based methodology) may shed light on the mechanisms underlying these associations, which are not yet fully understood. We thus aimed to evaluate the effect of NSW on serum metabolites in a sample of hospital female nurses.

METHODS: We recruited 46 nurses currently working in NSW in Milan (Italy), matched to 51 colleagues not employed in night shifts. Participants filled in a questionnaire on demographics, lifestyle habits, personal and family health history and work, and donated a blood sample. The metabolome was evaluated through a validated targeted approach measuring 188 metabolites. Only metabolites with at least 50% observations above the detection limit were considered, after standardization and log-transformation. Associations between each metabolite and NSW were assessed applying Tobit regression models and Random Forest, a machine-learning algorithm.

RESULTS: When comparing current vs. never night shifters, we observed lower levels of 21 glycerophospholipids and 6 sphingolipids, and higher levels of serotonin (+171.0%, 95%CI: 49.1-392.7), aspartic acid (+155.8%, 95%CI: 40.8-364.7), and taurine (+182.1%, 95%CI: 67.6-374.9). The latter was higher in former vs. never night shifters too (+208.8%, 95%CI: 69.2-463.3). Tobit regression comparing ever (i.e., current + former) and never night shifters returned similar results. Years worked in night shifts did not seem to affect metabolite levels. The Random-Forest algorithm confirmed taurine and aspartic acid among the most important variables in discriminating current vs. never night shifters.

CONCLUSIONS: This study, although based on a small sample size, shows altered levels of some metabolites in night shift workers. If confirmed, our results may shed light on the mechanisms potentially underlying the association between NSW and several pathologic states.

KEYWORDS: night shift work, targeted metabolomics, machine learning

P-1151 Towards the Exposome Project for Health and Occupational Research (EPHOR) Mega Cohort

Michelle Turner[1], Maria Albin[2], Jan Boon[3], Karin Broberg[2], Ute Bültmann[4], Daniel Falkstedt[2], Tina Garani-Papadatos[5], Anne Helene Garde[6], Calvin Ge[7], Lode Godderis[8], Marcel Goldberg[9], Per Gustavsson[2], Anke Huss[10], Tuija Jääskeläinen[11], Christer Janson[12], Ane Johannessen[13], Katarina Kjellberg[2], Päivikki Koponen[11], Seppo Koskinen[11], Steinar Krokstad[14], Taina Leinonen[15], Esben Meulengracht Flachs[16], Karen Oude Hengel[7], Susan Peters[10], Reiner Rugulies[6], Vivi Schlünssen[17], Jenny Selander[2], Torben Sigsgaard[17], Svetlana Solovieva[15], Anne Straumfors[18], Cecilie Svanes[13], Swenne van den Heuvel[7], Sander KR van Zon[4], Roel Vermeulen[10], Marie Zins[9], Anjoeka Pronk[7], Ingrid S Mehlum[18]

[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Groep IDEWE, Leuven, Belgium, [4]University of Groningen, University Medical Center Groningen, Groningen, the Netherlands, [5]University of West Attica, School of Public Health, Department of Public Health Policy, Athens, Greece, [6]National Research Centre for the Working Environment, Copenhagen, Denmark, [7]Netherlands Organisation for Applied Scientific Research (TNO), the Netherlands, [8]KU Leuven, Leuven, Belgium, [9]Université de Paris Saclay, Unité UMS 011 "Cohortes en Population" INSERM, UVSQ, Paris, France, [10]Utrecht University, Utrecht, the Netherlands, [11]Finnish Institute for Health and Welfare, Helsinki, Finland, [12]Uppsala University, Uppsala, Sweden, [13]Centre for International Health, Department of Global Public Health and Primary Care, University of Bergen, Bergen, Norway, [14]Norwegian University of Science and Technology (NTNU), Trondheim, Norway, [15]Finnish Institute of Occupational Health, Helsinki, Finland, [16]Department of Occupational and Environmental Medicine, Bispebjerg and Frederiksberg Hospital, University of Copenhagen, Copenhagen, Denmark, [17]Aarhus University, Aarhus, Denmark, [18]National Institute of Occupational Health (STAMI), Oslo, Norway

BACKGROUND AND AIM: Existing cohort studies in Europe capturing occupational information enrol millions of persons. They are invaluable resources for understanding relationships between occupation and health. Within the Exposome Project for Health and Occupational Research (EPHOR) we aim to systematically construct a mega cohort combining data from multiple individual cohort studies to study the working life exposome and health.

METHODS: Participating cohorts are registered in an open online inventory containing cohort meta-data. A set of harmonised variables is being prepared, including occupational as well as non-occupational factors (personal, lifestyle, sociodemographic, other), and a framework for de-centralized large-scale pooling of data for epidemiological analyses is being implemented. Lifetime occupational histories are being coded and harmonised across coding systems and will be linked with a European Job-Exposure Matrix (JEM) being developed. A range of harmonised outcome data including cancer, as well as respiratory, metabolic and cardiovascular, neurodegenerative, and musculoskeletal diseases, mental disorders, and work participation will be defined based on registry, record, or other follow-up methods.

RESULTS: The EPHOR mega cohort currently includes participation of 28 cohorts from eight European countries, as well as multi-country studies, containing data on over 20 million participants. Initial cohorts were selected from the inventory with cancer diagnoses, respiratory outcomes, and/or information on working time prioritised in this first phase. Additional cohorts will be invited to participate here. The mega cohort will be used for a range of exposome analyses including 1) systematic and agnostic exploration of multiple risk factors in relation to health outcomes, 2) to identify vulnerable life stages and population subgroups, 3) to study rare exposures/outcomes.

CONCLUSIONS: We expect collaboration to be useful to explore relationships between occupations, multiple work-related exposures and health. The mega cohort is intended to be a long-term resource for occupational health researchers.

P-1154 Rotating night shift work, sleep and thyroid cancer risk in the Nurses' Health Study 2

Kyriaki Papantoniou[1], Peter Konrad[1], Shahab Haghayegh[2], Susanne Strohmaier[1], Heather Eliassen[2,3], Eva Schernhammer[1,2,3]

[1]Medical University of Vienna, Center of Public Health, Department of Epidemiology, Vienna, Austria, [2]Channing Division of Network Medicine, Department of Medicine, Harvard Medical School, Boston, USA, [3]Department of Epidemiology, Harvard T.H Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Thyroid cancer is the most common endocrine malignancy with rising incidence worldwide. We prospectively evaluated whether rotating night shift work and sleep disturbances are associated with incident thyroid cancer risk in the Nurses' Health Study 2 (NHS2).

METHODS: We assessed rotating night shift work (≥3 nights/month) history (cumulative number of years) at baseline and throughout follow-up (1989-2015) and sleep duration and sleep difficulty in 2001. Cox proportional hazard models, adjusted for potential confounders were used to calculate thyroid cancer hazard ratios (HR) and 95% confidence intervals (CI) for shift work history (0.1-4.9yrs, 5-9.9yrs, 10+yrs), sleep duration (≤5, 6, 7, 8, ≥9hours) and difficulty falling or staying asleep (little or none of the time, sometimes, most or all of the time). We further stratified the analyses of night shift work by sleep characteristics.

RESULTS: We identified 588 incident cases among 114,534 women. We observed no association between night shift work history and thyroid cáncer risk (1-4.9 years: HR 1.19, 95% CI 0.98, 1.44; 5-9.9 years: HR 1.13 95% CI 0.86, 1.48; ≥10 years: HR 1.10, 95% CI 0.78, 1.54; Ptrend=0.55). Sleep difficulty was suggestively associated with higher incidence of thyroid cancer when reported sometimes (HR 1.26, 95% CI 0.95, 1.67) and most or all the time (HR 1.35, 95% CI 1.00, 1.81; Ptrend=0.03), compared to little or none of the time. Participants with >10 years of night shift work and ≤6 hours of sleep had a 2-fold increase in thyroid cancer risk (HR 2.23; 95%CI, 1.08-4.06). Shift workers with <5 years of shift work and frequent sleep difficulty had an increased risk of thyroid cancer (HR 1.95; 95% CI 1.03, 3.67).

CONCLUSION:

We found evidence that rotating night workers with frequent sleep difficulty or short sleep had an increased risk of thyroid cáncer.

KEYWORDS: night work, thyroid cancer

P-1155 Associations between BTEX-H/THC and neurological symptoms among Deepwater Horizon oil spill workers

Kristen Cowan[1], Emily Werder, Richard Kwok, Kaitlyn Lawrence, Patricia Stewart, Mark Stenzel, Dale Sandler, Lawrence Engel

[1]*University of North Carolina at Chapel Hill Department of Epidemiology, Carrboro, USA*

BACKGROUND AND AIM: Hydrocarbons are considered to be neurotoxic. However, less is known about health effects of generally lower exposures during oil spill response and clean-up. The Gulf Long-Term Follow-up (GuLF) Study follows individuals who were either involved in cleanup efforts ("workers") or were trained but not hired ("non-workers") following the 2010 Deepwater Horizon disaster. We studied the association of neurological symptoms with exposure to benzene, toluene, ethylbenzene, xylenes, and hexane (BTEX-H) individually and as a mixture among 23,641 workers.

METHODS: At enrollment, participants self-reported frequency of neurological symptoms including dizziness, nausea, sweating, heart palpitations, fatigue, insomnia, migraines, tingling, numbness, blurred vision, stumbling, and seizures in the preceding 30 days. Cumulative inhalation exposure to BTEX-H chemicals and total hydrocarbons (THC) was estimated using a job exposure matrix linking air measurement data to detailed self-reported cleanup work histories. We calculated adjusted prevalence ratios (PR) and 95% confidence intervals (CI) for the association between quartiles of exposure and neurological symptoms reported all or most of the time using multivariable log-binomial regression. Quantile G-computation was used to estimate the per-quartile increase in joint effects of the BTEX-H mixture on neurological symptoms.

RESULTS: 31% of participants reported experiencing at least one, and 21% reported 2 or more, neurological symptoms within the last 30 days. Exposure to THC was associated with increased risk of two or more neurological symptoms (Q4 vs. Q1 PR=1.57 (95% CI:1.45, 1.70)), with similar results observed for the individual BTEX-H chemicals. A quartile increase in exposure to the BTEX-H mixture was associated with an increased risk of reporting two or more neurological symptoms (PR=1.18, (95% CI: 1.15, 1.21)).

CONCLUSIONS: Exposure to oil spill-related THC and BTEX-H was associated with increased prevalence of neurological symptoms among cleanup workers.

KEYWORDS: Occupational epidemiology, crude oil, BTEX, neurological symptoms, disaster

P-1156 Forging Community Partnerships to Examine Pesticide Exposure and Risk Perceptions among Latinx Farmworkers

Carly Hyland[1], Irene Ruiz[2], Lisa Meierotto[3], Rebecca Som Castellano[4], Cynthia Curl[1]
[1]Boise State University Department of Public Health and Population Science, Boise, USA, [2]Idaho Organization of Resource Councils, Boise, USA, [3]Boise State University School of Public Service, Boise, USA, [4]Boise State University Sociology Department, Boise, USA

BACKGROUND: Research with structurally marginalized populations has a history of being extractive and providing a benefit primarily to the researchers rather than the participants. To address these concerns, there is an increasing emphasis in the field of environmental epidemiology to conduct community-based work and return exposure results to study participants. The aim of this work is to forge partnerships with trusted community organizations to support and help facilitate a mixed-methods investigation of pesticide exposure and risk perceptions among Latinx farmworkers, a population that faces many barriers to health protection. We further aim to create multi-media science communication products to effectively translate individual- and group-level study findings and to increase engagement and empowerment among participants.

METHODS: We focused six months of the one-year study period prior to data collection on community engagement and gaining trust, first with community partners and then study participants. We used various strategies, including social media engagement, holding teleconference and in-person meetings, and snowball sampling to establish and build upon existing partnerships. Focusing our study on the benefit to participants and research communication plan was key in obtaining buy-in from community partners.

RESULTS: We partnered with County Health Coalitions; migrant head start programs; non-profit organizations; housing providers; social media groups; and mobile health clinics to recruit participants, establish trusting relationships, and develop strategies to maximize the benefits of participating in the study. Examples include developing tailored research communication products; providing food boxes with organic, culturally appropriate food items; and providing childcare during data collection events.
CONCLUSION: Forging collaborations with diverse individuals and community groups is critical in establishing trust with structurally marginalized populations. Our work provides an example of how to develop these partnerships, center community priorities, and maximize the benefit of participation both for study participants and partner organizations.

KEYWORDS: pesticides, farmworker, community-engaged research

P-1157 The association between working with poultry and esophageal cancer mortality; a case-cohort study

Christina Joshua[1], Leanna Delhey[1], Kylie Chisum[1], Tyrone Gamble[1], Sharlene Brown[1], Mohammed Elfaramawi[1], Robert Delongchamp[1]
[1]*University of Arkansas for Medical Sciences, Little Rock, USA*

BACKGROUND AND AIM: Certain avian retroviruses are carcinogenic to poultry and potentially harmful to exposed persons. Higher rates of certain cancers are observed among poultry workers. We aimed to investigate the association between working with poultry and esophageal cancer while concurrently investigating other occupational and non-occupational risk factors.

METHODS: We conducted a case-cohort analysis from an American cohort of members of the United Food and Commercial Workers International Union (N=46,816). We conducted follow-up from 1950-2019 through the National Death Index. Cases consisted of those who died of esophageal cancer. A subcohort was randomly selected (N=2,666). We interviewed participants/relatives by telephone about their work and personal life (4,948 questions). We conducted multivariate cox regression to estimate the hazard of esophageal cancer mortality due to working with poultry among the full cohort and weighted regression for the subcohort and interviewed. We conducted exploratory analyses to estimate the hazard associated with each interview question, adjusted for confounders, and computed a false discovery rate (FDR).

RESULTS: In the full and subcohort, working in a poultry plant was associated with an increased hazard of esophageal cancer (HR= 1.623, 95% CI= 1.053, 2.500; HR= 1.651, 95% CI= 1.030, 2.649, respectively). Among responders, working in a poultry plant appeared protective (HR= 0.674; 95% CI= 0.335, 1.354). We identified six questions with a FDR < 0.05 – two risks (e.g., radiation treatment) and four protective factors (e.g., working in a chicken processing plant).

CONCLUSIONS: In the full cohort and subcohort, working in poultry plants was associated with increased hazard of esophageal cancer mortality. We obtained contradictory results among those interviewed, likely due to nonresponse bias. Working with poultry may increase the risk of esophageal cancer, but further research is needed to explore potential mechanisms.

P-1158 Exposure to engineered nanomaterials and early biological effects measured in the exhaled breath condensate: First results from the NanoExplore cohort

Irina Guseva Canu[1], Maud Hemmendinger[1], Giulia Squillacioti[2], Thomas Charreau[1], Ekaterina Plys[1], Giulia Antonello[2], Valeria Bellisario[2], Guillaume Suarez[1], Jean-Jacques Sauvain[1], Carlos Fito[3], Veronica Vela Vela[3], Federica Ghelli[2], Enrico Bergamaschi[2]

[1]Unisanté, University of Lausanne, Epalinges-Lausanne, Switzerland, [2]Department of Public Health and Pediatrics, University of Torino, Italy, Italy, [3]Instituto Tecnológico del Embalaje, Transporte y Logística (ITENE), Spain

BACKGROUND AND AIM: Activities involving engineered nanomaterials (ENM) may raise concerns of occupational exposure and subsequent health effects. We aimed to build a multicenter prospective cohort to assess the potential effects of ENM exposure using biomarkers of early effects measured in exhaled breath condensate (EBC).

METHODS: We recruited seven centers in three countries (Switzerland, Spain, and Italy), where we conducted a 4-day exposure monitoring campaign and two EBC samplings, at the beginning (T1) and end (T2) of working week. The recruited workers were split in three groups depending on their exposure and compared in terms of their baseline individual and professional characteristics, and health status. EBC biomarkers of oxidative and nitrosative stress (malondialdehyde, 8-isoprostane, nitrotyrosine), systemic inflammation (High-Sensitivity C-Reactive Protein (hsCRP)), activation of pro-fibrotic cascade and interstitial lung disease (Krebs von den Lungen glycoprotein 6 (KL6)) and inflammatory cytokines (Interleukins (IL-10, IL-1β), Tumor necrosis factor (TNF-α)) were analyzed using multilevel mixed interval regression models.

RESULTS: The cohort included 140 participants: 43 non-exposed, 55 with negligible to low exposure, and 43 with medium to high exposure. The latter were gradually more often men, older, and in overweight than lowly exposed and non-exposed workers. A statistically significant change between T1 and T2 average concentrations was observed for malondialdehyde and KL6. Between-group differences were observed for all biomarkers but KL6 and nitrotyrosine. In multivariate models adjusted for age, sex and body mass index, a linear exposure-response relationship was observed for malondialdehyde, 8-isoprostane, IL-10, IL-1β, and TNF-α. ENM exposure was also associated with higher hs-CRP and KL6 levels, but not monotonically.

CONCLUSION: These first results suggest that ENM exposure might lead to early biological effects in workers' airways. These findings need confirmation and a caution interpretation of their clinical significance, as most effects are non-specific and likely reversible.

P-1159 Occupation and risk of testicular cancer: A case-control study in France

Margot Guth[1], Astrid Coste[2,3], Marie Lefevre[1], Floriane Deygas[1], Aurélie Danjou[4], Shukrullah Ahmadi[4], Ann Olsson[4], Barbara Charbotel[1,5], Béatrice Fervers[2,3]

[1]UMRESTTE, UMR T 9405, IFSTTAR, Lyon 1 University, Lyon University, Eiffel University, Lyon, France, [2]INSERM UMR1296 Radiation: Defense, Health, Environment, Lyon, France, [3]Département Prévention, Cancer et Environnement, Centre Léon Bérard, Lyon, France, [4]Environment and Lifestyle Epidemiology Branch, International Agency for Research on Cancer/World Health Organization, Lyon, France, [5]Fédération Française des CECOS, Paris, France.7 CRPPE-Lyon, Hospices Civils de Lyon, Lyon, France

BACKGROUND AND AIM: Testicular germ cell tumors (TGCT) are the most frequently diagnosed cancer in young men and their incidence rate has increased dramatically in recent decades. Occupational factors may play a role in testicular cancer etiology. This study aimed to further explore the association between occupation, industry, and the risk of TGCT in adulthood in France.

METHODS: The TESTIS study included 454 histologically confirmed TGCT cases at ages 18-45 years. Controls (N=670) were frequency-matched to cases on 5-year age group and region. Occupational histories, with detailed description of each job, were ascertained through telephone interviews. Occupations were coded according to ISCO68, and industrial sectors according to NAF99. A manual backward stepwise selection procedure was performed to select the covariates to be included in our analyses. Odds ratios (ORs) and 95% confidence intervals (CIs), adjusted for potential confounders, were estimated using conditional logistic regression.

RESULTS: An increased risk of TGCT was observed for "machine fitters, machine assemblers" and "electrical fitters, electrical and electronic " workers (ISCO: 8-41; adjusted-OR = 2.46; 95% CI [1.08-5.62]/ISCO: 8-5; adjusted-OR = 1.80; 95% CI [1.11-2.91], respectively). Analyses by industry supported these findings. Moreover, an increased TGCT risk (adjusted-OR = 1.71; 95% CI [1.02-2.82]) and non-seminoma risk (adjusted-OR = 2.12; 95% CI [1.11-4.04]) was identified for “agricultural and animal husbandry workers” (ISCO: 6-2).

CONCLUSIONS: Our results suggest that occupational exposures may be associated with an increased risk of TGCT in agricultural, machine, and electrical/electronic workers in this population. Our findings were consistent with previously published studies. Since these jobs may involve exposure to a variety of potential carcinogens/endocrine disruptors, such as pesticides and solvents, complementary studies with the application of job-exposure matrices will allow an in-depth evaluation of the role of the substances involved in the high-risk professions identified.

KEYWORDS: Occupation, epidemiology, testicular cancer, agriculture

P-1160 Animal husbandry neglected in occupational research for antibiotic resistance

Erik Pieter de Jong[1], Chi-Hsin Sally Chen[2], Yi-Ching Hsiesh[2], Chang-Chuan Chan[1,2]
[1]Global Health Program, College of Public Health, National Taiwan University, Taipei, Taiwan, [2]Institute of Environmental and Occupational Health Sciences, College of Public Health, National Taiwan University, Taipei, Taiwan

BACKGROUND AND AIM: Antibiotic resistance entails a major threat to global health. Exposure to antibiotics and bacteria, potentially increases risks for workers in environments with high and prolonged exposure. The objective of this review is to assess the occupational risk of antibiotic resistance in high risk occupations.

METHODS: This systematic literature reviews selected articles in MEDLINE (September 1964 - October 2021) and Embase (March 1988 - October 2021). Duplicates, articles without abstracts and non-English articles were removed before screening. Articles not related to antibiotic resistance and high-risk occupations, were excluded. Besides the medical sector, animal husbandry including aquaculture was considered as high risk. Animal husbandry here includes aquaculture and poultry farming, besides livestock farming such as pig and kettle farming and occupations were defined according to ISCO-08. Included articles were analyzed on occupations, methodology, bacteria, resistance and location.

RESULTS: 117 Articles were found eligible for final analysis of the abovementioned risks, which is limited. Current research has a strong focus on the medical sector, with 80 articles describing the medical sector in general and a majority focusing on workers in hospital settings (over 60%) and around 70% of these articles focus on MRSA or Tuberculosis. 44 Studies were related to animal husbandry, with a strong focus on especially pig farming and abattoir workers (over 54%). MRSA was the predominant focus of the articles (52%) followed by S. Aureus (19%). With one study research on aquaculture is scarce.

CONCLUSIONS: The risks of antibiotic resistance in animal husbandry and more specifically aquaculture, seems to be neglected in current research. To truly address the issue of antibiotic resistance as a one health issue, other sectors need to be explored with integrated nationwide surveillance and specific occupational risk assessments.

KEYWORDS: AMR, antibiotic resistance, One Health, bacterial infections, occupational risk, animal husbandry, aquafarming.

P-1162 The necessary strengthening the global role of occupational and environmental epidemiology about Asthma. Analysis and discussion of diagnosis of Asthma and the Workforce in Brazil -2019

Telma Cassia dos Santos Nery[1], Rafaela G Dantas[2], Sonia Quezia G M Zago[3], Rafael Stelmach[1]
[1]Divisao de Pneumologia - Instituto do Coracao INCOR HCFMUSP, SAO PAULO, Brazil, [2]UNIFESP, Sao Paulo, Brazil, [3]UNINOVE, Sao Paulo, Brazil

Environmental factors such as air pollution and occupational factors contribute to the asthma cases. Asthma is an important cause of hospitalization. In 2017, its prevalence and incidence were estimated 273 million cases and 43 million cases, respectively. Is the second leading cause of death among chronic respiratory diseases, with 500,000 deaths in 2017 and a mortality rate of 6.48/100,000 inhabitants. Almost 7% of these deaths were work-related, and 21.5% of adult asthma is occupational (OA) and asthma aggravated or exacerbated by work (AA/ET). Knowing the diagnosis of asthma in the face of the characteristics of the workforce can contribute to strategies. AIM: to analyze the diagnosis of asthma according to the workforce in Brazil in 2019.Descriptive study. Analysis of an open database of the National Health Survey - Ministry of Health and Brazilian Institute of Geography and Statistics. In 2019, 108,525 households were visited and 94,114 interviews were conducted. Analyzed by condition in relation to the work ratio in the reference week and home situation. Analyzed, busy, unoccupied and outside the workforce, gender, age, regions of Brazil.

RESULTS: People aged 18 years. Workforce: employed workforce: 5,236; in the unoccupied workforce: 777; out of the workforce: 3,097. The coefficients of variation in the employed workforce: 3.5; in the unoccupied workforce: 11.2; outside the workforce: 4.5. Work force and household situation. In the occupied workforce - urban area (UA): 4,445; in the occupied workforce - rural area (RA): 456; in the unoccupied workforce - UA 590; unoccupied workforce - RA 47; outside the workforce - UA 2,523; out of the workforce: 323 people. Research with open data can contribute to preventive measures in health, the diagnosis of asthma in relation to the insertion and/or exit of the work can support actions and early interventions

KEYWORDS: Occupational, Asthma, Environmental

P-1163 Objectively-assessed physical activity and heat stress and the association with kidney function in female harvest workers in Spain

Cristina O'Callaghan-Gordo[1,2,3,13], Gabriel Pombo[1,4], Loes Werkman[1,5], Joren Buekers[1,2,3], Juan Gómez-Salgado[6,7], Lourdes Arjona[1,2,3,8], Francisco Brocal[9], Ben Caplin[10], Ana Espinosa[1,2,3], Manolis Kogevinas[1,2,3,8], Neil Pearce[11], Oriana Ramirez-Rubio[1,12], Carlos Ruíz-Frutos[6,7], Judith Garcia-Aymerich[1,2,3], Sarah Koch[1,2,3]

[1]Isglobal, Barcelona, Spain, [2]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [3]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [4]Universitat Autònoma de Barcelona, Barcelona, Spain, [5]University of Leiden, Leiden, Netherlands, [6]Preventive Medicine and Public Health Unit. Sociology, Social Work and Public Health Department, University of Huelva, Huelva, Spain, [7]Safety and Health Postgraduate Programme, University Espíritu Santo, Guayaquil, Ecuador, [8]IMIM (Hospital del Mar Medical Research Institute), Barcelona, Spain, [9]Universidad de Alicante, Alicante, Spain, [10]Centre for Nephrology, University College London Medical School, London, UK, [11]Department of Medical Statistics, London School of Hygiene and Tropical Medicine, London, United Kindom, [12]Department of Epidemiology, Boston University School of Public Health, Boston, USA, [13]Universitat Oberta de Catalunya (UOC), Barcelona, Spain

BACKGROUND AND AIM: Physical activity (PA) in hot environments has been associated with kidney damage. In harvest workers, PA has been primarily assessed by questionnaires in males. We aimed to study the association between objectively-measured PA intensity and incidence of acute kidney injury (AKI) over the course of one work shift, in female harvest workers in Spain.

METHODS: Ninety women working in greenhouses wore a Zephyr chest harness to measure PA intensity during one regular work shift in June 2020. We determined the mean (PA_mean), standard deviation (PA_sd), and 3-minute-maximum (PA_max, a proxy of peak PA intensity) of PA intensity (vector magnitude units). We estimated heat stress (HS) in greenhouses based on wet bulb globe temperature index (ISO 7243:2017). Serum creatinine and neutrophil gelatinase associated lipocalin (NGAL) levels were measured before and after the work shift. AKI was defined as an increase in post-shift serum creatinine by at least 0.3 mg/dl or at least 1.5 times the pre-shift serum creatinine levels. Additionally, we calculated pre-post-shift differences in NGAL. We used logistic regressions adjusted for age, body mass index, and HS. HS was also assessed as an effect modifier.

RESULTS: PA_sd and PA_max seemed to be associated with AKI (OR=1.57 (95%CI=0.82;3.21) and 1.41 (0.71;2.85), respectively), but not PA_mean. There was no interaction between any of the PA variables and HS (p-value LRT>0.1). Mean (SD) increase in NGAL levels over the course of a work shift was higher among participants with AKI (27.8 (7.5)) compared to those without AKI (12.2 (2.7)).

CONCLUSIONS: Results suggest that large changes and peaks in PA intensity should be avoided to protect renal function of harvest workers. Increased levels of NGAL among those with AKI are indicative of kidney damage among those with increased serum creatinine levels.

KEYWORDS: Occupational physical activity, acute kidney injury, ambient heat stress

P-1164 Cane Cutting and reduced kidney function at medical encounters among sugarcane workers in Nicaragua

Zsuzsanna Jeney[1], James Kaufman[2], Daniel Weiner[3], Tiffany Stallings[1], Nathan McCray[1], Daniel Brooks[4], Juan José Amador-Velázquez[4], Katie Applebaum[1]

[1]Department of Environmental and Occupational Health, Milken Institute School of Public Health, The George Washington University, Washington, USA, [2]Division of Nephrology, New York University Grossman School of Medicine and VA New York Harbor Healthcare Center, New York, USA, [3]Division of Nephrology, Department of Medicine, Tufts Medical Center, Boston, USA, [4]Department of Epidemiology, Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: Chronic kidney disease of non-traditional cause (CKDnt), a distinct form of kidney disease, has a high prevalence in agricultural communities in Central America. In Nicaragua's sugarcane industry, cane cutters have the greatest risk of developing CKDnt, possibly due to a high level of physical exertion and exposure to climatic heat. In a longitudinal study, we examined whether time worked as a cane cutter was associated with reduced kidney function during a medical visit.

METHODS: Employment and medical records from 1997-2010 were linked for 242 men employed at a Nicaraguan sugarcane plantation. Person-months worked were classified as cumulative months worked cutting cane. The outcome was experiencing an estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m2 at a medical visit. To examine the association between cane cutting and low eGFR, logistic regression based on generalized estimating equations for repeated events was used to estimate the odds ratio (OR) and the 95% confidence interval (CI), controlling for age.

RESULTS: During 14,592 person-months, half of workers were ever a cane cutter, with median of 23 (IQR=39) months cane cutting. 41 workers experienced a low eGFR, with a median of 6 (IQR=8) events. Compared with never cane cutters, the adjusted odds of low medical eGFR for cane cutters was 2.18 (95% CI, 1.11, 4.30), and 4.79 (95% CI, 2.09, 10.99) among those cane cutting for at least 74 months. Additionally, each 6-month increase in time cane cutting was associated with a 1.12-fold increase in low eGFR (95% CI, 1.07, 1.18).

CONCLUSION: Cumulative months as a cane cutter was associated with an exposure-response relationship between low eGFR at medical encounters. eGFR was not routinely taken at medical encounters; the outcome may have captured existing low eGFR or more acute events. Future research into recurrence of acute kidney injury among these workers should be undertaken.

P-1166 Updated findings from the International Nuclear Workers Study (INWORKS)

David Richardson[1], Klervi Leuraud[2], Dominique Laurier[2], Michael Gillies[3], Richard Haylock[3], Kaitlin Kelly-Reif[4], Stephen Bertke[4], Robert Daniels[4], Isabelle Thierry-Chef[5,6,7], Monika Moissonnier[8], Ausrele Kesminiene[8], Mary Schubauer-Berigan[8]

[1]University of California, Irvine, Irvine, USA, [2]Institute for Radiological Protection and Nuclear Safety (IRSN), Fontenay-aux-Roses, France, [3]UK Health Security Agency, Chilton, Didcot, Oxfordshire, UK, [4]National Institute for Occupational Safety and Health, Cincinnati, USA, [5]Barcelona Institute of Global Health (ISGlobal), Barcelona, Spain, [6]University Pompeu Fabra, Barcelona, Spain, [7]CIBER Epidemiologia y Salud Pública, Madrid, Spain, [8]International Agency for Research on Cancer, Lyon, France

BACKGROUND:
Despite being a recognized carcinogen, public exposure to ionizing radiation has increased in recent decades. An update to the International Nuclear Workers Study (INWORKS) is being undertaken to strengthen direct assessments of the risks from low dose, low dose rate exposure to penetrating forms of ionizing radiation. Follow-up has been extended by 10 or more years in each partner country.
METHODS: We are conducting a pooled analysis of cohort mortality studies of nuclear industry workers in the UK, France, and the USA. Individual annual estimates of whole-body dose due to external exposure to penetrating radiation are derived from personal occupational exposure monitoring data. Vital status has been ascertained through 2012, 2014, and 2016 for workers in the UK, France, and the USA, respectively.
RESULTS: The updated pooled study includes 309,932 workers and 10.7 million person-years of observation. Over the period of follow-up, there have been 103,553 deaths observed, of which 31,009 are deaths due to cancer.
CONCLUSIONS: This presentation will describe the motivation for an update of the INWORKS study, the major aims of the project, and the progress that we have made to-date. We will report on a major update of this highly-influential study; the person-time in INWORKS increases by a factor of 1.3 and the number of cancer deaths increases by a factor of 1.6. The updated INWORKS analyses will provide some of the most informative direct estimates of low dose radiation risks reported to-date.

P-1167 Associations Between Serum Perfluoroalkyl Acid (PFAA) Concentrations and Health Related Biomarkers in Firefighters

Sandra Nilsson[1], Kayla Smurthwaite[2], Lesa L Aylward[3], Margaret Kay[1], Leisa-Maree Toms[4], Leisa King[1], Shelby Marrington[1], Martyn D Kirk[2], Jochen F. Mueller[1], Jennifer Braeunig[1]
[1]The University of Queensland, Woolloongabba, Australia, [2]The Australian National University, Canberra, Australia, [3]Summit Toxicology LLP, La Quinta, USA, [4]Queensland University of Technology, Kelvin Grove, Australia

BACKGROUND AND AIM: Elevated serum levels of the persistent perfluoroalkyl acids (PFAAs); perfluorohexane sulfonate (PFHxS), perfluoroheptane sulfonate (PFHpS) and perfluorooctane sulfonate (PFOS) have been reported in firefighters who have used aqueous film-forming foam in occupational practices. The aim of the present investigation was to examine the association between potential health outcomes and serum concentrations of these three PFAAs, as well as perfluorooctanoic acid (PFOA), also frequently detected in human serum, in Australian firefighters.

METHODS: The relationship between PFAA serum concentration and cardiovascular disease, kidney-, liver- and thyroid function (assessed as biochemical marker serum concentrations, as well as self-reported health conditions), were assessed cross-sectionally in 782 firefighters. The relationships between PFAAs and biomarkers for cardiovascular disease and kidney function were further assessed longitudinally in a subset of the firefighters, where serum measurements were available from two timepoints, approximately five years apart (n=<130).

RESULTS: Increasing levels of one or several PFAAs were significantly associated with increasing levels of biomarkers for cardiovascular disease (total-cholesterol, and LDL-cholesterol), and biomarkers for kidney (urate) and thyroid function (TSH), in the cross-sectional analysis. However, increasing levels of PFAAs were not associated with biomarker levels outside the clinical reference values, or associated self-reported health conditions. No significant relationships were observed in the longitudinal analysis.

CONCLUSIONS: PFAAs may alter the homeostasis of several biomarkers. Further research is needed to determine if the associations observed in the present investigation are causal and if they are of clinical significance.

P-1168 Association of summertime daily mean temperature and sick leaves among employees of the City of Helsinki, Finland

Anne H. Lipponen[1,2], Pekka Tiittanen[2], Hasan Sohail[1,2], Santtu Mikkonen[1], Timo Lanki[1,2]
[1]University of Eastern Finland, Kuopio, Finland, [2]Finnish Institute for Health and Welfare, Kuopio, Finland

BACKGROUND AND AIM: Heat affects work productivity and well-being at work. People working outdoors are the most vulnerable to heat-related health issues that may cause absenteeism from work. However, the phenomenon concerns indoor workers without sufficient air conditioning as well. Previous studies concerning occupational heat stress have concentrated on health effects, the incidence of heat-related illness, preventative measures, and productivity losses. Correlation between heat waves and sickness related work absenteeism rates has not been studied. Therefore, this study aims to evaluate the relationship of daily summertime temperatures and heatwaves with sick leaves rates among employees of Helsinki City, Finland.
METHODS: We used Poisson time series models adjusted for potential confounders, such as time trend, air pollution, pollen, and barometric pressure to investigate the associations of daily temperature with daily rates of new sick leaves. Daily number of sick leaves for May-August 2002-2017 was obtained from the Helsinki City employee register and daily weather information from the Finnish Meteorological Institute.
RESULTS: Daily mean temperature ranged from 1.5 °C to 26.6 °C during the warm season. Preliminary results indicate that increased daily mean temperature is associated with decreased risk of sick leaves at lag 0 and lags 2-5. at 1 day lag, increased daily mean temperature is associated with decreased risk of sick leaves until the daily mean temperature exceeds 24 °C after which the risk begins to increase. Risk ratio [RR] is 1.003 at 26 °C compared to 24 °C.
CONCLUSIONS: Preliminary results indicate that increased daily summertime mean temperature is mostly associated with decreased daily sick leave rate. However, our preliminary analyzes suggest that there may be an increase in daily sick leave rate at 1 day lag when daily mean temperature exceeds a threshold. In further analysis, the effect of prolonged heatwaves will be evaluated.

P-1169 Assessment of chemotherapy drug contamination in occupational settings

Andrew Floeder[1], Jingfang Huang[3], Matthew Jeronimo[2], Peter Villalta[3], Antonella Borgatti[1], Silvia Balbo[3], Susan Arnold[1]

[1]University of Minnesota, Minneapolis, USA, [2]University of British Columbia, Vancouver, Canada, [3]Masonic Cancer Center, Minneapolis, USA

Chemotherapy drugs can persist on surfaces in cancer clinics where they are administered, resulting in potentially hazardous exposures to healthcare workers and cancer patient caregivers. Literature reports that contamination by these drugs has the potential to travel out of oncology clinics to care facilities and homes of chemotherapy patients; however, the extent of the surface contamination from these drugs is currently unclear. This project focuses on the development of a new liquid chromatography-mass spectrometry method for the simultaneous detection of doxorubicin, cyclophosphamide, methotrexate, 5-fluorouracil, paclitaxel, and etoposide to test for potential surface contamination. The parent ion and corresponding fragment ions for each drug were determined using direct infusion mass spectrometry for their characterization and quantitation. The developed method was validated by spiking 0.25µg of the chemotherapy drugs onto stainless steel plates, simulating clinical surfaces. An aliquot of the samples were injected onto a triple quadrupole mass spectrometer using a Zorbax SB C18 with a linear gradient and electrospray ionization. The drug recoveries ranged from 45-80%. Calibration curves were obtained by analyzing increasing amounts of drugs combined with set amounts of labeled internals standards to calculate the limits of detection (0.002 to 0.17 ng/mL) and limits of quantitation (0.010 to 0.71 ng/mL) for each drug. Finally, wipe sample collection was conducted for specific areas in an oncology treatment room at the University of Minnesota Veterinary Medical Center, where doxorubicin and cyclophosphamide are administered to veterinary patients. The method identified traces of these drugs localized to their individual administration areas, supporting the ability of this method to precisely detect contamination by these drugs in an occupational setting. These preliminary results set the stage for investigating levels of contamination in various clinical settings and testing decontamination products and protocols to reduce workplace and environmental exposures.

P-1170 Why are Silica Dust Exposures and Silica-Related Health Effects Still a Global Concern?

David F Goldsmith[1], Keven Hedges[2]
[1]George Washington University, Silver Spring, USA, [2]Occupational Health Clinics for Ontario Workers and Workplace Health Without Borders--International, Ontario, Canada

BACKGROUND AND AIM: Epidemiology studies of workers exposed to silica dust demonstrate that crystalline SiO2 is a multipotential hazard. Research among construction workers, miners, ceramic and brick workers, countertops workers, and sandblasters where respirable silica dust levels has been measured has demonstrated excess risk for silicosis, cor pulmopale, silica-tuberculosis (SiTB), several chronic respiratory conditions, coal workers pneumoconiosis (CWP), several auto-immune diseases, and cancers of the lung and gastro-intestinal tract.

METHODS: Despite knowledge of these links over the past decades, occupational and environmental health professionals have not been able to address three new silica-related health issues. They are silicosis and CWP among US coal miners, severe silicosis and auto-immune ailments among countertop workers; and ongoing risk for SiTB among Africa miners. The author examined the literature for other novel silica-related health risks.

RESULTS: Current workers and their managers seem to not have sufficient awareness of the occupational hazards of silica dust. There are new silica dust concerns including fracking sand, railroad ballast, and dust control in countertop machining. There are new cancer links with silica, including women and nonsmokers with excess lung cancer; excess lung cancer among patients with CWP; children's dust exposure in small-scale gold mining; and excess lung diseases and pulmonary cancer among railroad workers. There is need for research on improved silica sampling techniques and protective gear. Pathologists should explore whether silicosis leads to differences in cell characteristics that produce silica-linked lung cancers compared to 'garden variety' malignancies.
CONCLUSION:
Despite promises that global silica problems were controlled, that seems to be countered by excesses of CWP and SiTB that still bedevil the occupational medicine and public health communities. We need more worker education, prevention or regulatory policy, and basic silica biology and pathology to effectively intervene.

KEYWORDS: Silica health effects, future prevention efforts; improved sampling methods

P-1171 Work-related stress and the mental health status of retail commerce workers from Nicaragua: a cross-sectional web-based survey

Rosa Noemi Fuertes Toledo[1], Martha Gallo[1], María Fernanda Chamorro[2], Steven Cuadra[3]
[1]Casa Emilia Salud, Managua, Nicaragua, [2]Universidad Católica Redemptoris Mater (UNICA), Managua, Nicaragua, [3]Universidad de Occidente (UdO Managua), Managua, Nicaragua

BACKGROUND AND AIM: In Currently, there are very few studies, that evaluate the consequences of occupational stress on mental health in Nicaraguan workers. Here, we studied the association between the levels of work-related stress (WRS) and the mental health status of retail commerce workers from Nicaragua.
METHOD: We carried out a descriptive cross-sectional study by conducting a web-based survey between August 1st and September 30th, 2021 through an online self-administered questionnaire, which was made available on the Google Forms platform. Subjects were randomly selected from an available database at the Social Security National Institute and were invited to participate by e-mail. Out of 1,212 invitations, 910 subjects completed the questionnaire. The ILO-WHO Occupational Stress Scale was used to assess stress levels, and the mental health component of the Goldberg General Health Questionnaire (GHQ-12) was used to assess emotional health.

RESULTS: Overall, 40% of participants were classified as having WRS risk levels. On the other hand, 1out 5 workers experienced severe stress. The proportion of cases currently classified as experiencing a probable mental or emotional health disorder was 30% (GHQ-12 with a score ≥12 points). Workers with a significant level of stress or severe level of stress had a 3 to 5-fold increased risk of experiencing a probable mental or emotional disorder. Other factors that were also associated with the presence of a probable emotional health disorder were being female, sleeping less than 7 hours regularly, experiencing mobbing at the workplace, and having experienced workplace violence.
CONCLUSION: This study showed a highly significant association between work relates stress levels and the presence of mental or emotional health disorders. WRS continues to represent a serious occupational and public health problem in Nicaragua.

KEYWORDS: work-related stress, mental health, retail commerce, Nicaragua.

P-1173 Biological monitoring for exposure assessment of phthalatesby Korean firefighters at the fire site

Hyun Soo Kim[1], Kyoung Sook Jeong[2], Hyunjeong Oh[2]
[1]KOREAN INDUSTRIAL HEALTH ASSOCIATION, Seoul, Republic of Korea, [2]Wonju Severance Christian Hospital, Wonju, Republic of Korea

BACKGROUND AND AIM: The phthalates metabolites in urine for exposed phthalates were evaluated for firefighters who participated in the actual fire suppression to determine whether firefighters were exposed to hazardous chemicals, which is the basic data on health risk of firefighters

METHODS: The results of comparing the concentration of metabolites of phthalates immediately after fire suppression and after 3 weeks of fire suppression in spot urine.

RESULTS: The concentration of Mono-n-butyl phthalate(MnBP), Mono-benzyl phthalate(MBzP), and total phthalates(Σphthalates) increased significantly immediately after fire suppression than after 3 weeks of suppression. In case of adjusted for creatinine, the concentration of MnBP, MBzP and Σphthalates were equally increased.
There was a statistically significant difference in the geometric mean concentration(GM) of firefighters who performed fire suppression tasks as 55.59 μg/g as Cr and 29.69 μg/g as Cr for other tasks. The GM concentration of firefighters who were active within 50m from the fire site was 44.80 μg/g as Cr, and when it fell over 50m, there was a difference of 20.47 μg/g as Cr. The GM concentration of firefighters with subjective symptoms within 7 days after extinguishing the fire was 61.68 μg/g as Cr and without symptoms was 31.62 μg/g as Cr, which was different.

CONCLUSIONS: This study confirmed that fire fighters are exposed to various phthalates during the firefighting process.

KEYWORDS: Fire fighter, Phthalate metabolites

P-1247 Long-term exposure to nitrate and trihalomethanes in drinking-water and prostate cancer: A Multicenter Case-Control Study in Spain

Carolina Donat[1], Manolis Kogevinas[1], Gemma Castaño-Vinyals[1], Beatriz Pérez-Gómez[3], Javier Llorca[4], Mercedes Vanaclocha-Espí[5], Guillermo Fernandez-Tardon[6], Laura Costas Caudet[7], Nuria Aragonés[8], Inés Gómez-Acebo[4], Victor Moreno[9], Marina Pollan[3], Cristina Villanueva[1]

[1]Isglobal, Barcelona, Spain, [2]Karolinska Institutet, Stockholm, Sweden, [3]Carlos III Institute of Health, Madrid, Spain, [4]University of Cantabria-IDIVIAL, Cantabria, Spain, [5]Foundation for the Promotion of Health and Biomedical Research-Public Health Research FISABIO – Public Health Research, Valencia, Spain, [6]Health Research Institute of Asturias, ISPA, Oviedo, Spain, [7]Cancer Epidemiology Research Programme, Catalan Institute of Oncology, IDIBELL, Barcelona, Spain, [8]Epidemiology Section, Public Health Division, Department of Health of Madrid, Madrid, Madrid, [9]Catalan Institute of Oncology (ICO), Barcelona, Spain

BACKGROUND AND AIM: Nitrate and trihalomethanes (THMs) in drinking water are widespread and potential human carcinogens. We evaluated the association between drinking-water exposure to nitrate and THMs and prostate cancer (PC).

METHODS: During 2008-13, hospital-based incident PC cases (n=697) and population-based controls (n=927) were recruited in five Spanish regions, providing information on residential histories and type of water consumed. Average nitrate and THMs levels were linked with lifetime residential water consumption to calculate waterborne ingestion. Odds ratios (OR) and 95% confidence intervals (CI) for PC were estimated using mixed models with area as random effect. Effect modification by tumor grade (Gleason score), age, lifestyle, and dietary factors were explored.

RESULTS: Mean (SD) for average lifetime waterborne ingestion to nitrate (mg/day), brominated (Br)-THMs (µg/day) and chloroform (µg/day) were 12.8 (10.8), 19.2 (29.2) and 15.4 (14.0), respectively, in cases; and 11.5 (9.0), 20.7 (32.4) and 15.1 (14.7) in controls. for each 10 mg/day increase of waterborne ingested nitrate, PC risk increased by 49% (OR 1.49; 95%CI 1.26-1.77) overall, 70% (OR 1.70; 1.36-2.12) for low-grade PC (Gleason score <7), and 36% (OR 1.36; 1.11-1.68) for medium-high grade PC (score ≥7). Risks were higher in the youngest and in those with lower intake of fiber, total fruit/ vegetables, and vitamin C. Waterborne ingested THMs were not associated with PC. However residential levels of Br-THMs and chloroform showed, respectively, inverse and positive associations with PC.

CONCLUSIONS: Findings suggest long-term waterborne ingested nitrate could be a risk factor of PC. Increased intake of fiber, fruit/vegetables and vitamin C may lower and even avoid the risk. Results indicate non-linear and opposite associations for residential Br-THMs and chloroform, suggesting a potential role of inhalation and dermal exposures.

P-1248 Characterizing the coexistence of proteobacteria species and cyanobacteria in cyanobacteria positive lung cancer samples

Christina Joshua[1], Heather Robeson[1], Austin Porter[1], Mohammed Orloff[1,2]
[1]University of Arkansas for Medical Sciences, Little Rock, USA, [2]Winthrop P. Rockefeller Cancer Institute, Little Rock, USA

BACKGROUND AND AIM: Smoking and genetic factors cannot completely explain the risk of developing lung cancer. Inhalation of aerosol microbial insults can play a role in lung disease development. A recent lung microbiome cross-sectional study revealed an association between cyanobacteria and lung cancer. Further analysis of these patients showed a frequent coexistence between phylum cyanobacteria and proteobacteria in the lung tissues. Based on our findings and literature, we hypothesize that cyanobacteria and a proteobacteria species (Acidovorax temperans) are linked to the development of lung cancer.

METHODS: Nucleotide primers specific to Acidovorax temperans were used to screen Acidovorax temperans on lung cancer individuals positive for cyanobacteria. As a pilot analysis, the resulting amplicons were sequenced and the sequence analyzed.

RESULTS: A majority (66%) of the cyanobacteria positive samples were also positive for Burkholderia cepacia that shares the same lineage with Acidovorax temperans.

CONCLUSIONS: Based on our analysis, we were able to identify the presence of Proteobacteria in lung cancer individual samples with positive cyanobacteria presence. Further verification for the exact species will be done using 16S rRNA sequencing.

KEYWORDS: Bacteria, lung cancer, microbiome, water, blue algae, cyanobacteria, genome, aerosol inhalant

P-1249 Human enteric bacteria and viruses in five wastewater treatment plants in the Eastern Cape, South Africa

Olayinka Osuolale[1]
[1]*Elizade University, Ilara Mokin, Nigeria*

BACKGROUND AND AIM: Monitoring effluents from wastewater treatment plants is important to preventing both environmental contamination and the spread of disease. We evaluated the occurrence of human enteric bacteria (faecal coliforms and Escherichia coli) and viruses (rotavirus and enterovirus) in the final effluents of five wastewater treatment plants (WWTPs) in the Eastern Cape of South Africa.
METHODS: Human viruses were recovered from the effluent samples with the adsorption–elution method and detected with singleplex real-time RT–PCR assays. Culture based approach using a membrane filtration method, and the filtrates were then transferred the m-FC agar and E. coli chromogenic agar for isolation faecal coliform, and Escherichia coli.
RESULTS: Rotavirus was detected in several effluents samples, but no enterovirus was detected. at WWTP-C, rotavirus titre up to 10^5 genome copies/L was observed and present in 41.7% of the samples. at WWTP-B, the virus was detected in 41.7% of samples, with viral titres up to 10^3 genome copies/L. The virus was detected once at WWTP-E, in 9% of the samples analysed. The viral titres at WWTP-A were below the detection limit in all 25% of the 1.25 L samples in which the virus was detected. Rotavirus was not observed at WWTP-D. Faecal coliform bacteria and E. coli were detected in all the WWTPs, but no correlation was established between the enteric bacteria and viruses studied.
CONCLUSIONS: The occurrence of rotavirus in effluent samples discharged into surface waters highlights the importance of assessing viral contamination in the water sources used for domestic water use.

P-1253 Determination of human-pathogenic free living amoebas in drinking water supplies in Leicester, UK

Umar Anjum[1], Lucrecia Acosta[2], Antonio Peña-Fernández[1]

[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, UK, [2]Área de Parasitología, Departamento de Agroquímica y Medio Ambiente, Universidad Miguel Hernández de Elche, Ctra. Valencia Km 8.7, San Juan, Alicante, Spain

BACKGROUND AND AIM: Acanthamoeba spp. and Balamuthia mandrillaris are free-living amoebas (FLA) that can severely affect individuals. FLA are naturally resistant to harsh conditions such as pH, temperature and chemicals. Although we have previously reported the circulation of Acanthamoeba spp. and B. mandrillaris in open-water systems from Leicester (UK), little is known about their presence in public drinking water supplies. Thus, the aim was to identify potential risks due to their presence in tap water.

METHODS: Twenty-five tap water samples were collected in duplicate in March 2022 from public restroom facilities, located in parks (14), shopping/leisure centres (7), bus (2) and train (1) stations and a cemetery (1). Taps were appropriately cleaned before and between collecting the water samples. Samples were centrifuged at 2500rpm for 30 minutes for spore recovery. Pellets were suspended in phosphate-buffered saline to extract DNA by disrupting the spores using the Fast DNA® Spin kit and purified. A triplex real-time TaqMan PCR assay was performed for the simultaneous detection of FLA species, using established methodologies.

RESULTS: All fifty samples tested for FLA were negative. The drinking water supplies in the taps of Leicester's public restrooms are not sourced from storage tanks, which reduce the overall risk of the presence of FLA in tap water. However, limitations in the collection may have affected our results, as the incidence of Acanthamoeba keratitis in the UK is much higher than in the USA and Netherlands. This higher incidence has been linked to the use of water storage tanks, which would be in line with our preliminary results.

CONCLUSIONS: Regular monitoring of tap water quality would be required at a wider scale in the city including households, public institutions and hospitals in order to rule out the risks for the presence of human-pathogenic FLA, particularly Acanthamoeba spp.

P-1254 Endocrine disrupting activity, pharmaceutical and virus occurrence in selected water sources along the Limpopo River, South Africa

Sean Patrick[1], Ibukunoluwa Salako[1], Magdalena van Zijl[1]
[1]*University of Pretoria, Pretoria, South Africa*

BACKGROUND AND AIM: There are concerns globally about decreasing water quality due to the presence of endocrine-disrupting chemicals (EDC), pharmaceuticals, and potentially viruses in the water system, posing health risks to humans,. Rural communities in Limpopo, South Africa, are dependent on water sources such as rivers, dams and boreholes for drinking water and small scale subsistence farming. The aim of study investigated the occurrence of endocrine-disrupting activity, quantification of select pharmaceuticals, and screening of viruses in water samples from four study sites; Bende-Mutale (BM), Doreen Farm (DF), Madimbo (MO) and Nkotswi (NO), all along the Limpopo River, Limpopo Province, South Africa.

METHODS: Analyses were done on the water samples to determine EDCs using a battery of bioassays (T47D-KBluc and MDA-kb2 assays), pharmaceutical screening (using the Agilent Forensic Toxicology Personal Compound database and Library (PCDL) library of 9200 compounds) and quantification using LC/MS-QTOF, and viruses using real-time reverse transcription-polymerase chain reaction (RT-PCR).

RESULTS: Estrogenic activity was detected in the river water samples with estrogen equivalents (EEq) values ranging from 0.08 to 0.69 ng/L using the T47D-KBluc assay. Pharmaceuticals ciprofloxacin, sulfamethoxazole, and trimethoprim which were detected and quantified in water from the study sites. When screening against the PCDL, a wide range of compounds were identified, BM (n=49), DF (n=34). MO (n=42) and NO (n=46). The top five categories of compounds were antibiotics, antidepressants, immunosuppressants, insecticides and parasympatholytics. Nora Virus 1 and 2, were not detected in any water samples.

CONCLUSIONS: This is the first study in the Limpopo province to screen and quantify emerging contaminants in river, dam and borehole water sources, and the results are concerning. The emerging contaminants from the screening data provide a basis for a follow-up study to quantify and determine the source and removal of these potentially harmful compounds.

KEYWORDS: EDCs, emerging contaminants, pharmaceuticals, South Africa

P-1255 Evaluation of the sanitary quality of the water consumed by the population of the Sambwa mission village in the Democratic Republic of Congo

Paulin Kilufya Kalomo Kitikimo[1], Monsieur Célestin Banza Lubaba[1]

[1]*Université De Lubumbashi, Ecole de Santé Publique, Unité de Toxicologie et Environnement, Lubumbashi, Congo-Kinshasa (The Democratic Republic of the Congo)*

CONTEXT:
The village Sambwa mission has 5628 inhabitants and is located 30 km from the city of Lubumbashi along the river Kafubu, which river receives water from the different streams of Lubumbashi and its approximately would be more affected by various pollutants (mining, industrial and household). In addition, the populations located along this river are not served with drinking water they most often use the water of the river and wells to meet their needs. The objectives of this study were to identify the source of the water intended for human consumption of the population of the village Sambwa mission, to characterize the pollution of this water in trace metal elements in order to assess the health risk of the said population.

METHODS: The study was of the cross-sectional and analytical descriptive type, supported by a standardized questionnaire on a sample of 94 households present on the day of the survey. Water sampling was carried out at all the water supply points for human consumption and the determination of trace metal elements was carried out at the Robinson International laboratory in Lubumbashi.

RESULTS: The results show that the population of this village Sambwa mission has five points of water supply and that these waters are contaminated mainly by arsenic, cadmium and antimony. The highest concentrations of arsenic, cadmium and antimony were observed to be 0.031 mg/L, 0.010 mg/L and 0.046 mg/L, respectively, above the WHO drinking water standard with hazard quotients assessed to be greater than 1.
CONCLUSION:
The observed concentrations sufficiently demonstrate the poor quality of the water consumed by the population of the village of Sambwa mission and that the consumption of these waters constitutes a danger to human health in general and that of children in particular.

KEYWORDS: quality, health risk, water and population

P-1257 Microplastic Abundance and Distribution in a Wastewater Treatment Plant in Bangladesh

Rabeya Miazi[1], Mahfuza Mirza Sadia[1], Anika Nawar Ishika[1], Farzana Yasmin[2], Saif Shahrukh[3], Gazi Nurun Nahar Sultana[2], Mohammad Enayet Hossain[1]

[1]University of Dhaka, Dhaka, Bangladesh, [2]Centre for Advanced Research in Sciences, University of Dhaka, Dhaka, Bangladesh, [3]Bangladesh Council of Scientific and Industrial Research, Dhaka, Bangladesh

BACKGROUND AND AIM: Of late, microplastics have been considered an emerging contaminant for humans and the environment due to their long-term persistence and unique properties. As a result, a lot of attention has been drawn to microplastic pollution in soil, sediments, rivers, and oceans. However, little attention has been paid to wastewater treatment plants that can be a significant source of microplastic pollution in different niches of the environment. In this study, an investigation was carried out on the Pagla Sewage Water Treatment Plant to determine the abundance and occurrence of microplastics through a well-developed systemic procedure. The broader goal was to give a comprehensive idea for a better understanding of wastewater treatment plants (WWTPs) as an important pathway for microplastics introduced to the environment.

METHODS: Samples were collected from eight stations, including influent, distribution chamber, measuring chamber, sludge, lagoon, and effluent. Samples collected were analyzed using techniques such as visual, microscopic, and Fourier-transform infrared (FTIR) analysis to determine the abundance and composition of microplastics.

RESULTS: The type of microplastics obtained in the treatment plant included polyethylene, polypropylene, polyvinyl chloride, polystyrene, polyamide, and poly (methyl methacrylate). Interestingly, the total number of microplastics observed in the influent sample (34) was found to be decreased in the effluent sample (15) without any targeted treatment technology for the removal of microplastics. Therefore, the microplastics discharged in the effluent into the nearby Buriganga river may increase the load of microplastics in the river.

CONCLUSIONS: The present study provides an insight into the occurrence and abundance of microplastics in a wastewater treatment plant. Future research is needed to determine the role of wastewater treatment plants on the properties of microplastics and to develop technologies to mitigate the load of microplastics in the effluent.

O-SY-126 Natural disasters and sexual risk taking behaviour: correlation or causation? and what is the relevance for global public health?

Cato Dambre[1,2], Nick Julien Baumgart[1], Sarah Feron[1], Ofer Engel[1], Hamed Seddighi[1], Olivier Degomme[2], Valentina Gallo[1]

[1]University of Groningen, Leeuwarden, Netherlands, [2]University of Ghent, Ghent, Belgium

BACKGROUND - AIM: Natural hazards have intensified as a result of climate change. Their impact has a negative effect on people's health, including mental health. Increased risk-taking behaviour such as alcohol (ab)use, excessive smoking and illicit drug use have been observed. High-risk sexual behaviour has poorly been investigated, to date. The aim of this ecological study is to investigate the association of exposure to natural disasters and sexual risk-taking behaviour as measured by increased HIV incidence, at country level, worldwide.

METHODS: All data was extracted from publicly available sources. Crude and adjusted linear regression models were built to explore the association between the proportion of people affected by natural hazards and HIV incidence. Models were adjusted for socio-demographic variables (literacy, income and age), and then further adjusted for antiretroviral therapy coverage and the healthcare access and quality index.

RESULTS: In the crude regression, the total number of people affected by disaster over a 5-year period was positively associated with HIV incidence: for every 10 new people per 100,000/year affected by natural hazards, the HIV incidence in the country was 1.5 per 1,000 uninfected higher. After adjusting for socio-demographic variables, the association was lost. When further adjusted, only antiretroviral therapy coverage and health care access and quality were positively and negatively associated with HIV incidence, respectively. No interaction was found with income groups, world regions or categories of high and low HIV prevalence.
CONCLUSION: No association between exposure to natural hazards and increased sexual risk-taking behaviour at country level worldwide was found, after accounting for socio-demographic variables. Nonetheless, countries with a higher proportion of population affected by natural disasters were those whose health system quality and accessibility was poorer, and this in turn was associated with higher incidence of HIV potentially highlighting different mechanisms explaining the crude association.

O-SY-130 Census tracts aren't neighborhoods: Issues in examining the impact of historical redlining in the USA on present-day environmental exposures and health outcomes

Maret Maliniak[1], Leah Moubadder[1], Michael Kramer[1], Lauren McCullough[1]
[1]*Emory University, Atlanta, USA*

BACKGROUND AND AIM: In the 1930s, the US Home Owners' Loan Corporation (HOLC) developed residential security maps for 239 urban areas across the US, ranking the investment risk using a color-coded scale: "A" (green), "B"(blue), "C"(yellow), and "D"(red/hazardous). Areas in proximity to industrial facilities and other sources of pollution were downgraded and more likely to have Black and foreign-born inhabitants—resulting in disproportionate exposure of racial/ethnic minorities to environmental toxicants. HOLC-derived neighborhood boundaries do not align with Census tracts, making the examination of historical redlining on present-day environmental exposures challenging. Multiple methods exist to define redlining when using Census data, but how well they classify redlining exposure is unknown.

METHODS: We examined agreement in redlining status when assigning exposure based on area-level geographic data compared to having complete address data (gold-standard). Our analysis included 5,042 addresses located in census tracts that overlapped with the HOLC map for Atlanta. We classified redlining status using complete address data and census tract using four methods: the Centroid, Majority, Weighted Score, and Highest HOLC methods. Each method was compared to the HOLC grades assigned when superimposing complete address data onto the HOLC map.

RESULTS: of the 5,042 addresses, 3% were A-graded areas, 9% B, 24% C, 12% D, and 52% ungraded. Overall percent agreement was highest for the Weighted Score method, which correctly classified 70% of addresses. The Majority, Centroid, and Highest HOLC methods had 68%, 65%, and 53% agreement, respectively. However, these methods only correctly identified 40%, 49%, and 57% of HOLC graded areas (excluding ungraded) compared to 76% using the Weighted Score method.

CONCLUSIONS: Full address data are often unavailable in population-based studies examining environmental exposures on health outcomes, thus relying on census tract to classify redlining exposure. Investigators should carefully consider the method used to minimize misclassification.

KEYWORDS: Redlining, exposure misclassification, validation study

DAY 3 (Wednesday, 21 Sept 2022)

THEMATIC 04: Built and Physical Environment exposures

P-0248 Maternal Exposure to Magnetic Field Non-Ionizing Radiation During Pregnancy and the Increased Risk of Allergic Conditions in Offspring: A Longitudinal Cohort Study with up to 22 Years of Follow-up

Dekun Li[1], Andrew Hirst[1], Jeannette Ferber[1], Roxana Odouli[1]
[1]*Division of Research, Kaiser Foundation Research Institute, Oakland, USA*

BACKGROUND: Emerging epidemiologic studies and experimental animal studies have reported an impact of magnetic field (MF) non-ionizing radiation on the immune system. We examined the relationship between maternal MF exposure level during pregnancy and the risk of severe allergic conditions, having both asthma and atopic dermatitis (AD), in offspring.

METHODS: We enrolled 2,060 pregnant members of Kaiser Permanente Northern California. Consented participants were asked to wear an EMDEX meter for 24 hours in early pregnancy to measure MF exposure levels from all MF-emitting sources. To examine the risk of allergic conditions in offspring, 1,568 participants who delivered a livebirth were included. We used the median of the 24-hour MF measurements to determine maternal MF exposure level. Offspring were followed from birth to early adulthood (up to 22 years) to identify those with clinical diagnoses of both asthma and AD. Confounders were ascertained during in-person interviews. Cox Proportional Hazards regression was used for analysis.

RESULTS: After controlling for multiple confounders, a linear dose-response relationship between maternal MF exposure level during pregnancy and the risk of having both asthma and AD in offspring was observed. Every one milligauss (mG) increase of maternal MF exposure was associated with 21 percent increased risk of having both asthma and AD diagnoses in offspring: adjusted hazard ratio (aHR)=1.21, 95% confidence interval (CI): 1.03-1.43. Using categorical measures also showed a statistically significant dose-response relationship (p=0.04).

CONCLUSIONS: In this large cohort study with rarely-available objectively measured MF exposure, maternal exposure to high MF levels during pregnancy is associated with an increased risk of having both asthma and AD allergic conditions in offspring. This finding suggests that MF exposure could impact the human immune system, especially the fetal immune system which may be especially vulnerable to the impact of MF non-ionizing radiation.

KEYWORDS: Magnetic fields, non-ionizing radiation, allergy

P-0251 Soil Health as a Determinant to Health of People: Example of Soil Trace Elements Deficiencies in Kintampo Area of Ghana and Their Implications to Some Non-Communicable Diseases

Latifatu Alhassan[1], Samuel Tchum[1], Kenneth Wiru[1], Charlotte Tawiah, Kwaku Poku Asante[1], Emmanuel Arhin[2]
[1]Kintampo Health Research Centre, Kintampo- Bono East, Ghana, [2]University of Energy and Natural Resources, Sunyani, Ghana

BACKGROUND: Selenium is a trace metalloid that is a natural constituent of many foods, and also available as a dietary supplement. Although excessive intakes of dietary Selenium may be harmful, insufficient intake of dietary Selenium may contribute to thyroid failure, cretinism, cardiomyopathy, immune dysfunction, bone defects, inflammation, male infertility, and probably increased risk of certain human cancers. Health trends relative to Selenium exposure have a connection with the amount of Selenium in soils derived from the underlying rocks.
AIMS: The study was aimed at determining Selenium geo availability in stream sediments in central Ghana and its implications on health.

METHODS: In this study, a total of 43 stream sediment samples were collected along streams using geographic information system to predetermine co-ordinates in the Kintampo area of Ghana. Concentration of Se and pH were determined. Degree of contamination, pollution load and geo-accumulation indices were calculated. Information was gathered on the health indices from health centers of communities.

RESULTS: Our findings showed that sandstones, shales, mudstones and phyllite rocks present have pH levels of 6.4 in the sediments formed over the parent rocks. Checks on the quality analysis indicated good assay repeatability among the duplicate pairs of sediment samples ($p = 0.31$). The geometric mean was 0.11 ppm for selenium. The analyzed results of all samples showed Se-deficiencies at over 80 % of the area (i.e. Se <0.2 mg/kg).
CONCLUSION: The study found almost the entire area to be deficient in selenium. This deficiency is feared to hamper the antioxidant role of dietary supplementation of selenium for the population as they eat what they grow. The health indices data obtained from the health facilities in the study area confirmed the presence of Se-related–diseases. This thus makes healthy eating not effective mechanism of preventing element-related-diseases.

KEYWORDS: Selenium; Soil Health; Non-Communicable Diseases

P-0252 Associations Between Minute-Level Smartphone-Derived Exposure to Walkability and Consumer Wearable-Derived Physical Activity in the US-based Nurses' Health Study 3 Cohort 2018-2020

Grete Wilt[1], Charlotte Roscoe[1,2], Cindy Hu[1], Brent Coull[3], Jaime Hart[1,2], Steven Gortmaker[4], Francine Laden[1,2], Peter James[1,5]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Department of Biostatics, Harvard T.H. Chan School of Public Health, Boston, USA, [4]Department of Social and Behavioral Sciences, Boston, USA, [5]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA

BACKGROUND AND AIM: Walkable environments have been linked to increased physical activity and improved health outcomes. However, most studies measure exposure based on residential address alone, not accounting for mobility patterns. We aimed to explore the association of smartphone mobility-derived walkability exposure and wearable-based physical activity in a group of US women.

METHODS: We quantified associations of minute observation level smartphone GPS-based walkability with daily Fitbit wearable accelerometry data. The NHS3 mhealth study followed 348 participants who completed four seasonal seven-day sampling periods. GPS points collected every 10 minutes were linked to a census tract-level walkability index calculated by a summed z-score of road intersection density from 2018 TIGER/Line shapefiles, 2018 Infogroup business density, and 2015-2019 5-year American Community Survey population density estimates. Mean Fitbit-derived steps per minute was calculated for each 10-minute period (n=639,364). Generalized Additive Mixed Models accounting for correlated data within individuals and enabling penalized splines were used to explore associations. We adjusted for GPS based socioeconomic status, daily GPS temperature and precipitation, satellite-based greenness in the 30m around each GPS point, and individual factors.

RESULTS: Mean minute-level walkability was 0.24 (SD = 3.07) and mean steps per minute was 7.04 (SD = 14.98). Associations were non-linear in nature, trending steeply upward and plateauing at the highest levels of walkability. We found an increase of 2.24 (95% CI: 1.40, 3.09) mean steps per minute for each 1-point increase in walkability scores from -1.66 to 5.50.

CONCLUSIONS: We used data at fine spatial-temporal scales to present novel estimates on time-intensive longitudinal associations between walkability and physical activity, while accounting for within- and between-participant differences. Participants were more likely to be physically active in more walkable areas, suggesting improvements in the built environment may improve health outcomes downstream of physical activity.

KEYWORDS: Wearables, Walkability, Physical Activity, Mixed Models

P-0254 Suicide and transportation noise: a prospective cohort study from Switzerland

Benedikt Wicki[1], Beat Schäffer[2], Jean-Marc Wunderli[2], Martin Röösli[1], Danielle Vienneau[1]
[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]Empa, Swiss Federal Laboratories for Materials Science and Technology, Dübendorf, Switzerland

BACKGROUND: Evidence for effects of transportation noise on mental health remains scarce, mainly due to a lack of high quality studies. Meanwhile, psychiatric diseases are among the most prevalent non-communicable diseases worldwide, and suicide as a mortality outcome presents a pressing public health issue. The aim of this study is to investigate the association between transportation noise and suicide, while adjusting for air pollution.

METHODS: Road traffic, railway and aircraft noise exposure as well as PM2.5 exposure were linked to 5.1 million participants 15 years or older in the Swiss National Cohort, accounting for their address history. Mean noise exposure in 5-year periods was calculated. Individuals were followed for up to 15-years (2001-2015). Time-varying Cox regression models were applied to total suicides and cause-specific suicide deaths. Models included all three noise sources, PM2.5 plus individual and spatial covariates including socio-economic status. Effect modification by sex was also explored.

RESULTS: During the follow-up, there were 11,265 suicide deaths. Road traffic and railway noise were associated with total suicides (Hazard ratio: 1.039 [95% CI: 1.015-1.064] and 1.022 [1.004-1.041] per 10dB Lden, respectively), while no significant association was found for aircraft noise. Associations were stronger for females than males. The pattern was robust across all outcomes, with the strongest association seen in non-violent suicides (poisoning: HR 1.122 [1.042-1.209] per 10dB Lden road traffic noise). No robust association was observed for PM2.5, whether adjusted for noise or separately.
CONCLUSION: In this longitudinal, nationwide cohort study, we report a robust association between exposure to road traffic and railway noise and an increased risk for death by suicide. These findings add to the growing body of evidence that mental health disorders may be related to transportation noise exposure.

KEYWORDS: road traffic, railway, aircraft, Lden, air pollution, mental health

P-0255 Using publicly available data to describe multiple environmental pressures and explore the link with end-stage renal disease.

Martin Paumelle[1], Florent Occelli[1,2,3], Caroline Lanier[1,2,3], Damien Cuny[1,3], Annabelle Deram[1,2,3]
[1]Univ. Lille, IMT Lille Douai, Univ. Artois, Yncrea Hauts-de-France - ULR4515 Laboratoire de Génie Civil et Géo-Environnement (LGCgE), Lille, France, [2]Faculté d'ingénierie et management de la santé (ILIS), Loos, France, [3]Faculté de pharmacie de Lille – Laboratoire de sciences végétales et fongiques (LSVF), Lille, France

End-stage renal disease (ESRD) is the final stage of chronic kidney disease, where renal function is highly impaired leading to the need of a long-term dialysis or a kidney transplant. Etiology of ESRD remains partly unknown and in particular the role of the environment. The objective of this work is to identify new etiological hypothesis related to the environment. The main argument supporting its influence is the spatial and temporal heterogeneity observed in ESRD incidence at various geographical scales.
Since 2005, in Northern France, newly detected ESRD cases are recorded in a health register called Nephronor. On this basis, standardized incidence ratios were calculated at the municipal level after being adjusted for age, sex, social deprivation and distance to dialysis centers. Using an isotonic spatial scan statistic, six significant spatial clusters were detected three of high incidence and four of low incidence.
In parallel, a complete environmental database was built using publicly available data. After an exhaustive inventory of existing data, the most appropriate databases were selected and a long data management process was achieved. Finally, more than one hundred variables were included and allocated in one of the six following dimensions: Contamination levels (air, water, soils), Emission levels, Source locations, Land use, Agricultural practices and Climate. Therefore, physical environment was described as completely as possible and for each dimension, a composite indicator was built at the municipal level. Each of these composite indicators were used to test etiological hypothesis, by comparing high-incidence with low-incidence ESRD spatial clusters. With this territorial approach, the ambition is not to demonstrate causal effects but rather to identify hypothesis that could be tested at the individual level in future epidemiological studies.

KEYWORDS: spatial composite indices, multiple environmental pressures, publicly available data, spatial heterogeneity of incidence, end-stage renal disease.

P-0256 Living and working close to sports facilities and physical inactivity and obesity: a cross-sectional study

Auriba Raza[1], Anna Pulakka[2], Linda Hanson[1], Hugo Westerlund[1], Jaana Halonen[1]
[1]Stockholm University, Stockholm, Sweden, [2]University of Oulu, Oulu, Finland

BACKGROUND: The majority of previous studies on the associations between proximity of physical activity facilities and behavior-related health have focused on proximity from home address, while studies on proximity from work address are scarce. We add to the literature by investigating associations for proximity of these facilities to work and home address and including different types of physical activity facilities.

METHODS: Aim was to assess the associations of proximity of physical activity facilities from home and work address with self-reported physical inactivity and obesity. The analytical sample of 7358 participants was from the 2018 wave of the Swedish Longitudinal Occupational Survey of Health. Log-binomial regression was used for analyses. Covariates included age, sex, education, civil status, individual and neighborhood socioeconomic status, number of children under 12 years of age, work strain, and chronic disease.

RESULTS: We observed that longer distance from home to the nearest paid outdoor physical activity facility was associated with physical inactivity (fully adjusted Relative Risk 1.08, 95% CI 1.00-1.16). However, associations of any, free outdoor or paid indoor facility with physical inactivity were not robust for covariate adjustments. There were associations between long distance from workplace to the nearest any, outdoor, free outdoor and paid outdoor facility and physical inactivity in age and sex adjusted models, however, associations were not robust to full adjustments. Results for obesity were in the same direction as for physical inactivity, however, these were not statistically significant.
CONCLUSION: Proximity Longer distance to paid outdoor physical activity facility from home was associated with physical inactivity. There was an indication that proximity to work address could be an additional determinant of physical activity behavior and obesity, however, longitudinal and larger studies are needed to confirm these findings.

P-0257 Built and Social Environment Exposures association with Obesity in Kaunas Citizens'

Sandra Andrusaityte[1], Regina Grazuleviciene[1], Audrius Dedele[1], Aurimas Rapalavicius[1,2]
[1]Department of Environmental Science, Vytautas Magnus University, Kaunas, Lithuania, [2]Department of Family Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania

BACKGROUND AND AIM: The evidence for social and environmental factors that contribute to obesity are often underappreciated. This Citizen science study examined the relationship between built and social environment exposures and obesity in men and women.

METHODS: The cross-sectional study included 1071 18-74-year-old Kaunas citizens. Using GIS, we measured the surrounding greenness exposure level of each home address as NDVI for the participants' home addresses. We used questionnaires to determine participants' social factors, physical activity, and environmental quality perception and linked this information with personal data of anthropometric measurements of height and weight. The health outcome was participants body mass index (BMI): normal weight (BMI 18.5-24.9 kg/m2), overweight (BMI> or = 25 kg/m2) and obesity (BMI > or =30.00 kg/m2). We used multivariate logistic regression to assess the associations between environmental issues and BMI in men and women.

RESULTS: 578 women and 493 men with a mean baseline BMI of 24.71 (SD 4.71) kg/m2 and 26.14 (SD 3.92) kg/m2, respectively, were studied. Recommended physical activity was low in men and women (15.5% and 14.3%, respectively). The prevalence of obesity was significantly higher among men with lower education, the adjusted OR 1.79, 95% CI 1.02-3.09, while among women obesity was associated with part-time work (OR 1.88, 95% CI 1.09-3.23) after adjusting for confounders. Green space-health associations were stronger for women than for men. Low surrounding greenness NDVI in the place of residence and irregular park visits tended to increase the risk for obesity in women.

CONCLUSIONS: Our results suggest that improving the social environment and city green spaces might reduce health problems for all.

P-0258 Street-View Greenspace Exposure and Measured Adiposity in Early Adolescence

Peter James[1,2], Esra Suel[3], Sheryl Rifas-Shiman[1], Perry Hystad[4], Andrew Larkin[4], Steven Hankey[5], Allan Just[6], Marie-France Hivert[1,7], Emily Oken[1,2], Marcia Jimenez[1,8]

[1]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA, [2]Harvard TH Chan School of Public Health, Boston, USA, [3]ETH Zurich, Zurich, Switzerland, [4]Oregon State University, Corvallis, USA, [5]Virginia Polytechnic Institute and State University, Blacksburg, USA, [6]Icahn School of Medicine at Mount Sinai, New York, USA, [7]Massachusetts General Hospital, Boston, USA, [8]Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: Research on greenspace and adiposity in adolescents is dominated by satellite-derived exposure measures and self-reported adiposity. Google Street View (GSV) images measure ground-level specific greenspace exposures, which may better capture pathways linking greenspace to adiposity. We examined GSV-based greenspace assessed in childhood and adolescence and research-measures of adiposity in adolescence in Project Viva, a cohort in eastern Massachusetts participating in the Environmental influences on Child Health Outcomes (ECHO) consortium.

METHODS: We applied deep learning algorithms to GSV images to derive novel metrics of visible greenspace within 250m of participant's residential addresses in 2007-2010 (mid-childhood, mean age 7.9y) and 2012-2016 (early adolescence, 13.2y). We calculated % total greenspace (combined % grass, % trees, % plants, % fields, and % flowers) within each image, and % grass and % trees separately. at in-person early adolescence research visits, trained research assistants assessed age- and sex-specific body mass index (BMI) z-scores, waist circumference, and dual-energy x-ray absorptiometry (DXA). We used linear regression to examine cross-sectional (adolescence) and longitudinal associations (mid-childhood to adolescent) between greenspace (per IQR) and adiposity, adjusting for child's sex, race/ethnicity, and age; mother's education, marital status, and pre-pregnancy BMI; father's education and BMI; household income; neighborhood median income, and population density.

RESULTS: In cross-sectional analyses (N=652), higher % grass was associated with lower BMI z-score (-0.13 (-0.25, - 0.01)); lower waist circumference (-1.38cm (-2.65, - 0.10)); and lower DXA total fat (-0.30 kg/m² (-0.67, 0.08)) and trunk fat (-0.14 kg/m² (-0.32, 0.04)). No cross-sectional associations were observed for % total greenspace or % trees. In longitudinal analyses (N=400), there was a suggestion that higher % grass was associated with lower waist circumference (-0.86cm (-1.98, 0.27)), but no other associations were present.

CONCLUSIONS: Street-view grass exposure was associated with lower measured adiposity among participants in early adolescence in cross-sectional analyses.

P-0259 Street-View Greenspace Exposure and Childhood Asthma-Related Outcomes: Analyses in Project Viva

Pi-i Debby Lin[1], Marcia Jimenez[1,2], Esra Suel[3], Sheryl Rifas-Shiman[1], Perry Hystad[4], AndrewLarkin[4], SteveHankey[5], Allan Just[6], Marie-France Hivert[1,7], Emily Oken[1,8], Peter James[1,9]

[1]Division of Chronic Disease Research Across the Lifecourse, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA, [2]Department of Epidemiology, Boston University School of Public Health, Boston, USA, [3]Faculty of Medicine, School of Public Health, Imperial College London, London, UK, [4] College of Public Health and Human Sciences, Oregon State University, Corvallis, USA, [5]School of Public and International Affairs, Virginia Polytechnic Institute and State University, Blacksburg, USA, [6]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York City, USA, [7]Diabetes Unit, Massachusetts General Hospital, Boston, USA, [8]Department of Nutrition, Harvard T.H. Chan School of Public Health, Boston, USA, [9]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: While higher levels of greenspace can mitigate air pollution, reduce stress, and increase physical activity, its role in childhood asthma is unclear. The aim of this study is to examine the associations of neighborhood greenspace based on Google street view (GS) images with asthma-related measures among children in Project Viva, a cohort in eastern Massachusetts participating in the Environmental influences on Child Health Outcomes (ECHO) consortium.

METHODS: We leveraged GSV images from 2007 to 2011 within 250m of participants' home addresses at mid-childhood and applied deep learning algorithms to derive unique metrics of ground-level greenspace exposure. We calculated total greenspace exposure, which combined %grass, %trees, %plants, %fields, and %flowers within each image. Mothers reported the child's asthma status in mid-childhood (median 7.7 yr) and early adolescence (median 12.7 yr). Trained research assistants performed lung function tests (FEV1 and FVC) using spirometry and collected blood for total serum IgE measurement. We constructed linear and logistic regression models to examine associations of neighborhood greenspace with these asthma-related outcomes adjusting for child's sex, race/ethnicity, age at outcome, maternal and paternal education, marital status and household income (at enrollment), and census tract level household income and urbanicity (at delivery).

RESULTS: In adjusted cross-sectional analyses (N=486), each interquartile range increase in total greenspace was associated with lower FEV1 (-44.7 mL [95% CI: -82.7, -6.64]) and higher total IgE (56.4 kU/L [95% CI: 0.86, 112]). Similar associations were observed for %tree but not for %grass. Greenspace was not associated with asthma status cross-sectionally in mid-childhood. There were no longitudinal associations between any greenspace measures in mid-childhood and any asthma-related outcomes in early adolescence (N=414).

CONCLUSIONS: We observed cross-sectional but not longitudinal associations between GSV-based greenspace with FEV1 and total serum IgE in adverse directions and found no association between greenspace and asthma status.

P-0260 Urban Heat Islands and Heat-Related Cardiovascular Morbidity Among Adults Aged 65+ in US Metropolitan Areas

Stephanie Cleland[1,2], Lucas M. Neas[3], Ana G. Rappold[3]
[1]ORISE at US Environmental Protection Agency, Research Triangle Park, USA, [2]University of North Carolina at Chapel Hill, Chapel Hill, USA, [3]US Environmental Protection Agency, Research Triangle Park, USA

BACKGROUND AND AIM: Extreme heat increases the risk of hospitalization due to cardiovascular disease (CVD). The USA (US) population largely resides in urban areas where climate change is projected to increase temperatures, yet little is known about this association across urban heat islands (UHIs). We aimed to identify the urban populations most at risk of and burdened by heat-related CVD morbidity.

METHODS: We obtained daily counts of CVD hospital admissions (HAs) for Medicare enrollees (aged 65+) in 120 metropolitan areas (MSAs) in the contiguous US between 2000-2017. Daily average temperatures were estimated through the interpolation of monitor observations. A measure of UHI intensity was estimated from satellite-derived temperatures in urban vs. non-urban areas. We used quasi-Poisson regression with distributed-lag, non-linear models to estimate MSA-specific associations and pooled these estimates with multivariate meta-analyses. Stratified analyses were performed by UHI intensity quartile. We also calculated the number of CVD HAs attributable to heat in each MSA.

RESULTS: Overall, extreme heat (99th percentile, ~28.6°C) was associated with a 3.0% [1.4%, 4.6%] increase in CVD HA risk relative to the minimum hospitalization temperature (MHT) (91st percentile, ~25.4°C). MSA-specific risks showed substantial differences, with higher risk in MSAs with lower annual average temperatures. We estimate that 1.6% (31,498) of CVD HAs on days above the MHT were attributable to heat. Although the interquartile risk differences were not significant, the highest quartile of UHI intensity was responsible for 47% (14,636) of all heat-attributable CVD HAs.

CONCLUSIONS: Our results show that extreme heat increases the risk of CVD HAs among older adults in US urban areas, with considerable variation between cities. Areas with higher UHI intensity had the highest heat-related burden, indicating a potentially vulnerable subset of the urban population. This abstract does not necessarily reflect EPA policy.

P-0262 The Impact of Residential Greenness on Psychological Distress among Hurricane Katrina Survivors

Kate Burrows[1], Kelvin C. Fong[2], Sarah Lowe[3], Elisabeth Fussell[1], Michelle L. Bell[3]
[1]Brown University, Boston, USA, [2]Dalhousie University, Halifax, Canada, [3]Yale University, New Haven, USA

KEYWORDS: green space, mental health, disasters, extreme weather

BACKGROUND: Hurricanes are potentially traumatic events that can produce long-lasting health issues for survivors. Research shows that neighborhood-level social features, such as social and economic capital, are associated with lower risk of mental disorders among survivors. However, to our knowledge, there is no work assessing the impact of neighborhood-level environmental features, such as greenness. We hypothesize that, like community social features, the salutary effects of environmental features may modify recovery among disaster-affected populations.

METHODS: We used data from the Resilience in Survivors of Katrina Study, a cohort assembled in 2004-2005 (time 0 [T0]) of low-income parents in New Orleans, Louisiana, USA, most of whom later experienced Hurricane Katrina. We obtained data on psychological distress (Kessler [K]-6 scores), sociodemographics, and hurricane exposure for 214 participants who were interviewed again in 2006-2007 (T1) and in 2016-2018 (T2). We assessed greenness using average growing season Normalized Difference Vegetation Index (NDVI) in 300-m buffers around participants' homes at each timepoint and estimated neighborhood concentrated disadvantage (a common composite metric for neighborhood-level socioeconomic status) at the Census tract-level. We assessed the impact of residential greenness on psychological distress among Katrina survivors using adjusted linear regressions with sandwich clustering.

RESULTS: Preliminary results found that residential greenness was not significantly associated with distress at any time point. However, moving to a greener neighborhood immediately after Katrina (T1) was associated with a reduction in K6 scores, indicating lessened psychological distress (-1.43 [95% CI: -2.82, -0.04]) compared to moving to a neighborhood with the same or lower greenness. We found similar but non-significant associations at T2.
DISCUSSION: In this disaster-affected population, moving to a greener neighborhood was associated with reduced psychological distress in the short term. These findings suggest that neighborhood environmental features may provide temporary health benefits for disaster survivors.

P-0263 Dwelling type and risk of chronic obstructive lung disease

Stine Kloster[1], Anne Marie Kirkegaard[1,2], Michael Davidsen[1], Anne Illemann Christensen[1], Jørgen Vestbo[3], Niss Skov Nielsen[2], Lars Gunnarsen[2], AnnetteKjær Ersbøll[1]

[1]National Institute of Public Health, University of Southern Denmark, Copenhagen, Denmark, [2]Department of the Built Environment, Aalborg University, Copenhagen, Denmark, [3]Division of Infection, Immunity and Respiratory Medicine, University of Manchester, Manchester, UK

BACKGROUND AND AIM: Previous research has shown an association between dwelling type and chronic obstructive lung disease (COPD). However, existing research has primarily been based on cross-sectional data making the temporal relation between dwelling type and COPD uncertain. The temporal relation is of importance since people with existing COPD might move into a more COPD friendly type of dwelling (e.g., without stairs) or move due to consequences of their COPD (e.g., financial strains). Hence, we aimed to test the hypothesis that dwelling type was associated with risk of developing COPD.

METHODS: We performed a cohort study of participants who replied to the Danish Health and Morbidity survey in 2000. Participants were followed from inclusion in 2000 until end of 2018 for incident COPD based on information from the Danish National Patient Register and the Danish National Prescription Registry. Incidence rate ratios (IRR) of COPD with 95% confidence intervals (CI) were estimated using Poisson Regressions of incidence rates (IR). Analyses were adjusted for construction-year, urbanization, educational level, age, sex, smoking status and calendar year.

RESULTS: A total of 12,054 participants, free of COPD at inclusion, were included. Most participants lived in detached houses (56%) whereas 17%, 16% and 11 % lived in semi-detached houses, apartments, or other dwelling types, respectively. A total of 1,078 developed COPD during follow-up corresponding to an overall IR of COPD at 8.6. The IRR was 1.45 (95% CI: 1.21-1.73), 1.51 (95% CI: 1.26-1.81), 1.14 (95% CI: 0.86-1.52) and 1.45 (95%: CI 0.81-2.59) for people living in semi-detached houses, apartments, farms and others dwelling types, respectively, as compared to people living in detached houses.

CONCLUSIONS: The IR of developing COPD was significantly higher among participants living in semi-detached houses and in apartments as compared to participant living in detached houses.

KEYWORDS: Dwelling type; COPD; Cohort study

P-0265 The association between perceived annoyances in the indoor environment at home and respiratory infections: A Danish cohort study with up to 19 years of follow-up

Anne Marie Kirkegaard[1,2], Stine Kloster[1], Michael Davidsen[1], Anne Illemann Christensen[1], Jørgen Vestbo[3], Niss Skov Nielsen[2], Annette Kjær Ersbøll[1], Lars Gunnarsen[2]

[1]National Institute of Public Health, University of Southern Denmark, Copenhagen, Denmark, [2]Department of the Built Environment, Aalborg University, Copenhagen, Denmark, [3]Division of Infection, Immunity and Respiratory Medicine, University of Manchester, Manchester, UK

BACKGROUND AND AIM: The relation between perceptions of environment and respiratory infections has been studied by few and with inconsistent findings. Exposure to environmental contaminants may trigger the onset of respiratory infections, either directly or indirectly via annoyance. Perceived annoyance at home caused by the indoor environment is reported by 28% of Danish adults. This study aims to investigate the rate of respiratory infections for individuals exposed to perceived annoyance from the indoor environment, stratified by chronic respiratory disease.

METHODS: A total of 16,688 individuals completed a questionnaire and were interviewed to the Danish Health and Morbidity Survey in 2000. We grouped all eligible individuals based on whether they perceived a low, medium or high annoyance from their home indoor environment by latent class analysis of 13 items. The items covered sensory annoyance and discomfort by the indoor air, lighting, acoustics, and thermal comfort. Participants were followed for respiratory infections in Danish registers, until they met the criteria for censoring or end of study (1/1/2019). Poisson regressions of incidence rates were applied to estimate incidence rate ratios (IRRs) with 95% confidence intervals (CIs) for respiratory infections for each group of perceived annoyance.

RESULTS: We observed a significantly increased incidence of respiratory infections with increasing perceived annoyance. The highest IRR of respiratory infections was in the group with high perceived annoyance (adjusted IRR: 1.13, 95% CI: 1.07-1.20) and progressive decreases among the medium annoyance group (adjusted IRR: 1.05, 95% CI: 1.00-1.10) compared with low annoyance (reference).

CONCLUSIONS: We observed a significant dose-response relationship between the level of perceived annoyance and respiratory infections.

P-0266 Predictors of perceived neighbourhood comfort in urban and suburban areas in Finland

Tytti Pasanen[1], Timo Lanki[1], Taina Siponen[1], Anu W. Turunen[1], Pekka Tiittanen[1], Vuokko Heikinheimo[2], Maija Tiitu[2], Arto Viinikka[2], Jaana Halonen[3]

[1]Finnish Institute for Health and Welfare (THL), Kuopio, Finland, [2]Finnish Environment Institute (SYKE), Helsinki, Finland, [3]Finnish Institute for Health and Welfare (THL), Helsinki, Finland

BACKGROUND AND AIM: The quality of residential environment, or, neighbourhood, is one determinant of overall quality of life. International studies have observed that neighbourhood perceptions are associated with socio-demographic and dwelling-related factors, and subjective and objective neighbourhood qualities such as safety or low noise levels. However, only a few studies have examined all these attributes at once and assessed the role of inclusion in neighbourhood decision-making processes; these were the aims of this study.

METHODS: A survey was conducted among adults (aged 18-97) in urban centres and suburbs in five Finnish cities (n=2057; response rate 34%) in 2021. Ordinal mixed regression models (using the latent probit link function) were specified to assess the importance of socio-demographic, dwelling, and neighbourhood attributes for perceived neighbourhood comfort.

RESULTS: Almost 80% of the respondents perceived their neighbourhood as comfortable or very comfortable. Apart from age and relationship status, socio-demographic factors were not associated with perceived neighbourhood comfort. Concerning dwelling, neighbourhood comfort was related to being satisfied with the dwelling (vs unsatisfied/neither: b=.77), having a green view and looking at it often (vs seldom/no green view: b=.48) or sometimes (b=.16), and living in a detached house (vs a flat: b=.27). of subjective neighbourhood attributes, the strongest predictors of neighbourhood comfort were being satisfied (vs unsatisfied/neither) with neighbourhood safety (b=.66), green areas (b=.40), blue areas (b=.32) and maintenance of traffic routes (b=.31); and good/very good (vs poor/very poor) possibilities to influence the decisions regarding the neighbourhood (b=.42).

CONCLUSIONS: Supporting previous studies, perceived neighbourhood comfort was most strongly explained by satisfaction with dwelling and neighbourhood qualities -especially safety and natural environments- and, as a novel result, being able to influence neighbourhood decisions. In upcoming analyses, we will add objective neighbourhood attributes and examine whether selected factors moderate these relationships.

KEYWORDS: neighbourhood satisfaction, suburbs, green space, residential satisfaction

P-0267 Exposure to artificial light-at-night and cardiometabolic health: an urban perspective from the Catalan GCAT cohort study

Anna Palomar-Cros[1,2], Ana Espinosa[1,2,3,4], Salva Bará[5], Alejandro Sánchez de Miguel[6,7], Antonia Valentín[1,2,3], Marta Cirach[1,2,4], Gemma Castaño-Vinyals[1,2,3,4], Kyriaki Papantoniou[8], Beatriz Cortés[9], Anna Carreras[9], Natàlia Blay[9], Rafael del Cid[9], Dora Romaguera[1,10,11], Manolis Kogevinas[1,2,3,4], Barbara N Harding[1]

[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Department of Experimental and Health Sciences, Universitat Pompeu Fabra (UPF), Barcelona, Spain, [3]IMIM (Hospital del Mar Medical Research Institute), Barcelona, Spain, [4]Consortium for Biomedical Research in Epidemiology and Public Health (CIBERESP), Institute of Health Carlos III, Madrid, Spain, [5]A. Astronómica 'Ío', Coruña, Spain, [6]Environment and Sustainability Institute, University of Exeter, Penryn Campus, Cornwall, UK, [7]Departamento Física de la Tierra y Astrofísica, Universidad Complutense de Madrid, Spain, [8]Department of Epidemiology, Centre of Public Health, Medical University of Vienna, Vienna, Austria, [9]Genomes for Life-GCAT Lab, Institute for Health Science Research Germans Trias i Pujol (IGTP), Badalona, Spain, [10]Health Research Institute of the Balearic Islands (IdISBa), Palma de Mallorca, Spain, [11]CIBER Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Madrid, Spain

BACKGROUND AND AIM: It has been suggested that artificial light-at-night (ALAN) exposure may lead to metabolic disturbances through circadian misalignment and sleep disruption. The present study investigated associations between residential outdoor ALAN exposure and cardiometabolic risk factors and disease outcomes.
METHODS: We used data from 9,752 participants (59% women) in the Genomes for Life (GCAT) cohort study in Barcelona. Residential ALAN was assessed from images of the International Space Station with a 30m resolution. We estimated the visually relevant photopic illuminance and the metabolic and circadian-regulation relevant melanopic equivalent daylight (D65) illuminance, in lux. We examined cross-sectional associations between ALAN and cardiometabolic risk factors (obesity, glycaemia and hypertension). During a mean follow-up time of 2.5 years (SD 0.97) we prospectively assessed, in 5,743 participants, incident diseases (angina pectoris, myocardial infraction, stroke, diabetes, hypercholesterolemia and hypertension) ascertained through electronic health records. We adjusted our main models for demographic characteristics and further adjusted for greenness density and air pollution.
RESULTS: In cross-sectional analyses we found an association between photopic and melanopic Illuminances and hypertension, OR = 1.15 (95% CI 1.03-1.29) and 1.58 (1.08-2.32), per unit increase; associations remained stable after adjusting for other urban exposures. The association between illuminances and obesity was less consistent across adjustments. In incident analyses, photopic and melanopic illuminances were associated with hypercholesterolemia, OR = 1.94 (1.06-3.55) and OR = 1.30 (1.09-1.55), respectively. We had limited power, due to few incident cardiovascular events, and did not observe an association between ALAN and cardiovascular diseases nor diabetes.
CONCLUSIONS: The present study suggests an association between photopic and melanopic illuminance at night and risk of hypertension and hypercholesterolemia, key risk factors for cardiometabolic diseases. Results should be interpreted carefully since satellite-based ALAN assessment, even in high resolution, estimates individual exposure only partially.

KEYWORDS:
Light-at-night, circadian misalignment, hypercholesterolemia, hypertension, cardiovascular, obesity

P-0269 Associations Between Hospital Readmissions and Proximity to Brownfields in North Carolina

Nahnsan Guseh[1], Joshua Moyer[1], Lucas Neas[1], Cavin Ward-Caviness[1]
[1]*US Environmental Protection Agency, Chapel Hill, USA*

BACKGROUND: Contaminated sites known as brownfields contribute to air, water, and land pollution and also prevent the beneficial use of lands by the community. The health effects surrounding brownfields have been understudied which can impair efforts to quantify the benefits of their remediation.

METHODS: Our study cohort was composed of 21,776 heart failure patients diagnosed between 2004 and 2016 at a University of North Carolina Healthcare System affiliated hospital or clinic. We examined the associations between brownfields and hospital readmissions. We used proximity to the nearest brownfield as our exposure based on the primary residence at the time of heart failure diagnosis. Zero-inflated Poisson models were used to associate distance to the nearest brownfield with readmissions while adjusting for age, race, sex, and socioeconomic status indicators based on the 2010 US Census. In sensitivity analyses we examined log transformed distance, restricted to only those brownfields within 2 km of an individual, and further adjusted for county-level indicators of access to healthcare.

RESULTS: A 1 km increase in distance to the nearest brownfield was associated with a 1.29% (95% confidence interval = 0.43-2.14%) decrease in 7-day readmissions as well as a 0.55% decrease (95% confidence interval = 0.20-0.90%) in 30-day readmissions. Associations with 7-day readmissions remained when restricting to brownfields within 2km, in the log-transformed distance models, and after adjusting for county-level indicators of access to healthcare. Associations with 30-day readmissions were substantially attenuated under all sensitivity analyses.
CONCLUSION: Proximity to brownfields is associated with increases in hospital visits and readmissions among heart failure patients. These associations may reflect exposure to chemicals present in the brownfields as well as land disinvestment. Understanding the health risks surrounding brownfields may help communities to better protect their environmental health. This abstract does not necessarily represent the views or policies of the US EPA.

P-0270 Associations of greenness, public parks, and blue space with cardiovascular and respiratory disease hospitalization in the US Medicare cohort

Jochem Klompmaker[1,2], Francine Laden[1,2], Matthew Browning[3], Francesca Dominici[1], S Ogletree[4], Alessandro Rigolon[5], Jaime Hart[1,2], Peter James[1,6]

[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Brigham and Women's Hospital, Boston, USA, [3]Clemson University, Clemson, USA, [4]University of Edinburgh, Edinburgh, UK, [5]The University of Utah, Salt Lake City, USA, [6]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA

BACKGROUND AND AIM: Natural environments have been linked to decreased risk of cardiovascular disease (CVD) and respiratory disease (RSD) mortality. However, few cohort studies have looked at associations of natural environments with CVD or RSD hospitalization. Our aim was to evaluate these associations in a cohort of U.S. Medicare beneficiaries (~63 million individuals).

METHODS: Our open cohort included all fee-for-service Medicare beneficiaries (2000-2016), aged ≥65, living in the contiguous U.S. We assessed zip code-level average greenness (Normalized Difference Vegetation Index, NDVI), public park cover based on the USA Geological Survey Protected Areas Database, and percent blue space cover based on Landsat satellite images. Cox-equivalent Poisson models were used to estimate associations of the exposures with first CVD and RSD hospitalization in the full cohort and among those living in urban zip codes (≥1000 persons/mile2).

RESULTS: NDVI was weakly negatively correlated with percent public park cover (Spearman ρ = -0.23) and not correlated with percent blue space (Spearman ρ = 0.00). After adjustment for potential confounders, an IQR (0.27) increase in NDVI was negatively associated with CVD (HR: 0.97, 95%CI: 0.96, 0.97), but not with RSD hospitalization (HR: 0.99, 95%CI: 0.98, 1.00). In urban zip codes, an IQR increase in NDVI was positively associated with RSD hospitalization (HR: 1.02, 95%CI: 1.00, 1.03). Percent public park cover was not associated with CVD or RSD hospitalization in the full or urban population. In stratified analyses, percent public park cover was negatively associated with CVD and RSD hospitalization for Medicaid eligible individuals and individuals living in low socioeconomic status neighborhoods in the urban population. We observed no associations of percent blue space cover with CVD or RSD hospitalization.

CONCLUSIONS: This study suggests that natural environments may benefit cardiorespiratory health; however, benefits may be limited to certain contexts and certain health outcomes.

P-0271 Urban green spaces and suicide mortality in Belgium (2001-2011): a census-based longitudinal study

Hilbert Mendoza[1], Lucia Rodriguez Loureiro[2], Sylvie Gadeyne[2], Mariska Bauwelinck[2], Wouter Lefebvre[3], Charlotte Vanpoucke[4], Lidia Casas[1,5]

[1]University of Antwerp, Belgium, [2]Vrije Universiteit Brussel, Belgium, [3]Vlaamse Instelling voor Technologisch Onderzoek, Belgium, [4]Belgian Interregional Environment Agency, Belgium, [5]Institute for Environment and Sustainable Development, Belgium

BACKGROUND:
Exposure to green spaces is associated with improved mental health and may reduce the risk of suicide. Here, we investigate the association between long-term exposure to residential surrounding greenness and suicide mortality.
METHODS: We used data from the 2001 Belgian census linked to mortality register data (2001-2011). We included individuals aged 18 years or older at baseline (2001) and residing in the five largest urban areas in Belgium (n=3,549,514). Suicide mortality was defined using ICD-10 codes X60-X84, Y10-Y34, and Y870. Surrounding greenness was measured using the Normalized Difference Vegetation Index (NDVI) within 300m and 1,000m buffers around the residential address at baseline. To assess the association between residential surrounding greenness and suicide mortality, we applied Cox proportional hazards models with age as the underlying time scale. Models were adjusted for age, sex, marital status, migrant background, educational attainment, neighbourhood socio-economic position. We additionally explored potential mediation with residential outdoor nitrogen dioxide (NO2) concentrations. Associations are expressed as hazard ratios (HR) and their 95% confidence intervals (CI) for an interquartile range (IQR) increase in residential surrounding greenness.
RESULTS: Between 2001 and 2011, 8,577 suicide deaths were registered. We observed a 7% (95%CI 0.89-0.97) and 6% (95%CI 0.90-0.98) risk reduction of suicide mortality for an IQR increase in residential surrounding greenness for buffers of 300m and 1,000m, respectively. Furthermore, this association was independent of exposure to NO2. After stratification, the inverse association was only apparent among females, and residents of Belgian origin, and that it was stronger among residents aged 36 or older, those with high level of education, and residents living in socio-economic deprived neighborhoods.
CONCLUSION:
Our results suggest that urban green spaces may protect against suicide mortality, but this beneficial effect may not be equally distributed across all strata of the population.

P-0272 Effects of greenness, public parks, and blue space on neurodegenerative disease hospitalizations in the US Medicare cohort

Jochem Klompmaker[1,2], Francine Laden[1,2], Matthew Browning[3], Francesca Dominici[1], Marcia Jimenez[4], S Ogletree[5], Alessandro Rigolon[6], Antonella Zanobetti[1], Jaime Hart[1,2], Peter James[1,7]

[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Clemson University, Clemson, USA, [4]Boston University, Boston, USA, [5]University of Edinburgh, Edinburgh, UK, [6]The University of Utah, Salt Lake City, USA, [7]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA

BACKGROUND AND AIM: Exposure to natural environments has been associated with health outcomes that are related to neurological disorders. However, the few studies that examined associations of natural environments with neurological disorders reported mixed findings. Our goal was to evaluate associations of multiple features of natural environments with Alzheimer's disease and related dementia's (ADRD) and Parkinson's disease (PD) hospital admissions.

METHODS: We created an open cohort including all fee-for-service Medicare beneficiaries aged 65+, who lived in the contiguous US January 1, 2000 through December 31, 2016 (~63 million individuals). Zip code level greenness (Normalized Difference Vegetation Index, NDVI), percent public park cover, and percent blue space cover (≥1 % cover vs. <1% cover) were assessed. We examined associations of these exposures with first ADRD or PD hospitalizations based on primary or secondary discharge diagnosis, using a novel Cox-equivalent Poisson model. We also assessed if associations varied by demographics and area-level socioeconomic status.

RESULTS: We observed 7,910,111 and 1,196,981 first ADRD and PD hospitalizations, respectively. After adjustment for potential individual- and area-level confounders, NDVI was negatively associated with ADRD hospitalization (HR=0.95, 95%CI: 0.94-0.96, per IQR increase). Percent public park cover and blue space cover were not associated with ADRD hospitalization. for PD hospitalization, we observed negative associations of NDVI (HR=0.94, 95%CI: 0.93-0.95, per IQR), percent public park cover (HR=0.97, 95%CI: 0.97-0.98, per IQR), and blue space cover (HR=0.97, 95%CI: 0.96-0.98, ≥1% v. <1%). Patterns of effect modification by demographics differed between the exposures. for example, for PD hospitalization, negative associations of NDVI were strongest in the mid and high SES neighbourhoods, while negative associations of percent public park cover were strongest in the low SES neighbourhoods.

CONCLUSIONS: Features of natural environments are associated with a decreased risk of ADRD and PD hospitalization in this cohort of US-based older adults.

P-0274 School and residential green- and bluespace and academic performance in Polish schoolchildren with and without attention deficit hyperactivity disorder

Nitika Singh[1], Clemens Baumbach[1], Dorota Buczyłowska[1], Jakub Bratkowski[2], Yarema Mysak[1], Maja Wierzba-łukaszyk[1], katarzyna Sitnik-warchulska[3], Krzysztof Skotak[2], Małgorzata Lipowska[3,4], Bernadetta Izydorczyk[1], Marcin Szwed[1], Iana Markevych[1]

[1]Institute of Psychology, Jagiellonian University, Krakow, Poland, [2]Institute of Environmental Protection-National Research Institute, Warsaw, Poland, [3]Faculty of Management and Social Communication, Institute of Applied Psychology, Jagiellonian University, Krakow, Poland, [4]Institute of Psychology, University of Gdansk, Gdansk, Poland

BACKGROUND: Some ecological studies, mainly in the USA, reported that school greenspace is associated with better academic performance. Based on individual data, we investigated whether exposure to school and residential green- and bluespace can improve the academic performance of Polish schoolchildren.

METHODS: NeuroSmog is a case-control study currently being conducted to investigate the impact of air pollution on brain development of children with and without attention deficit hyperactivity disorder (ADHD) in Poland. Cases were recruited by study field psychologists, while controls were randomly recruited from schools across 18 towns in southern Poland. The analytic sample for the current analysis consists of 339 10 to 13-year-old children. Polish and maths grades are reported by parents, while perceived performance in these subjects is reported by children. Tree, grass, and water cover were abstracted in 500 and 1000m Euclidean buffers around residential addresses and school. Age, gender, mother's education, and financial status were selected as confounders by Directed Acyclic Graph. Adjusted logistical models were used to evaluate the associations.

RESULTS: We did not find any consistent associations between academic performance and residential or school green- and bluespace. This held true for population subsample and children with ADHD.

CONCLUSIONS: Residential and school green and bluespace do not boost academic performance in Polish schoolchildren. More studies on individual data and from different countries are needed to confirm this finding.

P-0275 Biophilia and “Body-Philia": Does positive body image change due to short visits in outdoor green environments?

Reem Mohsen[1], Itamar Lensky[2], Keren Agay-Shay[1]

[1]The Health Environment Research-HER lab, Department of Population Health, Azrieli Faculty of Medicine, Bar-Ilan University, Tzfat, Israel, [2]Department of Geography and Environment, Faculty of Social Sciences, Bar-Ilan University, Ramat -Gan, Israel

BACKGROUND: Mounting evidence suggests that exposure to natural environments has beneficial effects on positive emotion, but less is known about the effects on positive body image and on the beneficial effects of green walls.
Aim: The aim of the study is to examine the effects of short visits to different outdoor environments on positive body image.

METHODS: We recruited 200 healthy adult participants (139 women) and conducted a quasi-experimental study using within-subjects design. We examined the effect of short visits to randomly assigned ordered outdoor environments (green wall, small green garden and gray wall), as compared to baseline indoor environment on: mean positive body image, evaluated by SBAS-2 (State Body Appreciation Scale) and changes in sum of positive and negative emotions evaluated by PNAS (Positive and Negative Affect Schedule). The differences were examined using a repeated nonparametric Friedman test and any significant difference between environments was further explored using post hoc analysis with Wilcoxon signed-rank test, with Bonferroni correction.

RESULTS: The median of positive body image in the small garden environment [4.0, Inter Quartile Range (IQR):3.1- 4.74] and the green wall [3.9, IQR:3.08- 4.63] were higher compared to the gray wall [3.7, IQR:3.0 - 4.23] and to the indoor environment [3.7, IQR:2.8 - 4.53], [$X2(3) = 44.27$, $p < 0.00$]. for positive emotions, a higher but not significantly different sum was observed for small garden and green wall ([29, IQR: 23 to 35] and [28, IQR:21 to 34], respectively), and significantly higher compared to gray wall [25, IQR:20 to 31], [$X2(3) = 70.453$, $p < 0.00$]. for negative emotion, there was no significant differences between the environments.

CONCLUSIONS: Short visits to outdoor green environments compared to non-green, or indoor environments, raises participants’ body appreciation and positive emotions.

KEYWORDS: Positive body image, Positive and negative emotions, Green environment, Green vertical wall

P-0276 Walkability and Physical Activity in Nurses' Health Study 3 with Measurement Error Correction Using Smartphone Mobility Data

Grete Wilt[1], Charlotte Roscoe[1,2], Cindy R. Hu[1], Brent Coull[3], Jaime E Hart[1,2], Steven Gortmaker[4], Francine Laden[1,2], Peter James[1,5]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, USA, [4]Department of Social and Behavioral Sciences, Boston, USA, [5]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA

BACKGROUND AND AIM: Studies of walkability and physical activity often rely on residential measures that omit exposures occurring in other environments, likely leading to exposure misclassification. We measurement-error corrected traditional residential walkability measures using smartphone mobility-based walkability estimates and examined its association with self-reported physical activity in a US-based cohort.

METHODS: We calculated typical minutes per week spent walking and running from Nurses' Health Study 3 (NHS3) participants using validated physical activity questionnaires (n=23,983). We spatially joined residential addresses to census tract-level walkability, calculated by summing z-scores of 2018 TIGER/Line road intersection density; 2018 Infogroup business density; and 2015-2019 5-year American Community Survey population density estimates. A subset of NHS3 (n=337) provided smartphone GPS data every 10 minutes across four 7-day sampling periods that captured seasonal variability, which was used to create our 'gold standard' walkability exposure. We used standard regression calibration for generalized linear models to produce corrected estimates and 95% confidence intervals for associations of walkability with physical activity in the full NHS3, adjusting for confounders.

RESULTS: Participants reported on average 273.15 minutes of physical activity per week (SD = 257.00), had a mean residential walkability score of 0.03 (SD=2.64), and had a mean GPS based walkability score of 0.36 (SD=2.39). Each SD increase in uncorrected residential walkability was associated with a 7.95-minute increase in time spent walking and running per week (95% CI; 3.83, 12.08), whereas each SD increase in measurement error corrected walkability was associated with a 10.80-minute increase in time spent walking and running per week (95% CI: 4.96, 16.64).

CONCLUSIONS: Our study indicates that traditional residential estimates of walkability may underestimate associations between walkability and physical activity. These findings highlight the impact of exposure misclassification on epidemiological studies of physical activity and the built environment.

P-0277 Relations of Residential Greenness with Markers of Immunity and Inflammation in the Green Heart Study

Daniel Riggs[1], Marina Malovichko[1], Ray Yeager[1], Clara Sears[1], Israel Sithu[1], Hong Gao[1], Rachel Keith[1], Sanjay Srivastava[1], Aruni Bhatnagar[1]

[1]*Christina Lee Brown Envirome Institute, University of Louisville, Louisville, USA*

BACKGROUND AND AIM: Exposure to vegetation has been linked with long-term health benefits, including reduced risk of mortality, reduced cardiovascular disease, and improved mental health. However, the underlying mechanistic pathways remain poorly understood, and few studies have explored the relationship between greenness with markers of inflammation. Therefore, we examined the associations between residential greenness with circulating levels of inflammatory biomarkers and immune cells.

METHODS: We recruited adult participants, aged 20-70 years, from a neighborhood in Louisville, KY during the summer months of 2018 and 2019. A complete blood count panel, cytokines, and immune cells were measured in 606 participants at baseline. Surrounding greenness was assessed from Sentinel-2 satellite data by Normalized Difference Vegetation Index (NDVI) and by leaf area, within 100m and 500m buffers. To estimate associations between greenness and log-transformed outcomes we fit linear regression models adjusting for socio-demographic and behavioral risk factors.

RESULTS: Higher levels of all greenness metrics were associated with lower hsCRP, ranging from -10.6% to -17.7% lower levels of hsCRP per IQR higher greenness. Leaf area within a 100m radius was inversely associated with TNF-α (-4.0% per IQR; 95% CI: -7.3% to -0.5%), MIP-1α (- 5.65% per IQR, 95% CI: -10.93% to -0.04%), MIP-1β (-7.3% per IQR; 95% CI: -12.7% to -1.6%), while IL-6 was inversely associated within a 500m radius (-6.6%; 95% CI: -12.2% to -0.6%). In our analysis of immune cells, we found consistent inverse associations with white blood cell counts, B-cells, and monocytes with multiple metrics of greenness. Natural killer T-cells were positively associated with leaf area within a 500m radius (7.0% per IQR; 95% CI: 0.5% to 13.9%).

CONCLUSIONS: Residential greenness may lower levels of inflammation and improve immune responses that could be beneficial to cardiovascular health.

P-0278 Unintended impacts of the Open Streets program on noise complaints in New York City

Jaime Benavides[1], S.T. Rowland[1], Jeff Goldsmith[2], M-A. Kioumourtzoglou[1]
[1]Dept. of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York City, USA, [2]Dept. of Biostatistics, Columbia University Mailman School of Public Health, New York City, USA

BACKGROUND AND AIM: Exposure to high levels of environmental noise and noise annoyance have been associated with detrimental health outcomes. In 2012, a campaign in New York City (NYC) measured noise levels frequently exceeding recommended standards. Noise complaints have been used as a proxy of noise annoyance and exposure. NYC has been opening parts of its street network to recreation and physical activity through the Open Streets program. We aim to describe the citywide distribution of noise complaints by census tract percentage of Open Streets.

METHODS: We conducted analyses at the census tract level from 2019 to 2021 across NYC. We used noise complaints from 311 calls for specific locations and times, which we aggregated to daily census tract counts of noise complaints. We focused on two categories of noise complaints that may be impacted by Open Streets: vehicle and street/sidewalk noise complaints. We used a mixed-effects model with random intercepts for census tracts to estimate the association between changes in noise complaints and area covered by Open Streets (%) given tract-level socioeconomic status and street geometry. We allowed for nonlinear exposure–outcome relationships using natural splines. We also carried out sensitivity analyses using data from a citizen's survey on Open Streets implementation levels gathered by Transportation Alternatives (TA) to assess its impact on model results.

RESULTS: Census tracts with increasing use of street space as Open Streets (i.e. higher than 5%) reported more daily street/sidewalk noise complaints. for vehicle noise complaints, 5 to 10% of area covered by Open Streets showed increasing noise complaints but estimates plateaued at higher percentages. The sensitivity analyses using TA implementation data showed that our estimates were fairly robust.

CONCLUSIONS: Our preliminary results suggest that Open Streets were associated with increases in street/sidewalk noise complaints.

P-0280 Traffic noise in relation to markers of obesity in nine Nordic cohorts

Åsa Persson[1], Andrei Pyko[1,2], Mette Sørensen[3,4], Göran Pershagen[1,2], Charlotta Eriksson[1,2], The NordSOUND WP2 consortium

[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Center for Occupational and Environmental Medicine, Stockholm, Sweden, [3]Danish Cancer Society Research Centre, Copenhagen, Denmark, [4]Department of Natural Science and Environment, Roskilde University, Roskilde, Denmark

BACKGROUND AND AIM: Evidence suggests that transportation noise may increase the risk of obesity. However, there are uncertainties regarding e.g. exposure-response relations, potential threshold effects and interactions, in particular with air pollution. In this study, we aim to assess the exposure-response associations between residential exposure to road traffic noise and Body Mass Index (BMI), overweight and obesity, as well as to investigate interaction with air pollution ($PM_{2.5}$).

METHODS: The study was based on pooled analyses of nine cohorts from Denmark and Sweden, including 128 000 subjects, recruited 1990–2004. Road traffic noise was calculated as time-weighted average Lden exposure five years prior to the baseline of each cohort. Linear and logistic regression models were used to assess associations with BMI and overweight (BMI ≥25 kg/m²) and obesity (BMI ≥30 kg/m²), respectively, adjusting for individual and area-based demographic, socio-economic, lifestyle and environmental factors. Exposure-response relationships were assessed using restricted cubic splines.

RESULTS: In the fully adjusted model, exposure to road traffic noise was associated with an increased BMI of 0.07 kg/m² (95% confidence interval, 95% CI, 0.03–0.10) per 10 dB Lden, as well as with an excess risk of being overweight, odds ratio (OR) 1.03 (95% CI 1.01–1.05), or obese, OR 1.06 (95% CI 1.03–1.09). There appeared to be a threshold around 50–55 dB Lden in the exposure-response relationship for BMI. Furthermore, stronger associations were suggested at levels above the mean PM2.5 (15 µg/m³): 3rd quartile 0.11 kg/m² (95% CI 0.04–0.17) and 4th quartile 0.22 kg/m² (95% CI 0.16–0.28).

CONCLUSIONS: Preliminary findings from this study indicate positive associations between road traffic noise and BMI as well as with overweight and obesity. Stronger associations appeared at noise levels above 50–55 dB Lden and at higher $PM_{2.5}$ levels.

KEYWORDS: Road traffic noise, BMI, overweight, obesity, exposure-response function, interaction

P-0281 Time course of electromagnetic hypersensitivity in a prospective cohort of Dutch individuals

Eugenio Traini[1], Astrid L. Martens[2], Roel C.H. Vermeulen[1], Anke Huss[1]
[1]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands, [2]PBL Netherlands Environmental Assessment Agency, The Hague, The Netherlands

BACKGROUND:
Some individuals attribute health complaints to radiofrequency electromagnetic field (RF-EMF) exposure. This condition, known as electromagnetic hypersensitivity (EHS), can be disabling for those who are affected. Psychosocial factors are thought to play a role but little is understood about the time course of EHS.
In this study we assessed factors related to developing, maintaining, or discarding EHS over the course of 10 years, defined as reporting health complaints attributed to RF-EMF exposure.
METHODS: Participants (n=892, mean age 50 at baseline, 52% women) from the Dutch Occupational and Environmental Health Cohort Study AMIGO filled in questionnaires in 2011/2012 (T0), 2013 (T1), and 2021 (T2) where information pertaining to perceived RF-EMF exposure and risk, symptoms, sleep problems, and EHS was collected. We fitted multi-state Markov models to represent how individuals transitioned between states (yes, no) of symptom attribution to RF-EMF exposure.
RESULTS: At each time point, about 1% or study participants reported health complaints that they attributed to RF-EMF exposure. While this percentage remained stable, the individuals who reported such complaints changed over time: of 9 persons reporting health complaints at T0, only 1 reported EHS at both T1 and T2. Overall, participants had a 95% chance of transitioning from yes to no over a time course of 10 years, and a chance of 1% of transitioning from no to yes. Participants with a high RF-EMF exposure and risk perception had a general tendency to move more frequently between states.
CONCLUSIONS: We observed a low prevalence of symptom attribution to RF-EMF exposure in our population. Prevalence did not vary strongly over time but there was a strong aspect of change: over 10 years, there was a high probability of not attributing symptoms to RF-EMF exposure anymore. Being EHS appears to be a more transient condition than previously assumed.

electromagnetic hypersensitivity

P-0283 Interactions between multiple environmental factors and associations with generalized anxiety disorder in Nurses' Health Study II

Unnati Mehta[1], Grete E. Wilt[1], Olivia I. Okereke[2,3], Brent Coull[4], Peter James[1,5], Francine Laden[1,2,6], Hari S. Iyer[6,7], Nicole V. Deville[2,6], Jaime E. Hart[1,2]

[1]Department of Environmental Health, Harvard University T. H. Chan School of Public Health, Boston, USA, [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital, Boston, USA, [3]Harvard Medical School, Boston, USA, [4]Department of Biostatistics, Harvard University T. H. Chan School of Public Health, Boston, USA, [5]Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA, [6]Department of Epidemiology, Harvard University T. H. Chan School of Public Health, Boston, USA, [7]Division of Population Sciences, Dana-Farber Cancer Institute, Boston, USA

BACKGROUND AND AIM: Built and natural environments are linked to lower anxiety. Results are mixed due to heterogeneous study populations and definitions of anxiety. We longitudinally examined associations between generalized anxiety disorder (GAD) symptoms and exposure to residential greenness, walkability, and neighborhood socioeconomic status (nSES) and their interactions in the Nurses' Health Study II.

METHODS: 79,838 participants completed the 7-item GAD Assessment (GAD-7) in 2013 and/or 2017. GAD-7 scores for both time points were dichotomized at a clinically-relevant cutoff (GAD-7 ≥ 5), indicating at least mild anxiety symptoms. Annual average and peak (July) greenness were assigned to residential addresses using Landsat-based Normalized Difference Vegetation Index (NDVI) at 270m and 1230m buffers. Walkability was calculated from summed z-scores of 2010 Census population density, Tiger/Line shapefile road intersection density, and Infogroup business density. nSES z-scores were linked using 2010 Census data. We employed generalized estimating equations (GEE) for individual and joint exposure models to estimate odds ratios (OR) and 95% confidence intervals (95% CI) adjusted for sociodemographic and lifestyle risk factors for anxiety.

RESULTS: Interquartile range increases in peak 270m NDVI (OR: 0.98, 95% CI: 0.96, 1.00), peak 1230m NDVI (OR: 0.97, 95% CI: 0.95, 1.00), and nSES z-score (OR: 0.97 95% CI: 0.95, 0.99) were protective. Higher walkability (OR: 1.02, 95% CI: 1.01, 1.03) was associated with elevated odds of anxiety symptoms. Interaction models showed substantial heterogeneity. for example, peak 270m NDVI was more protective in lower nSES areas (lowest quintile OR: 0.94, 95% CI: 0.90, 0.98, highest quintile OR: 1.01, 95% CI: 0.96, 1.06). The adverse association observed with walkability was stronger in higher NDVI areas.
CONCLUSION: Higher residential NDVI and nSES and lower walkability were associated with decreased odds of anxiety symptoms. Interactions between these contextual factors identified subpopulations that could benefit from improved residential built and natural environments.

P-0284 Presence and distribution of Encephalitozoon spp. spores across different soil types

Antonio Peña-Fernández[1], Manuel Higueras[2], María Carmen Lobo-Bedmar[3], Lucrecia Acosta[4], Umar Anjum[1]
[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, UK, [2]Scientific Computation & Technological Innovation Center (SCoTIC), Universidad de La Rioja, Logroño, Spain, [3]Departamento de Investigación Agroambiental. IMIDRA. Finca el Encín, Crta. Madrid-Barcelona Km, 38.2, Alcalá de Henares, Spain, [4]Área de Parasitología, Departamento de Agroquímica y Medio Ambiente, Universidad Miguel Hernández de Elche, Ctra. Valencia Km 8.7, San Juan, Alicante, Spain

BACKGROUND AND AIM: The presence of Encephalitozoon spp. (E. intestinalis, E. hellem and E. cuniculi) in urban topsoils has been poorly studied despite increasing reports of infection in humans. The aim was to determine factors that could affect the presence/distribution of these species in Alcalá de Henares (Spain).

METHODS: 227 topsoil samples were collected in July 2017 across urban parks and green areas from: urban (155), industrial (60) and a public garden (12). DNA was extracted by disrupting the spores using Fast-Prep for Soil®, followed by SYBR Green real-time PCR. Urban/industrial areas were sub-divided into four and two areas to investigate distribution. Organic matter content (OM), pH, electric conductivity and the texture (percentages of sand, clay and silt) were also determined in the soils.

RESULTS: Encephalitozoon spp. were detected in 22 of the soil samples (16 urban, 6 industrial). The processes of the composting used for fertilising public gardens might have inactivated the potential presence of any spores. OM and silt were significantly higher in industrial vs. urban soils, meanwhile percentages of clay and sand were significantly higher in urban areas. Meanwhile E. cuniculi did not show any relationship with soil textural factors, E. intestinalis was associated with industrial soils that presented lower percentages of sand (14.5 vs. 21.7; $p<0.001$) and higher levels of silt (78.5 vs 64.9; $p=0.023$). Silt could provide adequate shade and moisture for the survival of the spores, meanwhile sand does not retain water well. E. intestinalis/E. hellem, species that could not be distinguish between them, were associated with urban soils with higher content of clay (19.02 vs. 11; $p=0.020$).

CONCLUSIONS: Our results indicate a moderate effect of soil conditions and types in the prevalence and distribution of Encephalitozoon spp. spores in Alcalá's topsoils, which could be used to reduce their presence.

P-0285 Higher proportion of agricultural land use around the residence is associated with higher urinary concentrations of AMPA, a glyphosate metabolite

Katrien De Troeyer[1,2], Lidia Casas[1,2], Esmée M Bijnens[3,4], Liesbeth Bruckers[5], Adrian Covaci[6], Stefaan De Henauw[7], Elly Den Hond[8], Ilse Loots[9], Vera Nelen[8], Veerle J Verheyen[10,11], Stijn Vos[3], Greet Schoeters[10], Hans-Wolfgang Hoppe[12], Helmut Dietrich Köster[12], Tim S Nawrot[2,3]

[1]Social Epidemiology and Health Policy, Department Family medicine and Population Health, University of Antwerp, Wilrijk, Belgium, [2]Centre for Environment and Health - Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium, [3]Centre for Environmental Sciences (CMK), Hasselt University, Diepenbeek, Belgium, [4]Department of Human Structure and Repair, Ghent University Hospital, Ghent, Belgium, [5]I-BioStat, Data Science Institute, Hasselt University, Hasselt, Belgium, [6]Toxicological Centre, University of Antwerp, Wilrijk, Belgium, [7]Department of Public Health and Primary Care, Faculty of Medicine and Health Sciences, Ghent University, Ghent, Belgium, [8]Provincial Institute of Hygiene, Antwerp, Belgium, [9]Department of Sociology, Faculty of Social Sciences, University of Antwerp, Antwerp, Belgium, [10]Flemish Institute for Technological Research (VITO-Health), Mol, Belgium, [11]Department of Biomedical Sciences, University of Antwerp, Wilrijk, Belgium, [12]Medical Laboratory Bremen, Bremen, Germany

BACKGROUND & AIM:
Pesticides are widely used and there are concerns about their health effects. Little research has been done into the extent to which agricultural land use in the residential surroundings contributes to exposure.
We investigated associations between proportion of agricultural land use around the residence and exposure to pesticides.
METHODS: We included 424 adolescents participating in a Flemish biomonitoring study (FLEHS IV) between 2016 and 2020. Proportions of agricultural land use around the residence were estimated in several buffers (300m, 500m, 1000m and 2000m) after geocoding of residential address. Concentrations of biomarkers of pesticides were measured in urine and adjusted for specific gravity: glyphosate and its metabolite, aminomethyl-phosphonic acid (AMPA); 3-phenoxybenzoic acid (3-PBA); 3,5,6-trichloro-2-pyridinol (TCPy) and 2,4-dichlophenoxy-acetic acid (2,4-D). We categorized pesticide biomarkers in three categories and used ordinal logistic regression models adjusted for sex, season and household education to estimate odds ratios for an interquartile range (IQR) increase of proportion of agricultural land use. We also used binary logistic regression models in which the highest exposure was compared to the lowest exposure and explored effect modification by sex and season.
RESULTS: We found a significant association between proportion of agricultural land use in 2000m buffer around the residence and levels of urinary AMPA (OR=1.35 for an IQR increase in proportion of agricultural land use around the residence; 95% CI: 1.00-1.83). This association was less pronounced and not statistically significant for other studied pesticides (OR between 0.95 and 1.16). Stratified analysis showed strongest associations of proportion of agricultural land use within 2000m buffer for AMPA among boys (OR=1.89; 95% CI: 1.19-3.04).
CONCLUSIONS: A higher proportion of agricultural land use around the residence might increase exposure to AMPA. A potential mechanism is wind erosion of contaminated soils.

P-0286 Awareness and Perception of Plant-Based Diets at an Urban Community College

Shannon Caravello[1,2], Elizabeth Helzner[3], Megan Hall[2,3], Laura Geer[2], Lori Hoepner[2]
[1]Department of Health Physical Education and Recreation, CUNY Kingsborough Community College, Brooklyn, USA, [2]Department of Environmental and Occupational Health Sciences, School of Public Health, SUNY Downstate Health Sciences University, Brooklyn, USA, [3]Department of Epidemiology and Biostatistics, School of Public Health, SUNY Downstate Health Sciences University, Brooklyn, USA

BACKGROUND AND AIMS:
Despite the environmental and human health benefits of consuming minimally processed plant-based foods, research on best education and promotion practices for plant-based diet (PBD) is lacking among urban community college students. Education on the benefits of a PBD and gardening may create more knowledgeable and environmentally conscious consumers. Potential benefits may result in positive health outcomes and assist a dietary shift towards a PBD. We explored awareness and perception of PBDs among young adults on an urban college campus containing an urban farm. We developed and implemented a cross-sectional survey instrument, tailored for the community college population, to examine dietary intake and gauge PBD familiarity/exposure, knowledge, perceptions, and attitudes.
METHODS: A cross-sectional survey was conducted Fall 2020 through Spring 2021 at Kingsborough Community College in Brooklyn, NY (N=8,849). Participants (N=287) completed a 70-item online survey that included sociodemographic questions, food frequency questions, and five PBD scales developed for this survey (familiarity, knowledge, attitudes, exposure, perception).
RESULTS: Cronbach's alpha reliability scores were run on the five PBD scales demonstrating strong reliability results for familiarity (α=.80), knowledge (α=.72), attitudes (α=.70); lower reliability for exposure (α=.48), and perception (α=.64). of all participants, 75% reported a 3-6 servings per week or less of fruit alone and vegetables alone. Those with exposure to growing fruits and vegetables reported higher intake of fruit (p-value=0.002) and vegetables (p-value=0.033) compared with those who reported no exposure to 'growing'. Those exposed to the 'campus farm/event' had higher fruit intake (p-value =0.042) when split into high/low intake.
CONCLUSIONS: These findings suggest that community college students in our sample generally have an awareness and positive perception of a PBD and are willing to consider trying it, though many are not actively following a PBD.

P-0289 A comprehensive evaluation of built-environment as a risk factor for sleep disruption

Jaclyn Parks[1], Millie Baghela[1], Parveen Bhatti[1,2]
[1]BC Cancer Research Institute, BC Cancer, Vancouver, Canada, [2]School of Population and Public Health, University of British Columbia, Vancouver, Canada

BACKGROUND/ AIM:
Sleep disruption is a significant public health issue, given its high prevalence and links to both injury and chronic disease. Interventions for improving sleep often focus on individual-level behaviour change. Modifying aspects of the built environment may be a strategy for population-level improvements. Few studies have evaluated the impacts of built environment on sleep. We assessed relationships between the built environment and sleep disruption using a well-characterized, population-based cohort.

METHODS: Analyses were conducted among participants of the British Columbia Generations Project (BCGP) with complete data on built environment factors and self-reported sleep duration and quality(n=23,556). Measures of air pollution ($PM_{2.5}$, NO_2), greenness (density within 250-metres) and intensity of light-at-night (LAN) were obtained from the Canadian Urban Environmental Research Consortium (CANUE), and linked to participants residential postal codes. Logistic regression analysis, adjusted for age and sex, was used to estimate the association between each built environment factor and self-reported sleep duration (<7 hours, ≥7 hours) and difficulty in falling or staying asleep (sometimes/most of the time/ always vs. rarely/never).

RESULTS: Increased $PM_{2.5}$ was associated with lower odds of insufficient sleep duration (OR=0.85/5µg/m³; 0.74-0.97) and greater odds of difficulty falling/staying asleep (OR 1.54/5µg/m³; 1.37-1.74). Increased LAN intensity was associated with greater odds of insufficient sleep (OR=1.04/10-unit; 1.02-1.07) but not with difficulty falling/staying asleep. Greenness exposure in the top quartile was associated with reduced odds of insufficient sleep (OR=0.92; 0.86-0.99) and difficulty staying/falling asleep (OR=0.97; 0.95-0.99) compared to those in the bottom quartile. Greenness, LAN and $PM_{2.5}$ were moderately correlated ($-0.5 < r < 0.5$).

CONCLUSIONS: BCGP's rich data enabled a comprehensive evaluation of the built-environment as a modifiable determinant of sleep disruption. Further analyses will elucidate the mediating effects of sleep on the links between built-environment and chronic disease.

P-0290 Geomagnetic Disturbances and Ventricular Arrhythmia in Patients with Implantable Cardioverter Defibrillators from a US-Based Hospital

William Borchert[1], Mark Link[2], Carolina Zilli Vieira[1], Heike Luttmann-Gibson[1], Eric Garshick[3,4,5], Adjani Peralta[1], Diane Gold[1,4,5], Jaime Hart[1,4,5], Francine Laden[1,3,4,6], Petros Koutrakis[1]

[1]Harvard TH Chan School of Public Health, Boston, USA, [2]Department of Medicine, UT Southwestern Medical Center, Dallas, USA, [3]Pulmonary, Allergy, Sleep and Critical Care Medicine Section, VA Boston Healthcare System, Boston, USA, [4]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital, Boston, USA, [5]Harvard Medical School, Boston, USA, [6]Department of Epidemiology, Harvard TH Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Episodes of ventricular arrhythmias (VA) have been associated with environmental exposures such as air pollution. Solar driven geomagnetic disturbances may alter autonomic nervous system activity, modify systemic oxidative stress, or induce changes in aerosols. However, few studies have investigated if there is an association between VA and geomagnetic disturbances (GMD). The aim of this study was to assess whether GMD is associated with the initiation of VA in patients with implantable cardioverter defibrillators (ICDs).

METHODS: This study examined the association between GMD driven by solar activity on VA, defined as sustained and non-sustained ventricular fibrillation or ventricular tachycardia, in patients with ICDs using a time-stratified case-crossover analysis between September 2006 and March 2010 from Tufts Medical Center's Cardiac Arrythmia Center in Boston, MA. Patients were identified from a single Massachusetts-based Medical Center and VAs were identified from retrieved ICD records as part of routine care. We considered several pollutants such as PM2.5, black carbon (BC), O3, NO2 and ultrafine particles (PN) in our analyses using time lags prior to the event. Daily GMD information was appended for the week previous to each event and matched control day.

RESULTS: During the study period, 91 patients had a total of 1,050 VA. During periods of increased GMD, patients with low ejection fraction and a history of a MI or coronary intervention had increased odds of VA, with patients who had a coronary bypass graph being the highest (OR: 1.63, 95% CI 1.05, 2.52).

CONCLUSIONS: Among patients with ICDs, exposure to GMD was associated with higher odds of VA in those with pre-existing heart disease and/or a history of coronary interventions. GMD driven by solar activity has the potential to affect heart health in patients with cardiac comorbidities.

KEYWORDS: Solar activity, geomagnetic disturbances, implantable cardioverter defibrillator, ventricular arrhythmia

P-0291 A tale of many neighborhoods: latent profile analysis to derive nationally representative neighborhood typologies in the US

Hiwot Zewdie[1], Jamaica R.M. Robinson[2], Anjum Hajat[1], Stephen J Mooney[1]
[1]Department of Epidemiology, School of Public Health, University of Washington, Seattle, USA, [2]Department of Epidemiology, Columbia University Mailman School of Public Health, New York City, USA

BACKGROUND AND AIM: Neighborhoods are critical to health, yet challenging to model effectively and consistently across geographies. We used latent profile analysis (LPA) to derive a typology of residential neighborhood found across the US, and then explored how self-reported health varies between neighborhood types.

METHODS: We defined neighborhoods as census tracts and compiled 2015-2019 ACS tract-level estimates for neighborhood indicators of commute mode, education, immigration, race, recent growth, and urban form. LPA models ranging from 1 to 6 classes were fit to these data. We the used a one-way ANOVA to compare tract-level 2019 prevalence estimates of poor physical health and poor mental health, provided by the US Centers for Disease Control and Prevention PLACES dataset, between neighborhoods grouped by latent profile.

RESULTS: Model fit statistics identified a 6-profile model permitting varying variances and covariances as the optimal categorization of neighborhood profiles. of the 73,057 census tracts classified, 55% of tracts fell into one of two profiles that were broadly characterized as rural typologies. The remaining 45% of tracts fell into four broadly urban profiles, differentiated by sociodemographic composition, education, and recent growth. Tracts characterized as rural and with a high racial/ethnic minority class had the highest poor health prevalence (MeanPoor Physical health(SD): 16.3 (3.96), MeanPoor Mental health(SD): 18.0 (3.42), whereas tracts characterized as urban with high education had the lowest poor health prevalence (MeanPoor Physical health(SD): 10.5 (2.40), MeanPoor Mental health(SD): 12.4 (2.6); $p<0.001$)
CONCLUSION: LPA can be used to derive meaningful and standardized partitioning of census tracts sensitive to the spatial patterning of health in the US. These neighborhood types can be used to quickly categorize tracts in the US, and there is potential to replicate these methods in non-US contexts to promote population health globally.

KEYWORDS: neighborhood, built environment, social environment, latent profile analysis

P-0293 The importance of ecological quality of public green and blue spaces for subjective well-being

Sarah Knight[1], Colin McClean[1], Piran White[1]
[1]*University of York, York, UK*

BACKGROUND AND AIM: There is now considerable evidence that the natural environment provides health and well-being benefits in urban environments. However, little is understood about the role of ecological quality in maximising well-being gains.

METHODS: We examine the relationship between the accessibility of public natural spaces of high ecological quality and two measures of subjective well-being for adults, using the British Household Panel Survey (BHPS), a large, longitudinal panel dataset. We then compare this relationship with that found with all Public Open Spaces, regardless of their ecological quality. We use the designation of Sites of Importance for Nature Conservation (SINC) as an objective indication of high-quality green- or bluespace, and life satisfaction and mental distress as measures of well-being. We use the Areas of Deficiency dataset from Greenspace Information for Greater London CIC (GiGL) to identify residential areas with more than a 1 km walk from a SINC, based on actual walking routes from known access points.

RESULTS: Postcode-level analysis using regression modelling reveals that living beyond a 1 km walk of a SINC decreases an individual's life satisfaction by 0.117 points on a scale of 1 to 7. No relationship is found for mental distress. We also do not find any significant relationship between either well-being measure and all Public Open Spaces.

CONCLUSIONS: These findings suggest that the ecological quality of publicly accessible open spaces is important for the well-being of residents in Greater London and highlights the need for improving the provision of, and access to, high-quality green- and bluespaces in urban areas.

KEYWORDS: Biodiversity; Greenspace; Bluespace; Well-being; BHPS

P-0294 Environmental, economic, and health co-benefits of a shift away from motor vehicles in London - Presenting a simplified modelling framework for preliminary screening of urban transport interventions

Livio Caputo[1], Audrey de Nazelle[2]
[1]Energy Futures Lab, Imperial College London, London, UK, [2]Centre for Environmental Policy, Imperial College London, London, UK

BACKGROUND AND AIM: Cities contribute to 75% of global greenhouse gas emissions, accelerating climate change and significantly impacting public health. Rapidly rising rates of urbanization and population growth are emphasizing these effects. This presentation investigates how co-benefits can be generated when redesigning cities to reduce car-reliance. It makes the case for a system-thinking approach that can leverage intersectoral relationships, exploit synergistic effects, and maximize health co-benefits of climate change strategies. It aims to bridge the gap between research and policy by offering an open-source framework that can quantify the co-benefits of traffic reductions in Europe.

METHODS: A suite of publicly available models was assembled into a unified framework to quantify health benefits of car reduction strategies in cities. These include: SHERPA and SHERPA-City to simulate impacts on NO_2 and $PM_{2.5}$; AirQ+ to calculate the respective premature deaths prevented; HEAT to estimate health benefits from physical activity stemming from traffic re-allocated to active travel; UTOPHIA methodology to assess benefits of noise reduction and green space improvements. Lastly, statistical analysis is used to highlight how system-thinking can be economically advantageous. The framework was applied to hypothetical scenarios in London.

RESULTS: for a reduction in traffic between 10 and 50%, annual mortality was impacted by changes in physical activity (169 to 878 deaths prevented), NO_2 (45 to 227 deaths prevented), $PM_{2.5}$ (7 to 52 deaths prevented), noise (34 to 167 deaths prevented), and green space (20 to 97 deaths prevented).
CONCLUSION: The results were in accordance with published literature, revealing co-benefits of modifying travel habits are substantial and attractive to multiple stakeholders. Physical activity from active transport was found to be particularly beneficial and should therefore be the focus of urban mobility interventions, proving to be greener, healthier, and more equitable than shifting to a carbon-neutral fleet.

KEYWORDS: Co-benefits, climate change, active transport

P-0296 Quantifying the public health benefits of expanding natural spaces in urban areas

Greta Martin[1], Susan Anenberg[1], Patrick Kinney[2], Marcia Pescador Jimenez[2]
[1]The George Washington University Milken Institute of Public Health, Washington, USA, [2]Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: Access to greenspace (e.g. parks, trees) has been shown to improve physical and mental health by facilitating physical activity and social interaction as well as reducing stress, air pollution, and the urban heat island effect. While the health impacts of blue space (e.g. coastline, lakes, rivers) have been less studied, blue space is also hypothesized to provide similar health benefits through many of the same pathways. Here we assess the combined benefits of green and blue spaces, or natural space, for reducing all-cause mortality in approximately 100 cities worldwide that are members of the C40 Cities network.

METHODS: We use 2021 normalized difference vegetation index (NDVI) derived from the Landsat 8 satellite to identify urban natural spaces. We then use an epidemiologically-derived health impact function from a systematic review of the effects of greenspace on mortality along with WorldPop population estimates and Global Burden of Disease mortality rates from 2020 to quantify the health benefits of natural spaces in terms of reductions in all-cause mortality in each city.

RESULTS: Cities vary in their extent of natural space, including green and blue space individually, as well as the combined natural space metric. We estimate that these natural spaces reduced all-cause mortality in each city, and that variation in mortality benefits across cities is driven both by differences in natural space extent, as well as population and baseline mortality rates.

CONCLUSIONS: Cities around the world experience different levels of natural spaces and associated health benefits. Expanding natural spaces to reduce carbon emissions and enhance urban sustainability and livability may further benefit local public health.

KEYWORDS: greenspace, blue space, natural space, NDVI

P-0299 Mixed methods (qualitative and quantitative) in environmental epidemiology : an industrial area study, France

Sandrine Coquet[1], Christophe Perrey[2], Christine Castor[1], Candice Roudier[3], Anna Siguier[1], Laurent Filleul[1]
[1]French National Public Health Agency, Nouvelle-Aquitaine Regional Office, Bordeaux, France, [2]French National Public Health Agency, Regions Division, Saint-Maurice, France, [3]French National Public Health Agency, Environmental and Occupational Health Department, Saint-Maurice, France

BACKGROUND AND AIM: The Lacq industrial area has been the site of numerous chemical activities over the past 60 years. To assess the impact of these activities on the local population health, the French national public health agency has developed a sequenced and participative approach, combining qualitative and quantitative studies.

METHODS: A qualitative local context study, based on 39 semi-directive interviews with different categories of local stakeholders and residents, was first conducted to identify the perceptions and expectations of local actors regarding the links between health and the environment around the industrial site.
Two geographical epidemiological studies were then launched to describe mortality and morbidity (cancers, acute and chronic diseases) near the industrial area.
Not clinically assessed health outcomes (irritation symptoms, anxiety), quality of life and their link with environmental disturbances will be assessed with an ongoing individual perceived health survey.

RESULTS: Social demand, analyzed in the local context study, led to the integration of diseases of concern (e.g. digestive cancers, thyroid disorders), reported by local residents and health professionals, in the mortality and morbidity studies. Furthermore, people's mistrust of authorities and desire for more transparency on the scientific process were taken into account and participatory citizen workshops were set up to co-create the perceived health survey questionnaire.
The mortality study reported non-cancerous respiratory and circulatory excess death rates. Those pathologies will be thoroughly explored in both morbidity (health care system use) and perceived health (irritations, discomfort) surveys for a more comprehensive overview of the population health, closer to their life experience.
CONCLUSION:
This innovative approach, mixed and participative, developed around Lacq industrial area shows the benefit of sequential mixed methods design in environmental health. It enables to better respond to social demand and to overcome blind spots of health surveillance around industrial areas.

P-0303 Does air pollution negate benefits of exercise in those with long-term health conditions? – Rapid review

Marios Panayi[1], Samuel Cai[2], Andre Ng[3,4], Anna Hansell[2], Joshua Vande Hey[1,2]
[1]School of Physics and Astronomy, University of Leicester, Leicester, UK, [2]Centre for Environmental Health and Sustainability, University of Leicester, Leicester, UK, [3]Dept. Cardiovascular Sciences, University of Leicester, Leicester, UK, [4]NIHR Leicester Biomedical Research Centre, Glenfield Hospital, Leicester, UK

BACKGROUND AND AIM: In healthy adults, exercise is generally beneficial for health unless air pollution levels are very high (Tainio, 2016). However, recent studies (e.g. Sinharay et al 2018) raise the possibility that air pollution at levels seen on busy streets in western countries may offset the physiological benefits of exercise for people with long-term health conditions.
The aim of this study was to conduct a rapid literature review to inform the European Space Agency funded Personalized Space Technology Exercise Platform (P-STEP) app development. The app will advise people with pre-existing conditions on exercising based on environmental conditions such as air pollution and meteorology.
METHODS: We identified papers in PubMed, with search terms on air quality, long-term conditions and exercise. Additional papers were identified from authors' own library. Papers selection and data extraction was conducted by a single reviewer (MP).
RESULTS: A relatively small number of papers were identified. Designs were heterogeneous including chamber and cardiac stress test (experimental), panel and cohort studies considering short or long-term exposures. Short-term exposure to traffic pollution may offset some of the beneficial cardiopulmonary effects of walking for individuals with ischemic heart diseases and COPD, affecting autonomic function, heart rhythm and associated with ST segment depression (a marker of ischaemia) and angina symptoms. On the other hand, long-term studies in Asia and Europe suggest long-term benefits of exercise on mortality and disease risk in those with chronic disease even in moderate air pollution settings, despite adverse effects seen in short-term studies.
CONCLUSIONS: More studies are needed to be able to quantify short-term air pollution concentrations that may offset beneficial effects of exercise in those with chronic disease. However, long-term studies available suggest exercise remains a good way to reduce future disease risk.

P-0305 Associations between greenness and hemodynamic markers at varied spatial scales and metrics of greenness

Ray Yeager[1], Daniel Riggs[1], Natasha DeJarnett[1], Rachel Keith[1], Joseph Kehrt[1], Anagha Uppal[1], Daniel Fleischer[2], Ted Smith[1], Jay Turner[3], Sanjay Srivastava[1], Aruni Bhatnagar[1]

[1]University of Louisville, Louisville, USA, [2]Hyphae Design Labratory, Oakland, USA, [3]Washington University in St. Louis, St. Louis, USA

BACKGROUND AND AIM: Residential greenness, often measured through NDVI, has been linked to cardiovascular disease (CVD) outcomes and associated risk factors. However, physiological mechanisms underlying these associations are not well understood, nor is the influence of differing types and scales of greenness. Therefore, we examined associations between CVD risk markers of systolic blood pressure (SBP) and arterial index (AI), a measure of arterial stiffness, with residential greenness at multiple greenness metrics and spatial scales.

METHODS: We recruited 723 adult participants from a 4.5sqmi area of Louisville, Kentucky, USA, and measured SBP and AI. We collected high resolution greenness metrics of NDVI, canopy, and leaf area in spatial radii of 20m to 500m around participants' residence via Aerial LiDAR and Sentinel-2 satellite imagery. We utilized adjusted linear regression with a hierarchical modeling approach to examine associations between greenness and hemodynamic markers.

RESULTS: We observed inverse associations between SBP and multiple greenness metrics at radii of 300m and 500m (-0.26 to -2.66% per IQR), but not 20m or 100m. We observed inverse associations between AI and metrics of greenness with all models at a 100m radius (-1.41 to -2.25% per IQR), but only leaf area and models with basic adjustments at 300m and 500m radii (-1.79 and -1.9% per IQR). When stratified, we observed significant associations between greenness and SBP among only females and those with higher levels of education. Among stratified results between greenness and AI, we observed significant associations only in females, participants <50 years of age, and higher educational attainment.

CONCLUSIONS: Greenness is associated with hemodynamic markers of SBP and AI with inconsistent associations between metrics and spatial scales. Future investigations of such high-resolution data may inform links between greenness and health and could help to design targeted greening interventions to address CVD.

KEYWORDS: Greenness, Blood Pressure, Hypertension, CVD

P-0306 Cadmium in the wild edible mushroom species of Agaricus bitorquis in Leicester, UK

Gurminderjeet Singh Jagdev[1], Mark Evans[1], Florette Nya[1], Tiziana Sgamma[1], Antonio Peña-Fernández[1]
[1]*Leicester School of Allied Health Sciences, De Montfort University, Leicester, UK*

BACKGROUND AND AIM: Consumption of urban garden products is increasing despite the risks that they can represent due to high urban contamination. Effects of urbanisation in wild edible mushrooms are scarce. The aim was to assess the risks to cadmium (Cd) present in wild edible mushrooms Agaricus bitorquis collected in Leicester (UK).

METHODS: Twenty-two A. bitorquis mushrooms were collected from an open green area close to St Augustine Road, a high traffic area within Leicester. Species identification was confirmed by DNA barcoding using internal transcribed spacer 1/4 primers after extracting DNA from 100 mg of frozen homogenised ground mushroom material using DNeasy Plant Mini Kit®. Cd was monitored by ICP-MS in cleaned, dried and homogenised mushrooms' caps and stipes mineralised with HNO3/H2O2 [LoD=0.081 mg/kg dry weight (dw)].

RESULTS: Cd was detected in all samples, with significantly higher levels in caps ($p<0.001$), median and ranges are provided in mg/kg dw: 3.878 (2.213-6.598) vs. 2.068 (0.899-3.679). Concentrations were similar to those recently reported in different species of the genus Agaricus collected in urban habitats within Berlin (Germany; <0.1-32.7 mg/kg DW), but much higher than the reported in sixteen A. bisporus (median 0.2 mg/kg DW) cultivated in high traffic areas within Berlin. All caps monitored exceeded the established maximum concentration limit for Cd in Europe (0.2 mg/kg wet weight, approximately 2 mg/kg dw), in line with the high accumulative metal capability described in the literature for Agaricus spp. Non-carcinogenic health risks in adults and children for Cd in the monitored mushrooms were 3.16E-07 and 1.47E-09, respectively.

CONCLUSIONS: Our results would suggest potential contamination by Cd in the inner city of Leicester that should be further investigated to protect human health. Although non-carcinogenic risks characterised for Cd were negligible, consumption of wild edible species should be limited and substituted by cultivated mushrooms when possible.

P-0309 Residential road traffic noise and pregnancy complications – The NordSOUND study

Timo Lanki[1], Pekka Tiittanen[1], Kerstin Persson Waye[2], Nina Roswall[3], Jenny Selander[4], Helena Skröder[4], Mikael Ögren[2], Mette Sørensen[3]

[1]Finnish Institute for Health and Welfare, Kuopio, Finland, [2]Gothenburg University, Gothenburg, Sweden, [3]Danish Cancer Society Research Center, Copenhagen, Denmark, [4]Karolinska Institutet, Stockholm, Sweden

BACKGROUND AND AIM: Only few studies have evaluated the effects of exposure to environmental noise on pregnancy. The NordSOUND project utilizes high-quality register data in four Nordic countries to comprehensively study the health effects of environmental and occupational noise. The present study evaluates associations between maternal exposure to road traffic noise during pregnancy and pregnancy complications.

METHODS: The study included metropolitan areas of Copenhagen, Denmark, Helsinki, Finland, and Gothenburg and Stockholm, Sweden. Data from Oslo, Norway, will soon become available, too. Gestational diabetes, gestational hypertension, and severe and mild pre-eclampsia were used as outcomes. Data sources were national population and patient registers. Residential yearly levels of transport-related noise and air pollution were modelled. Logistic regression analyses, followed by meta-analyses, were adjusted for age, parity, smoking, education, marital status, neighborhood income, traffic-related air pollution, green and blue areas, and other transport noise sources.

RESULTS: The total number of pregnancies in the final analyses was 417 000. No associations were observed between road traffic noise and gestational hypertension or pre-eclampsia. However, exposure to road traffic noise during pregnancy was associated with an increased risk of gestational diabetes: odds ratio (95 % confidence intervals) in a random effect model was 1.09 (1.03; 1.15) per 10 dB increase in exposure. The analyses will be repeated adding data from Norway.

CONCLUSIONS: These preliminary results suggest that maternal exposure to road traffic noise during pregnancy increases the risk of gestational diabetes.

P-0313 Exposure to Noise and Cardiovascular Disease in a Nationwide US Prospective Cohort Study of Women

Charlotte Roscoe[1,2], Stephanie T. Grady[1], Jaime E. Hart[1,2], JoAnn E. Manson[3], Kathryn M. Rexrode[4], Eric B. Rimm[2,5], Francine Laden[1,2], Peter James[1,6]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Harvard University, Boston, USA, [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Division of Preventive Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [4]Division of Women's Health, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [5]Departments of Nutrition and Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [6]Division of Chronic Disease Research Across the Lifecourse (CoRAL) Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA

BACKGROUND AND AIM: Long-term noise exposure is associated with cardiovascular disease (CVD); however, most longitudinal studies of noise and CVD have been conducted in Europe. We aimed to examine the prospective association of outdoor long-term noise from anthropogenic sources with incident CVD using a US-based, nationwide cohort of women.

METHODS: We linked L50 (median) nighttime and L50 daytime modelled anthropogenic noise estimates from a US National Park Service (NPS) model to geocoded residential addresses of 93,365 Nurses' Health Study participants. CVD (incident MI or stroke) was confirmed via medical record review. We used time-varying Cox proportional hazards models to estimate risk of incident CVD from 2000 to 2018 associated with long-term average noise exposure, adjusted for fixed and time-varying confounders and CVD risk factors. We assessed pre-determined effect modification by race, region, population density, air pollution, greenness (NDVI), and neighborhood socioeconomic status, and explored mediation by self-reported sleep duration.

RESULTS: Over 1,331,658 person-years, there were 6,409 incident CVD events. In fully-adjusted models, the hazard ratio (HR) for each interquartile range increase in L50 nighttime noise (3.73 dBA) was 1.02 (95% confidence intervals (CI) 0.99, 1.05) for CVD, 1.03 (95% CI 0.99, 1.07) for MI, and 1.01 (95% CI 0.97, 1.05) for stroke; daytime noise results were similar. Stratified analyses suggested that associations of noise with CVD were strongest among participants residing at addresses with the least surrounding greenness. for example, the fully-adjusted HR for nighttime noise and MI in the least green quintile was 1.07 (95% CI 1.00, 1.16). We found no evidence that short sleep duration (≤ 5 hours) mediated associations.

CONCLUSIONS: NPS modelled outdoor median nighttime and daytime noise was not associated with total CVD in this cohort, but was associated with an increase in MI risk for participants living at the least green addresses.

P-0314 Association between Residential Green Space and Healthcare Utilization

Stephen Van Den Eeden[1], Matthew Browning[2], Jun Shan[1], G. Tom Ray[1], Charles Quesenberry[1], Douglas Becker[3], Ming Kuo[4], Stacey Alexeeff[1]

[1]Kaiser Permanente Northern California, Oakland, USA, [2]Clemson University, Clemson, USA, [3]University of Idaho, Moscow, United State of America, [4]University of Illinois, Champaign-Urbana, Champaign-Urbana, United State of America

BACKGROUND AND AIMS:
Prior studies have shown greenness to be associated with beneficial health outcomes. We sought to determine if residential greenness correlated with healthcare utilization within an integrated health delivery system.

METHODS: We linked 5,189,303 members of Kaiser Permanente Northern California (KPNC) to Normalized Differentiated Vegetation Index (NDVI) values from Landsat satellite data (30m x 30m resolution) in 250, 500, and 1000 m radial buffers around each member's home. Healthcare utilization data for inpatient, outpatient, and emergency room visits were obtained by accessing data from the KPNC electronic health record.Using generalized estimating equations that adjusted for demographic, socioeconomic and other environmental factors, we regressed green space (in deciles) on healthcare utilization across the 2013 and 2017 study period.Adjustments were made for area sociodemographic and socioeconomic factors, and population and housing density.

RESULTS: We observed a significant trend across the decile range between higher levels of residential greenness and lower utilization of inpatient services ($p<0.01$) and emergency room visits ($p<0.01$).For outpatient visits, we observed a U-shaped curve where residing in middle of the NDVI range for this population was associated with greater outpatient visits than either the highest or lowest green space areas. Sensitivity analyses, including using various buffer sizes and tree canopy cover, an alternative measure of green space, yielded consistent findings.
CONCLUSION: Residing in an area with greater greenspace relative to low levels of greenspace was associated with greater in-patient and emergency room utilization. Residential greening can have a significant healthcare impact as measured by healthcare utilization.

KEYWORDS: green space, green cover, healthcare utilization, healthcare services

P-0315 Initial Findings of 80,000 US Residences: Structure, Behavior, Reported Symptoms

Carl Grimes[1]
[1]*Hayward Healthy Home Institute, Monterey, USA*

BACKGROUND AND AIM: The health and well-being of residential occupants is the purpose of an increasing number of research projects to create healthy homes. The COVID-19 pandemic with its increased occupancy of homes has intensified efforts. Information is lacking about the perceived house characteristics, occupant behavior, and reported symptoms. Subjective reporting is still information, and can be objectively explored. Consideration of the perceptions of the occupants of residential structures can assist the development of research questions, educational methods, and for supporting actionable behaviors.
METHODS: Hayward Score developed a free website questionnaire for the purpose of obtaining exploratory and descriptive data for cataloging selected characteristics of residential structures, occupant behaviors, and self-reported symptoms. With over 300 variables and 80,000 responses from all 50 states in the US, analysis and synthesis of the data is a daunting task. Initial analysis included: A) reporting calculated percentages of general statements; B) exploring a range of statistical methods of analysis, and C) providing examples of representative findings of the results. Once statistical categories have been developed, relationships between them can be explored for further investigation.
RESULTS: Preliminary analysis identified several general statements about house characteristics, behaviors, and reported symptoms. A follow-up of participants indicated that about two-thirds of those who made recommended improvements reported a reduction in symptoms. One in-depth analysis consistently associated house dust with the number of reported symptoms.
CONCLUSION:
In addition to initial findings, the combination of the three disparate categories crosses traditional boundaries of analysis. Instead of clearly differentiated categories a multifaceted exploration of open-ended relationships of the categories could provide an interesting future project. Specifically, does the structure affect the behavior of occupants? Do the occupants impact the structure? and what is the role of experienced symptoms because of the structure and behavior?

House characteristics, Behavior, Symptoms, Residential, questionnaire

THEMATIC 07: Climate change and Health

P-0553 Association of acute ambient temperatures with NICU admissions: results of a case-crossover analysis

Sarah Quinones[1], Pauline Mendola[1]
[1]*University at Buffalo, State University of New York, Buffalo, USA*

BACKGROUND: In the face of a changing climate, understanding the impacts of increasing temperatures on population health is critical, particularly for vulnerable groups such as pregnant people and neonates. Air pollution has been shown to increase risk for neonatal intensive care unit (NICU) admission, but the effect of temperature has not been studied.

METHODS: Using data from the Consortium on Safe Labor (n=27,189 infants admitted to NICU), we conducted a case-crossover analysis to assess NICU admission risk in association with ambient temperature during the week prior to delivery. Hazard ratios and 95% confidence intervals estimated NICU risk associated with a 1°C increase and 1°C decrease in temperatures in the warm and cold seasons, respectively with adjustment for time-varying air pollution and humidity. Analyses were repeated among infants born during weeks with average temperatures greater than 27°C.

RESULTS: Increased temperatures in the warm season were associated with higher risk of NICU admissions on the day of delivery, the day before delivery, and the entire week while days 2-7 prior to delivery were associated with reduced risk. During the cold seasons, decreases in temperature increased risk on the day of delivery but reduced risk at other times. NICU admission risk was highest in weeks with an average temperature exceeding 27°C with 12-38% increases observed in the week preceding delivery.

CONCLUSIONS: Ambient temperature, particularly increasing heat during the warm season in the week prior to delivery, was associated with NICU admission and the effects appear independent of air pollution exposures.

P-0555 The association of maternal exposure to ambient temperature with low birth weight is not positive in every single location: In Brazil, positive associations may occur only in the Amazon region

Weeberb Réquia[1], Stefania Papatheodorou[2]
[1]*Fundação Getúlio Vargas, Brasília, Brazil,* [2]*Harvard TH Chan School of Public Health, Boston, EUA*

BACKGROUND AND AIM: Exposure to extreme ambient temperature has been linked to adverse health outcomes, including cardiorespiratory and neonatal morbidities. Among the pregnancy outcomes, a large body of the epidemiological investigations has indicated low birth weight as an important public health concern, given that the consequences of low birth weight may extend through the life course. In this study, we assessed the association between low birth weight following pregnancy and ambient temperature exposure in about 1 million babies in Brazil.

METHODS: The ambient temperature exposure window was based on the gestational intervals, which included the first (week 1 to week 12), the second (week 13 to week 28), and the third trimesters (week 29 to week 37). for each birth record, we calculated the average values for the exposure and covariate variables in each trimester of gestation. We applied a case-control study design using logistic regression model to estimate the association between low birth weight and ambient temperature during a specific trimester of pregnancy. We adjusted the model for air pollution and meteorological variables, PM2.5, NO2, O3, sex, mother's age, mother´s race, mother´s marital status, mother´s education level, year of birth, and moth of birth.

RESULTS: In the primary analysis, we found positive associations only in the North region, where Amazon is located. We found that ambient temperature in the North region is associated with an increase of 3.39% (95%CI: 1.88; 4.92), 5.16% (95%CI: 3.60; 6.74), and 3.17% (95%CI: 1.63; 4.72) in low birth weight when the exposure occurred in the trimesters 1-3 of pregnancy, respectively. for the other regions, there were positive associations only in the sensitivity analysis.

CONCLUSIONS: Our study can provide a mechanism to improve pregnancy exposure assessment to ambient temperature while controlling for modifier effects related to air pollution sources.

KEYWORDS: Ambient temperature, Birth weight, Pregnancy

P-0556 Systematic review and meta-analysis for suicide associated with air pollution and ambient temperature

Seulkee Heo[1], Whanhee Lee[1], Michelle L. Bell[1]
[1]*School of the Environment, Yale University, New Haven, USA*

BACKGROUND AND AIM: Study results for air pollution, ambient temperature, and suicide are inconclusive. Given the health threats of climate change, a comprehensive review of the impacts of temperature and air pollution on suicide is needed with a focus on disparities of risks by population characteristics such as income and baseline health risks. We performed a systematic review and meta-analysis for suicide risks associated with short-term exposure to temperature and air pollution.

METHODS: Pubmed, Scopus, and Web of Science were searched for English-language publications using relevant keywords. Observational studies assessing risks of daily suicide and suicide attempts associated with temperature, particulate matter (PM_{10}, $PM_{2.5}$), ozone (O_3), sulfur dioxide (SO_2), nitrogen dioxide (NO_2), and carbon monoxide (CO) were included. Random-effect meta-analysis pooled risk ratios (RRs) for daily suicide for an interquartile range (IQR) increase in exposure. Meta-regression analysis examined effect modification by income level based on gross national income (GNI) per capita, national suicide rates, and average level of exposure factors.

RESULTS: In summary, 18 studies for air pollution and 32 studies for temperature across 24 countries were included. RRs of suicide per IQR increase in temperature, $PM_{2.5}$, PM_{10}, and NO_2 were 1.09 (95% CI: 1.06–1.13), 1.02 (95% CI: 1.00–1.05), 1.01 (95% CI: 1.00–1.03), and 1.03 (95% CI: 1.00–1.07), respectively. O_3, SO_2, and CO were not associated with suicide. RR of suicide was significantly higher in lower-income than higher-income countries (1.20, 95% CI: 1.14–1.26 vs. 1.09, 95% CI: 1.07–1.11 per 7.1°C increased temperature). Suicide risks associated with air pollution did not significantly differ by income level, national suicide rates, or average exposure levels.
CONCLUSIONS: Suicide was associated with temperature, PM, and NO_2. research gaps were found for addressing the interactions between air pollution and temperature on estimating suicide risks, which warrants future studies.

KEYWORDS: Air pollution, climate change, suicide, temperature, meta-analysis.

P-0558 Future mortality burden attributable to non-optimal temperatures under the dual threats from climate change and population aging

Kai Chen[1], Francesco Sera[2], Noah Scovronick[3], Evan de Schrijver[4], Leiwen Jiang[5], Dominic Roye[6], Eric Lavigne[7], Jan Kyselý[8], Aleš Urban[8], Alexandra Schneider[9], Veronika Huber[10], Joana Madureira[11], Malcolm Mistry[12], Antonio Gasparrini[12], Ana Vicedo-Cabrera[4,13]

[1]Yale School of Public Health, New Haven, USA, [2]University of Florence, Florence, Italy, [3]Rollins School of Public Health, Emory University, Atlanta, USA, [4]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, [5]Asian Demographic Research Institute, Shanghai University, Shanghai, China, [6]University of Santiago de Compostela, Santiago de Compostela, Spain, [7]Air Health Science Division, Health Canada, Ottawa, Canada, [8]Institute of Atmospheric Physics, Czech Academy of Sciences, Prague, Czech Republic, [9]Helmholtz Zentrum München – German Research Center for Environmental Health (GmbH), Neuherberg, Germany, [10]Chair of Epidemiology, LMU Munich, Munich, Germany, [11]Environmental Health Department, National Institute of Health, Porto, Portugal, [12]London School of Hygiene & Tropical Medicine, London, UK, [13]Oeschger Center for Climate Change Research, University of Bern, Bern, Switzerland

BACKGROUND AND AIM: Elderly population subgroups are amongst the most vulnerable to heat and cold. While temperature-related health impacts are projected to increase with progressive global warming, the influence of population aging on these trends remains unclear. Here we quantify the contribution of population aging to future temperature-related mortality in 729 locations across 42 countries at 1.5 °C, 2 °C, and 3 °C of warming using climate models of the latest Coupled Model Inter-comparison Project (CMIP6).

METHODS: We first estimated the location-age-specific temperature-mortality associations in a two-stage time-series analysis using quasi-Poisson regression with distributed lag nonlinear models and multivariate dose-response meta-regression using data from the Multi-Country Multi-City (MCC) Collaborative Research Network. We then combined the association estimates with future temperature series (18 models from CMIP6) to derive excess temperature-mortality projections at three warming levels. We derived age group-specific population and baseline mortality projections according to the Shared Socio-economic Pathway 5-8.5 to derive the corresponding excess mortality. Finally, we quantified the impact of population aging as the difference in the change in temperature-related mortality fractions (warming target minus historical period) between "climate-population" and "climate-only" scenarios (i.e., either accounting or not accounting for changes in population demographics).

RESULTS: Future heat-related mortality will increase by 0.8%-7.0% at 1.5-3.0 °C warming, among which 1 in 2 to 5 in 7 deaths would be attributable to population aging. Population aging would mostly offset the decrease of future cold-related mortality driven by climate only, leading to a net increase of 1.5%-5.3% at 1.5-3 ºC warming. Countries in Middle-East Asia, East-Asia, South-East Asia, and South America that have larger increases in population aging generally will face substantially elevated temperature-related mortality.

CONCLUSIONS: Our findings suggest that population aging would constitute a crucial driver for a larger impact of non-optimal temperatures under a warming climate.

P-0560 Blackout: A nationwide county-level accounting of power outages and vulnerability, 2018-2020

Vivian Do[1], Heather McBrien[1], Nina Flores[1], Jeffrey Schlegelmilch[2], Mathew Kiang[3,4], Joan Casey[1]
[1]Department of Environmental Health Sciences, Columbia Mailman School of Public Health, New York, USA, [2]National Center for Disaster Preparedness at the Columbia Climate School, New York, USA, [3]Department of Epidemiology and Population Health, Stanford University School of Medicine, Palo Alto, USA, [4]FXB Center for Health and Human Rights at Harvard University, Boston, USA

BACKGROUND AND AIM: Power outages – expected to increase as climate change accelerates and power grids age – threaten public health but remain understudied in the US. Outages have been linked to a variety of health outcomes including temperature-related illnesses and hospitalizations. We aim to characterize power outage exposure at the county level and to identify areas with high vulnerability and high exposure.

METHODS: We acquired outage data from PowerOutage.US and generated county-hour estimates of customers without power. Under our study, an outage event occurred whenever >0.5% of county customers were without power for 8+ and 1+ continuous hours. We characterized social vulnerability with the Centers for Disease Control and Prevention's Social Vulnerability Index and medical vulnerability with Medicare electricity-dependent durable medical equipment (DME) use. Bi-variate local indications of spatial association (LISA) analyses between each vulnerability characteristic and 8+ hour outages identified counties with high exposure disparities.

RESULTS: Between 2018-2020, the 2,978 counties in our study experienced a yearly median of 2 (IQR = 3) 8+ hour outages and 45 (IQR = 42) 1+ hour outages. of these counties, 92% and 99% faced at least one 8+ and 1+ hour outage respectively. Longer 8+ hour outages happened more in the summer, spring, and fall than winter. Outages occurred frequently along the Appalachia and portions of the Northeast and South. Counties with high 8+ hour outages and high SVI concentrated in Louisiana and West Virginia, while counties with high 8+ hour outages and high DME use were found in West Virginia and Ohio.
CONCLUSIONS: Power outages are an emerging environmental exposure that will likely increase with climate change. Our findings are important for future epidemiologic studies, equitable disaster preparedness, and energy policies.

P-0562 Optimal heat stress metric for predicting warm-season mortality varies from country to country

Eunice Lo[1], Dann Mitchell[1], Jonathan Buzan[2], Jacob Zscheischler[3], Malcolm Mistry[4,5], Eric Lavigne[6,7], Ben Armstrong[8], Aleš Urban[9], Jan Kyselý[9,10], Antonio Gasparrini[8,11,12], Ana M. Vicedo-Cabrera[13,14], Multi-Country Multi-City (MCC) Collaborative Research Network

[1]School of Geographical Sciences, University of Bristol, Bristol, UK, [2]Physics Institute, University of Bern, Bern, Switzerland, [3]Department of Computational Hydrosystems, Helmholtz Centre for Environmental Research GmbH – UFZ, Leipzig, Germany, [4]Department of Public Health, Environments and Society, London School of Hygiene and Tropical Medicine, London, UK, [5]Department of Economics, Ca' Foscari University of Venice, Venice, Italy, [6]School of Epidemiology & Public Health, Faculty of Medicine, University of Ottawa, Ottawa, Canada, [7]Air Health Science Division, Heatlh Canada, Ottawa, Canada, [8]Department of Public Health Environments and Society, London School of Hygiene and Tropical Medicine, London, UK, [9]Institute of Atmospheric Physics, Academy of Sciences of the Czech Republic, Prague, Czech Republic, [10]Faculty of Environmental Sciences, Czech University of Life Sciences, Prague, Czech Republic, [11]Centre for Statistical Methodology, London School of Hygiene and Tropical Medicine, London, UK, [12]Centre on Climate Change & Planetary Health, London School of Hygiene and Tropical Medicine, London, UK, [13]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, [14]Oeschger Center for Climate Change Research, University of Bern, Bern, Switzerland

BACKGROUND AND AIM: While heat combined with high humidity is frequently described as the main driver of heat stress, this remains unclear in epidemiological literature. A range of heat stress metrics, each being a different combination of temperature and humidity and sometimes other variables, are available in the literature. We compared eight heat stress metrics with warm-season mortality, with the aim of finding the optimal metric(s) for predicting mortality.

METHODS: We performed a two-stage time-series approach using quasi-Poisson regression with distributed lag nonlinear models to derive warm-season exposure-response associations between each heat stress metric and mortality, over 604 locations in 39 countries within the Multi-Country Multi-City (MCC) Collaborative Research Network. The metrics studied were dry-bulb temperature (Tmean), wet-bulb temperature (Tw), apparent temperature (AT), discomfort index, and swamp cooler temperatures at 20, 40, 60 and 80% efficiencies (Swmp20 to Swmp80). The goodness-of-fit of each exposure-response model was assessed using the Quasi-Akaike Information Criterion (qAIC). for each metric and country, we summed the qAIC values across all locations and identified the metric with the lowest country-level qAIC as the optimal metric. We also compared the heat-mortality fraction for each metric.

RESULTS: According to qAIC, AT, a metric combining temperature, humidity and wind speed, is the dominant driver of warm-season mortality, especially in Northern and Eastern Europe. Metrics with no or little humidity modification (Tmean and Swmp20) dominate in Southern and Western Asia, Eastern Asia, and Australia. Tw, a metric with large humidity modification, dominate in Caribbean, Central and South American countries but with large uncertainties. However, using Tmean as the only exposure metric does not result in significantly different attributable fractions compared to using the optimal metric.

CONCLUSIONS: There is no one-size-fits-all metric for predicting heat-related mortality, but Tmean is suitable enough for estimating impacts in present-day climate.

KEYWORDS: heat stress, mortality

P-0563 How is Australia progressing on climate change and health? - Evidence and implications of the MJA-Lancet Countdown

Ying Zhang[1], Paul Beggs[2]
[1]University of Sydney; Co-Chair, MJA-Lancet Countdown for Australia, Sydney, Australia, [2]Macquarie University; Co-Chair, MJA-Lancet Countdown for Australia, Sydney, Australia

BACKGROUND AND AIM: Australia has experienced unprecedented bushfires, heatwaves, floods and other weather extremes. It is imperative for Australia to build a detailed understanding of health and wellbeing-related responses to the impacts of climate change. In partnership with The Medical Journal of Australia (MJA) and the Lancet Countdown on health and climate change, the MJA-Lancet Countdown produces annual reports to assess Australia's health and climate change progress until 2030.

METHODS: The MJA-Lancet Countdown has published four national assessment reports since 2018, developing and tracking 40+ indicators in 5 sections: impacts, exposures and vulnerability, adaptation, mitigation, finance, and political and public engagement. The methodological framework largely followed the Lancet Countdown but adjusted for Australian contexts and databases. A few new indicators were developed uniquely for Australia population, e.g. bushfire adaptation, climate change and Indigenous Health, and commenwealth research funding on the topic.

RESULTS: These national assessment reports are the first to investigate Australia's broad progress on climate change and health, considering the social, economic, and political contexts and progress towards mitigation and adaptation. These reports have not only identified gaps in policies but also opportunities in responding to climate change in Australia. The MJA-Lancet Countdown has also published annual Policy Briefs for Australian policymakers, providing key policy recommendations through engagement with health professional organisations and other stakeholders.
CONCLUSIONS: Our reports indicate that Australia is vulnerable to climate change, but the responses are inefficient to protect people's health from changing climate. The presentation will provide an overview of the MJA-Lancet Countdown, including its key findings and policy recommendations, and the implications of the work in advancing climate change responses for Australia's health and wellbeing.

P-0565 Temporal changes of heat-attributable mortality in Prague, Czech Republic, over 1982-2019

Aleš Urban[1], Osvaldo Fonseca-Rodríguez[2], Claudia Di Napoli[3], Eva Plavcová[4]
[1]Faculty of Environmental Sciences, Czech University of Life Sciences, Prague - Suchdol, Czech Republic, [2]Department of Epidemiology and Global Health, Umeå University, Umeå, Sweden, [3]School of Agriculture, Policy and Development, University of Reading, Reading, UK, [4]Institute of Atmospheric Physics of the Czech Academy of Sciences, Prague, Czech Republic

BACKGROUND AND AIM: While previous research on historical changes in heat-related mortality observed decreasing trends over the recent decades, future projections suggest increasing impact of heat on mortality in most regions of the world. This study aimed to analyse temporal changes in temperature-mortality relationships in Prague, Czech Republic in the warm season (May-September), using a daily mortality time series from 1982 to 2019.

METHODS: To investigate possible effect of adaptation to increasing temperature, we divided the study period into four decades (1980s–2010s). We used conditional Poisson regression models to identify decade-specific relative risk of heat-related mortality and to calculate the annual number of heat-attributable deaths and the heat-attributable fraction of total warm season deaths. We estimated their trends over the whole study period by a generalized additive model with non-parametric smoothing spline.

RESULTS: Our results showed that the unprecedentedly hot 2010s was associated with approximately twice as large relative risk of heat-related mortality than in previous decades. This resulted in the reversal of the trend in heat-attributable mortality in the 1990s and its increase during the last two decades.
CONLCUSIONS: Our findings highlight the importance of further improvement of adaptation measures such as heat-and-health warning systems to protect the heat- susceptible population.

KEYWORDS: heat-attributable mortality, DLNM, trend analysis

P-0566 Short-term effects of heat on cardiovascular mortality and morbidity in Germany – Small-area analysis in the framework of the EXHAUSTION project

Alexandra Schneider[1], Siqi Zhang[1], Masna Rai[1], Francesca de' Donato[2], Massimo Stafoggia[2], Annette Peters[1,3], Susanne Breitner[1,3]

[1]Helmholtz Zentrum München, Institute of Epidemiology, Neuherberg, Germany, [2]Department of Epidemiology of the Lazio Region Health Service (ASL ROMA 1), Rome, Italy, [3]Institute for Medical Information Processing, Biometry, and Epidemiology, LMU Munich, Munich, Germany

BACKGROUND AND AIM: Short-term heat effects on cardiovascular outcomes have been examined mainly in major cities. So far, few studies have assessed heat effects in both urban and rural areas. This study aimed to investigate short-term associations of air temperature with cause-specific cardiovascular mortality and morbidity in the warm season (May-September) in German small areas.

METHODS: Daily counts of mortality and hospital admissions for ischemic heart disease (IHD), myocardial infarction (MI), heart failure (HF), and cerebrovascular diseases from 2000 to 2016 were collected at the small-area level (defined as districts for mortality and municipalities for hospital admission data). Daily mean air temperatures estimated by a spatio-temporal model were assigned to each small area. We applied district-specific Poisson regression using distributed lag nonlinear models to examine the heat effects on cardiovascular outcomes at lag 0-1 days. The district-specific estimates were pooled by random-effects meta-analysis to derive German-wide heat effects. We assessed effect modification by age and sex in subgroup analyses.

RESULTS: An increase in air temperature from the 75th to the 99th percentile was associated with increased cardiovascular mortality. The most substantial heat effect was observed for HF mortality, with a pooled risk ratio (RR) of 1.32 (95% CI: 1.29, 1.36). The heat effects on IHD, MI, and HF mortality were slightly stronger among the elderly (75+ years) and females. for cardiovascular hospital admissions, we found decreased risks associated with heat. for example, the pooled RR of HF hospital admissions for the same increment in temperature was 0.96 (95% CI: 0.95, 0.97).

CONCLUSIONS: This study provides evidence for the adverse heat effects on cause-specific cardiovascular mortality in Germany, considering both urban and rural areas. Besides, our findings indicate potentially different heat effects on cardiovascular mortality versus hospital admissions.

KEYWORDS: Air temperature, heat, cardiovascular, mortality, hospital admissions

P-0568 Associations of Weather Regimes and Ambient Temperature with the Timing of Birth in Southern Israel

Selin Girgin[1], Dorita Rostkier-Edelstein[2,3], Itai Kloog[4], Lena Novack[5,6], Offer Erez[7,8,9], Raanan Raz[1]
[1]Braun School of Public Health and Community Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel, [2]Department of Environmental Physics, Environmental Sciences Division, Israel Institute for Biological Research, Ness-Ziona, Israel, [3]Fredy and Nadine Herrmann Institute of Earth Sciences, The Hebrew University of Jerusalem, Jerusalem, Israel, [4]The Department of Geography and Environmental Development, Ben-Gurion University of the Negev, Beer-Sheva, Israel, [5]Soroka University Medical Center, Beer-Sheva, Israel, [6]Ben-Gurion University of the Negev, Beer-Sheva, Israel, [7]Division of Obstetrics and Gynecology, Soroka University Medical Center, Beer-Sheva, Israel, [8]Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, [9]Department of Obstetrics and Gynecology, Wayne State University, Detroit, USA

BACKGROUND AND AIM: Previous studies demonstrated associations between exposure to ambient temperature and timing of birth, but did not consider the role of weather regimes as an independent factor or as a modifier of the effect of temperature. We aimed to investigate associations of weather regimes and ambient temperature with the timing of birth in Southern Israel.

METHODS: We conducted a case-crossover study of 60,761 singleton live births in Southern Israel during 2004-2014. The case exposure period was the week before the birth date and the control exposure period was 28 days later. Ambient temperature was estimated using a spatio-temporal model at 1 km resolution in Israel. We fit separate conditional logistic regression models for preterm and term births using weekly mean temperatures divided into five quintiles, adjusting for seasonality. Additionally, we created similar models for assessing the associations between weather regimes and the timing of birth for each day preceding the delivery up to 6 days, adjusted for seasonality and temperature.

RESULTS: Higher temperature during the week before the birth was associated with the timing of term birth, with an adjusted odds ratio of 1.18 (95% CI: 1.07-1.31) for the highest quintile compared with the lowest, but no association for preterm births. The presence of a Persian Trough was consistently associated with timing of term births, with the strongest association on the date of birth (odds ratio = 1.07, 95% CI: 1.02–1.12) compared with Red Sea Trough. In addition, the association between temperature and term birth was stronger during weeks with a Persian Trough (odds ratio per 1 °C increase = 1.46, 95% CI: 1.44-1.49).

CONCLUSIONS: These findings demonstrate a possible role for weather regimes in determining the timing of birth beyond their influence on ambient temperature.

KEYWORDS: Ambient temperature, Weather regimes, Timing of birth

P-0572 Short-term heat effects on cardiopulmonary morbidity using national small area data – Results of the EXHAUSTION project

Siqi Zhang[1], Susanne Breitner[2], Masna Rai[1], Massimo Stafoggia[3], Francesca de' Donato[3], Kristin Aunan[4], Annette Peters[1,2], Alexandra Schneider[1]

[1]Helmholtz Zentrum München - German Research Center for Environmental Health, Neuherberg, Germany, [2]Institute for Medical Information Processing, Biometry, and Epidemiology, Ludwig Maximilian University of Munich, Munich, Germany, [3]Department of Epidemiology, Lazio Regional Health Service - ASL Roma 1, Rome, Italy, [4]Center for International Climate Research, Norway

BACKGROUND AND AIM: Short-term associations between heat and cardiopulmonary morbidity have been examined mostly in major cities. Given potential differences in the effects of heat between urban and rural areas, it is important to analyze areas of various degrees of urbanization to better understand the health effects of heat. This study investigated heat effects on cardiopulmonary hospital admissions in the warm season (May-September) in Italy and Germany at the small-area level.

METHODS: Daily counts of cardiovascular and respiratory hospital admissions were obtained for each municipality in Italy (2001–2015) and Germany (2000–2016). Spatio-temporal models estimated daily mean air temperatures at the municipality level. In each municipality-aggregated district, we first assessed heat effects at lag 0-1 days using district-specific Poisson regression with adjustment for a 4-way interaction between municipality, year, month, and day of the week, using the distributed lag non-linear model approach. Multivariate meta-analysis was then applied to pool the district-specific estimates in each country. Effect modification by age and sex was examined in subgroup analyses.

RESULTS: for an increment in daily temperature from the 75th to the 99th percentile, the risk for respiratory hospital admissions increased in both Italy [pooled risk ratio (RR): 1.112, 95% CI: 1.098-1.126] and Germany (pooled RR: 1.074, 95% CI: 1.067-1.081). We did not observe adverse heat effects on cardiovascular hospital admissions in either country. The heat effects on respiratory hospital admissions were stronger in the elderly (75+ years) and females.

CONCLUSIONS: Our study provides evidence for an adverse heat effect on respiratory morbidity, which was stronger in Italy with lower latitude. In both countries, the observed heat effects were more prominent in the elderly and females. Further analyses are ongoing to disentangle effects between urban and rural areas.

KEYWORDS: air temperature, heat, cardiopulmonary hospital admissions, small area

P-0573 Building Capacity for Disaster Research Response (DR2): Lessons, Tools and Resources from the University of Washington - National Institute of Environmental Health Sciences DR2 Workshop

Nicole Errett[1], Jamie Vickery[1], Resham Patel[6], Richard Kwok[2], Aubrey Miller[2], Daniel Abramson[1], Marissa Baker[1], April Bennett[2], Jeffrey Berman[1], Satish Bhagwanjee[1], Ann Bostrom[1], Tania Busch Isaksen[1], Youngjun Choe[1], Elizabeth Cox[1], BJ Cummings[1], Elaine Faustman[1], Derek Fulwiler[1], Betsy Galluzzo[4], Nicholas Gibbons[7], Cat Hartwell[1], Audrey Kessel[3], Amber Khan[1], Pam Kohler[1], Matias Korfmacher[1], Onora Lien[5], Sam Lovell[1], Stephen Morris[1], Isabel Nerenberg[1], Joan Packenham[2], Steven Ramsey[3], Juliette Randazza[1], Maria Savage[1], Dylan Scott[3], Charles Treser[1], Joseph Wartman[1], Nathan Weed[8], Rachel Wittenauer[1], Craig Wladyka[2]

[1]University of Washington, Seattle, USA, [2]National Institute of Environmental Health Sciences, Bethesda, USA, [3]DLH Corp, Raleigh-Durham, USA, [4]MDB, Inc, Bethesda, USA, [5]Northwest Healthcare Response Network, Renton, USA, [6]Public Health - Seattle and King County, Seattle, USA, [7]King County Office of Emergency Management, Renton, USA, [8]Washington Department of Health, Tumwater, USA

BACKGROUND AND AIM: Environmental health research in the aftermath of disaster is necessary to learn about short- and long-term health consequences, as well as response and recovery strategy effectiveness. However,several relational, logistical and administrative barriers facing disaster research necessitate intentional and collaborative planning among researchers, practitioners, funding agencies, and communities. In response, the University of Washington (UW) and the National Institute of Environmental Health Sciences (NIEHS) co-designed a "Disaster Research Response" (DR2) workshop to improve preparedness to conduct rapid environmental and health-related research that concurrently advances science and is responsive to community information needs. This presentation provides an overview of the DR2 workshop planning process and resultant tools, resources, and lessons learned.

METHODS: Over 50 NIEHS staff, UW faculty, students, and staff from environmental and occupational health, nursing, medicine, policy, planning, and engineering, and public health, healthcare and emergency management practitioners worked together for 2.5 years to build relationships, engage community members to identify research priorities, including through listening sessions and co-development of research protocols/plans, plan for ethical review of time sensitive research, and identify workforce development needs.

RESULTS: The workshop resulted in the development of several sharable tools and resources, including a Concept of Operations Plan; protocols for and highlights of community listening sessions, approaches to engaging communities in pre-disaster research planning, and research plans and protocols for conducting pre- and post-disaster data collection; institutional review board training; a gap analysis of disaster and health graduate training in the U.S.; and identification of lessons learned for communities embarking on similar efforts.

CONCLUSIONS: As climate change increases the global risk of disasters, processes, tools, resources, and lessons from the UW-NIEHS DR2 workshop can inform other communities seeking to build capacity to conduct environmental health disaster research.

KEYWORDS: Disaster research, climate change, community-engagement

P-0575 Integrative review to develop a holistic ecological framework exploring pathways to climate change impacts on mental health among priority groups

Monika Walia[1], Ben Wheeler[1], Anne Cleary[2]
[1]European Centre for Environment and Human Health, University of Exeter, Truro, UK, [2]Institute for Social Science Research, University of Queensland, Brisbane, Australia

BACKGROUND AND AIM: Climate change is already having a profound impact on human health. However, the impact of climate change on mental health remains poorly understood. Climate change impacts mental health directly via exposure to traumatic events such as floods, and bushfires and indirectly by compounding mental health impacts of socio-economic factors such as poverty, and unemployment. Climate-induced disasters can cause many forms of mental health issues such as increased anxiety, distress, depression, and post-traumatic stress disorder. Emerging evidence demonstrates more chronic impacts of changing climate on psychosocial health such as solastalgia and eco-anxiety. Although nearly one in ten people globally live with any mental health disorder, the current understanding of how climate change adds to the mental health burden is unknown.

METHODS: We have undertaken an integrative review to develop a conceptual framework underpinned by the ecological model explaining the mental health impacts of climate change. This study aims to develop a holistic socio-ecological system framework to understand the mental health impacts of climate change, with a particular focus on heightened vulnerabilities experienced among priority groups.

RESULTS: People and communities differ in their exposures, inherent sensitivity, and adaptive capacity to respond to and cope with mental health threats related to climate change. The proposed framework outlines different pathways through which mental health impacts of climate change may occur and maps these pathways to various priority groups such as children, adolescents, pregnant and postpartum women, older people, disadvantaged people, ethnic minorities, and Indigenous populations. These pathways are further aligned and extended to cover Bronfenbrenner's five environmental systems – microsystem, mesosystem, exosystem, macrosystem, and chronosystem.
CONCLUSION: A framework like this will serve as a crucial starting point for generating awareness around mental health impacts of climate change and for designing targeted interventions to mitigate mental health impacts of climate change.

P-0576 Short-term effects of heat on respiratory mortality and morbidity in Germany – small-area analysis in the framework of the EXHAUSTION project

Susanne Breitner[1,2], Siqi Zhang[2], Masna Rai[2,3], Francesca De'Donato[4], Massimo Stafoggia[4], Kristin Aunan[5], Annette Peters[1,2], Alexandra Schneider[2]

[1]LMU Munich, Institute for Medical Information Processing, Biometry, and Epidemiology - Chair of Epidemiology, Neuherberg, Germany, [2]Helmholtz Zentrum München - German Research Center for Environmental Health, Institute of Epidemiology, Neuherberg, Germany, [3]LMU Munich, Institute for Medical Information Processing, Biometry, and Epidemiology - Pettenkofer School of Public Health, Munich, Germany, [4]Lazio Regional Health Service - ASL ROMA 1, Department of Epidemiology, Rome, Italy, [5]CICERO - Center for International Climate Research, Oslo, Norway

BACKGROUND AND AIM: Short-term associations between heat and respiratory mortality and morbidity have been well recognized. However, most studies were conducted in major cities, whereas evidence for more rural areas is limited. In this study, we assessed the short-term associations between air temperature and cause-specific respiratory mortality and hospital admissions in the warm season (May-September) in Germany at a small-area level.

METHODS: Daily counts of mortality and hospital admissions for respiratory diseases, chronic obstructive pulmonary disease, asthma, lower respiratory tract infections, and pneumonia from 2000 to 2016 were obtained for Germany at the small-area level. Small areas were defined as districts for mortality data and municipalities for hospital admission data. Daily mean air temperatures estimated by a spatio-temporal model were assigned to each small area. We first applied small area-specific Poisson regression allowing for overdispersion, using Distributed Lag Non-linear Models to assess the heat effects at lag 0-1 days (average of same- and previous-day temperatures). Random-effects meta-analysis was then used to pool the small area-specific estimates. Besides, we conducted subgroup analyses to investigate effect modification by age and sex.

RESULTS: We observed increased risks for all investigated cause-specific respiratory mortality and hospital admissions associated with heat. The strongest heat effect was found for pneumonia. for an increment from the 75th to the 99th percentile of the temperature distribution, the pooled risk ratio was 1.49 (95% CI: 1.42, 1.57) for pneumonia mortality and 1.20 (95% CI: 1.19, 1.22) for pneumonia hospital admissions. The heat effects were stronger among the elderly (75+ years) and females.

CONCLUSIONS: Using data from both urban and rural areas, our study suggests the adverse heat effects on respiratory mortality and morbidity in the warm season in Germany. These heat effects were more pronounced among the elderly and females.

P-0578 The short-term effect of weather variables on heart rate variability in patients after open-heart surgery

Jone Vencloviene[1,2], Margarita Beresnevaite[2], Sonata Cerkauskaite[1], Nijole Ragaisyte[3]
[1]Vytautas Magnus University, Kaunas, Lithuania, [2]Institute of Cardiology, Lithuanian University of Health Sciences, Kaunas, Lithuania, [3]Department of Cardiology, Lithuanian University of Health Sciences, Kaunas, Lithuania

BACKGROUND: The effect of meteorological indicators may be more pronounced in more sensitive subpopulations. The aim of the study was to detect the associations between parameters of heart rate variability (HRV) and weather variables in patients who underwent coronary artery bypass grafting or valve surgery.

METHODS: The study was performed in Kaunas city, Lithuania, during 2008-2012. We used data of 220 patients. HRV was assessed by electrocardiographic data collected on a continuous 5-minute electrocardiogram (ECG). Data were collected at 1.5 months, 1 year, and 2 years after the surgery. The data of 495 ECG measurements were used. To investigate the associations, a mixed linear model was used adjusting for the linear trend, the month, and sociodemographic and health variables.

RESULTS: On days of a higher relative humidity (RH) (>89%), a lower mean average normal-to-normal interval between R waves (NN) was observed. Two days after RH>89%, a lower mean very low-frequency (VLF) in normalized units (n.u.) and a higher high frequency (HF) in n.u. was found; besides, the effect was stronger 1.5 months after the surgery. A lower mean value of the standard deviation of the RR intervals (SDNN, ms), VLF, a low frequency (LF), and HF powers were observed on days of air temperature (T) <-1 oC and this effect was weaker if T two days before was negative. A negative association of these HRV parameters with the daily North Atlantic Oscillation indices (NAOIs) was observed. Two days after low wind speed (<2.75 kt), a higher SDNN, VLF, and LF were found. The effect of low wind speed, the NAOI, and RH two days before was observed only in males, and the effects of changes in atmospheric pressure were stronger in females.
CONCLUSION: Among patients after open-heart surgery, the HRV variables may be related to specific weather changes.

P-0581 Early delivery following chronic and acute in utero ambient temperature exposure: a comprehensive survival approach

Ian Hough[1,2], Matthieu Rolland[1], Ariane Guilbert[1], Emie Seyve[1], Barbara Heude[3], Remy Slama[1], Sarah Lyon-Caen[1], Isabelle Pin[1,4], Cécile Chevrier[5], Itai Kloog[2], Johanna Lepeule[1]

[1]Inserm, U1209, Grenoble, France, [2]Department of Geography and Environmental Development, Ben-Gurion University of the Negev, Be'er Sheva, Israel, [3]Université de Paris, Centre for Research in Epidemiology and Statistics (CRESS), INSERM, INRAE, Paris, France, [4]Department of Paediatric Pneumology, Grenoble Teaching Hospital, Grenoble, France, [5]Université Rennes, INSERM, EHESP, IRSET (Research Institute for Environmental and Occupational Health), Rennes, France

BACKGROUND: Ambient temperature, particularly heat, is increasingly acknowledged as a trigger of preterm delivery, but study designs have been limited and results mixed. We aimed to comprehensively evaluate the association between ambient temperature throughout pregnancy and preterm delivery.

METHODS: We estimated daily temperature throughout pregnancy using a cutting-edge spatiotemporal model for 5,347 live singleton births from three prospective cohorts in France, 2002-2018. We performed Cox regression (survival analysis) with forward (weekly from conception) and backward (30 days before delivery) distributed lags to evaluate time-varying associations with preterm birth. We examined weekly mean, daytime, night-time, and variability of temperature, and heatwaves accounting for adaptation to location and season.

RESULTS: Preterm birth risk was higher following cold (5th vs 50th percentile of mean temperature) 7-9 weeks after conception [relative risk (RR) 1.3, 95% confidence interval (CI) 1.0-1.6 for 2°C vs 11.6°C] and 10-4 days before delivery (1.6 [1.1-2.1] for 1.2°C vs 12.1°C). Night-time heat (95th vs 50th percentile of minimum temperature; 15.7°C vs 7.4°C) increased risk when exposure occurred within five weeks of conception (2.0 [1.05-3.8]) or 20-26 weeks after conception (2.9 [1.2-6.8]). Overall and daytime heat (high mean and maximum temperature) showed consistent effects. We found no clear associations with temperature variability or heatwave indicators, suggesting they may be less relevant for preterm birth.
CONCLUSION: In a temperate climate, night-time heat and chronic and acute cold exposures were associated with increased risk of preterm birth. These results suggest night-time heat as a relevant indicator. In the context of rising temperatures and more frequent weather hazards, these results should inform public health policies to reduce the growing burden of preterm births.

P-0582 Trends in Tropical Nights and their Effects on Mortality in Switzerland across 50 years

Vanessa Rippstein[1,2], Evan de Schrijver[1,2], Sandra Eckert[3,4], Ana Maria Vicedo-Cabrera[1,2]
[1]Institute of Social and Preventive Medicine (ISPM), University of Bern, Bern, Switzerland, [2]Oeschger Center for Climate Change Research (OCCR), University of Bern, Bern, Switzerland, [3]Centre for Development and Environment (CDE), University of Bern, Bern, Switzerland, [4]Institute of Geography (GIUB), University of Bern, Bern, Switzerland

Despite its temperate climate, increasing temperature and more frequent and severe heat waves in Switzerland are leading to more heat-related health burden. Especially, high nocturnal temperature, usually associated to urban heat island effect, reduces the well-being of the society. We aimed to assess the spatiotemporal patterns in the frequency, the exposed population to Tropical Nights and its effect on daily mortality in Switzerland.
We derived the number of TN (night temperature ≥20°C) per district using district-specific population-weighted temperature series based on high resolution hourly mean temperature (ERA5-Land reanalysis data set) between 1969-2019. Through a spatiotemporal analysis, we assessed the change of TN frequency as well as the exposed population per district and decade. We then estimated the TN-mortality association by canton using conditional quasi-Poisson regression analysis using data on all-cause mortality at district level from 1980-2019. The model accounted for long-term and seasonal patterns and daily mean temperature.
We found an overall increase in the frequency of TN and exposed population in Switzerland between 1969-2019, mainly in the surrounding areas of the main cities of Lausanne, Geneva, Basel, Lugano and region of Zurich, and during the last 2 decades. Across Cantons, no clear spatial patterns were found in the level of vulnerability. In particular, TNs were associated with an increase of 37-22% in the risk of mortality in the cantons of Vaud (RR:1.37 [CI:1.19-1.59]), Zurich (1.33 [0.99-1.79]), Lucerne (1.33 [0.95-1.87]) and Solothurn (1.22 [0.88-1.69]), while a negative association was observed in Ticino (0.51 [0.37-0.7]), Basel-Land (0.4 [0.24-0.65]) and Thurgau (0.65 [0.5-0.85]). A null association was found in the remaining Cantons.
Our findings indicate that TN is a relevant health hazard for a large part of the Swiss population with potentially larger impacts in the future due to climate change and increasing urbanization.

P-0584 Temperature Variability and Birthweight: Epidemiological Evidence from Africa

Pin Wang[1,2], Kieran O'Donnell[3], Robert Dubrow[1,2], Kai Chen[1,2]
[1]Department of Environmental Health Sciences, Yale School of Public Health, New Haven, USA, [2]Yale Center on Climate Change and Health, Yale School of Public Health, New Haven, USA, [3]Yale Child Study Center & Department of Obstetrics Gynecology & Reproductive Sciences, Yale School of Medicine, Connecticut, USA

BACKGROUND AND AIM: In 2015, 14.6% of infants worldwide were born with a low birthweight (LBW), of which 91% were from low- and middle-income countries (LMICs). Although LBW has been reported to be associated with heat exposure, its relationship with temperature variability (TV) remains unclear. We aimed to quantify the association between TV and LBW among LMICs in Africa.

METHODS: Data on birthweight in 37 LMICs during 1990–2020 were collected from the Demographic and Health Surveys Program. Using hourly air temperatures at ~9km resolution from ERA5-Land, three TV metrics were calculated for the entire pregnancy and each trimester: 1) standard deviation (SD) of all daily maximum and minimum temperatures (overall TV during pregnancy); 2) average diurnal temperature range (intra-day TV during pregnancy); and 3) average absolute difference in mean temperatures between two adjacent days (inter-day TV during pregnancy). We employed generalized linear mixed logistic regression, with random effects for country and survey cluster, to regress the LBW indicator on various TV metrics separately, adjusting for sociodemographic characteristics.

RESULTS: There was a total of 333,392 children with birthweight available, of which 33,386 had LBW and 2,333 had very low birthweight (vLBW). Comoros has the highest prevalence of LBW (16.0%) whereas Rwanda has the lowest (6.2%). During the entire pregnancy, each one degree Celsius increase in overall, intra-day, or inter-day TV during pregnancy was associated with 3.3% (95% confidence interval (CI) 1.9–4.7%), 1.2% (95% CI 0.5–2.0%), or 13.2 (95% CI 3.8–23.5%) increase in the odds of having a LBW birth, respectively. The effects of TV on vLBW were consistently stronger for all pregnancy periods except for the 3rd trimester.

CONCLUSIONS: Our study suggests the adverse impact of TV on the risk of LBW in African LMICs, with the strongest association with inter-day TV.

KEYWORDS: Temperature variability, climate, low birthweight, pregnancy outcome

P-0587 Effect modification of greenness on the association between heat and mortality: a multi-city multi-country study

Hayon Michelle Choi[1], Whanhee Lee[1], Seulkee Heo[1], Antonio Gasparrini[2], Aurelio Tobias[3], Ben Armstrong[2], Dominic Roye[4], Francesco Sera[5], Ho Kim[6], Joel Schwartz[7], Klea Katsouyanni[8], Shilu Tong[9], Yuming Guo[10], Michelle L. Bell[1]

[1]School of the Environment, Yale University, New Haven, USA, [2]Department of Public Health Environments and Society, London School of Hygiene & Tropical Medicine, London, UK, [3]Spanish Council for Scientific Research (CSIC), Spain, [4]Department of Geography, University of Santiago de Compostela, Spain, [5]Department of Statistics, Computer Science and Applications "G. Parenti", University of Florence, Italy, [6]Graduate School of Public Health, Seoul National University, Republic of Korea, [7]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [8]Department of Hygiene, Epidemiology and Medical Statistics, National and Kapodistrian University of Athens, Greece, [9]Shanghai Children's Medical Centre, Shanghai Jiao Tong University School of Medicine, China, [10]Department of Epidemiology and Preventive Medicine, School of Public Health and Preventive Medicine, Monash University, Australia

BACKGROUND AND AIM: Identifying how greenspace impacts the temperature-mortality relationship in urban environments is crucial, especially given climate change and rapid urbanization. To date, studies on this topic have indicated conflicting findings and typically focus on a localized area or single country. We evaluated the effect modification of greenspace on heat-related mortality in a global setting.

METHODS: We collected daily ambient temperature and mortality data for 452 locations in 24 countries and used Enhanced Vegetation Index (EVI) as the greenspace measurement. We used a distributed lag non-linear model to estimate the heat-mortality relationship in each city and evaluated the effect modification of greenspace. City-specific average temperature, city-specific temperature range, city-specific population density, and GDP was adjusted as meta-predictors in a multivariate meta-regression. We derived the pooled heat-mortality relative risk (RR) comparing the 99th temperature percentile to the minimum mortality temperature (MMT) for each greenspace group (high, medium, low).

RESULTS: Cities with high greenspace value had the lowest heat-mortality relative risk of 1.19 (95% CI: 1.13, 1.25), while the heat-related relative risk was 1.46 (95% CI: 1.31, 1.62) for cities with low greenspace while comparing the 99th temperature percentile to the MMT. 20% increase of greenspace would reduce 9.02% (95%CI: 8.88, 9.16) heat-related attributable fraction, and this would result in saving approximately 933 excess deaths per year in 24 countries.
CONCLUSIONS: Our findings can inform communities on the potential health benefits of greenspaces in the urban environment and mitigation measures regarding the impacts of climate change.

BACKGROUND AND AIM: Climatic variables such as temperature and relative humidity (RH) impact lung function in the elderly. However, there is little research on the effect of temperature on lung function in adolescents. This preliminary study aims to assess the effect of temperature modified by season on lung function in adolescents.

METHODS: Spirometric lung function measurements (Forced vital capacity; FVC, forced expiratory volume; FEV1, and forced expiratory flow; FEF25-75%) were collected from GINIplus/LISAplus, two German birth cohorts at their 15-year follow up examination. A total of 2174 adolescents from the Wesel and Munich areas were assessed. We used generalised additive models to assess the linear effect of 8-day moving average temperature on FVC, FEV1, and FEF25-75%. The core model was adjusted for the 8-day moving average concentrations of RH, fine particulate matter ($PM_{2.5}$) and ozone (O_3), and was stratified by season (warm or cold).

RESULTS: We found that there was a decrease in FEF25-75% [relative risk (RR): 1.009 (95% Confidence interval (CI): 1.001 to 1.017)], FEV1 [RR: 1.013 (95%CI: 1.002 to 1.024)], and FVC [RR: 1.011 (95%CI: 1.001 to 1.021)] per 1°C increase in temperature (8-day moving average) during the warm season, respectively. Similarly, there was a decrease in FEF25-75%, and FEV1 when exposed to low mean temperature (8-day moving average) during the cold season, however, the results were not statistically significant.

CONCLUSIONS: Negative associations between prior exposure to 8-day temperature and lung function were apparent during the warm season but not necessarily in the cold season. The association remains robust after the addition of pollutants ($PM_{2.5}$ and O_3). We speculate that a decline in lung function associated with warm temperature could be due to behavioural changes on relatively warm days, because of increased participation in outdoor activities.

P-0589 Climate emergencies and health system resilience collaborative research action (CHESS): challenges and best practice from the UK and Australia

Ioannis Bakolis[1], Alexandra Barratt[2], Thomas Canning[1], Rebecca Haddock[3], Seeromanie Harding[4], Arnagretta Hunter[5], Daniela Espinoza Oyarce[5], Nina Lazarevic[5], Forbes McGain[6], Christopher Nolan[5], Lisa Page[7], Mark Pelling[8], Christine Phillips[5], Roslyn Prinsley[9], Nick Sevdalis[1], Richard Sullivan[10], Peter W Tait[5], Apostolis Voulgarakis[11], Shuo Zang[1], Kate Charlesworth[12], Sotiris Vardoulakis[5]

[1]Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UK, [2]University of Sydney, Sydney, Australia, [3]Institute for Health Transformation, Deakin University, Victoria, Australia, [4]School of Life Course and Population Sciences, King's College London, London, UK, [5]College of Health and Medicine,The Australian National University, Canberra, Australia, [6]School of Public Health, University of Sydney, Sydney, Australia, [7] Brighton and Sussex Medical School, Brighton, UK, [8]Department of Geography, King's College London, London, UK, [9]ANU Institute for Climate, Energy and Disaster Solutions,, Australia, [10]Centre for Conflict & Health Research, Institute of Cancer Policy, King's College London, London, UK, [11]Leverhulme Centre for Wildfires, Environment and Society, Department of Physics, Imperial College London, London, UK, [12]NSW Ministry of Health, New South Wales, Australia

BACKGROUND AND AIM: Health was chosen as a science priority area for the 2021 UN Climate Change Conference in Glasgow as well as in other international initiatives such as the UN Sustainable Development Goals, to bring a stronger focus to the environmental protection and disaster risk reduction agendas. Within this global context, the UK and Australian National Health Systems are committed to providing equitable, high quality health care, which requires capability and capacity to respond to the health emergencies of climate and humanitarian disasters.

METHODS: We have launched the climate emergencies and health system resilience collaborative research action (CHESS) between UK and Australian research institutions and healthcare associations to develop and strengthen a shared, evidence-based understanding of two key priorities: (1) Adaptation to climate change through building climate resilient health systems with people and nature in mind and (2) Mitigation of climate change through developing and implementing low carbon sustainable health systems. This collaborative research action is based on a series of roundtable discussions and comparative analysis of case studies.

RESULTS: CHESS includes case studies in the following areas to better inform planning of health systems: 1) Resilience of health services and communities to climate and humanitarian disasters with emphasis on how mitigation and adaption measures can be amplified to address disparities; 2) Support of workforce and patient physical and mental health and well-being, and training to champion and promote sustainable healthcare services; 3) Sustainability of the healthcare sector to reduce carbon emissions, waste and low value care. CHESS will foster the use of scientific evidence in evaluating specific interventions.

CONCLUSIONS: This talk will introduce the current research priorities and outline future research perspectives, considering the current evidence and gaps in knowledge in the UK and Australian healthcare systems.

P-0591 The Effects of Heat and Air Pollution on Mental Health Related Mortality in California

Mostafijur Rahman[1], Melissa Lorenzo[1], Rob McConnell[1], Zainab Hassan[1], Mehjar Azzouz[2], Sandrah Eckel[1], Hannah Schlaerth[3], Joseph Ko[3], Sam Silva[4], Frederick Lurmann[5], Lawrence Palinkas[1], Jill Johnston[1], Michael Hurlburt[1], Hao Yin[6], George Ban-Weiss[3], Erika Garcia[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [2]Occupational and Environmental Medicine, School of Public Health and Community Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [3]Department of Civil and Environmental Engineering, Viterbi School of Engineering, University of Southern California, Los Angeles, USA, [4]Department of Earth Sciences, University of Southern California, Los Angeles, USA, [5]Sonoma Technology, Inc., Petaluma, USA, [6]Department of Economics, University of Southern California, Los Angeles, USA

BACKGROUND: Higher ambient temperature and air pollution may play a role in increasing the risk of mental health related mortality; however, findings vary depending on study location. We examined the relationship between temperature and air pollution with deaths due to suicide and homicide in California—a region prone to high temperature and air pollution.

METHOD: California death certificates from 2014 to 2019 were used to identify the deaths due to suicide and homicide. Residential data for decedents were used to assign exposure to daily temperature (maximum [Tmax], minimum [Tmin]) and daily average air pollution concentrations (particulate matter <10 µm [PM10] and <2.5 µm [PM2.5], nitrogen dioxide [NO2], ozone [O3]). A time-stratified case-crossover study design using conditional logistic regression was used to assess the effects of daily exposure to Tmax, Tmin, PM10, PM2.5, NO2, and O3 on suicide and homicide mortality, adjusting for relative humidity as a potential confounder. Two-exposure models pairing temperature with a single pollutant and interactions between temperature and air pollution were also explored.

RESULTS: We observed 24,250 deaths due to suicide and 10,148 deaths due to homicide. A 1-ºC increase in same-day Tmax and Tmin was associated with 0.44% (95% confidence interval, CI, 0.02%–0.90%) and 0.76% (95%CI, 0.17%–1.35%) increased odds of death due to suicide, respectively. The increased odds of homicide mortality per 1-ºC increase in same-day Tmax and Tmin were 0.86% (95%CI, 0.23%–1.50%) and 1.05% (95%CI, 0.15%–2.00%), respectively. Associations for air pollution were null. Tmax and Tmin associations were robust to the adjustment of each air pollutant. We found marginally significant interaction effects of minimum daily temperature with PM10 and O3.

CONCLUSION: Our findings suggest that risk of suicide and homicide mortality increases with both increasing daily ambient maximum and minimum temperatures.

KEYWORDS: Temperature, Air pollution, Suicide, Homicide, Mortality

P-0593 Excess deaths after tropical cyclones in the USA

Robbie Parks[1,2], G. Brooke Anderson[3], Rachel Nethery[4], Francesca Dominici[4], Majid Ezzati[5,6,7], Marianthi-Anna Kioumourtzoglou[1]

[1]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York City, USA, [2]The Earth Institute, Columbia University, New York City, USA, [3]Department of Environmental & Radiological Health Sciences, Colorado State University, Fort Collins, USA, [4]Department of Biostatistics, T. H. Chan School of Public Health, Harvard University, Boston, USA, [5]MRC Centre for Environment and Health, School of Public Health, Imperial College London, London, UK, [6]Abdul Latif Jameel Institute for Disease and Emergency Analytics, Imperial College London, London, UK, [7]Regional Institute for Population Studies, University of Ghana, Legon, Ghana

BACKGROUND AND AIM: In the US, hurricanes and other tropical cyclones have a devastating impact on society and are an important public health concern. Knowledge of excess deaths is essential for understanding the true public health burden of climate-related disasters. However, methodology to calculate post-tropical cyclone deaths has been hitherto inconsistent; even estimates for the same tropical cyclone can vary greatly, such as for Hurricane Maria in 2017, for which official death counts were up to seventy times lower than the total number of excess deaths.

METHODS: We used mortality data from the National Center for Health Statistics and a comprehensive record of tropical cyclone occurrence in the US over 31 years (1988 – 2018). for each tropical cyclone, we formulated a Bayesian ensemble of forecasting models to estimate monthly all-cause and cause-specific death rates for the six months after exposure of tropical cyclone-impacted counties—defined as counties with a sustained maximal wind speed ≥34 knots—for the counterfactual scenario that these counties were not exposed to the tropical cyclone. We compared actual death rates to counterfactual rates and used population estimates to calculate excess deaths. We also examined how excess deaths varied by age group, sex, and social vulnerability.

RESULTS: There were 106 named tropical cyclones which contributed to US exposures in 1,206 counties during 1988 – 2018. In initial estimates, we found that for Hurricane Sandy in 2012, there were 172 [95%CrI,125–226] post-tropical cyclone excess deaths; the official figure is 72. for Hurricane Katrina in 2005, there were 1,793 [95%CrI,1,559–2,105] post-tropical cyclone excess deaths; the official figure is 1,836.

CONCLUSIONS: A full cataloguing of excess deaths by cause, age group, sex, and social vulnerability with a consistent methodology improves understanding of the true public health burden of hurricanes and other tropical cyclones.

P-0594 Rising temperatures and alcohol- and substance-related disorder hospitalizations

Robbie Parks[1,2], Sebastian Rowland[1], Vivian Do[1], Amelia Boehme[3,4], Carl Hart[5,6], Marianthi-Anna Kioumourtzoglou[1]
[1]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York City, USA, [2]The Earth Institute, Columbia University, New York City, USA, [3]Department of Neurology, Columbia University Medical School, New York City, USA, [4]Department of Epidemiology, Mailman School of Public Health, Columbia University, New York City, USA, [5]Department of Psychology, Columbia University, New York City, USA, [6]Department of Psychiatry, Columbia University, New York City, USA

BACKGROUND AND AIM: Temperature affects human health, but there is limited evidence on how temperature increases are associated with alcohol- and substance-related disorders. Over half of American adults regularly consume alcohol or substances. Plausible behavioral and physiological pathways exist for the association, including more perspiration in warmer weather, and temperature-dependent efficacies of substances. Our aim was to comprehensively evaluate associations between ZIP Code-level temperature and alcohol- and substance-related disorder hospitalization rates in New York State (NYS).

METHODS: Using a case-crossover design coupled with distributed lag non-linear terms, we examined how ZIP Code-level temperature was associated with daily alcohol- and substance-related disorder hospitalization rates up to six days before hospitalization, and how these estimated associations varied by location, age group, sex, and social vulnerability. Hospitalization records in NYS were collected from the NY Department of Health Statewide Planning and Research Cooperative System (SPARCS) along with a comprehensive record of temperature over 20 years (1995–2014). Daily individual-level hospitalizations were grouped into two causes (alcohol-, substance-related disorders) and four sub-causes (cannabis-, cocaine-, opioid-, sedative-related admissions).

RESULTS: We found a near-linear increase in alcohol-related disorder hospitalization rates between -28°C and 10°C (19.3% [95%CI,9.8%–28.9%]) and between 10°C and 20°C (4.7% [95%CI,3.3%–6.2%]), above which the association flattened at 32°C for a 6.0% [95%CI,1.5%–10.5%] increase relative to 10°C. Substance-related disorder hospitalization rates increased between -29°C and 10°C (36.1% [95%CI,26.1%–46.2%]) with no change from 10°C to 32°C (1.6% [95%CI,-2.8%–5.9%]). for cocaine, there was a near-linear increase from the coldest temperature to the mean (-29°C to 10°C) and an increase in rates above mean temperature, up to an 5.4% [95%CI,2.2%–13.0%] increase from 10°C to 32°C.

CONCLUSIONS: From 1995–2014, rising temperatures were associated with higher hospitalization rates for alcohol- and substance-related disorders up to a threshold, above which no association was detectible.

P-0596 Assessment of heat effects on all-cause and cardiopulmonary mortality and effect modification by air pollution in Attica prefecture, Greece; a small-area analysis in the framework of the EXHAUSTION Project

Sofia Zafeiratou[1], Antonis Analitis[1], Evangelia Samoli[1], Konstantina Dimakopoulou[1], Christos Giannakopoulos[2], Konstantinos Varotsos V[2], Alexandra Schneider[3], Massimo Stafoggia[4], Kristin Aunan[5], Klea Katsouyanni[1,6]

[1]Department of Hygiene, Epidemiology and Medical Statistics, Medical School, University of Athens, Athens, Greece, [2]Institute for Environmental Research and Sustainable Development, National Observatory of Athens, Athens, Greece, [3]Institute of Epidemiology, Helmholtz Zentrum München, Neuherberg, Germany, [4]Department of Epidemiology, Lazio Region Health Service, Rome, Italy, [5]CICERO Center for International Climate Research, Norway, [6]Environmental Research Group, MRC Centre for Environment and Health, Imperial College, London, UK

BACKGROUND AND AIM: The effects of short-term exposure to increased temperature on mortality are known, mostly based on time-series studies of city-wide data, whereas the evidence on temperature- air pollution interaction is limited. We investigated the association of short-term exposure to high temperatures with mortality in the Attica prefecture, Greece, by municipality, in the warm period (May-September) during 2000-2016, assessing daily air pollution exposure as effect modifier.

METHODS: We applied municipality-specific Poisson regression, allowing for overdispersion, on all-cause and cause-specific daily mortality, using Distributed Lag Nonlinear Models to assess temperature-mortality association. To evaluate interactions, a tensor product between mean temperature (lag 0–1) and PM_{10} or ozone (both lag 0–1) was defined and temperature estimates, corresponding to temperature increases from 75th to 99th percentile, were extrapolated at low, medium, and high levels of pollutants (5th, 50th and 95th percentile of pollutant's distribution respectively). Multivariate meta-analysis was applied to summarize results over the study area.

RESULTS: A rise in temperature was associated with a 20%(95% Confidence Interval (CI): 18.0, 23.0) increase in all-cause mortality. The increase was higher on days with higher pollution levels: 13.0% (95%CI: 8.4, 17.8) during low and 21.7% (95% CI: 18.4, 25.2) during high PM_{10} levels; 13.2%(95% CI: -3.0, 32.3) during low and 14.9% (95% CI:10.8, 19.1) during high O_3 levels. The same pattern was observed for cardiopulmonary mortality, with stronger heat effects for respiratory mortality, where, although the effects were not statistically significant for low air pollution levels, the increase in mortality was 55.1% (95% CI: 40.1, 71.6) and 45.0% (95% CI: - 27.4, 65.0) on days with high PM_{10} and O_3 levels, respectively.

CONCLUSIONS: A pattern of stronger heat effects on high air pollution days was observed. Under climate change, co-beneficial policies to mitigate heat and air pollution exposures are urgent.

P-0597 HEAL – Australian Research Network in Human Health and Environmental Change

Sotiris Vardoulakis[1], Veronica Matthews[2],Geoff Morgan[2],Linda Payi Ford[3], Brad Farrant[4], Daniela Espinoza Oyarce[1], Ivan Hanigan[5], Fay Johnston[6], Alan Cass[7], Craig Williams[8], Rebecca Bentley[9], Cordia Chu[10],Nicholas Osborne[11],Luke Knibbs[12], Bin Jalaludin[13]

[1]National Centre for Epidemiology and Population Health, Australian National University, Canberra, Australia, [2]University Centre for Rural Health, University of Sydney, Lismore, Australia, [3]Northern Institute, Charles Darwin University, Darwin, Australia, [4]Telethon Kids Institute, University of Western Australia, Perth, Australia, [5]WHO Collaborating Centre for Environmental Health Impact Assessment, Curtin University, Perth, Australia, [6]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [7]Menzies School of Health Research, Charles Darwin University, Darwin, Australia, [8]Clinical and Health Sciences, University of South Australia, Adelaide, Australia, [9]Melbourne School of Population and Global Health, University of Melbourne, Melbourne, Australia, [10]Centre for Environment and Population Health, Griffith University, Nathan, Australia, [11]School of Public Health, University of Queensland, Brisbane, Australia, [12]School of Public Health, University of Sydney, Sydney, Australia, [13]School of Population Health, University of New South Wales, Sydney, Australia

BACKGROUND AND AIM: The HEAL Network aims to strengthen the Australian community and health system resilience to climate change, extreme events, and other environmental change. This is achieved by building capacity and stimulating collaborative research that improves our understanding of the interactions between climate, the natural and built environment, public health, and their inequitable impacts across communities. HEAL is embedding systematic co-design processes with First Nations people on environmental change preparedness, capacity building, and mitigation and adaptation solutions.

METHODS: The HEAL Network is regionally distributed and includes multiple Communities of Practice (local knowledge exchange forums), comprising researchers, practitioners, community organisations, and decision-makers from across Australia. Based on initial gap analyses and stakeholder consultations, we have established 10 interdisciplinary research themes (Indigenous Knowledge Systems; Data and Decision Support Systems; Science Communication; Health System Resilience; Bushfires and Extreme Events; Food, Soil and Water Security; Biosecurity and Emerging Infectious Diseases; Urban Health; Rural and Remote Health; At-risk Populations and Lifecourse Solutions) and a range of capacity building activities that support communities and nurture early career researchers.

RESULTS: HEAL addresses capacity and capability gaps in health and environmental change, and credibility gaps in interactions between policy-makers, practitioners, industry and communities. One crucial outcome is developing the meta-capacity needed to formulate priorities, co-design research, and translate and implement research findings into policy and practice. New interdisciplinary collaborations springing from HEAL have led to development of community-based, solution-focussed research: e.g. facilitating Aboriginal community-led climate adaptation plans based on traditional Knowledges and environmental health data.

CONCLUSIONS: HEAL prioritises evidence and capacity needs, and local action with community-led co-design of solutions embedded in a monitoring and evaluation framework. This will lead to more effective national, regional and local policies to protect and improve public health and reduce inequalities within and across communities.

P-0598 Early exposure to ambient temperature is associated with newborn lung function with sex-specific effects

Ariane Guilbert[1], Ian Hough[1], Emie Seyve[1], Rémy Slama[1], Joane Quentin[2], Anne Boudier[1], Sarah Lyon-Caen[1], Itai Kloog[3], Isabelle Pin[2], Valérie Siroux[1], Johanna Lepeule[1]

[1]Inserm - IAB, La Tronche, France, [2]Grenoble Alpes University Hospital, La Tronche, France, [3]Ben-Gurion University of the Negev, Be'er Sheva, Israël

BACKGROUND AND AIM: Despite recognition of climate change, little is known on how ambient temperature may affect fetal development and child respiratory health. This study investigated the effect of prenatal and early postnatal exposure to ambient temperature on newborn lung function in France.

METHODS: Prenatal and early postnatal mean temperature and temperature variability at the mother's residence were estimated based on a validated spatiotemporally resolved exposure model in 343 mother–child pairs from the SEPAGES cohort. Newborn lung function was assessed at two months during unsedated sleep with tidal breathing and multiple breath washout test. Associations of ambient temperature with newborns lung function were analyzed using adjusted Distributed Lag Non-linear Models (DLNM) for the whole cohort and then stratified by sex. Both chronic (the first 35 gestational weeks and the 4 weeks after birth) and acute (the 7 days before the respiratory tests) exposures were investigated.

RESULTS: Among girls, chronic exposure to severe cold (the 5th percentile vs the median temperature) was robustly related to lower Functional Residual Capacity (FRC), lower tidal volume and higher respiratory rate. Chronic exposure to severe heat (the 95th percentile vs the median temperature) in girls was related to lower FRC and higher respiratory rate. Most of the significant windows of vulnerability to ambient temperature occurred between the second trimester of pregnancy and the first weeks of life.

CONCLUSIONS: Prenatal and early postnatal exposure to severe cold or heat may alter lung function among infants, especially in girls. Lung volumes appeared more specifically affected than airflows. Considering children and adults respiratory health are closely linked, long-term consequences may be substantial.

KEYWORDS: Ambient temperature; Climate change; DLNM; Infants; Lung function; Prenatal/Postnatal exposure; Restrictive lung disease

P-0600 What are the feelings prompted by manifestations of climate change among the young generations? A survey among University students in Fryslân (Northern Netherlands)

Sophie Beherens[1], Pelin Gul[1], Valentina Gallo[1]
[1]*University of Groningen, Leeuwarden, Netherlands*

BACKGROUND AND AIM: The threat posed by the changing climate potentially generates emotional anguish, anxiety, frustration, and grief (e.g. eco-anxiety or solastalgia). However, individuals can also experience positive emotions leading to the promotion of productive engagement with climate change. The wide range of feelings evoked by the same phenomena likely change across age, gender, and cultural background. Limited research has investigated the mental impact of climate change on young people. The aim of this research is to assess the type and intensity of feelings that different manifestations of climate change elicit in young people in Friesland, a rural region in North Netherlands.

METHODS: A questionnaire has been designed for this research. Two pictures per each of the nine climate change manifestations (melting glaciers and rising sea levels, warming oceans and acidification, extreme weather conditions that include droughts, floods, wildfires, extreme precipitation, tornadoes/storm/hurricanes, and frosts) were included. Participants were asked to associate one or more emotions (happiness, sadness, anger, boredom, fear, anxiety plus a distractor) to each of the pictures, and its relative intensity. Information on socio-demographic backgrounds was also collected.

RESULTS: A descriptive analysis of results will be conducted by tabulating the distribution of answers across several stratifying variables, i.e., gender, age. Furthermore, the researcher will look for correlations between each picture that depicts the same manifestation of climate change, to see whether different pictures of the same phenomenon evoke different emotions.
CONCLUSION: The same phenomenon can evoke different feeling in people, when fear prevails the anxiety feeling often leads to frustration and inaction; when rage prevails, this often leads to action, and change. Understanding the emotional impact of climate change on the new generations might help contribute and supporting campaigns aimed at triggering action rather than increasing anxiety and hopelessness.

P-0601 Associations of Extreme Precipitation with Emergency Department Visits Among Older Adults in the Upper Midwest, USA, 2006-2013

Carina Gronlund[1], Madeline Somers[2], Robert Melendez[1], Krista Latta[1], Peter Larson[1], Marie O'Neill[2]
[1]University of Michigan Survey Institute for Social Research, Ann Arbor, USA, [2]University of Michigan School of Public Health, Ann Arbor, USA

BACKGROUND: Extreme precipitation events have increased in the Upper Midwest. The impacts of precipitation on health here are poorly understood, especially for vulnerable populations. We examined the association between precipitation and gastrointestinal and respiratory emergency department (ED) visits in Medicare recipients age 65+ (N = 5.1 million ED visits) in 30 counties in Michigan, Ohio, and Pennsylvania.

METHODS: We used Poisson regressions of daily ED visit counts by ZIP/postal code on a daily population-at-risk offset; precipitation and temperature from 4 km resolution daily PRISM data; county; and time trends. We included distributed-lag non-linear transformations of precipitation and temperature for lags 0-20 days to account for delayed effects.

RESULTS: Overall, precipitation was non-linearly associated with both gastrointestinal and respiratory ED visits, with 20-day cumulative increased risk on days without precipitation and days with precipitation above the 75th percentile vs. 75th percentile (2 mm). Results varied by season--spring melt (March-May), warm (June-September), and cold (November-February)--and diagnosis. for gastrointestinal visits, in the warm season, risk was increased 13% (95% CI: 4.5%, 21%) at the 99.5th (45 mm) vs. 75th percentile. In the cold season, effects were deleterious at 0 mm but protective at high levels. In the spring season, effects were null. for respiratory visits in the warm season, risk was increased 20% (95% CI: 12%, 29%) at 99.5th vs. 75th percentile. In the spring and cold seasons, effects were deleterious at 0 mm and high values but null at very high values.

CONCLUSIONS: In the Upper Midwest, ED visits increased substantially following days with no precipitation and days above the 75th percentile, depending on season and cause of admission. A future project will explore effect modification by water distribution infrastructure age, which might increase health risks through drinking water contamination and increased flooding risk.

KEYWORDS: precipitation, emergency department visits, gastrointestinal, respiratory

P-0602 Trends in temperature-mortality projections across urban and rural regions under different climate change scenarios in Switzerland

Evan De Schrijver[1,2,3], Sidharth Sivaraj[1,2], Christoph Raible[2,4], Oscar Franco[1], Kai Chen[5], Ana Vicedo-Cabrera[1,2]
[1]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, [2]Oeschger Center for Climate Change Research, University of Bern, Bern, Switzerland, [3]Graduate School of Health Science, University of Bern, Bern, Switzerland, [4]Physics Institute, University of Bern, Bern, Switzerland, [5]Department of Environmental Health Sciences, Yale School of Public Health, New Haven, USA

Temperature vulnerability tends to be heterogenous between urban and rural regions, with usually larger risks in the former. However, it is unclear whether this pattern will persist under different climate change scenarios. Climate change combined with population growth, ageing and urbanization is expected to amplify the current temperature-related mortality burden, particularly since these drivers will follow diverse trajectories across urban and rural areas in the future. This study aimed to compare the impact of climate change regarding changes in heat- and cold-related mortality under various warming scenarios across urban/rural districts in Switzerland, while also accounting for changes in population demographics.

We first estimated the district-age-specific (<75/>=75years) temperature-mortality association between 1990-2010 in Switzerland using a two-stage time series design with distributed-lag nonlinear models. We then projected heat- and cold-related mortality under 1.5C, 2.0C, 3.0C and 4.0C warming scenarios using downscaled temperature projections under RCP8.5 while accounting for the Shared Socio-economic pathway (SSP5) population development storyline.

In Switzerland, heat- and cold-related mortality will increase by 2,420(95%CI:1654;3,884) and 993(82;1883) deaths /year, respectively, under 4.0C warming (vs. 1990-2010). Urban areas are more affected by both heat and cold and this pattern appears to be amplified under warmer scenarios. In particular, per 100 heat-related deaths in rural areas, there will be an increase from 362 to 391 deaths in urban areas, with similar results for cold (from 262 to 286 per 100 deaths in rural areas), indicating a slight increase in vulnerability to climate change in urban regions in the near future.

Our preliminary findings suggest that climate change will increase current heat and cold-related mortality in Switzerland, and moreover, urban areas will continuously more be disproportionately affected. Further analyses will aim to account for urbanization projections and disentangle the contribution of the different drivers across urban and rural regions.

P-0603 Examining the Relationship Between Extreme Temperature, Microclimate Indicators, and Gestational Diabetes Mellitus in Pregnant Women Living in Southern California

Anais Teyton[1,2], Yi Sun[3], John Molitor[4], Jiu-Chiuan Chen[5], David Sacks[6,7], Chantal Avila[6], Vicki Chiu[6], Jeff Slezak[6], Darios Getahun[6,8], Jun Wu[3], Tarik Benmarhnia[9]

[1]Herbert Wertheim School of Public Health and Human Longevity Science, University of California San Diego, La Jolla, USA, [2]School of Public Health, San Diego State University, La Jolla, USA, [3]Department of Environmental and Occupational Health, Program in Public Health, University of California, Irvine, Irvine, USA, [4]College of Public Health and Human Sciences, Oregon State University, Corvallis, USA, [5]Departments of Population & Public Health Sciences and Neurology, University of Southern California, Los Angeles, USA, [6]Department of Research & Evaluation, Kaiser Permanente Southern California, Pasadena, USA, [7]Department of Obstetrics and Gynecology, University of Southern California, Keck School of Medicine, Los Angeles, USA, [8]Department of Health Systems Science, Kaiser Permanente Bernard J. Tyson School of Medicine, Pasadena, USA, [9]Scripps Institution of Oceanography, University of California San Diego, La Jolla, USA

BACKGROUND AND AIM: Gestational diabetes mellitus (GDM), a form of glucose intolerance with an onset during pregnancy, impacts 5-10% of USA pregnant women. Previous studies have identified characteristics that increase GDM risk, including environmental exposures such as air pollution, temperature, and road traffic noise; however, few studies have assessed the influence of extreme temperature exposure on GDM risk at more refined temporal scales. We therefore aimed to investigate the relationship between extreme high and low temperature exposure and GDM risk at the weekly level during the first 24 weeks of gestation and to examine potential effect modification by microclimate indicators.

METHODS: Data from Kaiser Permanente Southern California electronic health records were used for pregnant women who gave birth from 2008-2018 (n=395,927). Daily maximum, minimum, and mean temperature exposures were linked to participants' residential addresses, and GDM screening occurred during 24-28 gestational weeks. Exposure-lag-response associations were examined between each of the 12 weekly extreme temperature exposures and GDM risk using distributed lag models coupled with logistic regression models that assessed the lag of gestational weeks from the first to the corresponding week. The relative risk due to interaction (RERI) was used to estimate effect modification of microclimate indicators on the relationship between extreme temperature and GDM risk.

RESULTS: GDM risk increased with extreme low temperature during gestational weeks 20-24 and with extreme high temperature at weeks 11-16. Microclimate indicators modified the influence of extreme temperatures on GDM risk, including non-NDVI, impervious surfaces, land surface temperature, water use efficiency, global human settlement, and evapotranspiration canopy.

CONCLUSIONS: Windows of susceptibility to extreme temperatures were observed during the second trimester of pregnancy. Microclimate indicators were identified that may be modified to attenuate extreme temperature exposures during these windows, which could in turn reduce GDM risk.

P-0605 More than a sneeze: Effects of daily airborne pollen exposure on blood pressure in adults (EPOCHAL study)

Alexandra Bürgler[1,2], Sarah Glick[1,2], Karin Hartmann[3,4], Marloes Eeftens[1,2]
[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]University of Basel, Basel, Switzerland, [3]Division of Allergy, Department of Dermatology, University Hospital Basel and University of Basel, Basel, Switzerland, [4]Department of Biomedicine, University Hospital Basel and University of Basel, Basel, Switzerland

BACKGROUND AND AIM: The dose-response relationship between pollen exposure and acute systemic health effects, such as elevated blood pressure (BP), has been inadequately studied. The EPOCHAL cohort study (Effects of Pollen on Cardiorespiratory Health and ALlergies) aims to investigate the association between pollen exposure and six different health outcomes, including BP.

METHODS: We collected seated systolic and diastolic BP (BPsys, BPdia) in 102 allergic and non-allergic adults repeatedly (minimum 14 days) over six weeks during their typical symptomatic period. A skin prick test was performed to confirm pollen sensitization. We applied mixed effects models to regress daily BPsys and BPdia on daily pollen concentration of two highly allergenic species (birch, grasses) as well as the total of twelve species. Daily pollen concentration (grains per m3) was log-transformed prior to analysis. We adjusted for age, sex, BMI, food consumption, medication use and exercise before the test, time of day, and daily air pollution (NO2, PM2.5) and temperature.

RESULTS: Total pollen concentration was associated with a significant increase of 0.54 mmHg in BPsys per increment of 1 log[Pollen]. The same increment for grass pollen was significantly associated with 0.39 mmHg higher BPsys as well as 0.28 mmHg higher BPdia. In a subgroup analysis of participants with self-reported symptoms and positive skin prick test (N=68), we found significant associations between total pollen concentration and elevated BPsys (0.69 mmHg) and BPdia (0.43 mmHg) as well as between birch pollen concentration and BPsys (0.79 mmHg) and BPdia (0.62 mmHg).
CONCLUSIONS: We found increased BPsys and BPdia related to higher same-day pollen exposure. Effect sizes increased if we restricted the analysis to objectively confirmed pollen allergy sufferers. After completion of data collection (N=400) in 2022, we will investigate lagged pollen exposure and splines to further describe pollen-BP dose-response relationships.

P-0610 High ambient temperature or ultrafine particles – which one has the largest effect on high burden diseases in New York State (NYS)?

Shao Lin[1,2], Quan Qi[3], Ian Ryan[1], Xinlei Deng[1], Gan Luo[4], Arshad A Nair[4], Fangqun Yu[4]
[1]Dept. of Environmental Health Sciences, University at Albany, SUNY, Rensselaer, USA, [2]Dept. of Epidemiology and Biostatistics, UAlbany, SUNY, Rensselaer, USA, [3]Dept. of Economics, UAlbany, SUNY, Albany, USA, [4]Atmospheric Sciences Research Center, UAlbany, SUNY, Albany, USA

BACKGROUND AND AIM: Exposure to fine particles and extremely high temperatures poses substantial health threats, but their health impacts are rarely compared, and the research estimating the disparities of exposure-health associations is lacking. This study compared the health risks of either increased temperature or ultrafine particles (UFPs) while controlling for other co-pollutants, and investigated if their association varied by sociodemographic (SES), different diseases, and season.

METHODS: We used a case-crossover study to examine the excess risk (%) for each interquartile range (ER_IQR%) increase of UFPs and temperature on five high burden diseases (HBDs), including ischemic heart diseases (IHD), diabetes, stroke, kidney diseases, and depression due to their large absolute increases in disability-adjusted life years. Daily temperature and pollutant exposure were obtained from GEOS-Chem+APM, a state-of-the-art chemical transport model with aerosol microphysical simulation. We used the principal diagnosis to define five HBDs from NYS Discharge Data, 2013-2018. Conditional logistic regression analyses were conducted while controlling for PM2.5, NH3, SO2, temperature, relative humidity, and various time-varying variables.

RESULTS: Among 1,268,526 cases, significant ER_IQR of UFPs on all HBDs occurred from lag 1-3 days (ER_IQR% ranges from 1.0 to 1.3, $P< 0.05$), and ER_IQR of temperature lasted from 0-4 days (ER_IQR% ranges from 1.1 to 7.3, $P< 0.05$). High temperature consistently impacted all five diseases the most. Males, older adults, Hispanics, and uninsured cases were more susceptible to the adverse effects of both heat and UFPs. Depression and IHD showed the highest ER_IQR% to high temperature (7.1 and 7.7, respectively). The risks of HBDs were higher in fall and winter.

CONCLUSIONS: We identified significant short-term associations between elevated temperature or UFPs and HBDs admissions. Temperature's effect was the highest. There were consistent disparities in exposure-health associations by SES, season, and different diseases.

KEYWORDS: ambient temperature, ultra-fine particles, high burden diseases, demographics, disparity.

P-0614 Hurricanes, Industrial Hog Operations, and Acute Gastrointestinal Illness in North Carolina, USA

Arbor Quist[1], Mike Fliss[3], David Holcomb[2], Paul Delamater[4], David Richardson[2], Lawrence Engel[2]
[1]University of Southern California, Los Angeles, USA, [2]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA, [3]Injury Prevention Research Center, University of North Carolina, Chapel Hill, USA, [4]Department of Geography, University of North Carolina, Chapel Hill, USA

BACKGROUND AND AIM: North Carolina (NC) is the third most hurricane-prone state and second leading hog producer. NC's hogs are housed in industrial hog operations (IHOs) in its eastern, hurricane-prone region. Hurricanes can inundate hog waste lagoons, transporting fecal bacteria that may cause diarrhea, vomiting, and/or nausea, collectively known as acute gastrointestinal illness (AGI). Hurricanes Matthew (2016) and Florence (2018) were NC's most recent deadliest hurricanes. We aim to understand the association between hurricanes and AGI in areas with and without IHOs.

METHODS: We used NC ZIP code-level surveillance data to calculate rates of AGI emergency department (ED) visits during 2016-2019. Using gridded PRISM precipitation data and swine permit data, we assessed the increase in AGI rate during the three weeks after Hurricanes Matthew and Florence in ZIP codes with heavy rain (>75th percentile of storm precipitation) and ≥10 IHOs and in ZIP codes with heavy rain but no IHOs by comparing AGI rates in these areas to their AGI rates during comparable non-hurricane time periods (2017, 2019).

RESULTS: The AGI rate in ZIP codes with heavy rain and ≥10 IHOs increased 13% (RR=1.13, 95% CI: 1.00, 1.29) after Hurricane Florence and 8% (RR=1.08, 95% CI: 0.87, 1.33) after Hurricane Matthew, while the AGI rates in ZIP codes with heavy rain and no IHOs experienced no increase (Florence: RR=0.99, 95% CI: 0.88, 1.12; Matthew: RR=0.98, 95% CI: 0.82, 1.16). ZIP codes with heavy precipitation and IHOs also had a higher proportion of Black, American Indian, and Hispanic residents than the state average.

CONCLUSIONS: Heavy rain from hurricanes in areas with IHOs may increase AGI rates, disproportionately harming people of color in NC.

KEYWORDS: Climate change, extreme weather, hurricane, disaster, flooding, industrial animal operations

P-0618 Method to set the wet bulb globe temperature criterion beyond which the heatstroke alert is issued

Yasushi Honda[1], Kazutaka Oka[1], Yasuaki Hijioka[1]
[1]*National Institue for Environmental Studies, Tsukuba, Japan*

BACKGROUND AND AIM: We have investigated the relation between daily maximum wet bulb globe temperature (= WBGTmax) and ambulance car visit due to heatstroke. Unlike WBGT-mortality relation, we could not find a minimum mortality temperature. Thus, so far there has been no good method to set the criterion for the heatstroke alert. Here, we propose the method that uses incremental “preventable number” of heatstroke cases.

METHODS: If a counterfactual "perfect action" is implemented at a certain WBGTmax criterion, all the EVs occurred on the day with the WBGTmax equal to or higher than the criterion should be prevented. This number can be regarded as “preventable number” (= PN). Our aim is to show the incremental PN, i.e., how many more visits would be prevented for each degC reduction, using Tokyo data as an example. Both the ambulance visit data and WBGT data were obtained from the respective governmental agencies. The observation period was from 2015 to 2019 during warmer months (from May to September). Using these data, we first modelled the relation between daily maximum WBGT (= WBGTmax) and the ambulance visits due to heatstroke, assuming quasi-Poisson distribution with log link in generalized linear model. With this model, we calculated 1 degC-incremental PN from the integer part of the highest daily maximum WBGTmax to that of the lowest WBGTmax.

RESULTS: The highest incremental PN was observed at 24, 26, 31, 32, and 29 degC for May, June, July, August and September, respectively. Here, 24 indicates 24.0 <= WBGTmax < 25.0. The current WBGTmax criterion in Japan is 33 degC, but the cumulative PN down to this criterion was less than half the total PN; the current criterion appeared too high.
CONCLUSIONS: The method shown here is a good method to set the criterion for the heatstroke alert.

P-0620 First steps for new extreme temperatures Health Early Warning System in Portugal

André Brito[1,2], Baltazar Nunes[1,3], Carlos Santos Silva[4], Rita Roquette[1], Susana Silva[1]
[1]National Institute of Health Doutor Ricardo Jorge, Lisbon, Portugal, [2]NOVA School of Science and Technology, Lisbon, Portugal, [3]Centro de Investigação em Saúde Pública, Escola Nacional de Saúde Pública, Universidade NOVA de Lisboa, Lisboa, Portugal, [4]Department of Mechanical Engineering, Instituto Superior Técnico, Lisboa, Portugal

Both extremely hot and cold temperatures are considered to have significant effects on population's health. More likely heat waves and cold spells due to climate change could result in excess deaths. Public health institutions play a crucial role in assessing the impacts of such events and, subsequently, in providing adequate early warnings and suitable mitigation recommendations.
AIM: In this work we propose an update of the heat and cold health early warning systems currently in use in Portugal. The aim was to develop a risk indicator, active throughout the whole year, and easily understood by the entire population, with the highest possible spatial resolution. Daily data of all-cause mortality and maximum, minimum and mean temperatures was gathered from public data sources for the 1995-2019 time period. District-specific temperature-mortality associations were estimated using quasi-Poisson with linear threshold distributed lag models for cold and hot semesters (minimum temperatures were considered in autumn/winter and maximum temperatures in spring/summer, to identify worst case exposure scenarios). Regressions included seasonality and long-term trends and year population estimates as an offset. Influenza incidence was also included in the model to improve predictive performance. Cold and hot thresholds were defined for each semester and for each district independently based on best data fit criteria.

RESULTS: show good predictive ability of the district-specific models and allowed the identification of different temperature-mortality associations between regions. The overall cumulative RRs estimated for low (4ºC) and high (34ºC) temperatures were 1.62 (95% CI: 1.65 - 1.69) and 2.35 (95% CI: 2.19 - 2.51) for the most populated district and 1.07 (95% CI: 1.04 - 1.11) and 1.03 (95% CI: 1.02 - 1.03) for the least populated district. Variation of optimum cold and hot thresholds between districts provided interesting insights about varied regional population vulnerability.

P-0621 Short-term impacts of ambient temperature on self-rated health in Augsburg, Southern Germany

Hasan Sohail[1,7], Siqi Zhang[2], Santtu Mikkonen[1,3], Susanne Breitner[2,4], Kathrin Wolf[2], Nikolaos Nikolaou[2], Annette Peters[2], Lars Schwettmann[5,6], Timo Lanki[1,7,8], Alexandra Schneider[2]

[1]Department of Environmental and Biological Sciences, University of Eastern Finland, 70211, Kuopio, Finland, Kuopio, Finland, [2]Helmholtz Zentrum München-German Research Center for Environmental Health, Institute of Epidemiology, 85764 Neuherberg, Germany, Neuherberg, Germany, [3]Department of Applied Physics, University of Eastern Finland, 70211, Kuopio, Finland, Kuopio, Finland, [4]LMU Munich, IBE-Chair of Epidemiology, 85764 Neuherberg, Germany, Neuherberg, Germany, [5]Helmholtz Zentrum München-German Research Center for Environmental Health, Institute of Health Economics and Health Care Management, 85764 Neuherberg, Germany, Germany, [6]Department of Economics, Martin Luther University Halle-Wittenberg, 06099 Halle, Germany, Germany, [7]Department of Health Security, Finnish Institute for Health and Welfare (THL), 70701, Kuopio, Finland, Finland, [8]School of Medicine, University of Eastern Finland, 70211 Kuopio, Finland, Finland

BACKGROUND AND AIM: Short-term exposure to low or high temperatures is known to be harmful for human health. Previous literature on associations between ambient temperature and health outcomes has mostly focused on mortality and hospital admissions in ecological studies. Self-rated health is a strong predictor of premature mortality but has rarely been used as a predictor for checking the effects of temperature on health. Our study was aimed to examine the short-term association of daily mean temperature with self-rated health and the potential effect modification by socio-demographic, lifestyle or medical history as well as air pollution covariates.

METHODS: The study is based on the KORA FIT follow-up study, a cross-sectional survey conducted in 2018/2019, which included 3,059 participants from Southern Germany. Self-rated health was assessed by the EuroQol Five Dimensions questionnaire (EQ5D). A higher score indicates better self-rated health. Daily mean air temperature was estimated by a highly resolved spatio-temporal model incorporating observation and remote sensing data and was assigned to participants' residential addresses. Generalized additive models using the distributed lag non-linear model (DLNM) approach with a lag period of 21 days, adjusted for potential confounders, were used to investigate the association between daily mean temperature and self-rated health.

RESULTS: The mean values of daily temperature and EQ5D were 9.01(min. = -12.18, max. = 26.90) degree Celsius and 0.91(min.= -0.13, max. = 1.00), respectively. No association was found between ambient temperature and self-rated health of participants. These are preliminary results and further analysis on effect modification is ongoing.

P-0622 Vulnerability and adaptation to climate change: perceptions and experience in an Arab urban locality in Israel

Alix Pahaut[1], Bnan Egbaria[1], Alaa Obeid[2], Maya Negev[1]
[1]University of Haifa, Haifa, Israel, [2]The Galilee Society, Shefa-'Amr, Israel

BACKGROUND AND AIM: Situated in a climate hotspot, Middle East cities should assess their vulnerability and build climate resilience. Understanding the population's perceptions and existing adaptation can support appropriate preparedness action. We aim to analyze climate change experience, vulnerability, adaptation, and perceptions in Shefa-'Amr.

METHODS: Mixed methods: 1) online questionnaire, 2) semi-structured focus groups; both with resident population.

RESULTS: Questionnaire respondents (n = 482) represented the three local religions, 58.2% women, overrepresentation of higher education. 96.8% indicated they believe climate change is happening, 50.6% answered they were "very worried" about it. 47.7% and 28.6% of respondents indicated that they have experienced "some" negative health consequences from extreme heat and heavy rain/flooding, respectively. Respondents indicated high rates of willingness regarding preparedness actions like signing a petition (89.8%), ensuring good housing drainage (88.3%), planting trees (85.6%), or designing buildings to require less air-conditioning (83.8%). They were relatively less interested about whether political candidates include climate preparedness in their agenda (65.5%). There was low willingness to sell or exchange land, a socio-politically sensitive topic, for developing local green spaces (32.8%). Social resilience was not very high, 1.64 ± 0.49 (1 – 3 scale).
Focus groups (n = 8, 4-8 per group, total 52 participants) revealed a contrast between traditional adaptation to heat methods and current reliance on air conditioning, lack of resilient urban infrastructure and inequality with neighboring Jewish municipalities, mixed attitudes towards preparedness (active and fatalistic) and towards social resilience, and frustration towards the municipality.
CONCLUSIONS: Mixed methods showed high levels of awareness and concern regarding climate change, and willingness to take a range of actions. Focus groups revealed a more complex picture of social resilience. These findings can be used to engage with and advocate for the community in resilience building.

P-0627 Large Scale Climate Indices, Environmental Variability, and Impact on human health

Kenza Khomsi[1]
[1]*General Directorate of Meteorology, Casablanca, Morocco*

BACKGROUND AND AIM: Large-Scale Climate Indices (LSCI) are numerical indicators of the strength and phase of teleconnections between the atmosphere, oceans, and continents for given regions. Most of the LSCI are interconnected and have been demonstrated to contribute to the climate variability, and extreme environmental conditions and then indirectly impact human health. The current work aims to further understand LSCI and their impacts on environmental variability, Skin temperature, and pollution by PM10 in Morocco.

METHODS: The current work has used LSCI, Skin temperature, and PM10 over the cities of Casablanca and Marrakech. Discontinuities in annual and seasonal datasets were analyzed using Pettitt and Hubert's approaches. Trends in datasets were studied using Theil and Sen's slope. Correlations between time series were estimated employing the Spearman coefficient.

RESULTS: Trends in annual LSCI were positive. Shifts in annual and seasonal large-scale patterns were recorded between the mid-1960s and early-1980s. at the annual and monthly scales, weak but significant connections were found between the SaOI and Skin temperatures in the cities of Casablanca and Marrakech. at the daily scale, all the LSCI were interconnected. PM10 was positively correlated to the Mediterranean Oscillation Index (MOI) and negatively to the Saharan Oscillation Index (SaOI).

CONCLUSIONS: In the studied area, Skin temperature and thus the thermal comfort, and particulate pollution and thus their impacts on human health may be partly explained by large scale atmospheric patterns. LSCI may be further explored in their relationships with environmental extremes. Mastering large-scale atmospheric patterns inducing phenomena that impact human health would be a good step toward a Climate/Air/Health warning system.

P-0628 Trends in wildfires caused by electrical power and the use of Public Safety Power Shutoffs in California

Alyson Harding[1], Marizen Ramirez[1]
[1]*University of Minnesota, Saint Paul, USA*

BACKGROUND AND AIM: Wildfires have increased in frequency and intensity in recent years, particularly in California. As climate change continues to alter weather patterns, producing high temperatures and drought conditions, catastrophic wildfires will persist. To prevent electrical lines from sparking wildfires, the California Public Utilities Commission has developed policies to implement Public Safety Power Shutoff (PSPS) events, which authorize utility companies to de-energize power lines to mitigate wildfire risk. This study aims to 1) characterize trends in fires caused by electrical power in portions of California between 2010 and 2020, 2) describe the use of PSPS events, and 3) examine if PSPS events are associated with fewer wildfires.

METHODS: Our study sample is the 27.5 million acres of land for which the California Department of Forestry and Fire Protection (CAL FIRE) and Contract Counties are responsible for preventing and suppressing fires. The area covers more than a quarter of the state, including much of the Wildland Urban Interface, where the human-built environment meets wildland vegetation. We obtained CAL FIRE's annual Wildfire Activity Statistics reports and extracted information on the number and causes of wildfires. Data about PSPS events were obtained from the California Public Utilities Commission. In further analysis, we will spatially link these data and use regression to examine the association between PSPS events and fires started by electrical power.

RESULTS: Preliminary results are focused on descriptive patterns of fires and PSPSs. Between 2010 and 2020, CAL FIRE and Contract Counties attended to 37,749 fires. Electrical power started approximately 9% of these fires. PSPS events, first approved in 2012, increased in frequency between 2017 and 2020.
CONCLUSIONS: Public Safety Power Shutoffs are a potentially powerful engineering intervention to prevent wildfires started by electrical power. Next steps will examine if PSPS events have prevented wildfires.

KEYWORDS:
Climate change, wildfires, intervention

P-0629 Extreme weather events and their impacts on malaria: historical records from the Nordic countries

Tzu Tung Chen[1]
[1]*University of Gothenburg, Gothenburg, Sweden*

BACKGROUND AND AIM: Warm summer temperature has been associated with historical malaria incidence in the Nordic countries with cool temperate climate, e.g., Finland, Sweden and Denmark. However, other weather factors, especially climatic extreme events and their impacts on malaria outbreak have rarely been rigorously studied. for example, coastal flooding caused by extreme sea level rise, could rapidly alter the larval habitat of brackish water malaria vectors. Other hydrological events like extreme rainfall and severe drought are also likely to impose nonlinear exposure responses and delayed effects of the climate–malaria relationship. This study aims to evaluate the historical malaria occurrence related to extreme precipitation events, and to distinguish the impact of different climate forces on malaria outbreaks by investigation whether there is statistically significant attribution of individual climate extremes to malaria epidemics.

METHODS: Historical symptom-based malaria cases during the 17-18th centuries were obtained from the Nordic countries, to compare with local long-term meteorological observations of temperature, precipitation and sea level. The non-linear relationship and delayed effect of precipitation events and malaria occurrence were further explored using the distributed lag nonlinear model (DLNM).

RESULTS: From long-period data of the Nordic countries, this study intends to investigate whether the magnitude of historical malaria epidemics was affected by local coastal flooding which mostly occurred during storm surges.
CONCLUSIONS: This study highlights the critical importance to distinguish the impacts induced by climate change perturbations, such as extreme rainfall and drought, and in particular coastal flooding, in order to provide a better understanding of diverse effects of climate change on the burden of malaria.

KEYWORDS:
Malaria, Nordic, sea level rise, extreme rainfall, drought, DLNM

P-0631 Home Medication and Heat-Sensitive Emergency Department Visits in Atlanta

Howard Chang[1], Yaoyao Qian[2], Noah Scovronick[1], Shannon Moss[1], Rohan D'Souza[1], Stefanie Ebelt[1]
[1]Emory University, Atlanta, USA, [2]University of Melbourne, Melbourne, Australia

BACKGROUND AND AIM: Several classes of drugs are known to affect heat tolerance by impairing sweat production, thermoregulation and thirst sensation. However, few population-based studies have considered the influence of prescribed medications on heat-related morbidity. This study aims to evaluate the hypothesis that patients on certain medications are more vulnerable to short-term high ambient temperatures.

METHODS: We obtained electronic health records of emergency department (ED) visits from Emory Healthcare hospitals during May to September for the period 2016 to 2018. Patients reported current prescriptions at ED intake and we categorized medications into 12 classes of interest. Daily meteorology from the Daymet 1km product was linked to patient residential ZIP codes. Using a case-crossover design, we examined associations between maximum temperature averaged over lag 0-2 days and ED visits for two heat-sensitive ED outcomes: acute kidney injury (AKI) and fluid and electrolyte imbalance (FEI). Effects of temperature were modeled non-linearly and effect modification by medication type was examined in age-matched stratified analyses.

RESULTS: There were 11,423 AKI and 22,506 FEI ED visits during the study period. for AKI, we found stronger associations with temperature (comparing 34 ^{o}C to 29 ^{o}C) among patients with prescriptions of antipsychotics (OR = 1.88, 95% CI: 1.17-3.01) and diuretics (OR = 1.32, 95% CI: 1.04-1.70) compared to patients without any reported medication. for FEI, stronger associations were observed among patients with prescriptions of beta-adrenergic blocking agents (OR = 1.20, 95% CI: 1.00-1.46) and diuretics (OR = 1.33, 95% CI: 1.07-1.64). No effect modification was observed for several common medication types, including ACE inhibitors, anticonvulsants, antihistamines, calcium channel blockers and statins.

CONCLUSIONS: We identified several subpopulations more vulnerable to short-term heat exposures based on self-reported home medications. These results are important for the development of more targeted strategies to reduce heat-related morbidity.

KEYWORDS: Heat, Medication, Morbidity

P-0635 Impact of extreme weather events on Sub-Saharan African child and adolescent mental health: The implications of a systematic review of sparse research findings

Hanna-Andrea Rother[1], R. Anna Hayward[2], Jerome A. Paulson[3], Ruth A. Etzel[4], Mary Shelton[5], Linda C. Theron[6]
[1]Division of Environmental Health, School of Public Health and Family Medicine,University f Cape Town, Observatory, South Africa, [2]Stony Brook University School of Social Welfare, Health Sciences Center, Stony Brook, USA, [3]George Washington University School of Medicine and Health Sciences and George Washington University Milken Institute School of Public Health, USA, [4]Milken Institute School of Public Health, The George Washington University, USA, [5]Health Sciences Library, University of Cape Town, Observatory, South Africa, [6]Department of Educational Psychology/Centre for the Study of Resilience, Faculty of Education, University of Pretoria, Pretoria, South Africa

BACKGROUND AND AIM: Over the past 10−15 years there has been increasing attention to the potential impact of extreme weather events (EWE) on children's mental health. Because sub-Saharan Africa (SSA) is experiencing an increase in the frequency and severity of these events, we decided it was necessary to conduct a systematic review. The focus was to examine research findings on EWE direct and indirect impacts on the mental health of children and adolescents living in SSA to inform protective adaptation strategies and promote resilience.

METHODS: In 2020 we conducted a systematic review in line with Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) and a grey literature review. The systematic review and grey literature search identified 1342 studies.

RESULTS: The titles and abstracts of 858 articles and grey literature were assessed for eligibility (e.g., mental health outcomes for children and adolescents linked to exposure to an EWE in SSA) with 21 articles identified for full-text review. of these, only two were eligible for full review. Both articles focused on extreme flooding events and associated psychological distress. Several protective factors were identified (e.g., age, sex, encouragement, and shared hardship) that ameliorated the psychological distress.
DISCUSSION: There is an alarming lack of research focusing specifically on the mental health of youth exposed to EWE in SSA, where EWE, especially extreme heat, flooding and droughts, continue to increase. The indication is that children and adolescents living in SSA are at risk of mental health impacts such as depression and post-traumatic stress disorder. With the severe shortage of SSA-specific research, SSA decision-makers, planners and adaptation strategy developers are not guided by local and regional evidence and may be missing areas of concern and opportunities for prevention.

THEMATIC 09: Environment and health in low and medium income areas

P-0690 Biomonitoring of Exposure to Metals in a Population Residing in an Industrial Area in Brazil: A Feasibility Study

Élida Campos[1,5], Carmen Freire[1,2,3], Fernando Barbosa[4], Cristina Lemos[5], Valéria Saraceni[5], Rosalina Koifman[1], Rafael Pinheiro[5], Ilce Silva[1]

[1]Department of Epidemiology and Quantitative Methods in Health, National School of Public Health, Oswaldo Cruz Foundation (FIOCRUZ), Rio de Janeiro, Brazil, [2]Instituto de Investigación Biosanitaria de Granada, Granada, Spain, [3]CIBER de Epidemiología y Salud Pública, Madrid, Spain, [4]School of Pharmaceutical Sciences of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, [5]Superintendence of Health Surveillance, Municipal Health Secretariat of Rio de Janeiro, Rio de Janeiro, Brazil

BACKGROUND: Industries are sources of environmental pollutants. However, there are few human biomonitoring (HBM) studies in the vicinity of industrial areas. Thus, we evaluate the feasibility of conducting an HBM study to assess exposure to metals in an industrial area in Rio de Janeiro, Brazil. METHODOLOGY: A cross-sectional survey was conducted near a steel factory. Adults (exposed = 775; controls = 775) were randomly selected and sex-matched. Subjects were interviewed using a questionnaire and a 24 h dietary recall. Blood samples were collected to analyze metal concentrations, blood count, biochemical parameters, and thyroid hormones. The feasibility of the survey was assessed following guidelines. The descriptive analysis was performed for the first 250 participants (pilot study).

RESULTS: Adjustments were made to the survey execution, including age-matching, fieldwork team, questionnaire, blood collection, and research awareness. The complete questionnaire was answered by ≥97% of participants; metals were measured in ≥98% and clinical parameters in ≥89%, except thyroid hormones (13–44%). The average age and family income were of 50 years and USD 575/month, respectively. The participants had equal distribution among sexes: 50% had a medium education level, and 59% were nonwhite.
CONCLUSION: This preliminary HBM study demonstrates feasibility for the total population, with results indicating representativeness of the target population.

KEYWORDS: survey; human biomonitoring; feasibility; toxic metals; steel industry; Brazil

P-0693 Detection and Genotyping of Toxoplasma gondii in the Environmental matrices (Soil and Water) in Gaza-Palestine

Adnan Al-Hindi[1], Zuhair Dardona[2,3], Mohamed Hafidi[2], Ali Boumezzough[2], Samia Boussaa[2,4]
[1]Medical Laboratory Sciences Department, Faculty of Health Sciences, Islamic University of Gaza, P.O. Box 108, Gaza, Palestine, Gaza, Palestine, [2]Microbial Biotechnologies, Agrosciences and Environment Laboratory (BioMAgE), Faculty of Sciences Semlalia, Cadi Ayyad University, Marrakesh, Morocco, [3]Governmental Medical Services, Gaza, Palestine, [4]ISPITS-Higher Institute of Nursing and Health Techniques, Ministry of Health, Rabat, Morocco

BACKGROUND AND AIM: The aim of the present study was to detect the prevalence as well genotyping of T. gondii oocysts, which is the environmental infectious stage, in Gaza- Palestine.

METHODS: for this purpose, 290 environmental samples were collected for T. gondii oocysts detection and genotyping through the use of sheather's solution and PCR techniques.
More specifically, soil samples were collected from five sites, which were Wadi-Gaza, Near trash dumpsters, residential house yards, open-air markets, public squares and gardens.

RESULTS: The results of the present study revealed that from the 290 environmental samples, 22 (7.58%) and 31 (10.68%) were contaminated with T. gondii oocyst according to the test methods of PCR and Sheather's solution, respectively. The highest rate of contamination detected was from samples collected from residential house yards, while public squares and gardens represented the lowest rate. Moreover, 26 (13%) from the 200 soil samples pool were contaminated according to the Sheather's solution method, while under the PCR, 18 (9.99%) samples were contaminated. Regarding the prevalence of contamination in water samples, only samples collected from Wadi-Gaza reported contamination levels.

CONCLUSIONS: The present study revealed that the contamination of T. gondii oocyst in soil is higher than water. The highest rate of soil contamination detected were from samples collected from residential house yards, while public squares and gardens represented the lowest rate. On another hand, the contaminated water samples are only from running water samples collected from Wadi- Gaza, while water which collected from other sources are free of contamination. Finally, this study concluded that all samples that were genotyped belong to T. gondii type I.
It is recommended that the Gaza Municipality should take measure towards the sanitation of the contaminated sites.

P-0695 Exploring the Relationship between Hog Farm Exposure and Chronic Obstructive Pulmonary Disease (COPD)

Alisha Crump[1], Mohammed Orloff[1], Austin Porter[2]
[1]University of Arkansas for Medical Sciences, Little Rock, USA, [2]Arkansas Department of Health, Little Rock, USA

BACKGROUND: Chronic Obstructive Pulmonary Disease (COPD) and related conditions continue to be a major public health concern. The primary cause of COPD is cigarette smoking; however, other risk factors include air pollution, work environment, infectious diseases and genetic predispositions. Related human studies have suggested that air quality and environment surrounding hog farms, specifically within low-middle income counties, have the potential to induce lung dysfunction.
AIM: The aim of this study is to explore the relationship between hog farming practices and chronic obstructive pulmonary disease .

METHODS: Geographical Information Software (GIS) was used to determine the association between state-wide hog farm location density and COPD. A retrospective (2000-2016) partial ecological study of 14 major Arkansas hog farm cities was conducted using the International Classification Code of Diseases- 10. Seven case cities (as those containing a hog farm) and seven control cities (as those without a hog farm) were identified.

RESULTS: Hog farm density was positively correlated with state-wide COPD prevalence and low median income. Further analysis, after controlling for county level race, gender, ethnicity, establishment year, alcohol abuse, drug abuse, smoking, obesity, and chronic neurological conditions, resulted in a protective association between hog farm exposure and COPD 0.78 (0.734, 0.840).

CONCLUSIONS: Given the study's results, city-wide hog farm exposure is not positively associated with county-level COPD prevalence. However, farm location density was determined to be correlated with state-wide COPD prevalence and low median income. A follow-up study using individual data, should be conducted to provide further insight in this exposure, outcome relationship.

P-0701 How agricultural droughts are contributing to child undernutrition in sub-Saharan Africa

Anna Dimitrova[1], Morgan Levy, Lara Schwarz, Alexander Gershunov, Marinelle Villanueva, Tarik Benmarhnia
[1]*University of California, San Diego, San Diego, USA*

Countries in sub-Saharan Africa (SSA) have some of the highest levels of child malnutrition, with more than one third of children under five in the region characterized as chronically undernourished. High reliance on subsistence farming, poor adoption of irrigation technologies and variable climate conditions make populations in SSA highly vulnerable to malnutrition during droughts. We use anthropometric data for 570,540 children under the age of five from 34 countries in SSA in combination with high resolution agricultural and climate data to estimate the association between agricultural droughts and child undernutrition in the region. We use global gridded data on the geographical distribution of crop areas for 19 major crops. Data on crop planting and harvesting dates are also collected for each crop. The Standardized Precipitation Evapotranspiration Index (SPEI), a multi-scalar drought index, is used to measure the intensity and spatial distribution of droughts during key periods of agricultural production (planting, growth and harvesting) and of different duration (seasonal and long-lasting droughts). Our preliminary analysis shows that droughts during the main crop growing season are associated with increased risk of child undernutrition in SSA. As a next step, we will quantify the impact of droughts during the planting and harvesting seasons and for specific crops. We will additionally investigate whether droughts impact pastoral communities, for example through livestock loss. The findings presented in this study call for urgent action to improve drought monitoring and response in SSA where the risks to child health posed by global warming are considerable. Under climate change, the severity and frequency of extreme weather and climate events, including droughts, are projected to increase in the future, which will place millions of children at risk of hunger unless timely actions plans are taken to improve food security in the region.

KEYWORDS: drought, undernutrition, agriculture, sub-Saharan Africa

P-0702 Household Air Pollution and Respiratory Health in Rural Crete, Greece: An Observational FRESH AIR Study

Marilena Anastasaki[1], Ioanna Tsiligianni[1], Dimitra Sifaki-Pistolla[1], Vasiliki-Eirini Chatzea[1], Andreas Karelis[1], Niels H Chavannes[2], Frederik van Gemert[3], Christos Lionis[1]

[1]Department of Social Medicine, School of Medicine, University of Crete, Heraklion, Greece, [2]Department of Public Health and Primary Care, Leiden University Medical Center, Leiden, The Netherlands, [3]Department of General Practice and Elderly Care, Groningen Research Institute for Asthma and COPD (GRIAC), University Medical Center Groningen, Groningen, The Netherlands

BACKGROUND AND AIM: During the Greek austerity, the unusual outdoor air-quality deterioration observed in cities was attributed to the increased use of biomass-burning fireplaces for domestic heating, resulting from rises in the price of conventional fuels. Indoor air data, particularly for the disproportionally affected rural periphery, was lacking. We explored levels of household air pollution and respiratory health in rural Crete, Greece.

METHODS: An observational, implementation science study with repeated design was conducted (November 2017- March 2018). PM2.5 and CO levels were measured in 32 purposively selected rural households, during periods of lesser (baseline) versus extensive (follow-up) heating. Residents' fuel-use practices, respiratory symptoms and respective awareness were assessed through questionnaires. McNemar and Wilcoxon tests were used to explore outcome differences between assessments.

RESULTS: Mean PM2.5 levels were not significantly different between measurements (36.34μg/m³ versus 54.38μg/m³; p=0.60) but exceeded WHO's air-quality guidelines (25μg/m³ for 24-hours mean). Mean CO levels were 0.56ppm (baseline) and 0.34ppm (follow-up; p=0.414). Maximal CO levels reached 26.1ppm (baseline) and 9.72ppm (follow-up; p=0.007). CO values were below WHO's cut-offs (26.6ppm for 1-hour and 6.1ppm for 24-hours mean). Overall, 90.6% of households were using wood-burning fireplaces/stoves, but half also owned clean-fuel devices. Differences between devices owned versus used were attributed to financial constraints. Most frequently reported respiratory symptoms [N=42 residents, 72.7% women, mean (SD) age: 66.8(14.9) years] were phlegm (27.3% versus 15.2%; p=0.34) and cough (24.2% versus 12.1%; p=0.22). Less than half of residents (48.5%) knew that indoor biomass-burning can harm health.

CONCLUSIONS: Levels of PM2.5 exceeding international standards were documented, in line with evidence regarding the return to harmful practices. Further research is required to confirm results. Advocating for fuel poverty, raising awareness and empowering communities seem important Public Health targets during austerity/energy crisis periods.

KEYWORDS: household air pollution, PM2.5, CO, respiratory health, fuel poverty, economic crisis, Greece

P-0703 Environmental Exposures in Lebanese Infants (EELI) Study: Methods, Findings, and Contextual Considerations to Launch A Birth Cohort in the Eastern Mediterranean Region

Myriam Mrad Nakhlé[1], Emile Whaibeh[1,2], Norma Aouad[3], Clara Chaiban[1], Hadiya Leya Affara[1], Jowy Abi Hanna[1], Nivine Abbas[1], Roubina Karhily[1], Georges Abi Tayeh[2,3]

[1]University of Balamand Faculty of Health Sciences, Beirut, Lebanon, [2]Saint-Joseph University, Beirut, Lebanon, [3]Hotel-Dieu de France Hospital, Lebanon

BACKGROUND AND AIM: The EELI Study is a longitudinal birth cohort launched in 2021 in Beirut, Lebanon to examine the long-term impact of environmental exposures on the health and wellbeing of prospective Lebanese mothers and infants and disease outcomes. The aim of the present study is to delineate the adopted study design and protocols, current progress, and contextual considerations for the planning and launching of a birth cohort in a resource-limited setting.

METHODS: Pregnant women expected to give birth at the Hôtel-Dieu de France University Hospital were recruited. During prenatal clinical visits and through phone interviews, they provided biological specimens and completed multiple questionnaires and semi-structured qualitative interviews. at birth, clinical records and samples of cord blood, colostrum, and meconium were collected. Nested cohort studies focused on the influence of maternal diet on infant gut microbiome and the influence of COVID-19 pandemic, economic crisis, and indoor environmental exposures on maternal mental health are conducted on sub-populations of the study.

RESULTS: A sample of n=123 participants has been recruited since the study launch. Over 500 variables have been recorded for each participant, and over 1000 biological specimens have been processed and stored in a biobank for further analysis. Household visits at 1 year from birth are set to be conducted starting May 2022 to complete more questionnaires and collect biological specimens from the infants. The retention rate in Year 1 is 92.2%.

CONCLUSIONS: The EELI study establishes a methodological and logistic basis to explore the concept of the exposome and its implementation in resource-limited settings and to establish a toolkit of the SOPs and questionnaires that can be employed by the other countries in the Eastern Mediterranean region.

KEYWORDS: birth outcomes, children's environmental health, exposure assessment, pregnancy outcomes; environmental exposures

P-0709 Wastewater-based epidemiology: an additional tool for TB surveillance?

Poovendhree Reddy[2], Hlengiwe Nombuso Mtetwa[1], Isaac Dennis Amoah[1], Sheena Kumari[1], Faizal Bux[1]
[1]Institute of Water and Wastewater Technology, Durban University of Technology, Durban, South Africa, [2]Department of Community health studies, Durban University of Technology, Durban, South Africa

BACKGROUND AND AIM: Tuberculosis (TB) is a global public health concern that causes a significant strain on healthcare systems, particularly in sub-Saharan Africa. Current surveillance using clinic and hospital data are inadequate as they exclude those patients who either cannot access healthcare or choose not to, due to potential stigmatisation associated with HIV/TB coinfection. Wastewater based epidemiology using molecular methods may be used as an alternate surveillance system to augment data.

METHODS: We used droplet-digital-PCR to assess the presence, quantity and diversity of tuberculosis-causing Mycobacterium spp. in wastewaters across several sub-Saharan African countries. Wastewater samples from Ghana, Nigeria, Kenya, Uganda, Cameroun and South Africa, from both influent and effluent (post-chlorination) were analysed.

RESULTS: Mycobacterium spp. (MTBC, M. tuberculosis, M.bovis, M africanum, M.caprae) were detected in wastewater samples pre and post-treatment from all six countries, at significantly varying concentrations. The highest median concentration detected in untreated wastewater was up to 4.8 (±2.73) log copies/ml for total mycobacteria, 4.6 (±3.86) log copies/ml for MTBC, 3.4 (±2.79) log copies/ml for M. africanum all from Ghana, 3.9 (±3.17) log copies/ml for M. tuberculosis from Uganda and 3.8(±0.10) log copies/ml for M. caprae from South Africa. Apart from a significant difference between Kenya and Cameroun, removal efficiency was similar in all tested treatment plants.

CONCLUSIONS: The detection of M. africanum in South Africa and other African indicates that migration should be considered in TB control strategies, particularly with developing resistant strains. The diversity of MTBC species in wastewater samples from these countries may be correlated to the prevalence of tuberculosis infections in the population served by these wastewater treatment plants and the migration of people across different countries. This study emphasizes the utility of wastewater-based epidemiology in tracking tuberculosis infections for use in surveillance.

KEYWORDS: Wastewater-based epidemiology, droplet-digital polymerase chain reaction, TB surveillance

P-0710 Prevalence and Antibiogram Signature of selected Vibrio species Recovered from Giant Shrimps (Penaeus Monodon) Samples in Malokun Sea, Ilaje, Ondo State, Nigeria

Ibukun Adesiyan[1], Olabisi I. Alaka[1]
[1]*Achievers University, Owo, Nigeria*

BACKGROUND: Giant shrimps (Penaeus monodon), an important native of the aquatic food chain and abundant crustaceans in Malokun sea, Ilaje, Ondo state, serves as significant seafood recipe. This study investigated the incidence and antibiotic susceptibility signature of Vibrio species isolated from crayfish sample from Malokun sea, Ilaje, Ondo State so as to evaluate its potential as reservoir of Vibrio species in this environment.
METHOD: A total of 30 fresh giant shrimp samples were obtained from Malokun sea and densities of Vibrio spp. were determined using MPN-PCR method. Shrimp samples were macerated in sterile blender and aliquots were processed using thiosulfate-citrate-bile salts-sucrose agar. The presumptive isolates were further confirmed as Vibrio spp. using PCR assay and then subjected to antibiotic susceptibility testing against a panel of 8 commonly used antibiotics using Kirby Bauer method.

RESULTS: Twenty (20) presumptive Vibrio isolates were randomly selected for molecular confirmation and 12 isolates were confirmed genotypically as Vibrio species. High antibiotic resistance was observed against penicillin (100%), ceftazidime (91.66%), cefepime (91.66%) doripenem while susceptibility to norfloxacin (75%), amikacin (100%), kanamycin (83.33%), streptomycin (66.66%) was likewise observed respectively. The multiple antibiotic resistance index (MARI) among Vibrio spp. ranged between MARindex 0.25-0.625 with highest MARI of 0.625 observed in 33.33% of Vibrio species showing resistance to five antibiotics.
CONCLUSION: This study revealed high prevalence of Vibrio species and multiple antibiotics resistance among examined marine shrimps in Malokun sea, Ilaje, Ondo state. as well as raised resistance against samples. We therefore concluded that the shrimps might pose health risk if undercooked contaminated shrimps were consumed and are potential reservoir of Vibrio species which could cause Vibrio associated infections in sea animals in this marine environment.

KEYWORDS: Vibrio spp., Shrimps, Penaeus Monodon, antibiotic resistance, Nigeria

P-0711 Differential Impact of Exposure to PM2.5 Composition and Contributing Sectors on Anemia Prevalence Amongst Children Under age five in India

Ekta Chaudhary[1], Sagnik Dey[1], Santu Ghosh[2], George Franciosalgeo[2], Sumit Sharma[3], Nimish Singh[4], Shivang Agrawal[5]

[1]Indian Institute of Technology, India, [2]St. John's Medical College, Bengaluru, India, [3]United Nations Environmental Programme, India, [4]The Energy and Resources Institute, India, [5]Environmental Defense Fund, India

Anemia, a condition of low red blood cell count and diminished hemoglobin levels, is highly prevalent in India. India has one of the highest anemia prevalence approx. 60% among children under age five (U5) in the world. Ambient PM2.5 exposure has been identified as a potential risk factor for anemia via systemic inflammation. Moreover, whether the impact varies with PM2.5 composition and sources contributing to such components is not known. Here, we examine the differential impact of exposure to ambient PM2.5 components on anemia prevalence among children U5 in India using exposure data from the CMAQ model and satellite-derived PM2.5, health data from the NFHS-IV. Here we focus on the exposure to PM2.5 components such as Black Carbon, Organic Carbon, nitrate (NO3), ammonium (NH4), sulfate, soil, and others, during the early life period. We use multilevel models adjusted for the risk factors - smoking, cooking fuel, BMI, wealth, and residence to assess the impact of PM2.5 components on anemia prevalence among children. at the ecological level, for every IQR increase in ambient PM2.5 exposure, the odds ratio for average anemia prevalence is 1.19 (95% UI: 1.17,1.22). for each IQR of NO3, anemia prevalence increased with an odds ratio of 1.26 (95% UI: 1.24,1.29). for the corresponding increase in NH4, others, BC, OC, SO4, and soil, anemia prevalence increased by odds ratio 1.19 (95% UI: 1.17,1.21), 1.16 (95% UI: 1.14, 1.18), 1.15 (95% UI: 1.13, 1.17), 1.11 (95% UI: 1.09, 1.13), 1.12 (95% UI: 1.11,1.13), and 1.10 (95% UI: 1.08,1.11), respectively. Sectorally, the domestic sector has the highest impact, followed by the unorganized sectors, road dust, agriculture waste, industry, etc. Our results will support the policymakers to target specific sectors that are contributing to exposure to PM2.5 and its components and, in turn, causing lethal health impacts.

P-0713 Hakuna matata! Can campus green spaces be restorative? A case study from Tanzania

Maria-Lydia Vardaka[1], Argyro-Anna Kanelli[1], Chrisovalantis Malesios[2], Olga-ioanna Kalantzi[1]
[1]Department of Environment, University of The Aegean, Mytilene, Greece, [2]Department of Agricultural Economics and Rural Development, Agricultural University of Athens, Athens, Greece

BACKGROUND: The majority of studies reporting the beneficial effects of urban green spaces on mental health, well-being and restoration have been conducted in developed and high-income countries. The present study explores the association of urban green spaces with mental health and restoration in a low/middle income country (LMIC) following exposure to the University of Dar Es Salaam's green spaces in Tanzania.

METHODS: In February 2022 an online survey was conducted among 108 participants working and studying on the University campus on their exposure to the University's green spaces (perceived greenness, quality, duration, frequency, availability, motivation and NDVI) and the impact on their mental health. Mental wellbeing and restoration were assessed with the Warwick–Edinburgh Mental Wellbeing Scale (WEMWBS) and Restoration Outcome Scale (ROS) respectively, while Nature Relatedness Scale (NRS-6) was used to determine the participants' connectedness with nature.

RESULTS: Participants' mental health improved after visiting the University's green spaces (WEMWBS: Mean= 24.7, SD = 4.6, ROS: Mean= 4.9, SD = 1.2). Multiple linear regression indicated an association between green space exposure and mental health. Participants' mental wellbeing (WEMWBS) was positively associated with the motivation to visit the University campus's green spaces ($p<0.05$). Objective greenness (NDVI) of the study areas (81% chose to spend their time in study areas with high NDVI, $p<0.05$) and nature relatedness scale (NRS-6) (Mean = 3.9, SD = 0.8, $p<0.05$) were both positively associated to restoration (ROS).

CONCLUSIONS: Our findings show the positive association between campus green space exposure and mental health improvement in an LMIC context, particularly for objective greenness and nature relatedness. Furthermore, the motivation for visiting green spaces can play an essential role in mental well-being and restoration.

KEYWORDS: University, campus, green spaces, LMIC, mental wellbeing, restoration

P-0714 Noise effects on health in studies in Low-Middle-income-countries (LMICs): a mapping review update of epidemiological evidence

Yingxin Chen[1], Anna Hansell[1], Yutong Cai[1]
[1]*University of Leicester, Leicester, UK*

BACKGROUND AND AIM: Noise has been linked to adverse non-auditory health problems, including annoyance, sleep disturbance, cardiovascular disease, and impaired cognitive function. However, most studies on these topics have been conducted in developed countries. This review focussed on studies in Low-and Middle-income-countries (LMICs), where populations are exposed to relatively higher levels of noise

METHODS: We conducted a literature search of Medline and Web of Science from 2009-2021 for studies in LMICs investigating environmental noise ((including road traffic noise, railway noise, aircraft noise, community noise, wind turbine noise, etc.) effects on health (including annoyance, cardiovascular disease, mental health condition).

RESULTS: Fifty-six papers were included in the review. Thirty-four (60.7%) of the 56 studies assessed exposure based on fixed-site sound level meter, thirteen with noise mapping, six with subjective ratings, three with personal monitoring. The mean level of noise exposure among all the reviewed studies ranged from 36.6 dB to 121.2 Db.
Twenty-two (39.3%) of the 56 studies looked at noise annoyance and perception and found, as with non-LMIC studies, higher noise levels are associated with higher annoyance. Eleven studies examined cardiovascular outcomes reported that short-term noise exposure may slightly increase blood pressure among children and long-term noise exposure was linked to higher prevalence of hypertension and coronary artery disease in adults. Studies on all other outcomes remain very limited which preclude a meaningful synthesis of the findings.
CONCLUSION: To our knowledge, this is the first review to summarize current evidence on the relationship between noise exposures and health outcomes in LMICs. This review provides critical and concise evidence on the knowledge gap to inform the future research agenda to help better understand noise pollution and human health in a global context.

KEYWORDS: Noise; Health; Low-and Middle-income-countries (LMICs)

P-0721 International variations in air pollution and cardiometabolic risk among Ghanaian migrants: The RODAM study

George Downward[1,9], Tess de Lange[1], Erik Beune[2], Karlijn Meeks[3], Ellis Owusu-Dabo[4], Silver Bakhendeka[5], Ina Danquah[6], Frank Mockenhaupt[7], Matthias Schulze[6], Liam Smeeth[8], Karien Stronks[2], Juliet Addo[8], Charles Agyemang[2], Kerstin Klipstein-Grobusch[1], Daniel Boateng[1]

[1]Julius Global Health, Julius Center for Health Sciences and Primary Care,University Medical Center Utrecht, Utrecht, Netherlands, [2]Department of Public and Occupational Health, Amsterdam UMC, Amsterdam, Netherlands, [3]Center for Research on Genomics and Global Health, National Human Genome Research Institute, National Institutes of Health, Bethesda, USA, [4]School of Public Health, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [5]MKPGMS-Uganda Martyrs University, Kampala, Ghana, [6]Department of Molecular Epidemiology, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, Germany, [7]Institute of Tropical Medicine and International Health Charité-Universitätsmedizin, Berlin, Germany, [8]Department of Non-Communicable Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, UK, [9]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands

BACKGROUND AND AIM: Long-term exposure to ambient air pollution has many links to cardiovascular diseases. However, its role on migrant populations, especially those who originated in low-and-middle-income countries is less well known. The aim of this project was to examine the relationship between ambient air pollution and cardiovascular risk factors in the Research on Obesity and Diabetes Among African Migrants (RODAM) study.

METHODS: We examined cardiovascular risk factors (hypertension and/or diabetes) for 5,889 Ghanaian migrants living either in Berlin (578), Amsterdam (1,663), London (1,120) or urban (1,449) or rural Ghana (1,109). Ambient PM2.5 and NO2 was predicted using global satellite models and paired to the residential co-ordinates for RODAM participants living in Europe and to pooled area co-ordinates for those in Ghana. Logistic regression models evaluated the relationship between ambient air pollutants and cardiovascular risk factors.

RESULTS: Overall, inverse or null relationships were observed for PM2.5 and NO2 when examining hypertension and diabetes separately. However, for those with one (or both) of these conditions, a positive association with NO2 was observed where a 5 µg/m3 increase in NO2 was associated with an OR of 1.16 (95% CI: 1.00, 1.34). This association varied across the various RODAM sites including an inverse relationship in rural Ghana (OR: 0.87, 95% CI: 0.24, 1.02) a null relationship in Berlin (OR: 0.99, 95% CI: 0.72, 1.27) and a positive relationship in London (OR: 1.05, 95% CI: 1.02, 1.63).

CONCLUSIONS: A positive association between having one or more cardiovascular risk factor and NO2 was observed. However, no such association was observed when examining risk facts individually. A more detailed analysis, including more precise pollution predictions (including more information on domestic fuel use) and a wider array of cardiovascular risk factors (e.g. BMI) is required to better understand this relationship.

KEYWORDS: Migrant health; Air pollution; Cardiovascular health

P-0722 The Folic Acid and Creatine Trial: Treatment effects on arsenic metabolite concentrations in blood

Ahlam Abuawad[1], Anne Bozack[1,2], Ana Navas-Acien[1], Jeff Goldsmith[3], Xinhua Liu[3], Megan Hall[4], Vesna Illevski[1], Angela Lomax-Luu[1], Faruque Parvez[1], Hasan Shariar[5], Mohammad Uddin[5], Tariqul Islam[5], Joseph Graziano[1], Mary Gamble[1]

[1]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA, [2]Division of Environmental Health Sciences, School of Public Health, University of California, Berkeley, Berkeley, USA, [3]Department of Biostatistics, Mailman School of Public Health, Columbia University, New York, USA, [4]Department of Epidemiology, Mailman School of Public Health, Columbia University, New York, USA, [5]Columbia University Arsenic Project in Bangladesh, Dhaka, Bangladesh

BACKGROUND AND AIM: Arsenic exposure is a global issue. Inorganic As (InAs) undergoes methylation to monomethyl (MMAs) and dimethyl-arsenical species (DMAs); full methylation to DMAs facilitates urinary excretion and can reduce risk of adverse health outcomes. Folate and creatine influence one-carbon metabolism which provides methyl groups for As methylation. We investigated the effects of folic acid (FA) and/or creatine supplementation on As metabolites and primary (PMI: MMAs/InAs) and secondary (SMI: DMAs/MMAs) methylation indices in blood in Bangladeshi adults.

METHODS: In this double-blind, placebo-controlled trial, 622 participants (20% folate deficient) were randomized to receive FA (400 or 800 µg/day), 3 g creatine/day, 3 g creatine+400 µg FA/day, or placebo for 12 weeks. for the following 12 weeks, half of the FA participants received placebo. All participants received As-removal water filters.

RESULTS: Blood As metabolite concentrations decreased in all groups due to filter use. After 1 week, the mean within-person increase in SMI for the creatine+400FA group exceeded the placebo group. The mean decreases in blood concentrations of MMAs (bMMAs) between baseline and week 12 was greater for all treatment groups compared to placebo, and the increase in bDMAs concentrations for the FA treated groups exceeded that of placebo. The decrease in PMI and increase in SMI in all FA groups at week 12 exceeded placebo. Data from week 24 showed evidence of rebound from week 12, with decreases in SMI in those who switched from 800FA to placebo, whereas for those who remained on 800FA, PMI and bMMAs concentrations continued to decline.

CONCLUSIONS: FA supplementation lowered bMMAs and increased bDMAs in adults in Bangladesh. Evidence of rebound in As methylation capacity following FA cessation suggests short-term benefits of supplementation and underscores the importance of long-term interventions such as FA fortification and As mitigation in drinking water.

KEYWORDS: Arsenic, Nutritional Intervention

P-0723 Ambient nitrogen dioxide exposures in Latin American cities

Josiah Kephart[1], N Gouveia[2], Daniel A. Rodríguez[3], Tania Alfaro[4], José Luis Texcalac-Sangrador[5], J. Jaime Miranda[6], Usama Bilal[1], Ana V. Diez Roux[1]

[1]Drexel University, Philadelphia, USA, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brasil, [3]University of California, Berkeley, USA, [4]Universidad de Chile, Santiago, Chile, [5]Instituto Nacional de Salud Pública, Cuernavaca, México, [6]Universidad Peruana Cayetano Heredia, Lima, Perú

BACKGROUND AND AIM: Ambient nitrogen dioxide (NO_2) is a ubiquitous urban air pollutant emitted by fossil fuel combustion. Exposure to NO_2 is associated with respiratory disease and all-cause mortality. Health research on ambient NO_2 is sparse in Latin America, despite high urbanization and the high prevalence of NO_2-associated respiratory diseases in the region. This study aims to describe highly-granular population exposures to ambient NO_2 and urban characteristics associated with NO_2 exposure within 326 Latin American cities.

METHODS: We leveraged estimates of annual surface NO_2 at 1km² spatial resolution, population counts from national census bureaus, and urban characteristics compiled by the SALURBAL project for the year 2019, aggregating all data to the neighborhood (i.e. census tract) level. We described the percent of the urban population living in neighborhoods with ambient NO_2 levels exceeding WHO Air Quality Guidelines (annual, 10 μg/m³). We used multilevel models to describe associations between neighborhood-level ambient NO_2 concentrations and population and urban characteristics at the neighborhood and city levels. All models were adjusted for country and included all characteristics concurrently.

RESULTS: We examined 47,251 neighborhoods in 326 cities representing eight Latin American countries. of the ≈236 million urban residents observed, 85% lived in neighborhoods with ambient annual NO_2 above WHO guidelines. In adjusted models, higher neighborhood-level educational attainment, closer proximity to the city center, and lower neighborhood-level greenness were associated with higher ambient NO_2. at the city level, higher congestion, population density, and intersection density were associated with higher ambient NO_2.

CONCLUSIONS: Almost nine out of every 10 residents of Latin American cities are exposed to ambient NO_2 concentrations above WHO guidelines. Increasing neighborhood greenness and reducing city-level congestion warrant further attention as potential actionable urban environmental interventions to reduce urban population exposure to ambient NO_2.

P-0725 SARS-CoV-2 Wastewater Based Epidemiology in Low and Lower Middle-Income Countries: A Systematic Review

Muhammad Mainuddin Patwary[1], Pervez Kabir[1,3], Mondira Bardhan[1,2], Sharif Mutasim Billah[1,2], Asma Safia Disha[1,2], Mahadi Hasan[1,2], Afrin Laila Parvin[1,2], Sardar Al Imran[1,4], Mehedi Hasan[1,5], Zahidul Haque[1,2], Ashraful Alam[6,7], Matthew H.E.M. Browning[8]

[1]Environment and Sustainability Research Initiative, Khulna, Bangladesh, [2]Environmental Science Discipline, Life Science School, Khulna University, Khulna, Bangladesh, [3]Department of Civil Engineering, Ottawa-Carleton Institute for Environmental Engineering, University of Ottawa, Ottawa, Canada, [4]Development Studies Discipline, Khulna University, Khulna, Bangladesh, [5]Department of Environmental Science and Disaster Management, Bangabandhu Sheikh Mujibur Rahman Science and Technology University, Gopalganj, Bangladesh, [6]Department of Global Health Policy, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [7] Tokyo Foundation for Policy Research, Tokyo, Japan, [8]Department of Parks, Recreation and Tourism Management, Clemson University, Clemson, SC, USA

BACKGROUND AND AIM: Wastewater based epidemiology (WBE) is a promising tool to monitor the prevalence of COVID-19 disease at community level through detection of SARS-CoV-2 RNA in wastewater. Although WBE has been largely adopted in developed countries as complementary to clinical surveillance, the approach is still not widely applied in low-and-lower-middle-income countries (LMICs) owing to number of drawbacks. Despite these limitations, a small number of studies on wastewater based epidemiology for SARS-CoV-2 detection have been conducted in LMICs. The current systematic review provides an overview of the efficacy of WBE in LMICs.

METHODS: We conducted keyword searches in PubMed, Web of Science, and Scopus for articles published between January 2020 to February 2022. A total of 2,057 relevant articles were identified, and 21 met our inclusion/exclusion criteria.

RESULTS: The most common analytical steps used in included studies are sampling, storage, concentration, extraction, and detection. Studies utilized either composite/grab raw sludge or influents mostly from wastewater treatment plants, which covered a population of one to ten million. Among the studies, Among the studies, the most commonly used concentration technique was Poly Ethylene Glycol (PEG), and the most frequently targeted gene was the N gene. The overall sample positivity was found 81.18%, with viral loads of 40 to 45,000 copies/L. Most of the studies found positive correlation between SARS-CoV-2 viral loads in wastewater and the detected COVID-19 cases. Besides, few studies found higher signals in wastewater with a time lag of one to two weeks before clinical case detection.

CONCLUSIONS: These findings of systematic review illustrate the analytical methods used in WBE research, as well as the future of WBE in LMICs, thereby allowing decision-makers to take strategic preventative actions to curb the spread of COVID-19 diseases in LMICs.

P-0728 The health effects of the 2020 Bangladesh floods in the rural and isolated areas

Shamsul Huda[1,2], Saori Kashima[1,3]
[1]Environmental Health Sciences Laboratory, Graduate School of Advanced Science and Engineering, Hiroshima University, Higashi-hiroshima, Japan, [2]BCS (General Education) cadre, Officer on Special Duty (OSD), Directorate of Secondary & Higher Education, Ministry of Education, Dhaka, Bangladesh, [3]Center for the Planetary Health and Innovation Science, IDEC Institute, Hiroshima University, Hiroshima University, Higashi-Hiroshima, Japan

BACKGROUND AND AIM: In Bangladesh, severe floods occurred in 2020, and the health effects such flood disasters in the rural areas are not clear. Identifying the environmental risk factors in health after the disaster is crucial for mitigating health burdens. The study aims to describe the effects of floods on the worsening of the perceived health conditions and identify those environmental risk factors in the rural and isolated coastal areas, which are severely affected by the 2020 Bangladesh floods.

METHODS: The questionnaire survey was conducted in the coastal areas of two upazilas (sub-districts) (Amtoli & Golachipa) in August 2021. By using logistic regression analysis, we evaluated the health effects according to the affected levels, evacuation status, sanitation, access to drinking water/food (within 3days) and medicine (within 7days) in the early emergency phase, and access to the prescription medications during floods.

RESULTS: Among 168 participants, 82.1% of people were affected (partially inundated: 29.8% and inundated: 52.4%), and 43.5% were evacuated to some places. Water supply (57.14%) and sanitation (73.80%) were severely disrupted and more than half of the participants could not access drinking water (57.1%), food (54.2%), and medicine (65.6%) in the early emergency phase. During floods, about 35% of people were difficult to get needed medicines, and 62.5% were experienced diarrhoea in their household members. People without accessing the medicine during floods had more experiences of diarrhoea [Odds ratio: 2.18 (95% CI: 1.08-4.38)], worsening their mental health [3.31 (1.69-6.46)] compared with people who could access. Childhood malnutrition, mental health problems and worsening chronic disease (hypertension/diabetes) in their family were more likely observed among people affected or evacuated.
CONCLUSION: In the isolated coastal areas, the disaster severely disrupted sanitation and access to adequate services and exaggerated the health conditions. Further investigations immediately after the disaster should be conducted in rural areas.

P-0730 Microbial Contamination of the Stem Bark of Mitragyna ledermannii, A Commercially Available Medicinal Plant in the District of Abidjan (Cote d'Ivoire)

Kouassi Bernadin Kouame[1], Mamidou Witabouna Koné[1], Kalpy Julien Coulibaly[1], Mireille Dosso[1]
[1]*Institut Pasteur Côte d'Ivoire, Abidjan, Côte D'Ivoire*

Raw plant material sold on markets may constitute hazardous risk to population due to storage conditions. This study aimed at assessing the microbial quality of Mitragyna ledermannii an important medicinal plant being used in Cote d'Ivoire for treating malaria and other diseases.
A total of 188 samples of stem barks of M. ledermannii were purchased from markets in 3 settings (Abobo, Adjamé, Yopougon) over a period of 3 months. The samples were analyzed using standard microbiological methods. Also, some physicochemical parameters were measured. The moisture of the samples varied from 5.3 to 61.18%, pH was 4.88-6.35 and temperature 24.5-31°C. The samples showed high rate of contamination to mesophilic aerobic bacteria (100%), total coliforms (99.50%), thermotolerant coliforms (99.50%), Escherichia coli (10%), Staphylococcus aureus (98.93%), Enterococci (85.56%), Pseudomonas (61%), yeasts and moulds (93%). Any Salmonella was found in all samples. Average loads of microorganisms ranged from 2.6 $x10^3$ to 8.7 $x10^7$ CFU/g for mesophiles, 4.0 $x10^3$ to 3.4 $x10^7$ CFU/g for total coliforms, 1 $x10^3$ to 6.6 $x10^6$ CFU/g for thermotolerant coliforms, 8.0 $x10^4$ to 4 $x10^8$ CFU/g for Staphylococcus aureus, from 3.2 $x10^3$ to 2.2 $x10^8$ CFU/g for Enterococci, and 2.0 $x10^4$ to 4.4 $x10^7$ CFU/g for yeasts and moulds. Most of samples had unsatisfactory microbiological quality compared to WHO standards.
This study demonstrates population exposure to health risk and the great need to carry out microbiological tests frequently in these medicinal plants marketed in Abidjan.

KEYWORDS: Medicinal plants; markets; storage; microbiology; quality; Cote d'Ivoire

P-0735 Household Air Pollution and the Nasal Microbiome in Children from Rural Ghana

Shoshannah Eggers[1], Seyram Kaali[2], Darby Jack[3], Mohammed Nuhu Muitaba[2], Steven N Chillrud[4], Musah Osei[2], Peggy Lai[5], Kathryn Dubowski[6], Rebecca Dwommoh Prah[2], Jose Clemente[7], Theresa Tawiah[2], Alison G Lee[6], Kwaku Poku Asante[2]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Kintampo Health Research Centre, Research and Development Division, Ghana Health Service, Kintampo, Ghana, [3]Department of Environmental Health Sciences, Mailman School of Public Health at Columbia University, New York, USA, [4]Lamont-Doherty Earth Observatory at Columbia University, Palisades, USA, [5]Department of Medicine, Harvard Medical School, Boston, USA, [6]Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai, New York, USA, [7]Department of Genetic and Genomic Sciences, Icahn Institute for Genomic and Multiscale Biology, Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: Associations between household air pollution exposure, the nasal microbiome and lung function in childhood are unknown.

METHODS: Analyses included n=53 children from the Ghana Randomized Air Pollution and Health Study (GRAPHS) in Kintampo, Ghana. Personal air pollution exposures (carbon monoxide, CO, and fine particulate matter, PM2.5) were measured prenatally, postnatally and at four years. Age four nasal swabs underwent DNA extraction and 16S rRNA gene sequencing on the Illumina MiSeq with subsequent taxonomic profiling using QIIME2. We employed linear regression to assess relationships with high vs low air pollution exposures and α-diversity, and we used permutational analysis of variance to assess associations with β-diversity. Associations between log transformed continuous exposures and individual taxa were assessed using MaAsLin2. We examined associations between α-diversity and individual taxa, considered separately, and age four impulse oscillometry lung function by linear regression.

RESULTS: High prenatal PM2.5 was associated with lower α-diversity (p = 0.04) and richness (p=0.02), as compared to low prenatal PM2.5. B-diversity was associated with high vs. low prenatal PM2.5 (R2=0.07, p=0.03), postnatal CO (R2=0.04, p=0.03), and age four PM2.5 (R2=0.04, p=0.07). Prenatal CO and postnatal PM were negatively associated with three bacterial genera each, while postnatal CO was positively associated with four (including Haemophilus) and negatively associated with 15. Prenatal PM was positively associated with two genera, and negatively associated with 23 (including Ralstonia and Brachybacterium). Age four PM was positively associated with 11 genera (including Ralstonia). A-diversity was associated with large airway resistance (R20 β=0.53 p=0.05). Lung function was inversely associated with Brachybacterium, and Haemophilus, and positively associated with Collinsella and Ralstonia.

CONCLUSIONS: Early life exposure to household air pollution is associated with differences in the nasal microbiome of children at age four, potentially influencing lung function.

KEYWORDS: Air pollution, nasal microbiome, low-middle income country, lung function

P-0736 Neighborhood socioeconomic status and the human gut microbiome composition: relating socioeconomic environment to microbial diversity and MDRO colonization

Ibrahim Zuniga-Chaves[1], Shoshannah Eggers[3], Ashley E. Kates[4], Nasia Safdar[4], Garret Suen[1], Kristen M.C. Malecki[5]
[1]Department of Bacteriology, University of Wisconsin-Madison, Madison, USA, [2]Microbiology Doctoral Training Program, University of Wisconsin-Madison, Madison, USA, [3]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York City, USA, [4]Division of Infectious Disease, Department of Medicine, School of Medicine and Public Health, University of Wisconsin-Madison, Madison, USA, [5]Department of Population Health Sciences, School of Medicine and Public Health, University of Wisconsin-Madison, Madison, USA

Low socioeconomic status is correlated with a greater vulnerability to both chemical and non-chemical stressors, however, there is limited research on how socioeconomic status relates to the human gut microbiome, and subsequent associations with downstream health outcomes. Here, we aimed to examine associations between neighborhood level economic hardship, an indicator of overall cumulative risk, gut microbiome composition and additional cofactors that might be involved in this association including diet quality and food insecurity. We conducted a cross-sectional analysis of 721 adults living in geographically diverse (urban vs. rural) regions of Wisconsin (USA). 16S rRNA gene amplicons were analyzed from human stool samples using QIIME2 to evaluate both the composition and diversity of the gut microbiotas from 721 participants. Next, we determined correlations with each individual's neighborhood score for socioeconomic status, or Economic Hardship Index (EHI), using simple and zero-inflated negative binomial regression models. Our model of EHI, with alpha diversity (Inverse-Simpson) as an outcome, found a correlation (β= 1.68, p=0.03) that it is partially mediated by food insecurity (p= 0.02). Moreover, we found differential abundances of known health-associated bacteria including members of the genera Bifidobacterium and Akkermansia, and the family Ruminococcaceae between high and low levels of EHI that were robust to correction for multiple comparisons. Finally, we discovered a higher prevalence (p=0.03) and number (p=0.02) of multi-drug resistant bacteria isolated from individuals with low alpha-diversity and high EHI. Our analyses suggest that living in low socioeconomic communities is associated with lower gut microbial diversity and potential increase in colonization by multi-drug resistant microbial pathogens. Mediation of associations by food insecurity is consistent with previous work from our group examining impacts of metal exposures on gut microbiome dysbiosis indicating dietary factors play an important role in mitigating environmental influences on gut microbial diversity.

P-0738 The Nigerian Environmental Epidemiology Accelerated Research Program (NEEAR): Evaluation of an Environmental Epidemiology Short Course for Nigerian Researchers

Adetoun Mustapha[1], Lisa Mason, Christine Ekenga
[1]*Nigerian Institute of Medical Research, Lagos, Nigeria*

BACKGROUND AND AIM: The Nigerian Environmental Epidemiology Accelerated Research (NEEAR) Program seeks to promote collaborative capacity and research development in environmental epidemiology in Nigeria. In 2021, a short course on environmental epidemiology was developed to strengthen the ability of Nigerian researchers to conduct environmental epidemiology research and thereby, to fill gaps in research capacity.

METHODS: The course was extensively advertised through social media and professional networks. Eligible applicants included Nigerian graduate students and scientists with degrees in Environment and Health related disciplines. Training was weekly 2-hour online sessions for 2 weeks and a 1-day in-person session in Nigeria. It included tutorial, videos, group work and hands-on exercises with faculty from Emory University USA and the Nigerian Institute of Medical Research. Session topics included study design, exposure assessment, data analysis, research ethics, and dissemination. A career talk and transferable skills sessions were also included. Pre- and post-session quizzes were administered during each session to assess whether the training improved participants' understanding of the session topics.

RESULTS: A total of 240 Nigerian researchers applied to the program, of which 35 (15%) top applicants were invited. Short course participants were 47% female and 53% male, with 87% possessing postgraduate qualifications. The participants came from 8 states within Nigeria. There was a marked improvement in participants post-session quiz scores compared to scores from the beginning of the sessions. Participants feedback was very positive. There was clarity on how the training will be applied in their current studies or work. CONCLUSIONS: The short course was impactful and fostered collaborative research capacity among Nigerian researchers. There is potential for more of such courses to be held due to the large number of eligible applications received. Future courses on intermediate/advanced epidemiology and biostatistics methods, internships and post-training connects are recommended.

P-0739 Socioeconomic Determinants of Household Stove Use-Choice and Stove Stacking Patterns in Ghana Using Multinomial Logit Models

Sulemana Watara Abubakari[1], Georgette Owusu-Amankwah[2], Edward Anane Apraku[1], Seidu Iddrisu[1], Abhishek Kar[2], Flavio Malagutti[3], Misbath Douda[2], Brooke Kelsey Jack[3], Kwaku Poku Asante[1], Darby Jack[2]
[1]Kintampo Health Research Centre, Kintampo, Ghana, [2]Mailman School of Public Health, Columbia University, New York, USA, [3]3Bren School of Environmental Science, University of California, Santa Barbara, USA

BACKGROUND AND AIM: Air pollution is the fourth-highest risk factor for premature deaths globally and the second-highest risk factor for premature deaths in Ghana. Understanding the socioeconomic correlates of cooking stove/fuel choices and stove stacking patterns is a precursor to designing effective household air pollution interventions.

METHODS: The study used a quantitative cross-sectional design to collect data from sampled districts in all 16 regions of Ghana, covering about 7,400 household-level respondents in 370 enumeration areas (EAs); across 177 urban EAs and 193 rural EAs. Face-to-face interviews were conducted at home. The questionnaire was designed to elicit information on primary, secondary, and tertiary cooking stoves and fuels.

RESULTS: Use of LPG correlates positively with education (Primary education-RRR:2.377, p<0.01, CI: 95), (Middle/JHS education-RRR:3.019, p<0.0, CI:95), (Technical/SHS education-RRR:6.491, p<0.01, CI: 95), (Post-secondary/University education-RRR:14.41, p<0.01, CI:95). Similarly, use of an LPG-charcoal stove mix compared to Charcoal stove-open fire mix correlates positively with education. All else equal, households with more than one cookstove (RRR:1.185, p<0.05, CI:95), and urban households (RRR:6.488, p<0.01, CI:95) reported usingLPG stoves as their primary cookstove more frequently than did households using a single stove or living in rural areas. The age of the primary cook (RRR:1.44, p<0.1, CI:95), household income (RRR: 1.052, p<0.1, CI:95), and urbanicity (RRR:4.134, p<0.01, CI:95) were statistically significant in predicting use of an LPG-Charcoal mix compared to Charcoal stove-open fire mix. LPG, charcoal and 3-stone (open fire) stoves refer to cooking devices that are fueled by combustible gas, charcoal and wood respectively.
CONCLUSION: Most households in Ghana use multiple cookstoves and fuels. Biomass fuel use is concentrated in poorer, less educated, and rural households. Equitable household energy transitions will require particular attention to encouraging sustained exclusive use of clean fuels in these communities to improve health.

KEYWORDS: socioeconomic factors, cookstove, choice, stove stacking,

P-0740 Health impacts of solid fuel use in Ghana: A nationally representative assessment of cooking-related burns

Misbath Daouda[1], Kaali Seyram[2], Sulemana W. Abubakari[2], Abhishek Kar[1], Iddrisu Seidu[2], Georgette Owusu-Amankwah[1], Flavio Malagutti[3], Kelsey Jack[3], Darby Jack[1], Kwaku P. Asante[3]
[1]Columbia Mailman School of Public Health, New York, USA, [2]Kintampo Health Research Centre, Kintampo, Ghana, [3]UCSB Bren School of Environmental Science, Santa Barbara, USA

BACKGROUND AND AIM: Burns and burn-related injuries are still a major public health problem. Every day, over 30,000 people suffer new severe burns worldwide. Low- and middle-income countries (LMICs) bear a disproportionate burden (70%) of these burns. While burn prevention strategies have successfully been implemented in high-income countries, a paucity of data regarding the incidence and risk factors of burns in LMICs limits their expansion. Here, we aimed to describe the country-level incidence of serious cooking-related burns in Ghana and to identify household-level risk factors for adults and children.

METHODS: We conducted a nationally representative household energy use survey in Ghana in 2020. The final sample included 7,389 households across 370 enumeration areas in all 16 regions of Ghana. An adapted version of the Global Alliance for Clean Cookstoves Burns Surveillance Module was administered to each respondent. We computed incidence rates and 95% confidence intervals using the Byar's approximation and conducted univariate logistic regression to identify potential risk factors.

RESULTS: Out of 7,389 households, we documented 129 serious cooking-related burns which had occurred in the previous 12 months. Slightly more than half (55%) of those burns occurred among adults. The incidence rate (95% CI) of cooking-related burns per 1000 person-years was 9.7 (7.7; 12) and 11 (8.5; 14) among adults and children respectively. Among adults, the odds (95% CI) of experiencing a serious cooking-related burn were 2.29 (1.02; 5.14) and 2.40 (1.04; 5.55) times higher among primary wood and charcoal users respectively compared to primary LPG users. No children burns were documented in households where LPG was primarily used.
CONCLUSIONS: Using a nationally representative sample, we characterized the incidence of cooking-related burns across demographic groups in Ghana. Solid fuel use compared to LPG use doubled the odds of experiencing such burns.

P-0741 Developing an Air Quality Health Index for Cape Town, South Africa – A time-series study

Temitope Adebayo[1,2], Janine Wichmann[3], Oluwaseyi Olalekan Arowosegbe[1,2], Nicole Probst-Hensch[1,2], Christian Schindler[1,2], Nino Kuenzli[1,2]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]University of Basel, Basel, Switzerland, [3]University of Pretoria, Pretoria, South Africa

BACKGROUND: South Africa currently uses a single-pollutant based air quality index (AQI) to communicate the air quality levels. However, this does not fully capture the risk associated with air pollution related illness as the index is reported using the highest concentration level of all the pollutants. Therefore, a revision of the AQI using a multipollutant approach could better reflect the combined health effect associated with multipollutant exposure.

METHODS: Using time-series analysis we derived the air pollution coefficient, daily concentration values for PM10, NO2, SO2 and O3 were regressed against total all-cause mortality in a Quasi-Poisson generalized additive model using data from Cape Town, 2006 – 2015. We estimated the short-term association after controlling for confounders, long-term trends and seasonality. Thereafter, we calculated the exponential function of the product of the coefficients from each single-pollutant model and the daily pollutant concentration – these calculated values were multiplied by 10 and further divided by the maximum daily percent excess mortality to scale the daily values for the AQHI. We provide preliminary findings, as the analysis is still ongoing.

RESULTS: The coefficients obtained per 10 µg/m3 were 0.007: PM10, 0.014: NO2, 0.009: SO2 and 0.017: O3. These values will be used to develop the multi-pollutant health based air quality index. The lag structure for the pollutant and cause-specific mortality models also showed significant evidence of mortality displacement for PM10 on both cardiovascular and respiratory mortalities from lag5–10.

CONCLUSIONS: This study serves as a framework that can be adopted and validated by the department of environmental affairs in South Africa. The presence of harvesting supports the need for an updated AQHI. It further merits consideration for review and update of the existing AQI. Thus, improving health risk communication of ambient air pollution for the general population and frail people.

KEYWORDS: AQHI, mortality, multipollutant, harvesting

P-0742 High-resolution air quality forecasts for LMIC using a combination of machine learning and earth model simulations

Noussair Lazrak[1], Kevin Cromar[1,5], Christoph A Keller[3,4], Bryan N Duncan[3]
[1]Marron Institute of Urban Management, New York University, New York, USA, [2]Cadi Ayyad University, Marrakesh, Morocco, [3]New York University School of Medicine, New York, USA, [4] Morgan State University, Baltimore, USA, [5]NASA Goddard Space Flight Center, Greenbelt, USA

BACKGROUND AND AIM: With the recent advancement of Earth observation, computer simulations, and low-cost monitoring technologies, the capacity to obtain accurate geospatial data has increased tremendously, particularly for locations without expansive in-situ monitoring networks. Here we present an optimized machine learning model to estimate near real-time air pollutant concentrations in selected locations in Africa and Latin America using a combination of NASA Goddard Earth Observing System Composition Forecasts (GEOS-CF) and low-cost sensor data.

METHODS: We use a machine learning approach to estimate near real-time air pollutants concentration at selected locations across Africa and Latin America. Several meteorological and chemical parameters are retrieved from NASA's GEOS-CF to train a bias corrector model and predict corrected concentration estimates for these locations which are then validated against local monitoring data. We also conduct an explainability approach via SHAP Analysis to quantify the model contributing factors across these locations and track the model performance in extreme conditions.

RESULTS: The optimized machine learning model shows good agreement with ground air quality data, with R2 values from 0.61- 0.65 for locations in Mexico City (Mexico), Bogotá (Columbia) and Kigali (Rwanda). Via SHAP analysis, we demonstrate the need to conduct a measure of variance to determine model performance for different conditions and intervals, knowing that the model performance can be affected by various training conditions.
CONCLUSION: Combining observations and optimized model simulations using machine learning techniques can significantly improve air quality forecasts in low- and middle-income countries, where the rapid pace of industrialization and communities are highly susceptible to air pollution health effects, and rarely have local air quality data and health risks alerting systems in place. These results are being used to assist air quality managers and environmental agencies in these locations to improve risk communication and reduce health burdens associated with outdoor air pollution.

P-0748 Building stronger public health institutions (BIS) project: Deciphering the burden of air pollution in Ethiopia, (2021-2025)

Abel Weldetinsae Kidane[1], Eleni Papadopoulou
[1]*Ethiopian Public Health Institute, Addis Ababa, Ethiopia*

Linking air pollution and health at a national level demands the use of a wide variety of data. The current state of science and practice recommends, countries to monitor pollutant concentrations in microenvironments and through satellite technologies. for this reason, countries with better policies and regulations are relentlessly assessing population exposure to air pollutants using air monitoring systems, from fixed atmospheric monitoring stations, atmospheric dispersion modelling, or spatial interpolation techniques for pollutant concentrations. Moreover, the use of systematic diseases surveillance system to document diseases distribution tandem with census data, administrative registers, and data on the patterns of the time-based activities at the individual scale, allowed them to better understand the burden of air pollution.

Hitherto, Ethiopia has not established a national air pollution and health impact surveillance program or system to generate data that can be translated into policy or action. for this reason, the global burden of diseases lacks to present the full depiction of Ethiopia. This was ascribed to the dearth of information available on temporal and spatially representative ambient and indoor air quality monitoring efforts; inadequate documentation of population exposure, activity pattern, and diseases incidence to represent wide range of the social fabric.

To this effect, the Norwegian public health institute (NIPH) through its four years program, building stronger public health institutions (BIS) (2021-2025), agreed to work with the Ethiopian public health institute (EPHI), to develop environmental epidemiological studies, to link air pollution and health. In doing so, establishing monitoring sites in collaboration with pertinent national authorities will be the first phase of the project. The second milestone will be identifying sentinel sites so as to track sex and age specific mortality and morbidity data of non-communicable diseases attributed to air pollution. Overall, the epidemiological studies will benefit Ethiopia to understand the burden of air pollution.

P-0750 Lead exposure is still a serious problem for pregnant women in Nicaragua

Rosa Noemi Fuertes Toledo[1], Martha Gallo[1], Steven Cuadra[2]
[1]Casa Emilia Salud, Managua, Nicaragua, [2]Universidad de Occidente (UdM), Managua, Nicaragua

BACKGROUND AND AIM: A series of studies were carried out in Nicaragua between 2000 and 2010 reporting concerning levels of lead in women and children in urban areas. However, during the last decade, no other study has been published. Current population levels of lead are unknown. We aimed to assess blood lead levels in pregnant women living in the urban area of Managua, the capital of Nicaragua.
METHOD: We conducted a cross-sectional descriptive study in 2017, assessing blood lead levels in 133 pregnant women (15 to 49 years of age), randomly selected among those treated at four health centers in Managua. We additionally explored the presence of potential lead exposure factors.

RESULTS: Overall, the median blood lead concentration (Pb-S) was 61.3 µg/L (range 15.1-336). Almost 25% of the women had Pb-S levels >100 µg/L, and 68% >50 µg/L. No significant association was observed between the levels of Pb-S and factors such as residence close to areas of intense traffic, presence of artisan car battery workshops in the neighborhood, personal exposure from car battery recycling, residence in homes that preserve walls with original paint prior to the 90's, etc. However, a significant difference was observed in relation to the area of residency.
CONCLUSION: The risk of negative effects on the offspring due to prenatal exposure to lead is important in our population of pregnant women. The levels observed in a considerable proportion of the investigated women are above those at which effects on the neuropsychomotor developmental development of the infant have been observed. These women and their children will most likely continue to be exposed to lead in their areas of residence if effective interventions are not made to control sources of exposure and reduce contamination levels.

KEYWORDS: Blood lead level, pregnant women, prenatal exposure, Nicaragua.

P-0753 Value of multiple correspondence analysis (MCA) to build road traffic crash typologies in low-income countries in Latin America

Steven Cuadra[1], Cristina Domínguez[2], Juan Diego Febres[2], Rosa Fuertes[3]
[1]Universidad de Occidente (UdO Managua), Managua, Nicaragua, [2]Universidad Técnica Particular de Loja (UTPL), Ciudad de Loja, Ecuador, [3]Casa Emilia Salud, Managua, Nicaragua

BACKGROUND AND AIM: There is a need to identify statistical tools that are both valid and feasible to be implemented in low-resource settings, focusing on identifying individual and event typologies of those at most risk of suffering a road traffic crash (RTC). Multiple correspondence analysis (MCA) has been previously used to build such typologies in other regions. Here, we aimed to explore the typology of both the people involved in the accidents and the events.
METHOD: We selected as a case study the city of Loja, located in southern Ecuador, and conducted a web bases survey. A total of 754 drivers agreed to participate, of whom 41.5% reported having been involved in a traffic accident at least once in life. MCA was used to build typology (profile) of people who have suffered an RTC, and typology of RTC events.

RESULTS: Typology of drivers who reported participation or involvement in an RTC was characterized by a predominance of people between 25 and 40 years of age, who drive mainly automobiles (cars) and experience frequent sensations of distraction, and frequently use a mobile phone when driving. Additionally, MCA indicated two distinctive typologies of RTC events. One is characterized by collision vehicle to vehicle, with behavioral factors as a main group of causes, and RTC occurring on low-speed limit roads during the afternoon. The second typology is characterized by collision vehicle-surrounding, occurring on medium speed limit roads during the evening or late evening.
CONCLUSION: MCA suggested the main determinants of RTC are modifiable, mainly related to behavioral factors. MCA is an easy technique to perform, does not require highly trained personnel, and is compatible with information commonly collected in community-based surveys, making MCA a valuable tool for accident research in low-income countries.

KEYWORDS: Road traffic crash, typology, multiple correspondence analysis

THEMATIC 10: Environmental Equity

P-0754 Patterns of personal care product use and their association with sociodemographic characteristics along with endocrine disrupting chemicals among reproductive-aged Black women

Kyla Taylor[1], Caroll Co[2], Symielle Gaston[1], Chandra Jackson[1], Quaker Harmon[1], Donna Baird[1]
[1]National Institute of Environmental Health Sciences, Durham, USA, [2]DLH, Durham, USA

BACKGROUND: Compared to White women, Black women in the USA are exposed to higher, more hazardous concentrations of endocrine disrupting chemicals (EDCs), which are found in personal care products. Personal care product use differs by race/ethnicity across multiple product categories such as hair care, skin care, and feminine hygiene products. These differential patterns of exposure are important as they may contribute to environmental health disparities including increased risk of breast cancer, cardiometabolic outcomes, adverse birth outcomes, and uterine fibroids. We previously examined hair product use patterns among reproductive-aged Black women and found that women with higher socio-economic status were more likely to use more products. Our objective was to expand that work to include a wider range of product types including cosmetics, skin care products, nail care products, and feminine hygiene products.
AIM: Identify and describe distinct personal care product use patterns and their correlates among a cohort of reproductive-aged Black women living in Detroit, Michigan.

METHODS: Using self-reported data, we employed latent class analysis to determine distinct personal care product use patterns among women enrolled in the Study of Environment, Lifestyle and Fibroids. We compared self-reported sociodemographic characteristics across latent classes and examined whether classes were associated with urinary concentrations of EDCs.

RESULTS: We will describe the latent classes and report their association with (1) sociodemographic characteristics, and (2) urinary concentrations of EDCs.

CONCLUSIONS: The results of this work may be used to address whether product use patterns and related chemical exposures are associated with health outcomes that disproportionately impact Black women. Such information would help identify subgroups of women who may particularly benefit from intervention and potentially modifiable exposures that may be amenable to targeted public health interventions.

KEYWORDS: personal care products; Black women; exposure; endocrine disrupting chemicals; latent class analysis

P-0757 Racial/ethnic disparities in nationwide PM2.5 exposure: perils of assuming a linear relationship

Misbath Daouda[1], Lucas Henneman[2], Jeff Goldsmith[3], Marianthi-Anna Kioumourtzoglou[1], Joan A. Casey[1]
[1]Department of Environmental Health Sciences, Columbia Mailman School of Public Health, New York, USA, [2]Department of Civil, Environmental, and Infrastructure Engineering, George Mason University, Fairfax, USA, [3]Department of Biostatistics, Columbia Mailman School of Public Health, New York, USA

BACKGROUND AND AIM: Studies of racial/ethnic disparities in air pollution exposure assume an equal magnitude of disparity across the demographic distribution, which may under- or over-estimate the true disparity. Further, historic practices such as racist zoning policies could plausibly drive non-linear relationships between racial/ethnic composition and air pollution exposure. We aimed to conduct a nationwide analysis in urban areas allowing for non-linearity in the relationship between racial/ethnic composition and ambient particulate matter less than 2.5 micrometers ($PM_{2.5}$), and test whether racial segregation modified this relationship.

METHODS: We obtained tract-level demographic information from the 2010 Census and computed the multi-group dissimilarity index, a metropolitan-area level measure of racial segregation. Ambient $PM_{2.5}$ data was obtained from a publicly available source. We evaluated the relationship between percent non-Hispanic Black and percent non-Hispanic White residents and ambient $PM_{2.5}$ using natural splines.

RESULTS: In 58,029 U.S. urban census tracts in 2010, we observed first a very steep and then a plateauing relationship between percent non-Hispanic Black residents and ambient $PM_{2.5}$ concentration. Moving from the 25th percentile (1%) to the median (5%) of non-Hispanic Black residents was associated with a 0.58 μg/m³ (95% CI: 0.56, 0.60) increase in $PM_{2.5}$, while moving from the median to the 75th percentile (16% non-Hispanic Black) was associated with a 0.005 μg/m³ (95% CI: -0.012, 0.020) increase. Reciprocally, in predominantly White census tracts, increases in the proportion of White residents was associated with a rapid decrease in ambient $PM_{2.5}$. Segregation modified these relationships in a non-monotonic manner.
CONCLUSIONS: Our results suggest larger than previously reported Black-White disparities in exposure to $PM_{2.5}$, especially in communities with a modest Black population, which make up the majority of urban census tracts in the US.

P-0759 Scoping report and interactive evidence map on studies of environmental exposures, psychosocial stressors, and cardiovascular diseases in disproportionally impacted communities

Ruth Lunn[1], Kate Helmick[2], Samatha Snow[2], Wren Tracy[2], Anthony Hannani[2], Melissa Miller[2], Darlene Dixon[1]
[1]NIEHS, RTP, USA, [2]ICF, Durham, USA

BACKGROUND AND AIM: Worldwide, cardiovascular disease (CVD) is the leading cause of death, with two-thirds of CVD- related deaths occurring in low- and middle-income countries. In addition to socioeconomic status (SES), CVD rates vary by race, ethnicity, and place. Environmental Health disparities (EHD) are predominately caused by systematic racism leading to higher exposure to environmental toxins, higher indicators of psychosocial stress, and social inequities. Our goal is to inform the scientific community and disproportionally affected populations (DAP) on the scope of the literature on CVD EHD and identify research gaps.

METHODS: To target relevant epidemiological studies and reviews, we searched PubMed using a broad range of terms for DAPs, environmental exposures, psychosocial stressors, and CVD outcomes. DAPs included racial, ethnic, and sexual minority groups and people with lower SES status or living in rural areas. Using exclusion/inclusion criteria, we screened the studies to determine relevancy. Included studies were reviewed and characterized by specific populations, environmental exposures, psychosocial stressors, and CVD outcomes. We visualized and explored the findings using six interactive evidence maps in Tableau.

RESULTS: We identified >1,400 relevant primary studies on CVD and psychosocial stressors or environmental exposures; >800 were conducted in DAP. The most studied racial/ethnic population was Black people (>300), and there were very few studies on sexual minorities (<10). Most DAP studies reported on personal behaviors (>60%), air pollution (~35%), SES indicators, and hypertension (~55%) for all DAP; however, some patterns differ according to the DAP. About 20% of studies reported allostatic load, and 7% evaluated racism and CVD. A research gap is the evaluation of environmental-psychosocial stressors interactions and CVD.

CONCLUSIONS: Our evidence map is a resource for DAP and scientific communities to explore the state of the science on CVD EHD and can be used to develop health equity solutions.

KEYWORDS: EHD, CVD

P-0763 The 2021 Texas Power Crisis: Distribution, Duration, and Disparities

Nina Flores[1], Heather McBrien[1], Vivian Do[1], Mathew V Kiang[2,3], Jeffrey Schlegelmilch[4], Joan A. Casey[1]
[1]Columbia University, Ny, USA, [2]Department of Epidemiology and Population Health, Stanford University School of Medicine, Stanford, [3]FXB Center for Health and Human Rights, Harvard University, Boston, [4]National Center for Disaster Preparedness at the Columbia Climate School, Columbia University, NY,

BACKGROUND AND AIM: Precipitated by an unusual winter storm, the 2021 Texas Power Crisis lasted from February 10 to 27. Such large-scale outages reflect aging electrical grids, underinvestment, and a changing climate. Power outages can have serious health consequences, especially among vulnerable subpopulations such as those reliant on electricity to power medical equipment, but limited studies have evaluated disparate exposures to outages. We used an environmental justice lens to characterize the distribution, duration, and disparities of the Texas Power Crisis.

METHODS: We used hourly Texas-wide county-level power outage data to describe the association and geographic clustering between outage exposure (distribution and duration) and six variables: electricity-dependent durable medical equipment (DME) usage, the Centers for Disease Control and Prevention Social Vulnerability Index (SVI), Black and Hispanic populations, nursing homes, and hospitals. We supplemented these county-level analyses with an internet survey among Texas residents to further investigate issues of environmental justice related to outage experiences and preparedness.

RESULTS: At the peak, nearly 1/3 of customers (N = 4,025,815) in the state lost power. County-level spatial analyses indicated racial/ethnic but not socioeconomic or medical disparities in power outage exposure. With individual survey data, we found less preparedness among younger individuals and those with lower educational attainment. Overall preparedness levels among Texans were low and were no higher among DME users (45% vs. 44%) – the group that likely faces the greatest health risks during outages.

CONCLUSIONS: Power outages coupled with extreme weather events can be deadly, and medically vulnerable, socioeconomically vulnerable, and marginalized groups may be disproportionately impacted. Climate and energy policy must consider these groups in planning and decision-making processes surrounding power outages including future grid improvements, and disaster preparedness and management

KEYWORDS: power outage, durable medical equipment, Texas, climate change, extreme cold weather, environmental justice

P-0765 Long-term Exposure to Particulate matter and cardiovascular disease in South Korea: investigating multi-level interaction with individual- and area-level factors

Garam Byun[1], Jong-Tae Lee[1]
[1]*Interdisciplinary Program in Precision Public Health, Korea University, Seoul, Republic of Korea*

BACKGROUND AND AIM: It has been well known that individuals or groups are not equally vulnerable to air pollution. However, few studies have investigated whether individual susceptibility to air pollution varies across different community environments. This study aimed to estimate the effects of long-term PM_{10} exposure on cardiovascular disease (CVD) in South Korea and to examine whether individual status of underlying disease and area-level medical infrastructure modify the effect.

METHODS: The study population comprised 392,104 subjects from the National Health Insurance Service-National Sample Cohort (2006-2015) residing in 120 districts in South Korea. The CVD event was defined as the first occurrence of a hospital visit or admission from 2006 to 2015. Time-varying Cox proportional-hazards models were used to estimate the association between five-year moving averages of PM_{10} and CVD events. Effect modifications by the individual status of underlying disease (cancer, diabetes, and hypertension) were determined by two-way interaction, stratifying by area-level medical index (calculated with the number of hospitals, hospital beds, and medical personnel).

RESULTS: Long-term exposure to PM_{10} was positively associated with the risk of CVD events (HR per 10 $\mu g/m^3$, 1.04; 95% CI, 1.02-1.06). In areas with a low medical index, PM_{10}-associated CVD risks were higher among those with cancer (HR 1.19; 95% CI, 1.00-1.42) as compared to those without (HR, 1.07; 95% CI, 1.02-1.12). In areas with a low medical index, subjects with cancer showed a lower risk of CVD associated with PM_{10} than those without.

CONCLUSIONS: This study suggests that the individual-level status of an underlying disease and area-level medical infrastructure could be interrelated in determining the health effect of PM_{10}. Consideration of this multi-level interaction in population vulnerability to air pollution can help understand the complex mechanisms by which air pollution creates health disparities.

KEYWORDS: Particulate matter, cardiovascular disease, effect modification, underlying disease, medical infrastructure

P-0768 Monitoring the environmental health status in the Swedish population 1999-2019

Anne-Sophie Merritt[1]
[1]*Public Health Agency of Sweden, Solna, Sweden*

BACKGROUND AND AIM: Since 1999, self-reported environmental health status and exposure has been monitored by questionnaires to the Swedish population in order to to follow up and act on emerging environmental health risks. This data, which is compiled in comprehensive environmental health reports, is unique and cannot be retrieved from any national register. The survey is administered by the Public Health Agency of Sweden, in close collaboration with the regions.

METHODS: Large random samples of the Swedish population (alternating between adults and children) have every 4th year since 1999 received a questionnaire about environmentally related diseases, exposures, annoyance and symptoms. The data has been completed with registry data, e.g. type of housing, educational level, income and country of birth. The last questionnaire (2019) was administered to caretakers of children, thereby completing two time series for adults and children, respectively, over a 20-year period. A focus on environmental health equity has been included in the data analysis of the results in recent years.

RESULTS: The number of administered questionnaires has increased from 15,750 in 1999 to 114,500 in 2019. However, the response rate has declined from 72% to 42% where it has stabilized, but due to the large sample sizes, the results are representative of the target populations. Among the noticeable trends are increasing annoyance from traffic noise and pollen allergies. A positive trend is a rapid decrease in indoor exposure to environmental tobacco smoke. New fields are also emerging, like urbanization, green space and climate change. In the last survey, inequity in exposures was especially elucidated.
CONCLUSIONS: Environmental health surveys are important as a complementary tool to other forms of monitoring environmental health and can be used for decision making at national and regional levels. Inequities can be identified and hence appropriate measures taken.

KEYWORDS:
Survey, environmental exposure, equity

P-0770 The Intersection of Immigrant and Environmental Health: A Review of the Literature

Kelvin Fong[1,2], Seulkee Heo[1], Chris Lim[3], Honghyok Kim[1], Alisha Chan[1], Whanhee Lee[1,4], Rory Stewart[1], Hayon Michelle Choi[1], Ji-Young Son[1], Michelle Bell[1]

[1]Yale University, New Haven, USA, [2]Dalhousie University, Halifax, Canada, [3]University of Arizona, Tucson, USA, [4]Ewha Womans University, Seoul, Republic of Korea

BACKGROUND: Transnational immigration has grown since the 1950s. In countries such as the USA, immigrants now comprise over 15% of the population. Although differences in health between immigrants and non-immigrants are well-documented, it is unclear how environmental exposures contribute to these disparities.
AIM: We systematically reviewed current knowledge on exposure to environmental pollutants for immigrants compared to non-immigrants. We also considered observational epidemiologic studies that estimated health effects associated with environmental exposures, separately for immigrants and non-immigrants.

METHODS: We screened 3705 articles identified through Pubmed and selected those that fit our inclusion criteria. After abstract and full-text review, we summarized findings from 50 studies.

RESULTS: We found a high degree of evidence for higher exposures to metals and fine particulate matter (PM2.5), as well as a moderate degree of evidence for higher exposures to select organic compounds and hazardous air pollutants in immigrants compared to non-immigrants. Among immigrants, there was some evidence for disparities by country of origin and time since immigration. of the 50 studies, 43 were conducted in North America. There was a low degree of evidence for disparities in health effects from exposures in immigrants compared to non-immigrants.

CONCLUSIONS: The environmental health of immigrants remains an understudied area, especially outside of North America. While most identified studies explored potential exposure disparities, few investigated subsequent differences in health effects. Future research should investigate environmental health disparities of immigrants, especially outside North America, and the role of country of origin, time since immigration, and combined effects with socioeconomic status, race/ethnicity, education, and related characteristics.

KEYWORDS: Environmental Equity, Environmental Justice, Immigrant Health, Health Disparities, Systematic Review

P-0771 Urban environmental vulnerability in Rome: a spatial composite indicator

Chiara Badaloni[1], Michela Leone[2], Paola Michelozzi[1]
[1]Department of Epidemiology-ASL Roma 1-Regional Health Service, Roma, Italy, [2]ASL Frosinone, Lazio Region, Italy, Frosinone, Italy

BACKGROUND AND AIM: In recent decades, in order to respond to the growing need for systematic information on complex realities, there have been increasing attempts to create synthetic and complex indicators, in many areas of knowledge, capable to integrate a large amount of information. The aim of this paper is summed the environmental dimension in a synthetic index able to inform on the urban risk in one of the largest cities in Europe, Rome, Italy.

METHODS: Rome is characterized by a complex landscape with various anthropogenic and natural source of pollutions. To analyses different landscape components and tries to make a synthesis 1km2 grid cells were fixed as the reference unit for all spatial predictor indicators. Variables include several aims: Anthropic Industrial pressure; Airport; Land cover data; Road data defined as road density and traffic intensity and noise; Green area, ndvi and lai; hydrogeologic risk; environmental pollution; temperature; socioeconomic status. The Geographically Weighted Principal Component Analysis (GWPCA) method was used to construct a composite indicator by integrating all the dimensions.

RESULTS: The first four components are used to explain the most variation in the data structure. The total percentage of variance (PTV) explained ranges from 78% to 85% with an average value of 82%. The overall value of the urban vulnerability composite indicator evidence the spatial variability of the landscape. Sign with high level the major urbanization areas and the main industrial sites of the city, detects also a gradient between the most populated areas and the green areas.

CONCLUSIONS: A spatial principal component analysis will be performed to integrate several indicators. Synthesis has the advantage of avoiding the presentation and interpretation of a large number of elementary indicators in order to perform simpler and faster analyses, especially in comparative terms.

KEYWORDS: Geographically Weighted Principal Component Analysis, composite indicator

P-0773 Adverse childhood experiences intensify retinal microvascular and inflammatory responses to semi-controlled acute traffic related air pollution exposure

Hector Olvera Alvarez[1], Scott Delaney, George Slavich, Matthew Campen, Laura Kubzansky
[1]*Oregon Health & Science University, Portland, USA*

BACKGROUND: Potential synergy between childhood exposure to psychosocial stressors and traffic-related air pollution exposure, two factors that commonly overlap in socially disadvantaged groups, could increase the risk of cardiovascular disease and lead to greater health disparity than what is currently attributed to these factors independently.
AIM: To test whether adverse childhood experiences (ACEs) potentiate the response of retinal microvasculature caliber and circulatory pro-inflammatory cytokines following a two-hour semi-controlled exposure to traffic related air pollution.
METHOD: In a crossover experiment, 57 participants were exposed to near-traffic ambient air and filtered ambient air, in separate occasions for two hours each time. Central retinal arteriolar/venular equivalent (CRAE/CRVE), blood pressure, pulse, and circulating interleukin (IL)-1β, IL-6, IL-8, and tumor necrosis factor-α (TNF-α) were measured pre-exposure and, again, 1 hour and 24 hours post-exposure. ACEs were documented using the ACE questionnaire. Based on ACE scores, participants were grouped into high (ACE ≥ 4) and low (ACE ≤ 1) ACE groups. Microvascular and inflammatory response to the exposure were analyzed across groups.

RESULTS: ACE scores significantly predicted CRAE, IL-6, IL-8, and pulse reactivity. Left eye CRAE narrowing was greater in the high- vs. low-ACE group at 1-hour and 24-hours post-exposure. 24-hours post-exposure, IL-8 and pulse were significantly higher in the high- vs. low-ACE group. IL-6 was significantly lower in the high- vs. low-ACE group at 1-hour post-exposure.
CONCLUSION: Our results support the hypothesis that ACEs may induce susceptibility to air pollution across the lifespan. These findings may thus help explain how health disparities develop and persist across the lifespan in persons who are most vulnerable to experiencing ACEs and poor air quality, leading to continued social disadvantage.

P-0774 Environmental justice and well waste disposal from oil and gas development in Pennsylvania

Wil Lieberman-Cribbin[1], Xin Fang[1], Rachel Morello-Frosch[2], David Gonzalez[2], Elaine Hill[3], Nicole Deziel[4], Jonathan Buonocore[5], Joan Casey[1]

[1]Columbia University Mailman School of Public Health, New York City, USA, [2]University of California Berkeley, Berkeley, USA, [3]University of Rochester School of Medicine and Dentistry, Rochester, USA, [4]Yale University School of Public Health, New Haven, USA, [5]Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Community socioeconomic deprivation (CSD) may be related to increased oil and natural gas development (OGD). We tested for distributive environmental injustice by examining whether waste disposal from OGD occurred disproportionately in areas with higher CSD in the Pennsylvania Marcellus Shale.

METHODS: Data on well waste type, disposal method, and disposal location from 2005-2019 were downloaded from the Pennsylvania Geologic Survey's Exploration and Development Well Information Network database. Analyses were restricted to waste disposed in-state and analyses were performed at the county subdivision level (n=1848). A CSD Index was created using 2005-2009 American Community Survey data. Regression analyses tested for nonlinear relationships, controlled for population density and well drilling prior to 2005, accounted for spatial dependence, and were stratified by urban/rural status. Logistic and linear regression analyses evaluated associations between CSD Index and receipt of any versus no well waste and cumulative volume of well waste deposited.

RESULTS: Between 2005-2019, we identified 7.0 million tons of solid waste and 19 million barrels of liquid waste disposed of in Pennsylvania, with the highest volumes occurring in 2017-2019. We observed that a higher CSD Index was linearly associated with any well waste disposal (urban county subdivisions: OR= 1.13, 95% CI: 1.00, 1.28; rural county subdivisions: OR= 1.02, 95% CI: 0.97, 1.08) and with cumulative volume of waste disposed (urban: β = 5627 bbl-equivalent, 95% CI: -1957, 13211; rural: β = 6198 bbl-equivalent, 95% CI: 2007, 10390).

CONCLUSIONS: We observed distributive environmental injustice with respect to well waste disposal in county subdivisions across the Pennsylvania Marcellus Shale. These results point to potential downstream disparities from OGD; future studies should investigate mechanisms that explain these disparities.

P-0775 Environmental Health and Justice Impacts of Steam Cracker Facilities

Nicholaus Johnson[1], Michelle Bell[2,3], Nicholas Perez[1,4], Robert Dubrow[1,3], Nicole Deziel[1,2,3]
[1]Yale University School of Public Health, New Haven, USA, [2]Yale School of the Environment, New Haven, USA, [3]Yale Center on Climate Change and Health, New Haven, USA, [4]Yale College, New Haven, USA

BACKGROUND/AIM: Steam crackers (SCs) convert gas feedstocks into ethylene and propylene (the building blocks of plastics) at high temperatures and release toxic/carcinogenic chemicals and greenhouse gases (GHGs). The recent shale boom in the USA (US) has incentivized the expansion of SCs, but analyses of their potential environmental health and justice impacts are limited. We described SC operations, constructed a US SC emissions inventory, and evaluated socioeconomic characteristics of populations residing in proximity to SCs.

METHODS: We searched peer-reviewed and gray literature to describe SC operations. We constructed an inventory using publicly available datasets from industry, government, and non-governmental sources. We used descriptive statistics and data visualization to sumarize emissions from the US Environmental Protection Agency's (EPA's) Toxic Release Inventory (TRI) and EPA's GHG Reporting Program. We compared population characteristics from US Census block groups (BGs) less than versus greater than 5km of an SC, within counties with a SC.

RESULTS: SC operations include: (1) pyrolysis, (2) quenching, (3) compression, cooling, and drying, and (4) fractionation. Major toxic emission sources include furnaces, fugitive emissions, and flaring. We identified 32 SC facilities across five states, with most in the Gulf Coast of Texas and Louisiana. TRI chemicals with the highest self-reported cumulative air-emission volumes from 1987-2019 were: ethylene, propylene, hydrochloric acid, benzene, n-hexane, 1,3-butadiene, ammonia, toluene, vinyl acetate, and methanol. SC facilities emitted >650 million metric tons (carbon dioxide equivalents) of GHGs in total from 2010-2019. We found that 752,465 people live in census BGs within 5km of an SC. BGs closer to SCs had higher proportions of residents who were Black, had non-professional occupations, lower educational attainment, and lower median household income.
CONCLUSION: SC operations have the potential for adverse human health impacts and environmental inequities, underscoring the need for additional research on hazards of petrochemical infrastructure.

P-0776 Geospatial assessment of racial/ethnic composition, social vulnerability, and lead service lines in New York City

Anne Nigra[1], Wil Lieberman-Cribbin[1], Benjamin Bostick[2], Steven Chillrud[2], Daniel Carrion[3]
[1]Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [2]Lamont-Doherty Earth Observatory of Columbia University, Palisades, USA, [3]Department of Environmental Health Sciences, Yale University School of Public Health, New Haven, USA

BACKGROUND/AIM: The state of New York expects to receive $115 million in 2022 from the US Infrastructure Investment and Jobs Act to replace lead water service lines. Our objective was to determine the number and proportion of Potential Lead water service lines across New York City (NYC), and the association between racial/ethnic composition, housing vulnerability, and child lead exposure vulnerability with service line type (Potential Lead, Unknown) at the census tract level for N= 2,083 NYC tracts.

METHODS: We used conditional autoregressive Bayesian Poisson models to assess the relative risk (median posterior estimates, and 95% credible interval, CrI) of service line type per 20% higher proportion of residents of a given racial/ethnic group, and per higher housing vulnerability and child lead exposure vulnerability index scores corresponding to the interquartile range. We also evaluated flexible natural cubic spline models.

RESULTS: Out of 854,672 residential service line records, 136,891 (16.0%) were Potential Lead and 227,443 (26.6%) were Unknown. In fully adjusted models, higher proportions of Hispanic/Latino residents and higher child lead exposure vulnerability were associated with Potential Lead service lines in flexible spline models and linear models (RR 1.15, 95% CrI 1.11, 1.21, and RR 1.11, 95% CrI 1.02, 1.20, respectively). Associations were modified by borough. Potential Lead service lines were associated with higher proportions of non-Hispanic White and non-Hispanic Asian residents in the Bronx and Manhattan, and with higher proportions of non-Hispanic Black residents in Queens.

CONCLUSIONS: NYC has a high number of Potential Lead and Unknown service lines. Communities with a high proportion of Hispanic/Latino residents and those with children who are already highly vulnerable to lead exposures from numerous sources are disproportionately impacted by Potential Lead service lines. These findings should inform equitable service line replacement efforts across NY state and within NYC.

KEYWORDS: lead; water; environmental justice

P-0778 Neighborhood Socioeconomic Context and Autism Spectrum Disorder

Xin Yu[1], Mostafijur Rahman[2], Sarah A. Carter[3], Jane C. Lin[3], Ting Chow[3], Frederick W. Lurmann[4], Jiu-Chiuan Chen[2], Mayra P. Martinez[3], Joel Schwartz[5,6], Sandrah P. Eckel[2], Zhanghua Chen[2], Rob McConnell[2], Daniel A. Hackman[7], Anny H. Xiang[3]

[1]Spatial Science Institute, University of Southern California, Los Angeles, USA, [2]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [3]Department of Research & Evaluation, Kaiser Permanente Southern California, Pasadena, USA, [4]Sonoma Technology, Inc, Petaluma, USA, [5]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [6]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [7]USC Suzanne Dworak-Peck School of Social Work, University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Neighborhood deprivation and autism spectrum disorder (ASD) risk associations are inconsistent across countries with different health systems. We examined associations between neighborhood SES during pregnancy and ASD in a U.S. mother-child cohort with good health care access.

METHODS: This retrospective cohort study included 318,826 children born in Kaiser Permanente Southern California (KPSC) hospitals in 2001-2014. Children were followed through electronic medical records until ASD diagnosis, non-KPSC membership, death, or December 31, 2019, whichever came first. Birth addresses were matched to U.S. Census tracts. A neighborhood deprivation index was developed using principal component analysis of seven census tract-level deprivation indicators (%poverty, %unemployment, %public assistance, %female-headed households, %less than high school, %bachelor and post, %professional occupation) obtained from the 2005-2009 and 2010-2014 American Community Survey and 2000 census. Hazard ratios (HRs) of ASD associated with neighborhood deprivation were scaled to interquartile range (IQR) and estimated using Cox regression models adjusted for birth year, child sex, maternal age, parity, maternal history of comorbidity, maternal race/ethnicity and education. Effect modification by maternal race, education, and child sex was assessed.

RESULTS: During follow-up 6,357 children (1.99%) had ASD diagnosis over a median of 9.0 follow-up years. Pregnancy residence in more deprived neighborhoods was associated with child ASD risk [HR=1.07 (95% confidence interval 1.02, 1.11) per deprivation IQR increase]. Maternal race interacted with neighborhood deprivation ($p<0.05$); deprivation-associated ASD risk was only observed among the White population [HR = 1.24 (1.11, 1.37)]. Results were consistent in alternative specifications of neighborhood deprivation.

CONCLUSIONS: Children living in more deprived neighborhoods had a higher risk of ASD among a population with uniform health care access. This association was mainly observed in White populations, suggesting that in other races factors such as systemic racism may overwhelm effects of ASD-associated neighborhood deprivation.

KEYWORDS: Neighborhood deprivation, Autism

P-0779 Changes in socioeconomic and demographic disparities for traffic-related air pollution exposure during pregnancy over a 20-year period in Texas

Mary Willis[1,2], Elaine Hill[3], Collette Ncube[2], Chunxue Xu[1], Lena Harris[3], Beate Ritz[4], David Schrank[5], Perry Hystad[1]
[1]Oregon State University, Corvallis, USA, [2]Boston University, Boston, USA, [3]University of Rochester, Rochester, USA, [4]University of California, Los Angeles, Los Angeles, USA, [5]Texas Transportation Institute, Bryan, USA

BACKGROUND AND AIM: Environmental justice issues surround population exposure to ambient air pollution; however, few studies have specifically examined traffic air pollution (a pollutant with localized concentration patterns) and pregnancy exposures (maternal-infant dyads may be particularly susceptible to air pollution effects). How socioeconomic and demographic disparities may change over time is also unclear but could have important policy implications.

METHODS: We identified ~ 6.9 million pregnant mothers in Texas from 1996 to 2016 using individual-level vital statistics records. We estimated traffic air pollution exposures using full residential addresses and calculated the total vehicle miles travelled (VMT) within 300 m, assigned nitrogen dioxide (NO2) concentrations from a spatial-temporal land use regression model (an indicator of vehicle tailpipe emissions), and linked the National Air Toxic Agency cancer risk index from vehicles emissions to maternal addresses. From census tract data, we examined median household income. We quantified annual absolute and relative mean percent differences in traffic air pollution across socio-demographic indicators of maternal race and ethnicity, educational attainment, and maternal birthplace.

RESULTS: We observed marked differences in traffic air pollution exposures by all socio-demographic variables examined. Overall, the strongest disparities were seen among non-White and foreign-born pregnancies. While the absolute level of disparity shrank from 1996 to 2016 (e.g., in 1996 Black individuals were exposed to NO2 levels 1.8 ppb higher than white individuals, while in 2016 NO2 levels were 1.5 ppb higher among Black compared to white individuals), the relative level of disparity continued to increase. Within census tracts (i.e., neighborhoods), we also observed sizeable disparities among socioeconomic and demographic groups.
CONCLUSION: Despite considerable reductions in traffic-related air pollution, the magnitude of disparity has increased when we compared groups with lower socioeconomic positioning to their higher socioeconomic positioned counterparts.

KEYWORDS: traffic-related air pollution, pregnancy, environmental justice

P-0780 Associations between long-term exposure to air pollution and cause-specific mortality in River Sacco Valley area

Matteo Renzi[1], Chiara Badaloni[1], Daniela Porta[1], Alessandro Trentalange[1], Paola Michelozzi[1]
[1]*Department of Epidemiology of Lazio Region, Rome, Italy*

BACKGROUND AND AIM: The River Sacco Valley is an industrial contaminated site in a central area of Italy. It is characterized by environmental pollution and socioeconomic deprivation. The study aim is to evaluate the chronic effects on cause-specific mortality of air pollution and socioeconomic deprivation (SEP) in an administrative cohort of residents in an industrial polluted site.

METHODS: Subjects who were resident in River Sacco Valley between 2008 and 2018 were enrolled by linking administrative data. We collected information about age, sex, residential address and cause of death. Exposure to PM10, PM2.5, NO2, SO2, Benzene and O3 were assessed by FARM models for each residential address, while socioeconomic deprivation has been derived by an area-level indicator. Cox proportional hazard models adjusted by age (as time-scale), sex and city of residence were used to evaluate the effects of exposure to air pollutants and SEP to natural, cardiovascular, respiratory and malignancies mortality.

RESULTS: 182578 subjects were enrolled in the cohort, among which 30% were aged 50+ years and 35% had high SEP. We observed 9205, 4019, 573, 2790 non-accidental, cardiovascular, respiratory and malignant cancer deaths, respectively. Each pollutant had average levels above the WHO guidelines standards. The results of main analysis showed positive hazard ratios (HR) per IQR increases up to 1.084 (95% confidence intervals: 0.99, 1.18) and 1.136 (0.99, 1.30) for PM10 and non-accidental and cardiovascular mortality, respectively. Furthermore, high deprivation was associated positively with each outcome. In particular, we registered HRs equals to 1.064 (0.98, 1.16) and 1.101 (0.97, 1.25) for non-accidental and cardiovascular mortality in high vs low SEP category.

CONCLUSIONS: Living in a polluted site worse the health status for several causes. We observe that high levels of air pollutants and socioeconomic deprivation are linked to excess of risk of cause-specific mortality in the River Sacco Valley area.

P-0781 Development of report-back materials of air pollution exposure results to participants in the HAPIN trial in Guatemala and Rwanda

Ashlnn Quinn[1], Mayari Hengstermann[2], Ajay Pillarisetti[3], Maggie Clark[4], Roberto Otzoy Sucuc[2], Laura Ruiz[5], Florien Ndagijimana[6], John P. McCracken[7], Anaite Diaz-Artiga[2], Ghislaine Rosa[8], Jennifer L Peel[4], Tom F. Clasen[9], Lisa M. Thompson[9,10]

[1]Berkeley Air Monitoring Group, Berkeley, USA, [2]Center for Health Studies, Universidad del Valle de Guatemala, Guatemala City, Guatemala, [3]Berkeley School of Public Health, University of California, Berkeley, USA, [4]Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, USA, [5]Independent graphic designer, Guatemala City, Guatemala, [6]Eagle Research Center, Kigali, Rwanda, [7]University of Georgia, College of Public Health, Athens, USA, [8]London School of Hygiene and Tropical Medicine, London, UK, [9]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [10]Nell Hodgson Woodruff School of Nursing, Emory University, Atlanta, USA

BACKGROUND: Interpretation of individual exposure information for reporting to research participants is an important aspect of the research process that can empower participants, increase community engagement with scientific research, and better tailor future community-engaged research. In the multi-country Household Air Pollution Randomized Intervention Network (HAPIN) trial, a randomized controlled trial among 3200 pregnant women that assessed the effect of a liquefied petroleum gas (LPG) stove and fuel intervention, we engaged a subset of study participants in Guatemala and Rwanda in the development of context-appropriate materials. The purpose of this study was to: 1) report and explain air pollution exposure levels to: 2) present strategies to increase awareness of the health effects of air pollution; and 3) discuss strategies to reduce personal exposure to air pollution.

METHODS: Local project staff in Guatemala and Rwanda were trained to conduct qualitative research. Individual interviews and participatory observations in participant homes (n=42 in Guatemala; n=20 in Rwanda) were followed by working groups to assess interpretability of different graphical displays of exposure data. Finally, focus groups assisted in iteration of contextually relevant visual aids illustrating exposure results, health impacts, and strategies to reduce exposures.

RESULTS: After iterations, visual materials depicting community and personal exposure to fine particulate matter (PM2.5) using a simple “thermometer-style” graphic were chosen, including a marker of community-level impacts of the liquefied petroleum gas (LPG) stove intervention. Educational material about the health impacts of air pollution and contextually feasible and available methods to reduce exposure were presented. Capacity was built among field teams to conduct qualitative research.

CONCLUSIONS: Development of materials to report back scientific results to study participants in accurate and understandable ways is an ethical obligation to communities participating in complex research and may yield important benefits to researchers and participating community alike.

P-0782 Environmental justice in Colorado: variation in proximity to oil and gas wells across race-ethnicity and income groups

Katherine Dickinson[1], Danielle Sansone-Poe[1], Lisa McKenzie[1]
[1]*Colorado School of Public Health, Aurora, USA*

BACKGROUND AND AIM: Oil and natural gas (O&G) extraction has moved closer to residential areas in Colorado, where population has also boomed. Proximity to O&G wells is associated with risks to health and quality of life. Evidence on whether socially disadvantaged groups – particularly low-income residents and people of color – tend to live closer to wells is mixed. We use a birth registry dataset to estimate the odds of living within 2 miles of O&G wells across income and racial groups and across counties in Colorado, USA.

METHODS: We combined large-N geospatial O&G datasets from the Colorado Oil and Gas Information System with data from the Colorado State Birth Registry (2007-2017) on birthing people's location, race-ethnicity, and low-income status (eligible for Medicaid). We used logistic regressions to estimate the relationship between demographics and proximity to O&G wells for a pooled sample and for county-specific samples.

RESULTS: for the pooled sample, Hispanic birthing people faced higher odds of living within 2 miles of an O&G well compared to White birthing people (OR: 1.15 [95%CI: 1.14-1.17]), while Medicaid eligibility was negatively associated with proximity to wells (OR: 0.86 [95%CI: 0.85-0.87]). However, pooled data mask significant variation across counties. In the county responsible for nearly 90% of Colorado's oil production (Weld), non-White and low-income groups were both more likely to live near wells. However, in the most populous O&G producing county (Adams), the opposite patterns were observed.

CONCLUSIONS: Patterns of proximity to O&G development vary with race-ethnicity and income in ways that differ substantially across counties. These patterns are linked to the timing and drivers of O&G development and residential growth across space, as well as policies and regulations. Investigating these patterns is key to assessing potential environmental injustices and their remedies.

P-0783 Trends in air pollution emissions in the contiguous USA from 1970 to 2010: an environmental justice analysis

Yanelli Nunez[1], Jaime Benavides[1], Misbath Daouda[1], Lucas R.F. Henneman[2], Randall V. Martin[3], Erin E. McDuffie[3], Jeff Goldsmith[4], Joan A. Casey[1], Marianthi-Anna Kioumourtzoglou[1]

[1]Dept. of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [2]Department of Civil, Environmental, and Infrastructure Engineering, George Mason University, Virginia, USA, [3]Dept. of Energy, Environmental & Chemical Engineering, Washington University at St. Louis, St. Louis, USA, [4]Dept. of Biostatistics, Columbia University Mailman School of Public Health, New York, USA

BACKGROUND: Air pollution emissions have substantially decreased in the US since the 1970 Clean Air Act. We examined racial and economic disparities in emissions reductions from specific pollution sources.

METHODS: We evaluated racial/ethnic and economic disparities in emissions reductions from six pollution sectors [industry (SO2), energy (SO2), agriculture (NH3), commercial (NOx), residential (organic carbon), and on-road transport (NOx)] across the contiguous US from 1970–2010. We used the CEDGBD-MAP emissions inventory to estimate the average relative emissions change from one decennial to the following and its link to demographics (percent White, Black, Asian, American Indian Hispanic, family income, property value, poverty, and unemployment) at the county level. We constructed hierarchical models with the relative emissions change as the dependent variable and demographics as independent variables. We modeled each pollutant and demographic variable separately, adjusting for potential confounding, and tested for nonlinearities.

RESULTS: On average, national emissions decreased from 1970 to 2010 except in the agriculture and the residential sectors. The largest reductions across the study period were in industry and energy SO2 emissions (-66% and -89%, respectively) and on-road transport NOx (-59%). Although average emissions decreased nationally, trends varied across counties. We found racial disparities in industry, energy, and agriculture emissions. An increase in % American Indian, Hispanic, or Asian was associated with increases in industry SO2, agriculture NH3, and energy NOx. We also found economic disparities: an increase in median family income was associated with decreases in emissions from all sectors except agriculture, and increases in unemployment or poverty were associated with increases in industry and energy SO2 emissions.

CONCLUSION: Although air pollution emissions, on average, decreased since 1970, the trends in emissions varied across counties. On average, low-income and communities of color have experienced smaller improvements or a relative increase in emissions despite the nationwide downward trends.

P-0787 Is it you or your neighborhood: what matters more when it comes to air pollution exposure?

Hiwot Zewdie[1], Carolyn Fahey[1], Mary Jewell[1], Claire L. Leiser[1], Elizabeth Spalt[1], Sabah M. Quraishi[1], Joel D. Kaufman[1], Anjum Hajat[1]
[1]*University of Washington, Seattle, USA*

BACKGROUND AND AIM: Studies have examined individual and neighborhood social factors and air pollution independently; few have investigated which is more strongly associated with air pollution exposure. We leverage individual harmonized data from large observational cohorts to cross-sectionally interrogate this question.

METHODS: Data came from three US cohorts at time of enrollment (1989-2007): Cardiovascular Health Study, Reasons for Geographic and Racial Differences in Stroke, and Multi-Ethnic Study of Atherosclerosis (ntotal = 39,860). Individual exposures include race and ethnicity and income (ISES). Neighborhood exposures include SES (NSES) and divergence, a spatial multi-race measure of racial residential segregation (RRs), both derived from 1990-2010 Census data and linked to participants' residence. Annual averaged fine particulate matter (PM2.5) and nitrogen dioxide (NO2) were estimated from spatiotemporal models. Random intercept multilevel models estimated and compared associations between z-scores of individual and neighborhood social factors and unit changes in air pollution concentrations, adjusting for individual sex, age, cohort, and urbanicity.

RESULTS: The mean (SD) air pollution exposure was 12.9 µg/m3 (3.55) for PM2.5 and 13.3 ppb (8.72) for NO2. We observed lower air pollution exposure among those with higher ISES (βISES-PM2.5= -0.05, 95% CI: -0.07, -0.03) and higher exposure among racial and ethnic minority participants. In fully adjusted models including individual and neighborhood-level variables, lower NSES and higher RRS were associated with higher air pollution (βNSES-PM2.5= -0.56, 95% CI: -0.61, -0.51; βRRS-PM2.5= 0.98, 95% CI: 0.83, 1.13), but ISES-PM2.5 and Black race-PM2.5 associations become null (βISES-PM2.5= -0.00, 95% CI: -0.02, 0.02; βBlack race-PM2.5= 0.03, 95% CI: -0.03, 0.9).
CONCLUSION: Findings suggest the neighborhood social environment may be more correlated with air pollution burden than individual-level factors. Careful consideration should be made when considering how to analytically account for social factors in air pollution-health associations.

KEYWORDS: air pollution, social environment, socioeconomic status, racial residential segregation

P-0788 Differential changes in air pollution exposure by racial residential segregation in the USA: a longitudinal multi-cohort study

Carolyn Fahey[1], Hiwot Zewdie[1], Mary Jewell[1], Claire Leiser[1], Elizabeth Spalt[1], Sabah Quraishi[1], Joel Kaufman[1], Anjum Hajat[1]
[1]*University of Washington, Seattle, USA*

BACKGROUND AND AIM: While levels of ambient air pollution have declined over time in the USA, studies have found persistent exposure disparities by race and ethnicity. Racial residential segregation may contribute to differential reductions in air pollution and perpetuate related health inequities.

METHODS: We analyzed harmonized data from three longitudinal cohort studies, spanning the years 1990-2017: Cardiovascular Health Study (CHS), Multi-Ethnic Study of Atherosclerosis (MESA), and Reasons for Geographic and Racial Differences in Stroke (REGARDS) (N=466,513 person-years). Annual average NO_2 and $PM_{2.5}$ exposures for residential addresses were estimated from national spatio-temporal models. Neighborhood segregation indices of multi-race divergence, Black-White dissimilarity, and single-race isolation were created from Census tract-level data, with linear interpolation for intercensal years. We evaluated percent changes in NO_2 and $PM_{2.5}$ over time by segregation z-score and race using log-linear repeated measures models adjusted for age, sex, individual and neighborhood socioeconomic status, urbanicity, and cohort.

RESULTS: From 1990 to 2017, mean (SD) NO_2 exposure decreased by 62.2% for Black participants [from 23.3 (9.6) to 8.8 (4.8) ppb] and 61.8% for White participants [17.0 (8.0) to 6.5 (4.1) ppb]; since 1999, $PM_{2.5}$ respectively declined by 54.5% [16.5 (2.5) to 7.5 (1.0) µg/m3] and 54.4% [14.9 (2.8) to 6.8 (1.2) µg/m3]. Among Black participants, exposure levels were consistently higher in more segregated neighborhoods, where the rate of decline lagged: each standard deviation increase in divergence was associated with 0.19% (95% CI: 0.14-0.24) and 0.14% (0.12-0.16) slower average annual declines in NO_2 and $PM_{2.5}$, respectively, with similar trends for dissimilarity and isolation.
CONCLUSIONS: Despite improvements in air quality, Black individuals continue to experience higher levels of air pollution than White individuals, particularly in more segregated neighborhoods. These trends may contribute to enduring racial inequities in health outcomes, warranting further research and action to improve environmental injustice.

Air pollution, segregation

P-0789 Estimating the Effect of Congestion Mitigation on Traffic Air Pollution and Local Housing Prices

Helen Harris[1], Mary Willis, Max Harleman, Elaine Hill, Perry Hystad, Beate Ritz
[1]*University of Rochester, Rochester, USA*

BACKGROUND AND AIM: Billions of dollars are spent on roadway congestion mitigation projects annually, however there's limited evidence on the air quality consequences of these. Additionally, changes in environmental quality may result in local neighborhood change due to changes in housing prices. We examined the influence of congestion projects on local air quality and housing prices.

METHODS: We spatially locate congestion projects across Texas from 2005-2020 (n=1,483). We compiled daily EPA air pollution monitor data and residential housing transactions, which we linked to projects within 300, 500, and 1,000m (n=1,285,646 residences, 144 monitors). We rescale pollutants by their interquartile range (IQR): 19 parts/billion for NO2 and 6 micrograms/m3 for PM2.5. We then implemented a spatial differences-in-differences design to explore the associations among congestion projects, outdoor air pollution, and housing costs.

RESULTS: Our preliminary results show projects have a limited, negative impact on air quality. During project construction, both PM2.5 (0.16 IQR increase, 95% CI: [0.086, 0.239]) and NO2 (0.13 IQR increase, 95% CI: [0.046, 0.212]) increase within 300m of the project. After project completion, PM2.5 remained elevated (0.105 IQR increase, 95% CI: [0.019, 0.191] while NO2 returned to pre-project levels (0.041 IQR increase, 95% CI: [-0.076, 0.159]). Housing prices increased modestly both during (1.11%, 95% CI: [-0.09%, 2.30%] and after a project (1.18%, 95% CI: [-0.13%, 2.29%]), though the confidence intervals are somewhat wide.

CONCLUSIONS: We present preliminary evidence that congestion projects lower local air quality during construction and after project completion. This highlights the trade-off between traffic congestion and volume. This pollution effect is either not apparent to homebuyers or is countered by other neighborhood improvements, as housing prices instead increase with congestion mitigation. This provides suggestive evidence that congestion mitigation results in neighborhood change through more channels than just air quality.

KEYWORDS: traffic-related air pollution, hedonics, environmental justice

P-0790 A ranking of environmental indicators among historically redlined neighborhoods in Detroit, Michigan, USA

Abas Shkembi[1], Lauren Smith[1], Richard Neitzel[1]
[1]*University of Michigan School of Public Health, Ann Arbor, USA*

BACKGROUND AND AIM: The Home Owners' Loan Corporation (HOLC) in the 1930s drew maps of cities across the US that labeled neighborhoods by mortgage risk. This historical practice, commonly called "redlining", labeled neighborhoods deemed "hazardous" with the color red. This policy denied mortgage loans to minority persons seeking homes in White/affluent neighborhoods, segregating these areas by race and ethnicity. This legacy of de jure segregation shaped neighborhoods today and influenced their environmental exposures, a form of environmental racism. The aim of this study was to identify the most pervasive exposures associated with redlining.

METHODS: The Detroit shapefile defined by the HOLC and digitized by the Mapping Inequality project overlaid onto the Environmental Protection Agency's EJSCREEN and the Department of Transportation National Transportation Noise Map was used to determine modern environmental exposures and transportation noise within historical boundaries. Differences in demographic and environmental hazards between redlined (red or D grade) and non-redlined neighborhoods (grades A, B, and C) were assessed using hypothesis testing and a boosted classification tree algorithm.

RESULTS: Historically redlined Detroit neighborhoods experience significantly higher environmental hazards than non-redlined neighborhoods from diesel particulate matter (PM), traffic volumes, hazardous road noise, cancer risk from air pollution, and are closer to hazardous waste and Risk Management Plan (RMP) sites. With all factors taken together, boosted regression trees indicated the most pervasive environmental exposures among redlined neighborhoods in Detroit are the proximity to RMP sites, hazardous road noise, diesel PM, and cancer risk from air pollution.

CONCLUSIONS: Institutional segregation via historical redlining is associated with environmental injustices in Detroit today. Policies targeting transportation-related air and noise pollution, particularly from sources of diesel exhaust, in redlined neighborhoods may ameliorate some of the disproportionate impacts of historical redlining, providing a proof-of-concept to apply to other redlined cities.

KEYWORDS: environmental justice; redlining; EJSCREEN; noise, Detroit

P-0791 An association between historical redlining and road, rail, and air transportation noise today among eleven cities in Michigan, USA

Lauren Smith[1], Abas Shkembi[1], Richard Neitzel[1]
[1]*University of Michigan - School of Public Health, Ann Arbor, USA*

BACKGROUND AND AIM: Maps of >200 US cities, including 11 in Michigan, were drawn by the Home Owners' Loan Corporation (HOLC) in the 1930s to classify neighborhoods by mortgage risk. The HOLC used descriptions, grades, and colors to define neighborhoods as "best-A-green", "still desirable-B-blue", "definitely declining-C-yellow", and "hazardous-D-red". This practice of "redlining" systematically segregated neighborhoods by denying mortgage loans to minority populations in predominately-white neighborhoods. These policies continue to shape neighborhoods today; however, to our knowledge, no studies have assessed its impact on transportation noise. The objective was to assess how transportation noise (air, road, and rail) varies by HOLC grade within and across redlined cities in Michigan.

METHODS: The US DOT National Transportation Noise Map and the 1930s HOLC-maps of 11 Michigan cities, digitized by the Mapping Inequality Project, were used to access how various metrics (average, 90th percentile, and maximum noise by transportation source and cumulatively) varied by HOLC grade. To understand if redlined neighborhoods experience a higher proportion of hazardous noise, we estimated the proportion of hazardous transportation-related noise (24-hr Leq ≥70 dBA) for each neighborhood. T-tests between redlined and non-redlined neighborhoods and mixed effects linear regression with city as a random intercept were performed to assess the relationship across all redlined Michigan cities for each noise metric.

RESULTS: Redlined neighborhoods in Michigan experience more high noise exposure more often than A-grade neighborhoods. Average difference in maximum noise levels between redlined and non-redlined neighborhoods ranged from 6.5 to 12.4 dBA depending on the transportation source. Redlined neighborhoods have more than twice the prevalence of hazardous transportation noise (24-hr Leq ≥70 dBA) when considering all sources.

CONCLUSION: Noise exposure should be considered in environmental justice research, and dismantling environmental racism is critical to alleviating excess burden on minority communities.

P-0792 Translating scientific evidence into policy and practice: the European Urban Health Cluster

Dimosthenis Sarigiannis[1,2,3], Eleni Feleki[1], Spyros Karakitsios[1], Alberto Gotti[4]
[1]Environmental Engineering Laboratory, Department of Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]HERACLES Research Center – CIRI, Aristotle University of Thessaloniki, Thessaloniki, Greece, [3]Environmental Health Engineering, School for Advanced Study IUSS, Pavia, Italy, [4]EUCENTRE Foundation, Pavia, Greece

BACKGROUND AND AIM: Over the past decades the impacts of urbanization on public health have been investigated and analyzed extensively. It is now the time to increase visibility for urban health research and bring stronger contribution to policies such as the EU Urban Agenda, translate scientific evidence into policy and practice, while identifying mechanisms for action locally and careful attention to closing the gaps in the societal distribution of health and wellbeing gains.

METHODS: In this direction, six European projects (eMOTIONAL Cities, ENLIGHTENme, HEART, RECETAS, URBANOME and WELLBASED), resulting from the Horizon 2020 call "Innovative actions for improving urban health and wellbeing -addressing environment, climate and socioeconomic factors", have established the European "Urban Health Cluster'' (UHC). The cluster will facilitate international cooperation with other relevant ongoing and potential future initiatives on urban issues and health. It will deliver more robust evidence for policy making on improved urban health in the EU, will enhance population health, physical and mental, while reducing health inequalities.

RESULTS: The UHC comprises six working groups with clear targets and objectives, where more than one hundred research institutions are represented, to draw and build upon individual project results and working closely with an International Advisory Board to connect the UHC to significant urban initiatives, including the European Urban Agenda. The Cluster launch event has been organized on May 20th 2021 and brought together in an open event representatives from the European Commission, the six projects and representatives of European initiatives and Networks, international pioneers in the field of urban health and political decision makers.

CONCLUSIONS: The Urban Health Cluster will operate for four years to improve and safeguard health and wellbeing of citizens, leaving none behind and to promote an alliance between cities and different actors where citizens will be an important part to support decision making.

P-0793 Development of the Navigation Guide Evidence-to-Decision Framework for Environmental Health

Max Aung[1], Courtney Cooper[2], Susan Norris[3], Lisa Bero[4], Devon Payne-Sturges[5], Jessica Reyes[6], Roger Chou[3], Wendy Wagner[7], Tracey Woodruff[2], Nicholas Chartres[2]

[1]University of Southern California, Los Angeles, USA, [2]University of California San Francisco, San Francisco, USA, [3]Oregon Health and Science University, Portland, USA, [4]University of Colorado Anschutz Medical Campus, Aurora, USA, [5]University of Maryland, College Park, USA, [6]Amherst College, Amherst, USA, [7]University of Texas Austin, Austin, USA

BACKGROUND: Globally there are hundreds of thousands of registered and unknown chemicals in production. There is sufficient evidence that industrial chemicals can increase the risk of adverse health outcomes across the lifecourse and these effects are amplified in historically marginalized communities that experience systemic racism and injustice. As such, there is a need for timely and effective decisions and policies on interventions to prevent and mitigate the exposures and health effects attributable to harmful chemicals, while ensuring health equity.

METHODS: To meet this need, we developed a transparent framework to guide decision making for environmental health interventions. We convened a multi-disciplinary Steering Committee to evaluate current evidence-to-decision frameworks in medicine and public health. Building from a scoping review of this literature, we proposed the Navigation Guide Evidence-to-Decision Framework for Environmental Health. We then assembled a diverse group of researchers, government and non-profit practitioners, and community-based leaders working on environmental justice to provide feedback.

RESULTS: This new framework considered several criteria previously published in the World Health Organization's INTEGRATE framework. The framework includes three key criteria for decision making: environmental justice, sociopolitical climate, and maximizing benefits and reducing harms for communities that are affected by harmful chemical exposures. for each of these criteria, we proposed potential signaling questions for data gathering. In addition, three foundations are relevant to all criteria: human rights, quality and strength of evidence, and essentiality.

CONCLUSIONS: This proposed framework can improve the basis of decision making by incorporating key considerations, including health equity and social justice, when formulating recommendations, in addition to scientific evidence on harmful effects. This will facilitate effective and timely decisions that reduce harmful exposures and protect public health, particularly for the most vulnerable populations. Piloting of the framework at local and national levels of decisions will further refine its utility in real-world settings.

P-0795 Historical redlining and change in ambient air pollution in the USA, 2000-2016

Leah Moubadder[1], Howard H Chang[2], Alexandra J White[3], Ashley Naimi[1], Michael R Kramer[1], Lauren E McCullough[1]
[1]Department of Epidemiology, Emory University, Atlanta, USA, [2]Department of Biostatistics, Emory University, Atlanta, USA, [3]National Institute of Environmental Health Sciences, Durham, USA

BACKGROUND: Studies have identified drivers of racial inequities, of which most are attributable to structural racism. In the 1930s, the Home Owners' Loan Corporation (HOLC) developed residential security maps classifying neighborhoods that were "best" (outlined in green) to "hazardous" (outlined in red, hence the term "redlining") for real estate investments, overtly basing the grading on the neighborhood's racial makeup. Though redlining became illegal in 1968, the structures it created remain largely intact. Through the siting of highways and emission sources proximate to areas made low-income through historical investment policies, redlined neighborhoods experience increased exposure to environmental hazards, such as poorer air quality, increased intra-urban heat, and a lack of greenspace. Though air pollution has improved in the past several decades, the rate of change is differential by race and class. However, the extent to which housing policies may have perpetuated environmental disparities as a consequence of systematic disinvestment has been limitedly explored.
Aim: We are currently examining the rate of change in air pollutants PM2.5 and NO2 in 202 U.S. cities over 16 years by historical redlining.

METHODS: Nationwide annual mean concentrations of the census tract level PM2.5 and NO2 were predicted from 2000 to 2016 from three machine learning models that incorporated satellite data, meteorological variables, land-use variables, elevation, and chemical transport model predictions. Historical redlining was defined at the census tract level according to the graded investment risk assigned by the HOLC. I will use a linear mixed model to analyze the association between redlining on the change in air pollution over 16 years.

RESULTS: Results from this analysis are forthcoming and will be presented in September.
CONCLUSION: This research will advance our understanding of how environmental hazards may result from historical practices that fail to center underserved communities in adapting environmental amenities.

KEYWORDS: environmental justice, air pollution

THEMATIC 12: Exposome

P-0798 Associations of perfluoroalkyl substances (PFAS) with non-targeted metabolomics across two independent cohorts of elderly individuals

Samira Salihovic[1], Susan Hurley[2,4], Miaomiao Wang[3], David Nelson[4], Lars Lind[5], Myrto Petreas[3], June-Soo Park[3,6], Peggy Reynolds[4,6]

[1]School of Medical Sciences, Örebro University, Örebro, Sweden, [2]Office of Environmental Health Hazard Assessment, CAL-EPA, USA, [3]Department of Toxic Substances Control, CAL-EPA, USA, [4]Cancer Prevention Institute of California, USA, [5]Department of Medical Science, Uppsala University, Uppsala, Sweden, [6]University of California-San Francisco, USA

BACKGROUND AND AIM: Perfluoroalkyl substances (PFAS) have been linked to adverse health effects including increased blood cholesterol levels and hepatic toxicity. Alterations in metabolism and oxidative stress are among the hypothesized mechanisms by which PFAS exposure may exert effects; however, studies of associations between PFAS and metabolome are scarce. The main aim of this study was to assess associations of PFAS exposure and metabolome by using non-targeted metabolomics in two independent cohorts of elderly individuals.

METHODS: In two population-based cohorts of elderly individuals from Sweden and California (the Prospective Investigation of the Vasculature in Uppsala Seniors [PIVUS, n = 901, median age 70 years]; and the California Teacher Study [CTS, n = 325, median age 69 years]), plasma/serum PFAS concentrations were determined using isotope-dilution ultra-pressure liquid chromatography (UHPLC) coupled to tandem mass spectrometry. Non-targeted metabolomics was performed using UHPLC high-resolution mass spectrometry (QTOFMS). Associations of PFAS and metabolomics signatures was assessed using a discovery-validation approach with multivariable linear regression.

RESULTS: In the discovery cohort 89 annotated metabolites out of 204 could be associated with levels of five PFAS following adjustment for age, sex, and correction for multiple testing. Eleven associations could then be replicated in the CTS. The metabolites being replicated in the CTS were primarily lipid related metabolites such as lysophosphatidylcholine, phosphatidylcholine, sphingomyelin as well as amino acids such as betaine.

CONCLUSIONS: Using a non-targeted metabolomics discovery-validation approach, we the previously reported associations between PFAS and lipid related metabolites and identified and replicated novel associations. Our results encourage additional studies investigating the underlying mechanisms of our findings.

KEYWORDS: PFAS, PFOS, PFOA, Metabolomics, Lipid metabolism

P-0799 Benchmark dose modelling of blood lead levels and thyroid hormones – Study in Serbian population

Dragana Javorac[1], Katarina Baralić[1], Stefan Mandić-Rajčević[2], Đurđica Marić[1], Miloš Žarković[3], Danijela Đukić - Ćosić[1], Zorica Bulat[1], Aleksandra Buha Djordjevic[1]

[1]Department of Toxicology "Akademik Danilo Soldatović", University of Belgrade – Faculty of Pharmacy, 11221 Belgrade, Serbia, [2]Institute of Social Medicine and School of Public Health and Health Management, Faculty of Medicine, University of Belgrade, 11000, Belgrade, Serbia, [3]Faculty of Medicine, University of Belgrade, 11000, Belgrade, Serbia

BACKGROUND AND AIM: There is limited understanding of the effects of lead (Pb) on endocrine health, specifically thyroid function. Our study aimed to identify the relationship between blood Pb levels (BLLs) of the Serbian population and thyroid hormone levels and to determine a benchmark dose (BMD).

METHODS: The study included 435 participants, 218 females, and 217 males. BLLs and levels of free triiodothyronine (fT3), free thyroxine (fT4), and thyroid-stimulating hormone (TSH) in were measured. Multivariate linear regression analyses of BLLs (Pb µg/dL) and levels of hormones were performed. Further, BMD-response modelling for tested endpoints using PROAST70.1 software was performed, where hormone levels were coded as quantal data (0–in normal range and 1–out of normal range).

RESULTS: Male BLLs (β = -0.01, P = 0.0281) and overall BLLs (β = -0.0041, P = 0.0143) were negatively correlated with fT4 levels, but no correlation was found in the female group. Dose-response modelling showed a positive incidence of abnormal hormone levels. for TSH, related BMDLs were 0.702 µg/dL for males and 0.686 µg/dL for females. In males, derived BMDL was 0.268 µg/dL and in females, 1.8 µg/dL for fT3. In case of fT4, derived BMDLs were 0.736 µg/dL and 0.478 µg/dL in males and females, respectively.

CONCLUSIONS: The presented results suggest that Pb acts as a thyroid hormone disruptor in males. BMD modelling has shown a clear dose-response relationship with a positive trend between BLLs and levels of TSH, fT3 and fT4. The observed BMDLs were lower than median BLLs. In males, the lowest BMD was derived for fT3 (0.268 µg/dL), while in females, the lowest BMD was for fT4 (0.478 µg/dL), providing new insight into assessing human health risk assessment of low Pb exposure, especially with regards to its endocrine-disrupting effects. (PROMIS DecodExpo project: 6066532)

P-0801 Characterizing the heat stress exposome to assess acute kidney injury in New York City runners

Nicholas Defelice[1], Alison Sanders[2], Chris Gennings[1], Steven Coca[1], Gohar Mosoyan[1], Gregory Klimaytis[3], Homero Harari[1]

[1]Icahn School of Medicine at Mount Sinai, New York, USA, [2]university of Pittsburgh school of public health, Pittsburgh, PA, USA, [3]Queens College, CUNY, New York, USA

BACKGROUND AND AIM: Heat stress occurs when the body's ability to regulate internal temperature begins to fail, which may result from intense physical exertion (exercise-induced or occupational), shifts in environmental conditions, (i.e., temperature and humidity) or a combination of these factors. Chronic and repeated acute heat stress exposures can result in damage to the kidneys and other systems further priming an aberrant sequelae of subsequent acute kidney injury (AKI) and chronic disease. Yet, population-based methods to assess heat stress exposure (including internal body temperature, sweat rate, heart rate variability, minute ventilation, etc) and subsequent kidney function changes in real-time are limited.

METHODS: Here, we will assess acute recurrent heat stress exposures in a cohort of long-distance runners to better understand how metabolic heat and ambient temperature impact kidney function. During the summer of 2022, 24 athletes (12 men, 12 women) will be solicited to run 21km three times, with 7 days between each run. Before each run, we will provide several environmental sensors on the athlete to capture individual-level exposures of ambient temperature, humidity, internal core temperature, volume loss, sodium loss, minute ventilation, heart rate variability and air pollution. Additionally, after each run, we will collect plasma and urine to analyze traditional and novel renal biomarkers.

RESULTS: Using a within-host state-space model to evaluate individual exposure profiles, we will develop a heat stress exposure index to assess changes in subclinical renal biomarkers. We will evaluate several environmental exposures to understand the association of ambient temperature, humidity, internal core temperature, volume loss, sodium loss, minute ventilation, heart rate variability and air pollution of these exposures and the athlete's kidney function.
CONCLUSIONS: Our methodologies developed herein for heat stress assessment will be broadly applicable to future environmental and occupational exposure assessment scenarios.

P-0802 Comparison of untargeted chemical profiles of dried blood spots, dried blood microsamplers, and plasma

Lauren M. Petrick[1,2], Megan M. Niedzwiecki[1,2], Georgia Dolios[1], Miao Yu[1], Anu Joshi[1], Robert O. Wright[1,2], Rosalind J. Wright[1,2]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Institute for Exposomic Research, Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: Capillary blood collection is minimally invasive, easy to perform, and when dried, is more stable at higher temperatures than liquid blood, making dried capillary blood microsamplers a promising alternative to venous blood for epidemiological research. To evaluate the utility of dried blood samplers for use in exposome studies, comparisons of metabolite profiles between capillary dried blood and conventional plasma collection are needed.

METHODS: Commercially purchased whole blood from a single adult smoker was used for experiments. Dried blood spots were generated by pipetting 50 µL for 5-mm punches, 10 µL VAMS were generated from the whole blood following manufacturer's instructions, and 10 µL plasma aliquots were generated by centrifugation. Samples were stored overnight at -80C. Triplicate samples were randomized and analyzed for each device using Liquid Chromatography-High Resolution Mass Spectrometry (LC-HRMS). Metabolites were identified using Agilent Profinder software. Metabolite levels (abundance) were compared for each sample type using a one-way ANOVA and fold change (FC).

RESULTS: We identified 305 metabolites from LC-HRMS analysis. Among those compounds, 222 metabolites show significant differences in abundance among Guthrie, VAMS, and plasma samples (p value<0.05). 42 compounds have higher abundance (>3 FC) in Guthrie or VAMS than plasma samples. Among these compounds, carboxylic acids and derivatives (7) and organooxygen compounds (7) are the major compound classes, but also included two metabolites of alcohol exposure. Three compounds have a higher abundance (>3 FC) in plasma than Guthrie or VAMS.

CONCLUSIONS: Several metabolites have a higher abundance in Guthrie or VAMS than in plasma samples. However, most compounds showed a comparable fold change among these three sample types. Depending on the group of metabolites or exogenous compounds of interest, microsampling devices are an alternative to conventional plasma collection for exposome studies.

KEYWORDS: Untargeted chemical analysis, dried blood spots, microsamplers, exposome.

P-0803 Urban exposome and stroke incidence across Europe

Jeroen De Bont[1], Kathrin Wolf[2], Åsa Persson[1], Massimo Stafoggia[1,3], Evangelia Samoli[4], Konstantina Dimakopoulou[4], Klea Katsouyanni[4,5], Cathryn Tonne[6,7,8], Sergio Olmos[6,7,8], Dorina Ibi[9], Jelle Vlaanderen[9], Annette Peters[2], Marc Chadeau-Hyam[10,11], Barbara Bodinier[10,11], Roel Vermeulen[9], Regina Pickford[2], Petter Ljungman[1,12]

[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Institute of Epidemiology (EPI), Helmholtz Zentrum München – Deutsches Forschungszentrum für Gesundheit und Umwelt GmbH, Neuherberg, Germany, [3]Department of Epidemiology, Lazio Region Health Service /ASL Roma 1, Rome, Italy, [4]Department of Hygiene, Epidemiology and Medical Statistics, School of Medicine, National and Kapodistrian University of Athens, Greece, [5]MRC Centre for Environment and Health, Environmental Research Group, Imperial College London, London, UK, [6]ISGlobal, Barcelona, Spain, [7]Universitat Pompeu Fabra, Barcelona, Spain, [8]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [9]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, [10]School of Public Health, Imperial College London, London, UK, [11]MRC Centre for Environment and Health, School of Public Health, Imperial College London, London, UK, [12]Department of Cardiology, Danderyd University Hospital, Stockholm, Sweden

BACKGROUND AND AIM: Multiple environmental factors of urban environments may influence cardiovascular health, however their complex interplay has scarcely been studied. Within the EXPANSE project, we evaluated the association between multiple urban exposures and stroke incidence across Europe.

METHODS: We will conduct a meta-analysis including 3 population-based cohorts (from Sweden, Netherlands, Germany) and 6 administrative cohorts (from Greece, Rome, Catalonia, Switzerland, Sweden, Netherlands). Participants were followed-up until incident stroke, death, migration, disappearance or end of study period. We estimated multiple long-term exposures at residential addresses from different domains: ambient air pollution (nitrogen dioxide, particulate matter <2.5 m, black carbon, ozone), built environment (green and blue spaces, impervious surface) and meteorology (mean and standard deviation temperatures during summer and winter). Associations between environmental exposures and incident stroke were estimated in single and multiple-exposure Cox proportional hazard models, and Principal Component Analyses (PCA) derived prototypes for exposures domain (i.e built environment).

RESULTS: Preliminary results from Sweden (N=19,247), from single and multiple exposures, indicate associations between increased levels of NDVI and reduced incident stroke (hazard ratio (HR) per 0.1 units = 0.92, 95%CI 0.85; 0.99). The first component of each domain in the PCA explained more than 60% of the variability. The built environment domain (capturing high levels of green spaces and low levels of impervious surface) showed a borderline association with incident stroke (HR per interquartile range of the component = 0.92, 95%CI 0.83; 1.01). We also found a suggestive association between air pollution and increased stroke incidence.

CONCLUSIONS: In preliminary results in Sweden, we found a suggestion for independent effects of green space and air pollution on incident stroke. Further analyses on the other cohorts are ongoing.

KEYWORDS: stroke, urban exposome, meta-analysis, air pollution, green space, temperature, blue space.

P-0805 DNA methylation and multiple pollutants exposures from petrochemical industries

Chi-Hsin Sally Chen[1], Tzu-Hsuen Yuan[2], Tzu-Pin Lu[3], Hsing-Yi Lee[3], Yi-Hsuen Chen[1], Liang-Chuan Lai[4], Mong-Hsun Tsai[5], Eric Y Chuang[6], Chang-Chuan Chan[1]

[1]Institute of Environmental and Occupational Health Sciences, College of Public Health, National Taiwan University, Taipei, Taiwan, [2]Department of Health and Welfare, College of City Management, University of Taipei, Taipei, Taiwan, [3]Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan, [4]Graduate Institute of Physiology, College of Medicine, National Taiwan University, Taipei, Taiwan, [5]Institute of Biotechnology, College of Bio-Resources & Agriculture, National Taiwan University, Taipei, Taiwan, [6]Department of Electrical Engineering, College of Electrical Engineering & Computer Science, National Taiwan University, Taipei, Taiwan

BACKGROUND: This study aims to clarify the association between exposure levels, SNPs, and DNA methylation in residents living in areas with multiple industrial pollutants.

METHODS: We compared DNA methylation between high (HE) and low exposure (LE) groups, and analyzed association between urine concentrations of As, Hg, and V with DNA methylation, respectively among 159 residents near No. 6 Naphtha Cracking Complex in Taiwan. HE (n=78) and LE (n=81) were based on urine PAHs exposure biomarker 1-OHP and V concentrations. All participants were analyzed for 11 pollutants urine exposure biomarkers, DNA methylation, and 11 SNPs.

RESULTS: Urine levels of 1-OHP, V, As, Hg, Cr, Mn, Sr, and Tl were significantly increased in HE compared to LE. We identified 68 CpG probes corresponding to 45 known human genes using Wilcoxon's rank sum test comparing between HE and LE. We used DAVID for pathway analysis and found 16 pathways associated with exposure in KEGG pathway hsa04940: Type I diabetes mellitus (two gene hits PTPRN2, HLA-B,). We further used correlation analysis and found 70 CpG probes associated with urinary As levels, two with Hg, and 46 with V, which correspond to 62, none, and 32 known human genes, respectively. GSEA pathway analysis found four biological pathways associated with As (including ascorbate and aldarate metabolism), four with Hg (including linoleic acid metabolism), while no pathways were found associated with V. Fisher's exact test and Wilcoxon rank sum test results showed 11 SNPs significantly associated with CpG probes methylation. Linear regression revealed rs11085020 (NFIC) and rs199442 (NSF) could be associated with exposure, the translated proteins of which are associated with activating gene transcription and replication, and vesicle-mediated transport, respectively.

CONCLUSIONS: We identified industrial pollutants-associated SNPs, DNA methylation, and biological pathways among exposed population.

P-0807 Cardiometabolic Health Associated with Exposures to Mixtures of Chemical Pollutants: Results from the EHES-LUX Study

Giovana M Ciprián[1], Gwenaëlle Le Coroller[2], Achilleas Pexaras[3], Torsten Bohn[4], Guy Fagherazzi[5], Brice M. R Appenzeller[6], Maria Ruiz-Castell[1]

[1]Luxembourg Institute of Health, Department of Precision Health, Strassen, Luxembourg, [2]Luxembourg Institute of Health, Competence Centre for Methodology and Statistics, Strassen, Luxembourg, [3]Integrated BioBank of Luxembourg, Dudelange, Luxembourg, [4]Luxembourg Institute of Health, Nutrition and Health Research Unit, Department of Precision Health, Strassen, Luxembourg, [5]Luxembourg Institute of Health, Deep Digital Phenotyping Research Unit, Department of Precision Health, Strassen, Luxembourg, [6]Luxembourg Institute of Health, Human Biomonitoring Research Unit, Department of Precision Health, Strassen, Luxembourg

BACKGROUND AND AIM: The recent decades have seen a worldwide increase in cardiometabolic diseases. This study analyses associations of mixtures of chemical pollutants with cardiometabolic health.

METHODS: We analysed information from 606 randomly selected adults from the European Health Examination Survey. We analysed 152 chemical pollutants in hair samples, of which 74 were present in more than 6% of the samples and classified into groups (subdivided into banned and currently used): 6 flame-retardants, industrial wastes and plasticizers, 32 insecticides, 21 herbicides and 15 fungicides. We used weighted quantile sum (WQS) regressions adjusted by age, education, job status and physical activity to estimate the associations of groups of chemicals and cardiometabolic outcomes in men and women separately.

RESULTS: In women, a quartile increase of mixtures of banned insecticides, currently used insecticides, banned herbicides and currently used fungicides was associated with risk of hyperglycemia (WQS adjusted odds ratio [95% Confidence Interval] 1.81 [1.06, 3.10], 3.05 [1.29, 7.21], 2.00 [1.18, 3.38], 3.77 [1.82, 7.81], respectively). We also observed a quartile increase of banned herbicides mixtures associated with risk of low HDL-cholesterol in women (1.68 [1.09, 2.60]). Additionally, a quartile increase of currently used insecticides mixtures and currently used herbicides mixtures was associated with an increased risk of hypertriglyceridemia in men (2.76 [1.25, 6.10], 3.09 [1.33, 7.18], respectively). A quartile increase of currently used herbicides mixtures was associated with lower risk of abdominal obesity in men (0.46 [0.23, 0.94]). The most highly weighted chemicals associated with hyperglycemia among women were γ-HCH, β-HCH, Cl2CA, imidacloprid, trifluraline, metolachlor, boscalid and prochloraz. Among men, the most highly weighted chemicals associated with hypertriglyceridemia were 2-ClBA, IMPy, 1-(3,4-dichlorophenyl)-3-methylurea and fenuron.

CONCLUSIONS: This study contributes with further evidence on the possible negative effects of exposure to chemical mixtures on cardiometabolic health.

P-0810 Omics associations with non-persistent endocrine-disrupting chemicals (EDCs) exposure in humans: a scoping review

Léa Maitre[1], Paulina Jedynak[2], Marta Gallego[1], Karine Audouze[2], Maribel Casas[1], Martine Vrijheid[1]
[1]ISGlobal, Barcelona, Spain, [2]INSERM, France

Health effects of non-persistent EDCs, characterised by short half-lives and fast metabolism, are challenging to be detected in the general population due to EDC intra-individual variability, general ubiquity and latent effects. Omics are becoming increasingly common to detect subtle early biological changes before the apparition of clinical symptoms and to explore EDC-related toxic mechanisms increasing the biological plausibility of epidemiological associations.
This scoping review systematically summarises the application of omics technologies in epidemiological studies that assessed biological effects associated with non-persistent EDC exposure, in order to identify potential gaps and set priorities for future exposome research planning to use omics.
Ninety-eight human studies (2004-2021) were identified through database searches (PubMed, Scopus), and citation chaining. Most of the studies focused on one family of EDCs, including phthalates (34 studies), phenols (19), and PFASs (17), while PAHs and pesticides were studied less frequently (12 and 3, respectively). The sample sizes ranged from 10 to 12,476 (median = 160), involving non-pregnant adults (42 studies) or pregnant women (34), or children/adolescents (27). Several studies included occupational workers (12) and/or high-exposed groups (10) focusing on PAHs, PFASs, and pesticides while studies on phenols (30) and phthalates (46) were performed on the general population only. Omics measured included metabolic profiles (44, including targeted analyses), gene expression (31) and DNA methylation (12).
Overall, studies had common limitations, in particular the small sample size, the cross-sectional designs, and single sampling for exposure biomonitoring that could explain the lack of replication across studies. We also identified clear research gaps such as the lack of omic studies on currently used pesticides (organophosphate pesticides or pyrethroids).
Standardising research methods and reporting are recommended to facilitate result comparison. Future studies should consider differences in study methodology, use of prospective design, influence from co-exposure confounding and measurement errors.

KEYWORDS: scoping review, endocrine disruptors, omics

P-0811 The urban exposome profile of Limassol, Cyprus: integration of biomonitoring data with drinking water and quality of life indicators

Corina Konstantinou[1], Xanthi Andrianou[1], Thibaut Delplancke[1], Pantelis Charisiadis[1], Konstantinos Christos Makris[1]
[1]*Cyprus International Institute for Environmental and Public Health, Cyprus University of Technology, Limassol, Cyprus*

BACKGROUND AND AIM: Cities currently host the majority of the global population and generate more than 80% of the global gross domestic product. Societal changes, e.g., urbanization and migration shape population health, quality of life and urban exposures. Extending the human exposome framework, the urban exposome can be defined as the totality of environmental and health indicators that shape quality of life and urban populations' health, using the city and smaller, intra-city areas as measurement units. The aim of this study is to describe the urban exposome profile of Limassol in summer 2017.

METHODS: A cross-sectional study was conducted in the municipality of Limassol, Cyprus with collection of household tap water samples, urine samples and questionnaire data from residents. We integrated data on drinking water and quality of life indicators with urinary data on untargeted metabolomics and biomarkers of pyrethroid and neonicotinoid pesticides. We mapped the urban exposome parameters (i.e., water quality, urinary pesticides, green space access) across the urban center and explored associations among them.

RESULTS: Overall, 132 residents participated in the study, 83% of which provided two urine samples (different days). 89% of the participants self-reported very good or good health. 64% reported living close to green spaces, which based on their assessment were not well-maintained, and thus, not used. Overall, 2% of households' tap water exceeded 100 μg/L of total trihalomethanes and less than 1% were outside the parametric values for E. coli and Enterococci spp (zero CFU/100 mL). Correlations between all parameters were explored and linear-mixed effect models described associations among the urban exposome variables.

CONCLUSIONS: The application of urban exposome concept and its exposomic tools allowed continuous monitoring of urban health indicators to inform policy makers for the development of public health interventions for healthier living in sustainable societies.

BACKGROUND AND AIM: Untargeted HRMS metabolomics provides an agnostic global profiling of small molecules in a biological system capturing an overview of exposure to exogenous compounds, and their effects on metabolic pathways, rendering an essential tool for characterising the exposome. Disinfection by-products (DBPs) are a complex mixture of halogenated organic compounds present in drinking and swimming pool water. Although several epidemiological studies have pointed their potential to induce adverse health outcomes such as bladder cancer, their mixture effect and the downstream molecules perturbed by their exposure have been poorly explored. In this work, we aim to identify molecular signatures of exposures to mixtures of DBPs in individuals with measured exposures.

METHODS: In PISCINA-II study, metabolomics, transcriptomics, proteomics in serum, and levels of DBPs in exhaled breaths, were measured in 60 subjects before and after swimming. Pre-processing of HRMS data from PISCINA-II study was customised to include more halogenated compounds. Multivariate normal (MVN) and partial least square (PLS) models were used to identify metabolic features associated with DBP exposures. Conditional correlation networks were constructed to understand the holistic relationship amongst the metabolic features and their relationship with proteomics and transcriptomics.

RESULTS: 98 metabolic features were identified to be associated with exposure to DBP mixture, of which 39 were not identified in the previous analysis without specific reprocessing and inclusion of halogenated compounds. In conditional network analysis, the 98 features showed cluster structures, suggesting they could contribute to different downstream biological pathways. Multi-omic networks showed that transcriptomic and proteomic signals were differentially connected to the different clusters of the metabolic signatures.

CONCLUSIONS: New data processing approach allowed identification of novel metabolic signatures of DBP mixture exposure. Conditional correlation network implied the functional proximity of these signatures with other measured omic signals.

THEMATIC 14: Health Impact Assessment, Risk communication and Participatory Epidemiology

P-0905 Environmental health competence in Basque health workers. Analyzing the soil before sowing the seed

Mikel Subiza-Perez[1,2,3,4], Kalliopi Vrotsou[4], Agurtzane Mujika[2], Eulalia Marinelarena[5], Pilar Aizpurua[5], Xabier Mitxelena[6], Uxune Apalategi[5], Aitana Lertxundi[2,3,4], Jesus Ibarluzea[2,3,4,7]

[1]Bradford Institute for Health Research, Bradford, UK, [2]University of the Basque Country UPV/EHU, Donostia - San Sebastian, Spain, [3]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Madrid, Spain, [4]Biodonostia Health Research Institute, Donostia - San Sebastian, Spain, [5]Osakidetza - OSI Donostialdea, Donostia - San Sebastian, Spain, [6]Osakidetza - OSI Tolosaldea, Tolosa, Spain, [7]Ministry of Health of the Basque Government, SubDirectorate for Public Health and Addictions of Gipuzkoa, Donostia - San Sebastian, Spain

BACKGROUND AND AIM: Modifiable environmental factors account for the 23% and 22% of mortality and morbidity respectively. However, it is unclear whether health practitioners – especially those in primary care – are sufficiently aware of the connections between environmental exposures and health and able to intervene in this domain. The objective of this study was to assess environmental health (EH) literacy and competences among health professionals working in the Basque Public Health System.

METHODS: We recruited a sample of 366 (85% females) including nurses, family doctors, paediatric doctors, gynaecological doctors and advanced university students of nursery and medicine. The online questionnaire measured 1) general and specific EH competences, 2) use of exposure clinical history, 3) perceived competence to deliver medical advice on several exposures, and, 4) perceptions of Basque Public Health Services. Data were analysed with descriptive statistics, chi-squared tests and ANOVA with post-hoc comparisons.

RESULTS: Overall, we found low to moderate general and specific EH competence and found that nurses and nursery students reported higher perceived general and specific competences than the rest of the profiles at the $p < .001$. These differences were small to large in size according to the Hedges' g statistic. The sample was scarcely educated in the use of exposure clinical history and only 6 participants confirmed its use. The EH topics that more frequently appeared in the consultation room (e.g. passive smoke exposure or sun protection) were the ones for which the professionals reported a higher competence level and vice versa (least frequent topics were biomarkers and industrial emissions). Finally, even though Basque Public Health Services were highly regarded, participants rarely contacted them.

CONCLUSIONS: Interventions addressing environmental health knowledge and competences among health professionals in the Basque Health System are needed to improve population's health.

P-0906 Indicators of psychosocial and physiological effects of forest therapy: A systematic review

Hae-Ryoung Chun[1], Yoon Young Choi[1], Inhyung Cho[1], Hee-kyoung Nam[1], Geonwoo Kim[2], Su-jin Park[2], Sung-il Cho[1]
[1]Seoul National University, Seoul, Republic of Korea, [2]National Institute of Forest Science, Seoul, Republic of Korea

BACKGROUND: Current research on forest therapy and its health outcomes involves various health indicators without unification of measure. Information on the therapeutic elements of forest and forest-therapy programs is insufficient. We investigated forest-therapy programs, therapeutic elements of the forest environment, and health-outcome measures to standardize health indicators of forest therapy.
METHOD: A systematic review was conducted on the health outcomes of forest therapy from 2010 to 2021. We summarized therapeutic elements, forest-therapy sites, characteristics, and health outcomes. Additional cross tabulation was performed by using SAS software

RESULTS: Twenty-nine articles were analyzed. Among them, walking and physical activity were conducted most frequently as forest therapy. Also, meditation was used frequently in Pinales environments and viewing sessions in Fagales environments. In Fagales and Pinales environments, stress, psychological status, depression and endocrine function were improved. Apart from the forest therapy environment, stress and depression were most frequently observed psychological outcome. Cardiovascular and endocrine function were most frequently measured physiological outcome which reported positive result. functions were improved. Walking, five-senses stimulation, physical activities, and meditation benefited psychological (stress and depression) and physiological (cardiovascular and endocrine function) outcomes. Viewing sessions benefited both sentiment and cardiovascular function, and meditation benefited both stress and endocrine function.
CONCLUSION: We evaluated therapeutic elements of the forest-environment program and health outcomes. This systematic review can be used as a reference for planning and operation of forest-therapy programs.

KEYWORDS: Systematic literature review, forest bathing, Shinrin-yoku, forest elements, health promotion, therapeutic effect, health-related indicators, cross-tabulation

P-0907 Developing an environmental health knowledge questionnaire for health practitioners

Kalliopi Vrotsou[1,5], Mikel Subiza[1,2,6,7], Itziar Vergara[1,5], Maider Kortajarena[2], Itxaso Martí[3], Irene Duo[3], Carmen Sanchez[3], Amaia Valero[3], Jesus Ibarluzea[1,2,4]

[1]Biodonostia Health Research Institute, San Sebastian, Spain, [2]University of the Basque Country UPV/EHU, Spain, [3]Basque Public Health System-Osakidetza, Spain, [4]Sub-directorate of Public Health of Gipuzkoa, San Sebastián, Spain, [5]REDISSEC, RICAAPS, Spain, [6]Bradford Institute for Health Research, UK, [7]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Spain

BACKGROUND AND AIM: Environmental health (EH) is a crucial public health aspect, usually overseen by health-care practitioners. Partly, this is due to a lack of awareness and knowledge on this area. The few existing tools available for measuring EH knowledge focus on specific health profiles (nurses) or population groups (children). Currently no tools evaluating the competence of different health specialties on EH issues concerning the general population exist. The objective of this work was to develop such a tool.

METHODS: A group of public health-care professionals and epidemiologists developed an initial pool of 38 EH related items. After a pilot study, a reduced version of this instrument was derived. Items had 3 response options (correct/incorrect/doesn´t know). Rasch analysis was applied with acceptable fit statistics: KR-20>0.80, separation>2, reliability>0.80, infit and outfit<2. Participants were mainly health practitioners of the Basque Public Health System-Osakidetza, or health students studying at the University of the Basque Country. Statistical analyses were performed with the SAS and Winsteps softwares.

RESULTS: Initially 38 EH questions were established, covering the areas of environmental risk factors for childhood/adolescence, air pollution, urban pests, drinking water problems, among others. The n=151 pilot participants had a mean age of 31.9 (SD: 13.2) years, 87% females. of those 48% were health-care university students, 31% nurses and 21% medical doctors. at this stage, several too easy and too difficult items were identified, while others evaluated more than one concept. The second 33-item version was tested in n=366 health professionals and students, 85% females, 54% working in primary care. KR-20 was 0.82 and all fit statistics were adequate. Item targeting had improved and unidimensionality of the tool was sustained.

CONCLUSIONS: The developed questionnaire can be used as a means of assessing EH competences and knowledge, detecting areas of improvement.

KEYWORDS: Environmental health, health-care professionals, Rasch analysis

P-0908 Lithuanian Refugee Crises: Comparing Middle Eastern/African and Ukrainian Migrants

Ruta Brazinskaite[1], David F. Goldsmith[1]
[1]*The George Washington University, Milken Institute School of Public Health, Washington, USA*

BACKGROUND AND AIM: Recently, Lithuania has received a large number of Ukrainian refugees fleeing the war, in addition to refugees from Middle Eastern and African (MEA) countries. Refugees have unique clinical and mental health needs, including anxiety, depression, and post-traumatic stress disorder. Culturally relevant access to care and language skills are essential for responding to health problems. We aim to contrast the MEA and Ukrainian refugees' situation in Lithuania.

METHODS: This comprehensive literature review examined the refugee situation in Lithuania, focusing on physical and mental health, living conditions, and integration into Lithuanian society, including published research studies. R.B conducted direct conversations with refugees and with organizations that provide assistance to migrants.

RESULTS: The Lithuanian government and private sector assistance provided to Ukrainian and MEA refugees differed vastly. While the MEA refugees struggled to obtain the minimum standard of health care in Lithuania, the Ukrainian refugees received free primary and emergency care, and psychological support. MEA were housed in refugee camps, some of which used to serve as correctional facilities. Many Ukrainian refugees were hosted by Lithuanian families inviting them to their homes. There is an ongoing concern about the health needs of both of these groups, particularly physical health, and overall mental health conditions arising from being a refugee. A shared issue is finding employment and integrating into Lithuanian society.
CONCLUSIONS: National policies should be standardized to provide the same assistance to refugees regardless of the country of origin. Lithuania demonstrated that it can welcome Ukrainian refugees and provide excellent care by mobilizing the entire nation's efforts. Immigrants from other countries should not be discriminated against or treated differently. Health professionals need to play leadership roles in the continuum of care and to provide culturally competent assessments to identify the refugee needs.

KEYWORDS: Refugees, Mental Health, Discrimination, Traumatic Immigration

P-0909 A health risk matrix for assessing the impacts of heat and cold exposure in residential buildings

Shih-Che Hsu[1], Anna Mavrogianni[2], Ian Hamilton[1], Zaid Chalabi[2]
[1]Energy Insitute, University College London, London, UK, [2]Institute for Environmental Design and Engineerin, University College Londong, London, UK

BACKGROUND AND AIM: With people in developed countries spending 70% of their time at home, the impact of the built environment on human health is vital. Although there has been ample epidemiological evidence on the relationship between high/low outdoor temperature exposures and adverse health impacts, there is a paucity of research investigating how residential characteristics and human behaviours might affect temperature-related health risks. This research aims to fill this gap.

METHODS: A health risk matrix was obtained by applying a four-stage spatiotemporal health risk assessment framework (comprising hazard identification, exposure assessment, exposure-response assessment and risk characterization) to estimate the temperature-cardiovascular mortality relationship in Greater Taipei, Taiwan, using paired observations of outdoor-indoor temperatures and PM2.5 concentrations in dwellings.

RESULTS: Residential characteristics and household energy use acted as moderators, and indoor temperature functioned as a mediator in the temperature-mortality relationship. A three-dimensional matrix projected outdoor temperature, human vulnerability and dwelling type along three axes to visualise the cardiovascular mortality risk. Human vulnerability represents the interaction between outdoor temperature and household energy use. By multiplying the risk levels (1-3) of each of the three axes, a total of 27 levels of health risk are obtained.
CONCLUSIONS: This study encourages carefully-planned climate change mitigations and adaptations to achieve healthier indoor environments: (1) Strategies for reducing temperature-related cardiovascular mortality should incorporate the energy use for heating/cooling, which may affect human vulnerability and be affected by the household income, prevalence of air conditioning systems, green area, and population rate of older people. (2) Building retrofits for improving energy efficiency should carefully consider dwelling thermal types, which may vary with occupants' behaviours and cause unintended health consequences when indoor temperature closely follows outdoor temperature and makes dwellings overheat or excessively cold.

P-0910 Increased risk of osteoporotic fractures after long-term exposed to high levels of perfluoroalkyl substances through drinking water in a Swedish population

Yiyi Xu[1], Emelie Hansson[2], Eva M Andersson[1], Kristina Jakobsson[1], Huiqi Li[1]
[1]University of Gothenburg, Gothenburg, Sweden, [2]Kungälv Hospital, Kungälv, Sweden

BACKGROUND: Several studies have reported inverse associations between perfluoroalkyl substances (PFAS) and bone mineral density, but there are fewer studies on its relationship with osteoporosis and fractures, especially in highly exposed populations. This study aimed to investigate the risks of osteoporotic fractures in a Swedish population with long-term exposure to PFAS through drinking water.

METHODS: We used Ronneby Register Cohort that included 61504 individuals who have ever lived in Ronneby from 1985-2013. PFAS exposure was assessed based on the yearly residential address and categorized as 'never-high' and 'ever-high' exposure. The latter was further divided into 'early-high' and 'late-high' depending on whether the exposure was before or after 2005. Diagnoses of various fractures were retrieved from the National Patient Register. Primary outcomes were major osteoporotic fractures (MOF) including fractures located in the hip, vertebrae, proximal humerus or distal forearm, and hip fractures themselves. Cox proportional hazard models were used to estimate the hazard ratios (HRs). Stratified analyses were performed in sex and age groups (<50 or ≥50).

RESULTS: Elevated risks of MOF (HR 1.11, 95% CI 1.03 – 1.19) and hip fractures (1.12, 1.00 – 1.24) were observed when comparing 'ever-high' to 'never-high' exposure. The HRs were even higher for 'late-high' (MOF: 1.29, 1.16 – 1.44; hip fractures: 1.22, 1.01 – 1.47), but less evidence for 'early-high' exposure. Further adjusting for the highest achieved education only slightly attenuated the estimates. People above age 50 showed higher HRs. Similar patterns were found for all fractures.

CONCLUSIONS: Our findings provided more evidence supporting the adverse effects of PFAS on bone, shown by the clinically relevant outcome, osteoporotic fractures. Senior people (above age 50) were more susceptible. The findings are concerning and call for a better understanding of dose-response relationships as a basis for risk assessment.

KEYWORDS: Perfluoroalkyl substances, osteoporotic fractures, cohort study

P-0916 Pesticide Residue Trends in Fruits and Vegetables from Farm to Fork in Kampala Metropolitan Area, Uganda - A Mixed

METHODS: Study

Charles Ssemugabo[1], David Guwatudde[2], David Ssempebwa[1], Asa Bradman[3]
[1]Department of Disease Control and Environmental Health, School of Public Health, Makerere University College of Health Sciences, Kampala, Uganda, Kampala, Uganda, [2]Department of Epidemiology and Biostatistics, School of Public Health, Makerere University College of Health Sciences, P.O. Box 7072 Kampala, Uganda, Kampala, Uganda, [3]Department of Public Health, School of Social Sciences, Humanities and Arts, University of California Merced, Merced, CA 95343, USA, Merced, USA

BACKGROUND: Improper agricultural use of pesticides in Uganda results in elevated residues in fruits and vegetables. This study examined pesticide residue trends in produce and handling and processing practices for fruits and vegetables from farm to fork in the Kampala Metropolitan area in Uganda.

METHODS: We used pesticide laboratory d, semi-structured questionnaires, and in-depth interview data collected from stakeholders along the farm to fork chain. We present descriptive summaries of quantitative data and pesticide residue trends along the farm to fork chain using the nptrend test. Qualitative data was inductively coded and analysed using conventional content analysis for sub and overarching themes.

RESULTS: of the 50 farmers visited, 34 (68.0%) sold their fruits and vegetables to transporters, 11 (22.0%) to market vendors, and 4 (8.0%) homes and restaurants. Majority 42 (93.3%) of the consumers (home/restaurant) purchased their fruits and vegetables from market vendors and transporters. Washing with water or vinegar, wiping with a cloth, peeling the outer layer, blending and cooking were the most common post-harvesting processing methods used by stakeholders along the supply chain. Some farmers and market vendors reported spraying fruits and vegetables with pesticides either prior-or post-harvest to increase shelf life. Statistically significant decreasing pesticide residue trends along the farm to fork chain were observed for dioxacarb, likely due to degradation or washing, peeling, cooking, blending, or wiping by consumers. Increasing trends were observed for methidathion and quinalphos possibly due to pesticide applications.
CONCLUSION: Overall, pesticides concentration in fruits and vegetables significantly decreased (dioxacarb) and increased (methidathion, and quinalphos) from farm to fork chain. The decreasing and increasing trends were due to processing measures including washing, peeling, cooking, blending, wiping and applications of pesticides. There is a need in Uganda to promote practices that minimize pesticide use and exposure through diet, while maintaining food integrity.

P-0919 Effect of Heavy Metal Leaching on Elemental Composition of Rice commonly consumed in the USA

Mom Tatah Mentan[1], Syprose Nyachoti[1], Tewodros Godebo[1]
[1]*Tulane University, New Orleans, USA*

BACKGROUND AND AIM: Exposure to Arsenic (As), Cadmium (Cd), and Lead (Pb) in rice is associated with adverse health effects. Studies have shown that soaking can decrease As content in rice and potentially reduce poor outcomes. This study aims to measure elemental composition of soaked rice and determine the optimum rice: water ratio that allows for maximum and minimum loss of toxic and essential elements in rice, respectively.

METHODS: Two rice brands with high As concentrations were soaked at different rice: water ratios (1:1, 1:3, 1:6, 1:9, 1:12, 1:15), various time intervals: 10 seconds, 1, 3, 6, 12, 18, and 24 hours. Filtered rice leachates and samples were analyzed using inductively coupled plasma mass spectrometry (ICPMS) for As, Cd, and Pb. Mann Whitney U-test, and Two-Way Anova assessed differences in elemental composition of soaked vs unsoaked samples.

RESULTS: for all ratios and rice brands, elemental loss of As ranged from (0.96% to 29%), Cd and Pb loss ranged from (10% to 72%), and (8% to 100%), respectively. Essential elemental loss ranged from (3%-70%). The pH values of the leachates decreased with increasing soaking time for all the ratios. This is probably because of adsorption of As, which led to its quicker dissolution and decreased pH levels. Significant differences were found for As and Cd concentrations by each brand $p < 0.05$.

CONCLUSIONS: Soaking rice at different time intervals and rice: water ratios had varying effects on As, Cd and Pb and essential elements in the samples. The reduced pH is indicative of leached Arsenate which is more favorable under aerobic conditions. Future work will explore probabilistic risk analysis from soaked rice, pollution index calculation and principal component analysis. This research informs approaches of decreasing dietary exposure to toxic metals.

KEYWORDS: pH, Rice, Heavy metal leaching

P-0920 Behavioral determinants of arsenic-safe water use among Great Plains Indian Nation private well users: results from the Strong Heart Water Study

Kelly Endres[1], Tracy Zacher[2], Francine Red Willow Richards[2], Lisa Bear Robe[2], Martha Powers[1], Joseph Yracheta[2], David Harvey[1,3], Lyle G. Best[2], Reno Red Cloud[4], Annabelle Black Bear[2], Steve Ristau[5], Dean Aurand[5], Leslie Skinner[2], Christa Cuny[2], Marie Gross[2], Elizabeth Thomas[1], Ana Rule[6], Kellogg Schwab[6], Lawrence Moulton[1], Joel Gittlesohn[1], Barbara Howard[7], Jason Umans[7], Marcia O'Leary[2], Ana Navas-Acien[8], Christine Marie George[1]

[1]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA, [2]Missouri Breaks Industries Research, Inc, Rapid City, USA, [3]Indian Health Service, Rockville, USA, [4]Environmental Resource Department, Oglala Sioux Tribe, USA, [5]Mid Continent Testing Labs, Inc, Rapid City, USA, [6]Department of Environmental Health and Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA, [7]MedStar Health, Washington DC, USA, [8]Department of Environmental Health Science, Columbia University Mailman School of Public Health, New York, USA

BACKGROUND AND AIM: Long-term arsenic exposure in potable water remains a serious public health challenge in the USA. Rural communities with a high reliance on private wells, including American Indian communities, are disproportionately impacted by arsenic contaminated water. However, efforts to decrease arsenic exposure are limited. The objective of this study is to evaluate the behavioral determinants associated with exclusive arsenic-safe water use in the Strong Heart Water Study (SHWS).

METHODS: The SHWS is a randomized control trial designed to reduce arsenic exposure in American Indian Great Plains communities. All households received point-of-use arsenic filters installed at baseline and were followed for up to two years. at each visit questionnaires were administered evaluating water use and behavioral determinants based on the RANAS (risks, attitudes, norms, abilities, and self-regulation) model of behavior change.

RESULTS: Among 75 participants, exclusive use of arsenic-safe water for drinking and cooking at follow-up was associated with higher baseline levels of perceived disapproval from friends and family for using arsenic-unsafe water for drinking (OR: 0.06, 95% CI: 0.01-0.34) and cooking (0.13, 0.02-0.72) (injunctive norms), greater concern for getting sick from arsenic exposure (0.17, 0.04-0.65) (perceived vulnerability), more self-efficacy to use the arsenic filter for drinking (10.5, 1.49-73.2) and cooking (12.5, 1.88-83.1), and higher arsenic knowledge (6.88, 1.07-44.4). Higher commitment to using the arsenic filter was also a significant predictor of exclusive arsenic-safe water use for drinking (11.7, 1.63-83.5) and cooking (8.43, 1.17-60.8) at follow-up. Exclusive arsenic-safe water use was not associated with sex, age, or education. From baseline to follow-up, the SHWS trial significantly increased perceived vulnerability, self-efficacy, and injunctive norms, and decreased concern about the cost of arsenic filters.

CONCLUSION: Future arsenic interventions in our partner communities should target these behavioral determinants of use of arsenic safe water.

KEYWORDS: arsenic, health behavior, water treatment, water

P-0923 Achieving the WHO Air Quality Guidelines brings benefits to the health and economy of Member States across the Western Pacific Region

Nicole Egerstrom[1], David Rojas-Rueda[2], Marco Martuzzi[3], Bin Jalaludin[4], Rina So[5], Youn-Hee Lim[5], Steffen Loft[5], Zorana Jovanovic Andersen[5], Thomas Cole-Hunter[5]

[1]Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA, [2]Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, USA, [3]Department of Environment and Health, National Institute of Health, Rome, Italy, [4]School of Population Health, University of New South Wales, Sydney, Australia, [5]Department of Public Health, University of Copenhagen, Copenhagen, Denmark

BACKGROUND AND AIM: Air pollution continues to greatly burden population heath worldwide, and this burden is over-represented in the Western Pacific Region (WPR). As a risk communication exercise, we quantified the number of avoidable annual deaths and associated economic impact among WHO WPR Member States by meeting current (2021) WHO Air Quality Guideline (AQG) ambient annual concentration levels for fine particulate matter (PM2.5: 5 µg/m3).

METHODS: We performed a health impact assessment comparing latest (factual) and 2021 WHO AQG (counter-factual) PM2.5 levels among individual Member States, using AirQ+ (v.2.1.1). PM2.5 data was obtained from the WHO Global Health Observatory platform for the latest annual estimate available (2016). Population and all-cause mortality (standardized to 100,000 population) data were obtained from the UN World Population Prospects database for the latest 5-year period available (2015-2019) averaged to 1-year (annual) estimates. Global meta-analyses provided mortality risk estimates (all-cause: Chen & Hoek, 2020) and integrated exposure-response functions (COPD, lung cancer: Burnett et al., 2018) within AirQ+. Our economic evaluation used World Bank values of statistical life adjusted to Member-State-specific Gross Domestic Product in USA Dollars (US$).

RESULTS: Data was complete for 21 of 27 Member States. Amongst those 21, achieving the 2021 WHO AQG for PM2.5 avoids an estimated total of 3.1 million premature deaths annually; ranging from 2094 (People's Republic of China) to 5 (Brunei Darussalam) per 100,000 population. COPD and lung cancer exposure-response functions gave generally higher and lower estimates, respectively. Total avoidable deaths translated to economic savings ranging from 583 (Singapore) to 14 (Solomon Islands) million US$ per 100,000 population.
CONCLUSIONS: Implementing effective policy and regulations to reduce PM2.5 emissions and exposure, meeting current WHO AQG, is essential to save thousands of lives and millions of US$ across the WPR.

air quality guidelines; PM2.5; health impact assessment; mortality; Western Pacific

P-0924 The Health Burden of Outdoor Air Pollution in Lagos, Nigeria, between 2020 and 2021

Joseph V. Spadaro[1,2], Francesco Forastiere[3], Christopher Weaver[4], Mofoluso Fagbeja[5], Joseph Akpokodje[6]
[1]Spadaro Environmental Research Consultants (SERC), Philadelphia, USA, [2]European Centre for Environment and Health, World Health Organization (Consultant), Bonn, Germany, [3]Environmental Research Group, School of Public Health, Imperial College London, London, UK, [4]California Air Resources Board, Riverside, USA, [5]ARCSSTEE - National Space Research and Development Agency (NASRDA), Ile-Ife, Nigeria, [6]The World Bank Group, Abuja, Nigeria

BACKGROUND AND AIM: Air pollution, especially particulate matter is the leading environmental risk factor worldwide. According to the latest Global Burden of Disease (GBD) study, 6.7 million deaths, primarily NCDs, are attributable to the joint effects of ambient and household air pollution, with the largest share occurring in low and middle income countries. We compute the air pollution health burden in Lagos during 2020–2021.

METHODS: A health impact assessment was carried out to quantify premature mortality in infants and adults plus evaluate respiratory and circulatory morbidity. Measured $PM_{2.5}$, PM_{10} and lead concentrations across the city of Lagos between August 2020 and July 2021 were used. Alternative population compositions were estimated using data from Lagos and Nigeria statistical bureaus. Baseline data were derived using national and international databases. Cause-specific mortality was calculated with the GBD 2019 risk functions. Infant mortality was calculated using an African-derived risk function, while the Global Exposure Mortality Model provided death estimates in the broader category of NCDs. Morbidity effects were quantified using WHO HRAPIE risk functions.

RESULTS: 1. Ambient population-weighted $PM_{2.5}$ exposure in Lagos was 47μg/m³.
2. Morbidity was high amongst children (180,000–350,000 respiratory infections in <5yr), and infant mortality contributed one-half of total mortality (8,000–15,000 deaths).
3. For one industrial-residential area, lead exposure contributed 6.2 IQ-points lost in children (<6yr), or 1 million IQ-points lost district-wise.
4. $PM_{2.5}$ mortality was 16,000–30,000 deaths (18% of natural deaths) plus 250–500 PM_{10} deaths from exposure to Harmattan winds, and 300–400 adult cardiovascular deaths due to lead.
5. Achieving WHO IT1 target (35 μg/m³) would avert 4,300 deaths (28% reduction), and prevent 64,000 childhood respiratory infections.

CONCLUSION:
$PM_{2.5}$ poses a serious health hazard in Lagos, particularly amongst children, and urgent action is needed to address this preventable environmental risk.

KEYWORDS: Mortality, Infants, Health impact assessment, Lagos (Nigeria), $PM_{2.5}$

P-0926 Agent-based Modeling of Urban Exposome Interventions: Prospects, Methodological Considerations and Challenges

Tabea Sonnenschein[1,2], Simon Scheider[1], G. Ardine de Wit[2,3,5], Cathryn C. Tonne[4], R.C.H. Roel Vermeulen[1,2]
[1]Utrecht University, Utrecht, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands, [3]National Institute of Public Health and the Environment (RIVM), Bilthoven, Netherlands, [4]Barcelona Institute for Global Health, Barcelona, Spain, [5]Vrije Universiteit Amsterdam, Amsterdam, Netherlands

BACKGROUND AND AIM: With ever more people living in cities worldwide, it becomes increasingly important to understand and improve the impact of the urban habitat on health behaviors and health outcomes. However, implementing interventions that tackle the exposome in complex urban systems can be costly and have long-term, sometimes unforeseen, impacts. Hence, it is crucial to assess the health impact, cost-effectiveness, and social distributional impacts of possible urban exposome interventions before implementing them. Spatial agent-based modeling (ABM) can capture complex behavior-environment interactions, exposure dynamics, and social outcomes in a spatial context. This paper discusses methodological architectures and challenges for successfully modeling urban exposome interventions using spatial ABM.

METHODS: We review the potential and limitations of the method; model components required to capture active and passive exposure and intervention effects; human-environment interactions and their integration into the macro-level health impact assessment and social costs benefit analysis; strategies for model calibration.

RESULTS: Major challenges for a successful application of ABM to urban exposome intervention assessment are (1) the design of realistic behavioral models that can capture different types of exposure and that respond to urban interventions, (2) the mismatch between the possible granularity of exposure estimates and the evidence for corresponding exposure-response functions, (3) the scalability issues that emerge when aiming to estimate long-term effects such as health and social impacts based on high-resolution models of human-environment interactions, (4) as well as the data- and computational complexity of calibrating the resulting agent-based model.
CONCLUSION: This paper suggests possible strategies for addressing these challenges and provides a roadmap for further implementing spatial ABM for urban exposome intervention assessment. Future work should analyse the level of detail that is needed and the short-cuts that can be made.

P-0928 Assessing the environmental urban exposure to high tech-metals (Co, Li) in a healthy group of Spanish adolescents

Antonio Peña-Fernández[1], Manuel Higueras[2], Mark Evans[1], María Carmen Lobo-Bedmar[3]
[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, UK, [2]Departamento de Matemáticas y Computación, Universidad de La Rioja, Logroño, Spain, [3]Departamento de Investigación Agroambiental, IMIDRA, Alcalá de Henares, Madrid, Spain

BACKGROUND AND AIM: Demand for high-technology metals is increasing in green technology development, which can have potential effects on human health. The aim was to determine the environmental presence of cobalt (Co) and exposure to Co and lithium (Li) in topsoils and a teenage population group living in Alcalá de Henares (Spain).

METHODS: Scalp hair was collected from 97 adolescents (13-16 years-old; 68 girls) from Alcalá. Metals were analysed by ICP-MS after appropriate removal of exogenous contamination. Co was monitored in 97 topsoil samples randomly collected from different urban parks. Data was processed using statistical methods applied to censored data available in the 'NADA' statistical package. Non-carcinogenic risks to Co were also characterised.

RESULTS: Limits of detection in hair of Li (0.019928) and Co in hair/soils, respectively, were (in µg/g): (0.001488; 0.059271). Co was non-detected in only one topsoil sample [median and percentiles in mg/kg: 1.577 (1.092, 2.584)], meanwhile Co was detected in 73/97 hair samples. Li had a high percentage of censored data (98.97%), detected (0.024091 µg/g) in one female participant. Co showed sex dependency, with significantly higher ($p<0.001$) concentrations in hair of female participants samples [median and percentiles in µg/g: 0.0051 (0.0028, 0.0103) vs. 0.00217 (<0.00149, 0.00333)], as reported in similar studies. Our findings could indicate that females could be more vulnerable to exposure to Li and Co, which would contradict the common belief that boys spend more time outdoors and therefore would be more exposed, although the endocrine system may play a significant role in the detoxification of both elements.

CONCLUSIONS: Alcalá's teenage population would not have been significantly exposed to these high tech-metals, especially Li, as hair has been suggested as a good matrix to assess environmental exposure. Non-carcinogenic risks derived from the ingestion/inhalation/dermal contact to Co in soils and resuspended soils in Alcalá were negligible.

P-0930 The impact of urban environmental exposures on health: An assessment of the attributable mortality burden in Sao Paulo city, Brazil

Evelise Pereira Barboza[1,2,3,4], Mark Nieuwenhuijsen[1,2,3], Albert Ambròs[1,2,3], Thiago Herick de Sá[5], Natalie Mueller[1,2,3]
[1]Barcelona Institute for Global Health ISGlobal, Barcelona, Spain, [2]Department of Experimental and Health Sciences, Universitat Pompeu Fabra, Barcelona, Spain, [3]CIBER Epidemiología y Salud Pública, Madrid, Spain, [4]École de Hautes Etudes en Santé Publique (EHESP), Paris/Rennes, France, [5]Center for Epidemiological Research in Nutrition and Health, University of São Paulo, Sao Paulo, Brazil

BACKGROUND:
Currently, more than half of the global population lives in cities. Contemporary urban planning practices result in environmental risk factors (e.g. air pollution, noise, lack of green space, excess heat) that put health and well-being of city dwellers at risk and contribute to chronic diseases and premature death. Despite a growing body of evidence on adverse health impacts related to current urban and transport planning practices, especially for cities in the Global North, not much is known about associated health impacts in South American cities. Therefore, we estimated the mortality burden attributable to breaching internationally-recommended or locally-preferable exposure levels of urban planning-related environmental exposures in Sao Paulo, Brazil.

METHODS: We carried out a health impact assessment study, following the comparative risk assessment framework, to assess preventable mortality impacts of breaching exposure recommendations for air pollution, green spaces, and temperature at the census tract (CT) level (n = 18,363). We also assessed the distribution thereof by the socioeconomic vulnerability.

RESULTS: We estimated that annually 11,372 (95% CI: 7921; 15,910) attributable deaths could be prevented by complying with recommended exposure levels. The largest proportion of preventable mortality was due to breaching air pollution limits (i.e. 8409 attributable deaths), followed by insufficient green space (i.e. 2593), and excess heat (i.e. 370). Adverse health impacts were larger in CTs of lower socioeconomic vulnerability, due to demographic profile, traffic density, and residential area configurations.
CONCLUSIONS: Not complying with the health limits for air pollution, green space, and temperature exposures resulted in a considerable preventable mortality burden (i.e. 17% of total expected deaths) in Sao Paulo. This burden can be reduced by improving current urban and transport planning practices.

Health impact assessment; Mortality; Air pollution; Green space; Urban planning.

P-0931 Air pollution and health impact of population living in industrial areas in Italy: SENTIERI project

Lisa Bauleo[1], Alessandra Fabri[2], Marco De Santis[2], Maria Eleonora Soggiu[2], Carla Ancona[1]
[1]Department of Epidemiology, Lazio Regional Health Service, Rome, Italy, [2]Department of Environment and Health, Italian National Institute of Health (ISS), Rome, Italy

BACKGROUND AND AIM: We estimated the impact of PM2,5 and PM10 in the Italian industrial areas included in the SENTIERI project characterized by industrial plants with combustion processes deriving from point emissions (chimneys).

METHODS: Using satellite data, the Population Weighted Exposure to PM2.5 and PM10 for 2011 and 2015 was estimated. for the selection of industrial plants, the European database on emissions of the European Pollutant Release and Transfer Register was used. Residents in areas of 1km x 1km, 4 km x 4 km from the industrial plants under study were considered. The concentration-response functions available were used to estimate the number of premature deaths from non-accidental causes, cardiovascular and respiratory diseases, lung cancer attributable to exposure to industrial emissions. The counterfactual levels recommended by the new WHO AQGLs were used.

RESULTS: Residents were exposed to PM2.5 values of 17.3 µg / m3 (north 23.3) and to 24.3 µg / m3 (north 30.3) of PM10. PWE for both pollutants tends to increase as the size of the area under study is reduced and is generally higher everywhere in 2011 than in 2015 with values that are always higher than the average (overall) in the north of Italy. In 2011, we estimated 1,709 (IC 1,309-1,903) and 1,611 (IC 1,225-2,353) non accidental premature deaths attributable to PM2.5 and PM10, respectively in residents close to the industrial plants (1km x 1km). Deaths attributable to exposure to PM2.5 and PM10 tend to follow a north-central-south gradient for all observed causes and for both years of analysis.
CONCLUSION: The results of the study are suggestive of an impact on health from PM exposure in the industrial areas considered, with a greater impact in the vicinity of the plants, recommending the implementation of urgent impact reduction actions.

P-0932 Benefits of Increasing Greenness on All-Cause Mortality in the Largest Metropolitan Areas of the USA within the Past Two Decades

Paige Brochu[1], Marcia Jimenez[1], Peter James[2,3], Patrick Kinney[1], Kevin Lane[1]
[1]Boston University School of Public Health, Boston, USA, [2]Harvard T.H. Chan School of Public Health, Boston, USA, [3]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA

BACKGROUND AND AIM: Across the globe, cities are creating sustainability and climate action plans (CAPs) that call to increase local vegetation. Greening initiatives have the potential to benefit the environment and human health. In epidemiologic literature, greenness has a protective association with mortality through various direct and indirect pathways. We aimed to longitudinally quantify how many deaths could be prevented by increasing greenness in urban areas in the US across two decades.

METHODS: Using publicly available county-level mortality data from the CDC, Landsat 30m 16-day satellite imagery from April to September for 2000, 2010, and 2019, and a recently published exposure-response function, we estimated the age-adjusted reduction in all-cause mortality for those 65 years and older associated with trends in greenness in the most populated US metropolitan areas. County-level data were downscaled to estimate census tract mortality rates. Normalized Difference Vegetation Index (NDVI) was processed to calculate cloud-free mean seasonal greenness for each census tract.

RESULTS: On average, greenness increased across time with a 2.86% increase from 2000 to 2010 and 11.11% from 2010 to 2019. Most metropolitan areas had an increase of 0.05 NDVI across twenty years, with El Paso, TX having the lowest increase in greenness (0.02) compared to Austin-Round Rock, TX that had the highest increase in greenness (0.13). We estimated that that over 34,000 deaths could be prevented according to 2000, 2010, and 2019 data, with an increase in green vegetation by 0.1 unit across the most populated metropolitan areas.

CONCLUSIONS: These results can be used to support CAPs by providing a quantitative assessment to the impact local greening initiatives can have on mortality. Urban planners and local governments can use these findings to calculate the co-benefits of local CAPs through a public health lens and support policy development.

KEYWORDS: greenness; all-cause mortality; built environment; greenspace

P-0935 Lead Exposure Through Food: An Observational Study of Glazed Ceramics within Oaxaca and Mexico City

Kristina Brandveen[1], Marcela Tamayo Ortiz[2]
[1]*Colorado School of Public Health, Denver, USA,* [2]*Instituto Mexicano del Seguro Social, Ciudad de México, México*

BACKGROUND & AIM:
Lead-Oxide (PbO) is used to create beautiful pieces of ceramic art and cookware in México. Substituting lead-free glazed ceramics poses an issue due to the marketability of traditional Mexican ceramics even with government legislation supporting lead free glazes. The aim of our study was to estimate the frequency of street and market food stands that offer prepared and served food from lead-glazed ceramics.

METHODS: We visited three types of market stalls in touristic areas in Mexico City and Oaxaca. We used a handheld counter and registered the total number of stalls at the given date and location. The number of stalls in markets was followed by a count of those with using ceramics for food and beverages as well as stalls with ceramics being sold as artwork/kitchenware (PbO product). We calculated the prevalence of PbO stalls and products for each market and for the overall study.

RESULTS: The market stalls classified as Permanent (n=2), Semi-Permanent (n=2), and Weekly (n=2) in Mexico City and Oaxaca. Both Permanent and Weekly market stalls showed the highest prevalence rates. Oaxaca had a period prevalence of 2.00% (Permanent), 0.20% (Semi-Permanent), and 26.00% (Weekly) for stalls selling prepared food in ceramics. for comparison, Mexico City's period prevalence was 27.50% (Permanent), 13.10% (Semi-Permanent), and 36.40% (Weekly).

CONCLUSION: Permanent Market Stalls throughout México have a higher prevalence of lead-glazed ceramics, representing a possible major source of lead exposure than Semi-Permanent and Weekly Market Stalls. Non-lead glaze is not commonly used in Mexican ceramic work. Although we did not test the ceramics, lead-glazed ceramics are still those most frequently produced and marketed in Mexico, suggesting that residents of México and tourists alike can be exposed to lead in popular public marketplaces serving prepared food.

KEYWORDS: lead, ceramic, food, potter, Oaxaca, Mexico City, market, stall, exposure, glaze

P-0936 Health impact assessment of urban and transport developments in Barcelona: a case study

Ana Ramos[1,2], Marta Cirach[1], Evelise Pereira Barboza[1,2], Tamara Iungman[1,2], Sasha Khomenko[1,2], Carolyn Daher[1], Natalie Mueller[1], Martin Dijst[3], Mark Nieuwenhuijsen[1]
[1]Isglobal, Barcelona, Spain, [2]Pompeu Fabra University Faculty of Health and Life Sciences, Barcelona, Spain, [3]Luxembourg Institute of Socio-Economic Research, Luxembourg, Luxembourg

BACKGROUND AND AIM: Urban areas are drivers of climate vulnerability and a key public health concern due to their increasing population. However, they can also provide the adequate setting for adaptation and mitigation strategies for tackling these challenges. Barcelona already started rethinking urban spaces, such as superblocks, an urban development which have proven health benefits. The aim of this study is to explore urban and transport developments in Barcelona and estimate the health impacts of their related exposures.

METHODS: On our first phase, we reviewed secondary data such as policy documents (urban and mobility plans), publicly available health and population data on Barcelona Metropolitan Area. We approached stakeholders involved in the development of these activities for environmental data review.
The second stage of this study would be to implement a health impact assessment focused on the health impacts of the air pollution, greenspace, and physical activity that these scenarios bring.

RESULTS: As preliminary findings there are short and mid-term planning scenarios. On the urban transport scenario, we found the combined effect on air pollution as NOx of three different interventions: the low emission zone area, tactical urban planning (reducing car traffic lanes), and eight superblocks. The three interventions combined have an estimated 25% private car use reduction and a NOx emission reduction of 30%. The reduction in private car use also implies a change in mode of transport of: increases of 15.7% for public transport, 7.5% for walking and 129.4% for cycling. Another scenario is the implementation of new green infrastructures on peri-urban areas of the Metropolitan Area of Barcelona and their effect on air pollution as NOx and PM2.5.
CONCLUSION:
Barcelona is focusing different transport activities that reduce private car use, promote change in mode of transport and increase green areas.

P-0937 A Pilot Study of an Usability of a Mobile Application to target Neglected Skin Diseases in Côte d'Ivoire

Kouame Kouadio[1], Sakiko Itoh[2], Yao Didier Koffi[3], Kazuko Ugai[4], Koffi Aubin Yao[5], Rie Roselyne Yotsu[6]
[1]Institut Pasteur of Côte D'ivoire, Kouassi Datékro, Côte D'Ivoire, [2]Department of Genome Informatics, Graduate School of Medicine, Osaka University, Suita, Osaka, Japan, Osaka, Japan, [3]National Buruli Ulcer Control Program, Abidjan, Côte d'Ivoire, Abidjan, Côte d'Ivoire, [4]School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan, Nagasaki, Japan, [5]Hope Commission International Inc., Abidjan, Côte d'Ivoire, Abidjan, Côte d'Ivoire, [6]School of Public Health & Tropical Medicine, Tulane University, New Orleans, Louisiana, USA, tuluane, USA

This study investigated the usability of a mobile phone-based system, "eSkinHealth", for healthcare providers in Côte d'Ivoire. The eSkinHealth can be used both online and offline to address the poor Internet connectivity of these rural settings. Data recorded in the mobile application were synchronized with an online database, and specialists in Abidjan, Côte d'Ivoire and in Japan advised local healthcare providers on difficult cases. In this pilot study, 21 healthcare providers used the eSkinHealth and completed questionnaires assessing the usability. The average score of a system usability scale for eSkinHealth was 84.2 (SD 11.7), which can be interpreted as excellent. The average registration for patient information (e.g., name, sex, age, area of residence) was 8.6 (SD 15.5). Further studies with more targeted areas and participants are needed to evaluate the usability of eSkinHealth in rural Côte d'Ivoire

P-0940 Evidence synthesis of Observational Studies in Environmental Health: Lessons Learned from a Systematic Review on Traffic-Related Air Pollution

Hanna Boogaard[1], Richard Atkinson[2], Jeffrey Brook[3], Howard Chang[4], Gerard Hoek[5], Barbara Hoffmann[6], Sharon Sagiv[7], Evangelia Samoli[8], Audrey Smargiassi[9], Adam Szpiro[10], Danielle Vienneau[11,12], Jennifer Weuve[13], Frederick Lurmann[14], Francesco Forastiere[15]

[1]Health Effects Institute, Boston, USA, [2]University of London, London, UK, [3]University of Toronto, Toronto, Canada, [4]Emory University, Atlanta, USA, [5]Utrecht University, Utrecht, Netherlands, [6]University of Düsseldorf, Düsseldorf, Germany, [7]University of California Berkeley School of Public Health, Berkeley, USA, [8]National and Kapodistrian University of Athens, Athens, Greece, [9]University of Montreal, Montreal, Canada, [10]University of Washington, Seattle, USA, [11]Swiss Tropical and Public Health Institute, Basel, Switzerland, [12]University of Basel, Basel, Switzerland, [13]Boston University School of Public Health, Boston, USA, [14]Sonoma Technology, Inc., Petaluma, USA, [15]Imperial College London, London, UK

BACKGROUND: There is a long tradition in environmental health of using frameworks for evidence synthesis. Recently, frameworks were developed for evidence synthesis in clinical medicine, including Grading of Recommendations Assessment, Development and Evaluation (GRADE). The US Office of Health Assessment and Translation (OHAT) elaborated a GRADE type protocol for evidence synthesis in environmental health to assess the "quality in a body of evidence".

METHODS: We describe lessons learned in synthesizing evidence from observational studies of environmental health effects, drawing on our experience of applying the OHAT approach in a large systematic review on traffic-related air pollution and health outcomes.

RESULTS: We outlined key elements of and suggested improvements to the GRADE/OHAT approach. To maximize what can be learned from observational studies in environmental health, a "narrative" approach is needed to complement the mechanistic up-and-downgrading of certain factors in the evaluation of the quality of a body of evidence. This "narrative" approach links more directly to current and widely accepted evidence synthesis frameworks, such as from the US EPA and IARC. We argue that observational studies can offer high confidence evidence in environmental health, where randomized controlled trials are generally not feasible. All relevant studies should be included in evidence synthesis, beyond the subset of the available evidence often included in meta-analyses. Sources of heterogeneity can both strengthen and weaken the confidence in the evidence. Consistency of associations across study designs, populations, and exposure assessment methods provides additional confidence in the results. Publication bias should be explored beyond statistical methods and is not necessarily expected in large and collaborative studies. We call for identifying and quantifying possible key biases, their most likely direction, and their potential impacts on the results.

CONCLUSIONS: GRADE-type frameworks require substantial modification to align better with features of environmental health questions and the studies that address them.

P-0942 Contamination by mercury in Alcalá de Henares (Spain): temporal and spatial variability and risk assessments

Antonio Peña-Fernández[1], Manuel Higueras[2], Mark Evans[1], Maria Carmen Lobo-Bedmar[3]
[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, UK, [2]Scientific Computation & Technological Innovation Center (SCoTIC), Universidad de La Rioja, Logroño, Spain, [3]Departamento de Investigación Agroambiental, IMIDRA, Alcalá de Henares, Madrid, Spain

BACKGROUND AND AIM: Data on mercury (Hg) in urban topsoils in Europe are limited despite its involvement in extensive air-soil exchange, which increases the likelihood of the population being exposed to this metal. The aim was to assess the temporal variation and distribution of Hg in Alcalá de Henares (Madrid region, Spain), and its risks for the population.

METHODS: Ninety-four topsoil samples were collected in July 2017: 66 urban, 24 industrial and 4 public garden. Hg was analysed by ICP-MS after acid digestion in a microwave system. Data was processed using the 'NADA' statistical package, and compared with topsoils collected in the same locations in 2001 (97 urban, 22 industrial; 18 garden). Non-carcinogenic risks were also characterised.

RESULTS: Hg was only detected in topsoil samples collected in 2017 (7 urban, 3 garden, 1 industrial; LoD=0.1598 mg/kg), suggesting a recent emission, as soil is an important reservoir in the biogeochemical cycling of Hg. Potential emissions could be related to technological devices (fluorescent lamps, thermostats, electrical switches and pressure sensing devices), meanwhile the high presence detected in the garden might be explained by application of fertilisers/fungicides. A higher contamination in urban>garden>industrial soils was observed, respectively (ranges; mg/kg): (0.1753-5.0575>0.1833-0.2230; 0.2038 concentration in industrial sample); meanwhile higher levels were detected in the topsoil samples collected within urban areas with more presence of industries. Lower levels of total-Hg were found in topsoils in Seville (0.11-1.6 vs. 0.1753-5.0575 mg/kg), supporting the anthropic input observed in Alcalá. All Hg values detected fell below the regulatory guidance value set by Madrid Government, for urban (7 mg/kg) and industrial (15 mg/kg) areas.

CONCLUSIONS: Health risks for the population of Alcalá from the ingestion/inhalation of Hg in soils and resuspended soils seem to be small. However, the recent contamination of Hg detected highlights the need of performing future monitoring studies.

P-0944 Characterisation of risks from lanthanum and europium in topsoils from the East Midlands (UK)

Antonio Peña-Fernández[1], Manuel Higueras[2], Gurminder S. Jagdev[1], Mark D. Evans[1], M. Carmen Lobo Bedmar[1]
[1]Leicester School of Allied Health Sciences, De Montfort University, Leicester, LE1 9BH, UK, [2]Scientific Computation & Technological Innovation Center (SCoTIC), Universidad de La Rioja, Logroño, Spain, [3]IMIDRA, Alcalá de Henares (Madrid), Spain

BACKGROUND AND AIM: Light-group rare earth elements (LREEs) are increasing their environmental presence, with unknown implications for human health. The aim was to determine the risks to lanthanum (La) and europium (Eu) in urban/rural topsoils from Leicestershire (UK).

METHODS: A total of 850 soil samples were collected (2017-18); 26 composite samples were appropriately prepared per park/location (18 urban, 8 rural), which were further processed in duplicate. Both LREEs were measured in triplicate in the 52 composite samples by ICP-MS. Provisional reference doses were used to characterise noncarcinogenic risks following US EPA methods.

RESULTS: Slightly higher levels were found in the rural area (data presented as median and ranges, in mg/kg) for La [19.245 (11.395-28.493) vs. 18.121 (11.711-28.144)] and Eu [0.786 (0.369-1.141) vs. 0.725 (0.486-1.137)], which might be attributed to the agricultural use of La and Eu in fertilisers. The technological uses of Eu in flat screen displays, optical fibres, phosphors and La in catalytic converters and phosphors could be important sources of these LREEs. The urban mean concentrations of La (18.7 vs 3.9 mg/kg) exceeded the soil screening level (SSL) value for non-carcinogens established by the US EPA for residential soils (there is currently no SSL proposed for Eu). However, the non-carcinogenic risks for La and Eu for ingestion/dermal contact were lower than the unit, with the highest non-carcinogenic risks quotients found for La (HQs; 0.735 and 0.0261, respectively).

CONCLUSIONS: The presence of La in Leicester's topsoils is similar to those reported in other similar European cities. Our results would suggest a minimal risk to both LREEs present in Leicester's urban topsoils, although the soils monitored may require decontamination, specifically for La. Further toxicological studies are required to investigate whether the levels of Eu found in the urban soils would also require decontamination.

KEYWORDS: Lanthanum, Europium, Leicester, topsoils, risks.

P-0947 Ambient Fine Particulate Matter reduction and mortality benefit during the COVID-19 Crisis in Korea

Hyun-joo Bae[1], SHIJIN KIM[2], YURA LIM[3]
[1]Korea Environment Institute, Sejong, Republic of Korea, [2]Korea Environment Institute, Sejong, Republic of Korea, [3]Seoul National University, Seoul, Republic of Korea

The COVID-19 outbreak forced into diverse measures such as social distancing and increased telecommuting in Korea and the stringent lockdown measures of China, which led to an improvement in air quality.
This study estimated the change of PM2.5 and health benefits of PM2.5 reduction during the COVID-19 crisis in Korea.
To calculate the mortality burden attributable to PM2.5, we obtained population data, mortality data, and air pollution monitoring data for Korea from publicly available databases. We calculated the avoided mortality attributable to decreases in daily PM2.5 on the basis of CRFs from Krewski et al. study.
The average PM2.5 concentration from January to December in 2020 (11.90~29.52 μg/m3) was the lowest in the last 5 years. We found that decreases of average PM2.5 concentration ranged from 0.01 $\mu g/m^3$ to 10.35 $\mu g/m^3$ was observed in 2020 compared to the previous year.
We estimated that PM2.5 reduction during the mitigation period lowered air pollution-related total deaths. An estimated 6,639(95% CI 4,514~8,749) PM2.5-related prematrue deaths were alverted throughout Korea.
Our estimates suggest that diverse measures to control the COVID-19 outbreak led to improvements in air quality that brought health benefits in non-COVID-19 deaths.
Our findings show the health benefits related to morbidity and mortality that can be achieved when aggressive control measures for air pollution are taken to reduce emissions.
when efforts to reduce measures for air pollution are taken to reduce emissions.

P-0949 Effectiveness of community and household level Interventions for reducing impact of air pollution on health outcomes - A systematic review

Harshal Ramesh Salve[1], Huma Nawaz[1], Preeti Sharma[1], Sagnik Dey[2], Karan Madan[1], Anand Krishnan[1]
[1]All India Insitute of Medical Sciences, New Delhi, New Delhi, India, [2]Indian Institute of Technology, Delhi, India

BACKGROUND AND AIM: We aimed to synthesize scientific evidence about effectiveness of various community and household level interventions on improving air quality and its impact on health outcomes using systematic approach.

METHODS: Comprehensive strategy using key words and MeSH terms was used to carry out literature search in PubMed, Cochrane and Google scholar by two independent investigators. Research articles published till year 2021 focusing on interventions for improvement in air quality and health were selected using pre-specified eligibility criteria. All abstracts and full text articles for inclusion were reviewed independently by two investigators. Disagreements resolved by discussion with the third investigator. Quality of the studies was assessed using Joanna Briggs Institute critical appraisal tool and Cochrane Risk of Bias tool. PRISMA guidelines were used and review was registered in PROSPERO (CRD42022295393).

RESULTS: The search resulted in identification of 79,742 studies and 25 (trials and quasi experimental trials) were finally included in the review. The community level interventions (7 studies) were traffic rationing system, diesel emission control policies and industrial reforms. Household interventions (18 studies) were use of air purifiers/electric heaters, improved cookstove and behavioral change practice. Community based interventions resulted in reduction in all-cause mortality by 6% to 11%, cardiovascular mortality by 11% to 17.9%, respiratory mortality by 22% to 22.8%, infant mortality rates by 20% and number of asthma acute events by 41.6%. Household interventions resulted 0.8% change in lung function. PM 2.5 was most commonly reported air pollutant, its concentrations reduced in the range from 31% to 53% across the studies. Most of the studies scored higher in quality assessment.
CONCLUSION: Our review provided robust evidence for substantial improvements in morbidity and mortality related to air pollution due to household and community level interventions.

KEYWORDS: - Air pollution; community; interventions; household; health impact

THEMATIC 15: Mechanisms and Molecular Biomarkers

P-0950 Genome-wide SNP-by air pollution interaction and airflow obstruction development in the Dutch population-based Lifelines cohort

Dimitra Sifaki-Pistolla[1,2], Judith M. Vonk[2,3], Ioanna Tsiligianni[1], H. Marike Boezen[4]

[1]Department of Social Medicine, School of Medicine, University of Crete, Greece, Heraklion, Greece, [2]University of Groningen, University Medical Center Groningen, Department of Epidemiology, Groningen, The Netherlands, The Netherlands, [3]University of Groningen, University Medical Center Groningen, GRIAC, Groningen, The Netherlands, The Netherlands, [4]Deceased in Oct 2021. University of Groningen, University Medical Center Groningen, Department of Epidemiology, Groningen, The Netherlands, The Netherlands

BACKGROUND: Research has shown that exposure to air pollution is associated with the development of airflow obstruction (AO). However, not everybody is equally susceptible and individual risk may depend on genetics.
Aim: To identify single nucleotide polymorphisms (SNPs) that carry higher odds to develop AO upon exposure to air pollution.

METHODS: We included 25,506 participants of the Lifelines cohort study without AO (FEV1/FVC < lower limit of normal) at baseline. AO development was determined after 4.5 years of follow-up. Black carbon (BC), NO2, PM10, and PM2.5 exposure at the baseline home-address was estimated using land-use regression models. Logistic regression analyses including genome-wide SNP-by air pollution interactions for 2,769,714 SNPs and each air pollutant were performed. Different p-value thresholds were checked and independent loci were identified by LD-pruning (R2 < 0.8).

RESULTS: at follow-up, 2,464 (9.7%) subjects had developed AO. Depending on the p-value thresholds, 3 (p<1*10-6) to 202 (p<5*10-5) independent interacting loci were identified. The lowest p-value was found for rs16825276-by-PM2.5 interaction (p=1.7*10-7, annotated to ECE1 gene). Rs0183947394 (CD53 gene) significantly interacted with PM10 (p=4.6*10-7). SNPs in the LEMD1 gene significantly interacted with both BC and PM10. The lowest interaction p-value for NO2 was found for rs79787553 (p=5.3*10-6, SCL28A1 gene).

CONCLUSIONS: This study identified up to 202 significant independent SNP-by-air pollution interactions for AO development. Future studies will focus on analyzing the function of the identified genes and SNPs.

P-0955 Mediation effect of DNA methylations in the association between bisphenol A exposure and blood pressure

Da Hae Kim[1], Sanghyuk Bae[2], Yun-Chul Hong[3,4], Jin Hee Kim[1]

[1]Sejong University, Seoul, Republic of Korea, [2]The Catholic University of Korea, Seoul, Republic of Korea, [3]Seoul National University College of Medicine, Seoul, Republic of Korea, [4]Seoul National University Medical Research Center, Seoul, Republic of Korea

BACKGROUND AND AIM: Bisphenol A (BPA) has been known to induce hypertension. However, BPA-related hypertension mechanism remains unclear. Our study aim was to explore epigenetic mechanism for how BPA exposure increases blood pressure (BP).

METHODS: We obtained information including urinary BPA levels, genome-wide DNA methylation levels, and blood pressure (BP) from an clinical trial study conducted with Korean elderly and evaluated the relations among them. Because the dataset had repeated measures, we analyzed the relations using mixed-effect model after adjusting for age, sex, body mass index, drinking status, a diabetic history, the round of visits, and visit date.

RESULTS: We found a positive association between BPA exposure and BP ($\beta = 1.28$ and $p = 0.0241$ for SBP; and $\beta = 0.58$ and $p = 0.0527$ for DBP) and the mediation effect of 285 DNA methylation sites in the association. Furthermore, downstream target genes of the 285 DNA methylation sites were significantly related with KEGG pathways including oxytocin signaling, calcium signaling, circadian entrainment, and amphetamine addiction as well as disease classes including immune and pharmacogenomic ($p < 0.05$ for all pathways and disease classes).

CONCLUSIONS: Our results indicate that BPA exposure could increase BP through DNA methylation changes and further this BPA-related methylation changes could affect several pathways, resulting in the development of various diseases.

KEYWORDS: bisphenol A, DNA methylation, blood pressure.

P-0956 Traffic-related air pollution in utero modifies cytokine responses to stimuli of umbilical cord blood cells: results from the NELA cohort

[1]University of Murcia, Murcia, Spain, [2]Biomedical Research Institute of Murcia (IMIB-Arrixaca), Murcia, Spain, [3]Network of Asthma and Adverse and Allergic Reactions (ARADyAL), Spain

BACKGROUND AND AIM: Effects of prenatal exposure to air pollution on offspring cytokine responses to stimuli have been poorly studied. We examined the associations between in utero exposure to traffic-related air pollutants (TRAP) and cytokine responses to stimuli in newborns.

METHODS: Data come from 235 participants of the NELA cohort. Inflammatory cytokines (IL-6, IFN- α, IL1-β and TNF-α), Th1-related (IFN-γ and IL-2), Th2-related (IL-4, IL-5 and IL-13), Th17-related (IL-17 and IL-23) and Treg-related IL-10 were assessed by Luminex technology in umbilical cord blood cultured with mitogens, pathogen associated with molecular patterns (PAMPs) stimuli and common allergens. In utero residential exposure to traffic-related nitrogen dioxide (NO_2), particulate matter ($PM_{2.5}$ and PM_{10}) and ozone (O_3) was estimated using dispersion/chemical transport modelling. Multivariable linear regression models were performed.

RESULTS: for every 10μg/m³ increase in prenatal exposure to NO_2, we found an increased IL-6 response to mitogens Concanavalin A (12.5%, 95% CI: 3.6, 21.4) and Phytohemagglutinin (PHA) (14.9%, 95% CI: 7.3, 22.5); to PAMPs Lipopolysaccharide (11.6%, 95% CI: 3.8, 19.5), Peptidoglycan (PG) (12.0%, 95% CI: 4.1, 20.0) and p:IC (13.0%, 95% CI: 4.9, 21.2); and to allergens Der p 1 (11.6%, 95% CI: 3.4, 19.9) and olive extract (9.7%, 95% CI: 0.4, 19.0). IL-6 response to PHA also increased in relation to PM (19.0% per 5μg/m³ increase in $PM_{2.5}$, 95% CI: 5.5, 32.5; and 20.2% per 10μg/m³ increase in PM_{10}, 95% CI: 6.0, 34.4). Per 10μg/m³ increase in NO_2, IFN-α responses to PHA and PG increased by 7.5% (95% CI: 0.6, 14.5) and 7.6% (95% CI: 0.1, 15.1), respectively. In utero NO_2 also induced an increased Th1-related IFN-γ response to mitogen Concanavalin A (7.5% per 10μg/m³ increase in NO_2, 95% CI: 0.1, 14.9).

CONCLUSIONS: Prenatal exposure to TRAP may promote higher proinflammatory and Th1-related cytokine responses to stimuli in the offspring.

P-0957 Oxidative potential in the exhaled air (OPEA): a candidate biomarker for respiratory diseases screening

Irina Guseva Canu[1], Maud Hemmendinger[1], Antonio Toto[1], Pascal Wild[1], Caroline Veys-Takeuchi[1], Semira Gonseth Nussle[1], Murielle Bochud[1], Guillaume Suarez[1]
[1]*Unisanté, Epalinges-Lausanne, Switzerland*

BACKGROUND AND AIM: OPEA is a physiological-related metric measured with a photonic sensing system, OPEA analyzer. OPEA must be corrected for the oxidative potential in ambient air (OPAA) as a dimensionless ratio OPEA/OPAA (cOPEA). In a hospital setting, OPEA allowed us distinguishing patients with and without chronic obstructive pulmonary disease, particularly among non-smokers. Using the setting of the Swiss health study, we aimed to assess whether OPEA would be increased in participants with abnormal spirometry parameters and in those who demonstrated an immunity against SARS-CoV-2. We also aimed to estimate OPEA reference interval (RI) necessary for interpreting clinical biomarker values.

METHODS: Swiss adult residents of the Vaud Canton randomly selected from the Federal Statistical Office's registries, speaking French or German were included and examined between 1.10.2020 and 31.12.2021. General health status and presence of respiratory diseases were assessed by questionnaire and spirometry. Spirometric results were compared with predicted values and their lower limits of norms for spirometric parameters (LLN) of the Global Lung Function Initiative. Seroprevalence was assessed using Luminex-based test of IgG. cOPEA means were compared using univariate t-test and multivariable regression. RI (lower and upper limit of OPEA values with associated 90%-confidence interval (90%CI) were estimated for the sub-sample of healthy adults by bootstrap, after excluding outliers.

RESULTS: The study sample included 247 participants. A borderline statistically significant difference in cOPEA was observed in participants with an obstructive syndrome. SARS-CoV-seropositive participants had a significantly higher cOPEA than seronegative participants did. After outlier exclusion, the reference sample included 184 participants and RI partitioning appeared unnecessary. Estimated RI was: 0.88 (90%CI=0.85;0.92); 0.97(90%CI=0.93;1.00).
CONCLUSION: OPEA could predict some respiratory affections, but needs further validation as a disease predictive biomarker in different settings. Our study sample was small and the estimated RI should be considered as preliminary and further confirmed.

P-0958 Metal exposure and oxidative stress biomarkers in subway workers

Irina Guseva Canu[1], Maud Hemmendinger[1], Tesnim Ben Rayana[1,2], Amelie Debatisse[2], Valérie Jouannique[2], Guillaume Suarez[1], NB. Hopf[1], JJ Sauvain[1]
[1]Unisanté, Epalinges-Lausanne, Switzerland, [2]RATP, Paris, France

BACKGROUND AND AIM: Rich in metals, subway particles could induce more oxidative stress (OS) than ambient PM. We aimed at investigating relationships between subway particle exposure and OS biomarkers measured in urine and exhaled breath condensate (EBC).

METHODS: Nine subway workers (station agents, locomotive operators and security guards) were monitored during their 6-h shifts over two consecutive weeks. Time-weighted average mass concentrations expressed as PM10, PM2.5 and their metal concentrations were determined. Urine and EBC samples were collected pre- and post-shift to measure metals, malondialdehyde, 8-isoprostane, and 8-hydroxy-deoxyguanine concentrations. Associations were first explored using correlation and hierarchical cluster analysis. The identified clusters were then investigated using linear mixed regression models adjusted for age and sex, with participant's ID as random effect.

RESULTS: PM concentrations varied significantly between jobs. Locomotive operators had the highest exposure (189 and 137 µg/m3 for PM10 and PM2.5, respectively). The most abundant metals in PM were Fe, Cu, Al and Zn; in EBC, Zn, Cu and Ni; and in urine, Si, Zn, Mo, Ti, and Cu. Regarding OS biomarkers, in EBC, only malondialdehyde was detected. Urinary malondialdehyde and 8-hydroxy-deoxyguanine concentrations varied according to the weekday and workers' age. Zn or Ni exposure clusters were identified. Modeled urinary Zn concentration was negatively associated with urinary malondialdehyde and positively associated with malondialdehyde in EBC. PM10 Zn was also negatively associated with urinary malondialdehyde and 8-isoprostane, but with borderline significance. PM10 Ni was negatively associated with urinary 8-hydroxy-deoxyguanine. In models adjusted for all exposure metrics of a given metal, associations remained between urinary Zn and malondialdehyde and between urinary Ni and 8-hydroxy-deoxyguanine.
CONCLUSION: These findings suggest Zn and Ni influence in OS reflected by urinary malondialdehyde and 8-hydroxy-deoxyguanine concentrations. Further investigations based on larger datasets and in-depth time-series analysis are needed to understand the underlying mechanism of these associations.

P-0959 A modern biodosimetric re-assessment of three mile island exposures using whole genome directional genomic hybridization (DGH)

Aaron Datesman[1], Doug Brugge[2], Christopher Tompkins[3], Erin Robinson[3], Susan Bailey[4], Heidi Hutner[5]
[1]University of Virginia, Charlottesville, USA, [2]University of Connecticut, Farmington, USA, [3]KromaTiD, Inc., Longmont, USA, [4]Colorado State University, Fort Collins, USA, [5]Stony Brook University, Stony Brook, USA

BACKGROUND AND AIM: About 22,000,000 Curies of radioactive xenon-133 escaped into the environment following the 1979 accident at the Three Mile Island nuclear power station in Pennsylvania. Anecdotal evidence of symptoms consistent with radiation exposure were contemporaneously reported, and a limited biodosimetric investigation performed in 1994 produced evidence consistent with significant radiation exposure. Subsequent epidemiological investigations have produced equivocal findings. We aim to re-assess the impact of the unique TMI exposure using a state-of-the-art method of cytogenomic analysis by joining, for the first time, the recently proposed physics of radiobiological shot noise with environmental epidemiology.
METHODS: We employ a modern cytogenomics technology for evaluation of radiation-induced DNA damage. Our innovative technology is known as directional genomic hybridization (dGH). The dGH methodology enables high-resolution detection of both translocations and inversions, which when symmetrical are stable biomarkers of prior radiation exposure. The strand-specificity of the dGH methodology enables detection of inversions at much higher resolution than was possible previously, while simultaneously also detecting translocations. Inversions are induced at a greater rate than are translocations, creating a more sensitive "biodosimeter". The detection power of the approach is enhanced by employing five colors to paint all twenty-three chromosome pairs, while adding automation using artificial intelligence and machine learning to speed aberration scoring.

RESULTS: AND CONCLUSIONS: Based on preliminary data from four exposed and four unexposed individuals, matched for location, age, and sex, we have demonstrated the feasibility of our approach. Although at the present time no inference regarding the degree of exposure can be supported, representative images demonstrating the resolution of the dGH technology will be presented. We have laid the foundation for a larger study of TMI-exposed individuals to come. Our approach may evolve to become the new standard for quality and sensitivity in retrospective biodosimetry.

KEYWORDS: biodosimetry, cytogenetics, ionizing radiation

P-0960 Newborn Metabolomic Signatures of Maternal Serum Per- and Polyfluoroalkyl Substance Levels and Reduced Length of Gestation: A Prospective Analysis in the Atlanta African American Maternal-Child Cohort

Kaitlin Taibl[1], Anne L. Dunlop[2], Dana Boyd Barr[1], Yuan-Yuan Li[3], Stephanie M. Eick[1], Kurunthachalam Kannan[4], P. Barry Ryan[1], Madison Schroder[3], Blake Rushing[3], Timothy Fennell[5], Che-Jung Chang[1], Youran Tan[1], Carmen Marsit[1], Dean P. Jones[6], Donghai Liang[1]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Department of Gynecology and Obstetrics, School of Medicine, Emory University, Atlanta, USA, [3]Metabolomics and Exposome Laboratory, Nutrition Research Institute, University of North Carolina, Chapel Hill, USA, [4]Departments of Pediatrics and Environmental Medicine, New York University School of Medicine, New York City, USA, [5]Analytical Chemistry and Pharmaceuticals, RTI International, Durham, USA, [6]Division of Pulmonary, Allergy, and Critical Care Medicine, Department of Medicine, School of Medicine, Emory University, Atlanta, USA

BACKGROUND AND AIM: Preterm birth (PTB; 22–<37 gestational weeks) and early term birth (ETB; 37–38 gestational weeks) disproportionately affect marginalized populations. Exposure to per- and polyfluoroalkyl substances (PFAS) has been reported to reduce length of gestation, but the underlying mechanisms are unknown. Our aim was to characterize the molecular signatures of prenatal PFAS exposure and gestational age at birth outcomes in the newborn dried blood spot (DBS) metabolome.

METHODS: This prospective cohort study included 267 African American pregnant people who gave birth to a singleton in Atlanta, Georgia between 2016 and 2020. Maternal PFAS concentrations were measured in serum samples obtained between 6–17 gestational weeks. Linear and logistic regression was used to assess associations between PFAS concentrations and gestational weeks at birth or PTB and ETB compared to full-term birth, respectively. Molecular signatures of the exposure-outcome relationships were phenotyped in newborn DBS samples with high-resolution metabolomics.

RESULTS: The mean gestational age was 38.7±2.0 weeks. Relative to the lowest quartile, the second quartile of serum perfluorooctanoic acid (PFOA) concentration was significantly associated with increased odds of ETB (odds ratio (OR), 2.85; 95% CI 1.16, 7.02) and the second quartile of perfluorohexane sulfonic acid (PFHxS) concentration was significantly associated with medically-indicated PTB or ETB (OR, 6.39; 95% CI 1.20, 34.09) versus healthy full-term birth. After false discovery rate correction, 8 pathways and 52 metabolites were associated with PFAS exposure and gestational age at birth outcomes.
DISCUSSION: In this study, pregnant people with higher PFOA and PFHxS concentrations had increased odds of an early birth prior to full-term. The effect of prenatal PFAS exposure on reduced length of gestation was associated with perturbed tissue neogenesis, neuroendocrine function, and redox homeostasis in the newborn DBS metabolome. These mechanisms may be translated into strategies for addressing maternal and child health disparities affecting African Americans.

P-0961 Epigenetic biomarkers of lead exposure and cardiovascular disease: prospective evidence in the Strong Heart Study

Wil Lieberman-Cribbin[1], Arce Domingo-Relloso[1,2,3], Ana Navas-Acien[1], Shelley Cole[4], Karin Haack[4], Jason Umans[1,5], Maria Tellez-Plaza[2], Elena Colicino[6], Andrea Baccarelli[1], Xu Gao[7], Allison Kupsco[1]

[1]Columbia University Mailman School of Public Health, New York City, USA, [2]National Center for Epidemiology, Carlos III Health Institute, Madrid, Spain, [3]University of Valencia, Valencia, Spain, [4]Texas Biomedical Research Institute, San Antonio, USA, [5]Georgetown-Howard Universities Center for Clinical and Translational Science, Washington DC, USA, [6]Icahn School of Medicine at Mount Sinai, New York City, USA, [7]Peking University, Beijing, People's Republic of China

BACKGROUND AND AIM: Lead is a cardiotoxic metal associated with adverse health effects. Data on lead exposure, however, is difficult to collect and often missing from population-based studies of cardiovascular disease (CVD) and risk factors. In the absence of lead data, epigenetic biomarkers can serve as indicators of lead exposure. Here, we leveraged novel epigenetic biomarkers of lead exposure to investigate their association with CVD incidence and mortality in the Strong Heart Study (SHS), a study of CVD in American Indian adults.

METHODS: Blood DNA methylation was measured using the Illumina MethylationEPIC BeadChip among 2,231 SHS participants at baseline (1989-1991). Epigenetic biomarkers of lead concentrations in blood, patella, and tibia were estimated using previously identified CpG sites developed in the Normative Aging Study, a study of aging in adult men. Cox proportional hazards models were performed to estimate the risk of incident CVD and CVD mortality.

RESULTS: Median concentrations of lead epigenetic biomarkers were 13.8 µg/g, 21.3 µg/g, and 2.9 µg/dL in tibia, patella, and blood. In fully adjusted models, the hazard ratio (HR) (95% CI) of CVD mortality per doubling increase in lead epigenetic biomarkers were 1.42 (1.07-1.87) for tibia lead, 1.22 (0.93-1.60) for patella lead, and 1.57 (1.16-2.11) for blood lead. The HRs for incident CVD were 0.99 (0.83-1.19), 1.07 (0.89-1.29), and 1.06 (0.87-1.30), respectively. The association between the tibia lead epigenetic biomarker and CVD mortality was modified by sex (interaction p-value: 0.014), with men at increased risk (1.42, 1.17-1.72) compared to women (1.04, 0.89-1.22).

CONCLUSIONS: Tibia and blood epigenetic biomarkers were associated with increased risk of CVD mortality, potentially reflecting the cardiovascular impact of cumulative and recent lead exposures. These findings support that these epigenetic biomarkers may capture some of the CVD disease risk associated with lead exposure.

P-0962 Associations between air pollution, residential greenness, and glycated hemoglobin (HbA1c) in the three prospective cohorts of U.S. adults

Melissa Fiffer[1], Huichu Li[1], Hari S. Iyer[2,3], Rachel C. Nethery[4], Qi Sun[2,5,6], Peter James[1,7], Francine Laden[1,2,6], Jaime E. Hart[1,6]

[1]Harvard T.H. Chan School of Public Health, Department of Environmental Health, Boston, USA, [2]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, USA, [3]Dana-Farber Cancer Institute, Division of Population Sciences, Boston, USA, [4]Harvard T.H. Chan School of Public Health, Department of Biostatistics, Boston, USA, [5]Harvard T.H. Chan School of Public Health, Department of Nutrition, Boston, USA, [6]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [7]Harvard Medical School and Harvard Pilgrim Health Care Institute, Department of Population Medicine, Boston, USA

BACKGROUND AND AIM: While studies suggest impacts of individual environmental exposures on type 2 diabetes (T2D) risk, the biological mechanisms remain poorly characterized. Glycated hemoglobin (HbA1c) is an important biomarker for diagnosing prediabetes and predicting T2D risk. We explored associations between multiple environmental exposures and HbA1c.

METHODS: HbA1c was assessed in 12,698 non-diabetic women and men in three U.S.-based prospective cohorts: the Nurses' Health Study (NHS) in 1990, the Nurses' Health Study II (NHSII) in 1998, and the Health Professionals Follow-up Study (HPFS) in 1993. Residential greenness data within 270m and 1,230m (normalized difference vegetation index, NDVI) was obtained from Landsat. Fine particulate matter ($PM_{2.5}$) and nitrogen dioxide (NO_2) were estimated from nationwide spatiotemporal models. Three-month and one-year average exposures prior to blood draw were assigned to participants' addresses. We used single and multi-exposure linear regression models, as well as mixture methods such as models with component scores from Principal Components Analysis (PCA), to assess associations with HbA1c. We first applied basic models adjusted for age and year at blood draw, BMI, alcohol use, and neighborhood socioeconomic status (nSES). In fully-adjusted models, we included overall diet quality, race, family history, smoking status, postmenopausal hormone use, population density, and season. We assessed potential modification via stratification.

RESULTS: Based on HbA1c thresholds, 19% of participants had prediabetes. In basic models, we observed a small negative association between $PM_{2.5}$ and HbA1c: an IQR increase was associated with a 0.28% (95% CI: 0.54%, 0.02%) lower HbA1c. In fully-adjusted models, we did not find any associations between the individual exposures or the component scores and HbA1c. There was no evidence of differing associations by sex, nSES, or population density.

CONCLUSIONS: In this study of adults, environmental exposures were not associated with HbA1c. More work is needed to elucidate biological pathways between the environment and prediabetes.

P-0963 Associations between Oxidative/Nitrosative Stress and Thyroid Hormones in Pregnant Taiwanese Women- A Birth Cohort Study

Po-Chin Huang[1,2,3], Po-Keng Cheng[1], Hsin-Chang Chen[4], Pao-Lin Kuo[5], Jung-Wei Chang[6], Wan-Ting Chang[1]
[1]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli County, Taiwan, [2]Research Center for Environmental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, [3] Department of Medical Research, China Medical University Hospital, China Medical University, Taichung, Taiwan, [4]Department of Chemistry, Tunghai University, Taichung, Taiwan, [5] Department of Obstetrics and Gynecology, National Cheng Kung University Hospital, College of Medicine, Tainan, Taiwan, [6] Institute of Environmental and Occupational Health Sciences, School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan

BACKGROUND AND AIM: Thyroid function has been related to oxidative and nitrosative stress in both animal and human studies. In this study, we investigated the link between oxidative and nitrosative stress and thyroid hormones in pregnant women.

METHODS: During the first, second, and third trimesters, 97 Taiwanese pregnant women were measured. Levels of five oxidative and nitrosative stress biomarkers (8-hydroxy-2'-deoxyguanosine [8-OHdG], 8-nitroguanine [8-NO2Gua], 4-hydroxy-2-nonenal-mercapturic acid [HNE-MA], 8-isoprostaglandin F2α [8-isoPGF2α], and malondialdehyde [MDA]) were measured using urine samples, and levels of five thyroid hormones (triiodothyronine [T3], thyroxine [T4], free T4, thyroid-stimulating hormone [TSH], and T4-binding globulin [TBG]) were measured in blood samples. The correlations between oxidative or nitrosative stress biomarkers and thyroid hormones in pregnant women were investigated using multiple linear regressions and linear mixed model regressions.

RESULTS: We found that TSH was negatively and significantly correlated with 8-NO2Gua and HNE-MA levels. However, T4 and free T4 levels were positively and significantly correlated with 8-NO2Gua. The T4 to TBG and free T4 to TBG ratios were positively and significantly correlated with 8-NO2Gua level. But, the TSH to T4 ratio was negatively and significantly correlated with 8-NO2Gua level. The T3 to TSH ratio was positively and significantly correlated with HNE-MA level. Nevertheless, the TSH to T4 and TSH to free T4 ratios were negatively and significantly correlated with HNE-MA level.

CONCLUSIONS: Our findings imply that an imbalance of oxidative and nitrosative stress during pregnancy might affect thyroid hormone homeostasis. During pregnancy, disruption of the maternal thyroid homeostasis might have an impact on embryonic and fetal development.

KEYWORDS: oxidative stress; nitrosative stress; thyroid hormone; lipid peroxidation; pregnancy

P-0964 Mediation Effects of Thyroid Function in the Associations between Phthalate Exposure and Glucose Metabolism in Taiwanese Adults

Po-Chin Huang[1,2,3,4], Han-Bin Huang[5], Chi-Ying Siao[5], Yuan-Ting C. Lo[5], Shu-Fang Shih[6], Chieh-Hua Lu[7]
[1]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli, Taiwan, [2]Department of Medical Research, China Medical University Hospital, China Medical University, Taichung, Taiwan, [3]Research Center for Environmental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, [4]Department of Safety, Health and Environmental Engineering, National United University, Miaoli, Taiwan, [5]School of Public Health, National Defense Medical Center, Taipei, Taiwan, [6]Department of Health Administration, College of Health Professions, Virginia Commonwealth University, Richmond, USA, [7]Department of Internal Medicine, Division of Endocrinology and Metabolism, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan

BACKGROUND AND AIM: The mediating influence of thyroid function on the association of phthalate exposure with glucose metabolism, including insulin resistance, remains unclear. We explored the mediating influence of thyroid hormone levels on the phthalate exposure-insulin resistance association.

METHODS: This cross-sectional study of 217 Taiwanese adults assessed insulin resistance (Homeostatic Model Assessment for Insulin Resistance, HOMA-IR scores) and the levels of 11 urinary phthalate metabolites and 5 thyroid hormones. Multiple regression models were used to analyze the associations among serum thyroid hormone levels, urinary phthalate metabolite levels, and HOMA-IR scores. The mediation analysis assessed the influence of thyroid function on the phthalate exposure-HOMA-IR association.

RESULTS: Our data indicated urinary mono-ethylhexyl phthalate (MEHP) levels was negatively associated with free thyroxine (T4) (β=-0.018; 95% confidence interval [CI]: -0.031, -0.005) and positively associated with HOMA-IR scores (β=0.051, 95% CI: 0.012, 0.090). The study also revealed urinary mono-(2-ethyl-5-oxohexyl) phthalate (MEOHP) levels was negatively associated with free T4 (β=-0.036, 95% CI: -0.056, -0.017) and HOMA-IR (β=0.070, 95% CI: 0.013, 0.126). Free T4 and HOMA-IR had a negative association (β=-0.757, 95% CI: -1.122, -0.392). In the mediation analysis, free T4 mediated 24% and 35% of the associations of urinary MEHP and MEOHP with HOMA-IR, respectively.

CONCLUSIONS: Our findings revealed the mediating role of thyroid function in the phthalate exposure-glucose metabolism association in adults.

P-0969 Solar activity and urinary melatonin levels in the US-based Nurses' Health Study, Nurses' Health Study II, and the Growing Up Today Study

Cindy Hu[1], Susanne Strohmaier[3], Petros Koutrakis[1], Carolina Zilli Vieira[1], Trang VoPham[5], Jorge Chavarro[4,6], Francine Laden[1,2], Eva Schernhammer[3], Jaime Hart[1,2]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [2]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA, [3]Department of Epidemiology, Medical University of Vienna, Vienna, Austria, [4]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [5]Epidemiology Program, Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, USA, [6]Department of Nutrition, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: The Sun's magnetic field flips over the course of an 11-year period, oscillating between increased and reduced solar activity, referred to as a solar cycle. These fluctuations in solar activity during the solar cycle are reflected in variation of solar electromagnetic radiation and of geomagnetic disturbances. Solar activity has been linked to adverse health effects, potentially due to circadian disruption. We evaluated the associations between urinary melatonin (6-sulfatoxymelatonin) and solar activity exposures (sunspot number, Kp index, and interplanetary magnetic field strength (IMF)) in the prospective US-based Nurses' Health Study (NHS), Nurses' Health Study II (NHSII), and Growing Up Today Study (GUTS) cohorts.

METHODS: From 1996 to 2017, 7,936 participants from NHS, NHSII, and GUTS provided urinary samples that were assayed for 6-sulfatoxymelatonin (aMT6). Daily exposures to sunspot number, Kp index, and IMF were estimated from NASA Goddard Space Flight Center. We used Spearman correlations and linear regression to estimate the beta coefficients for a one standard deviation increase in each solar activity exposure on log-transformed aMT6 adjusted for creatinine. We examined same day and 7-day moving average exposures, and adjusted for age, sex, BMI (body mass index), time of urine collection, seasonality, if the urine was a first morning sample, and UV (ultraviolet) exposure.

RESULTS: There were statistically significant negative correlations between all of the solar exposures and aMT6. However, after adjustment for potential confounders, there were no associations between same-day exposures to sunspot number (0.28; 95% CI: -0.072, 0.016), Kp index (0.012; 95% CI: -0.019, 0.044), or IMF (-0.005; 95% CI: -0.036, 0.025) and aMT6. Similarly, we found no associations with 7-day moving averages.

CONCLUSIONS: In these three prospective US-based cohorts, we did not find evidence of an association between solar activity exposures and urinary melatonin after adjustment for potential confounders.

KEYWORDS: Solar activity, melatonin

P-0970 PFAS concentrations associate with placental transcriptomic activity: a pilot study

Todd Everson[1], Kartik Shankar[2], Andrew Morris[3], M. Abdul Mottaleb[4], Kevin Pearson[5], Aline Andres[6]
[1]Gangarosa Department of Environmental Health, Rollins School of Public Health at Emory University, Atlanta, USA, [2]Department of Pediatrics, Section of Nutrition, University of Colorado School of Medicine, Aurora, USA, [3]University of Arkansas for Medical Sciences and Arkansas Children's Nutrition Research Center, Little Rock, USA, [4]Institute of Drug & Biotherapeutic Innovation (IDBI), Doisy Research Center (DRC), Saint Louis University, St Louis, USA, [5]Department of Pharmacology and Nutritional Sciences, University of Kentucky, Lexington, USA, [6]Department of Pediatrics, University of Arkansas for Medical Sciences and Arkansas Children's Nutrition Center, Little Rock, USA

BACKGROUND AND AIM: Endocrine-disrupting chemicals (EDCs) such as environmentally ubiquitous per- and polyfluoroalkyl substances (PFAS) likely contribute to the obesity epidemic. The prenatal period is a critical window for EDC exposures and the placenta is a potential target due to its plethora of endocrine-activities and roles in supporting fetal growth. Yet, the placenta is an understudied target of PFAS. In this pilot study, we aimed to examine whether placental concentrations of PFAS were associated with placental gene expression profiles.

METHODS: Study participants were enrolled in the Glowing study, and the placental transcriptome was assessed with mRNA-sequencing. Concentrations of PFBS, PFOS, PFNA, PFOA, and PFHxS were measured in 29 term placental samples using ultra-performance liquid chromatography-tandem mass spectrometry. We tested for differential gene expression associated with increasing placental PFAS concentrations while adjusting for surrogate variables and other potential confounders.

RESULTS: In placental samples, PFOS had the highest median concentration (5.54 ng/g), followed by PFHxS (3.0 ng/g), PFNA (0.89 ng/g), PFOA (0.72 ng/g) and PFBS (0.45 ng/g). PFOA exhibited the strongest associations, with 13 genes (FAM38D, TTK, DDIAS, CDC20, CDCA3, BUB1B, EME1, TOP2A, BRCA2, RAD51, CCDC18, E2F2, and ESPL1) having decreased expression associated with increased PFOA (FDR < 10%). The other PFAS were not significantly associated with gene expression levels at FDR < 10%, which may be due to the limited sample size of this pilot study.

CONCLUSIONS: PFAS may influence placental function via altered gene-expression, which requires further study. Interestingly, of the 13 genes whose expression levels decreased with higher PFOA concentration, 7 have been implicated for having roles in obesity, cholesterol levels, and anthropometric characteristics via prior GWAS. Ongoing analyses are underway to encompass the entire Glowing study, and to investigate the relationships between prenatal PFAS, placental molecular activity, postnatal growth and adiposity.

KEYWORDS: Placenta, PFAS, Transcriptome, Gene Expression

P-0971 Metabolic signatures associated with diet quality in young adults

Elizabeth Costello[1], Jesse Goodrich[1], William Patterson[2], Douglas I. Walker[3], Brittney Baumert[1], Sarah Rock[1], Tanya L. Alderete[2], Frank Gilliland[1], Zhanghua Chen[1], David V. Conti[1], Leda Chatzi[1]

[1]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, USA, [2]Department of Integrative Physiology, University of Colorado Boulder, Boulder, USA, [3]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND/AIM:
Poor diet is a known risk factor for many noncommunicable diseases, including cancer and type 2 diabetes. Metabolomics is an emerging exposure assessment method that may improve nutrition assessment and identify biomarkers related to diet and disease. The purpose of this study was to identify metabolites and metabolic pathways associated with diet quality.

METHODS: We used untargeted metabolomics, determined using liquid chromatography-mass spectroscopy, to evaluate the relationship between metabolic pathways and diet quality in young adults from the Metabolic and Asthma Incidence Research (Meta-AIR) cohort (n=124). Four diet quality indices were evaluated: Dietary Approaches to Stop Hypertension (DASH) score, Healthy Eating Index 2015 (HEI-2015), Mediterranean diet score (MDS), and the Diet Inflammatory Index (DII). Functional pathway analysis was performed with MetaboAnalyst version 5.0, using effect estimates generated from metabolome-wide association studies to identify metabolic pathways with significant ($p<0.05$) enrichment. Analyses were performed for each diet index separately and adjusted for age, sex, ethnicity, and body mass index.

RESULTS: MDS, HEI-2015, DASH, and DII were associated with 13, 8, 6, and 5 pathways, respectively. Enriched pathways related to lipid metabolism were associated with DASH (arachidonic acid metabolism, $p=0.030$), HEI-2015 (carnitine shuttle, $p=0.0078$), and MDS (de novo fatty acid biosynthesis, $p<0.001$; fatty acid activation, $p<0.001$; fatty acid metabolism, $p=0.034$). These three were additionally significantly associated with vitamin B6 metabolism (DASH: $p=0.043$, HEI-2015: $p=0.0026$, MDS: $p=0.036$) and the metabolism of other vitamins and cofactors. Enriched pathways related to amino acid metabolism were also identified for all four diet indices.
CONCLUSIONS: Diet quality was associated with biological pathways related to the metabolism of important nutrients, some of which are involved in inflammatory responses. These associations may be used to identify biomarkers indicative of diet quality or describe the metabolic effects of higher quality diets.

P-0973 Using Follicular Fluid Metabolomics to Investigate the Association between Air Pollution and Oocyte Quality

Sueyoun Hwang[1], Robert Hood[1], Russ Hauser[2], Joel Schwartz[2], Francine Laden[2], Dean Jones[3], Donghai Liang[1], Audrey Gaskins[1]

[1]Emory University Rollins School of Public Health, Atlanta, USA, [2]Harvard T.H. Chan School of Public Health, Boston, USA, [3]Emory University School of Medicine, Atlanta, USA

BACKGROUND AND AIM: Our objective was to use metabolomics in a toxicological-relevant target tissue to gain insight into the biological processes that may underlie the negative association between air pollution exposure and oocyte quality.

METHODS: Our study included 125 women undergoing in vitro fertilization at an academic fertility center in the northeastern USA (2005-2015). A follicular fluid sample was collected during oocyte retrieval and untargeted metabolic profiling was conducted using liquid chromatography with ultra-high-resolution mass spectrometry and two technical columns (C18 negative, HILIC positive). Daily exposure to nitrogen dioxide (NO2), ozone, fine particulate matter, and black carbon was estimated at the women's residence using spatiotemporal models and averaged over the period of ovarian stimulation (2-weeks). Multivariable linear regression models were used to evaluate the associations between the air pollutants, number of mature oocytes, and metabolic feature intensities. A meet-in-the-middle approach was used to identify overlapping features and metabolic pathways.

RESULTS: of the air pollutants, NO2 exposure had the largest number of overlapping metabolites (C18:105, HILIC:91) and biological pathways (C18:3, HILIC:6) with number of mature oocytes. Key pathways of overlap included vitamin D3 metabolism (both columns), bile acid biosynthesis (both columns), C21-steroid hormone metabolism (HILIC), androgen and estrogen metabolism (HILIC), vitamin A metabolism (HILIC), carnitine shuttle (HILIC), and prostaglandin formation (C18). Three overlapping metabolites were annotated with level-1 evidence. for example, hypoxanthine, a metabolite that protects against oxidant-induced cell injury, was positively associated with NO2 exposure and negatively associated with number of mature oocytes. Minimal overlap was observed between the other pollutants and number of mature oocytes retrieved.

CONCLUSIONS: Higher exposure to NO2 during ovarian stimulation was associated with many metabolites and biologic pathways involved in endogenous vitamin metabolism, hormone synthesis, and oxidative stress that may mediate the associations with lower oocyte quality.

P-0974 Prenatal exposure to outdoor air pollution and miRNA expression in cord blood at birth: the NELA study

Azahara Maria Garcia-Serna[1,2], Lucas A. Salas[3], Pedro Jimenez-Guerrero[1,2], Luis Garcia-Marcos[1,2,4], Eva Morales[1,2]
[1]University of Murcia, Murcia, Spain, [2]Biomedical Research Institute of Murcia (IMIB-Arrixaca), Murcia, Spain, [3]Department of Epidemiology, Geisel School of Medicine, Dartmouth College, Lebanon, NH, USA, [4]Network of Asthma and Adverse and Allergic Reactions (ARADyAL), Madrid, Spain

BACKGROUND AND AIM: Air pollution is a complex chemical mixture known as a risk factor for non-communicable diseases. Mechanisms underlying its adverse effects could involve changes in miRNA expression. We aimed to identify the effects of maternal exposure to air pollution during pregnancy on miRNAs expression in cord blood at birth; and to unravel windows of vulnerability across gestation.

METHODS: Data came from 362 participants of the Nutrition in Early Life and Asthma (NELA) study, a prospective population-based birth cohort from Spain. RNA samples were isolated from umbilical vein cord blood samples at birth; miRNAs were hybridized and analyzed using SurePrint miRNA microarrays. Residential exposure to outdoor air pollution was estimated using dispersion/chemical transport modelling. Exposures showed high correlation coefficients, so a cluster analysis was performed to reduce dimensionality and avoid multi-collinearity. Associations between groups of exposure and miRNA expression were studied using multivariate linear regression models and over-representation analysis. Air pollutant mixture analyses were performed using the Bayesian Kernel machine regression model, to assess mixture effects and the relative contribution of each pollutant, and the Lagged kernel machine regression, to identify specific windows of vulnerability.

RESULTS: Exposure to PM_{10} and O_3 levels during the first and third trimesters of pregnancy showed changes in 32 miRNAs in cord blood, and two enriched pathways were found: Alzheimer's disease and adherens junction. Mixture analysis estimated that maternal exposure to O_3 altered hsa-miR-30a-5p and hsa-miR-30c-5p expression, in the second and third trimester of pregnancy, respectively.

CONCLUSIONS: Prenatal exposure to air pollution alters miRNA expression in the offspring at birth. Our results suggest that windows of vulnerability vary depending on the specific pollutant affecting distinct miRNA

P-0977 Prenatal Bisphenol S and Postnatal High-Fat Diet Influence DNA Methylation of the Mest Gene in F1 Male Mice

Jaehyouk Lee[1], Junbo Park[1], Eugene Lim[1], Dongmin Song[1], Yehoon Jo[1], Eukyung Jo[1], Sungkyoon Kim[1]
[1]*Department of Environmental Health Sciences, Graduate School of Public Health, Seoul National University, Seoul, Republic of Korea*

BACKGROUND AND AIM: Exposure to environmental chemicals during development may increase the susceptibility to adiposity/obesity in adolescence and adulthood. Bisphenol S (BPS) has been suspected as an obesogen after perinatal exposure. Previously, we reported adipocyte hypertrophy in the gonadal white adipose tissue (gWAT) of F1 male mice after the prenatal exposure to BPS followed by high-fat diet (HFD) in adulthood. The expression of the mesoderm-specific transcript (Mest) gene is shown to correlate with adipocyte size and adiposity. Our study aimed to investigate the environmentally induced epigenetic modulation, such as DNA methylation changes in Mest, leading to gonadal adiposity of male offspring.

METHODS: The mRNA expression of Mest in the gWAT of F1 male mice (C57BL/6N) was analyzed by reverse transcription-quantitative PCR (RT-qPCR). We performed bisulfite amplicon sequencing (BSAS) analysis to identify the CpG dinucleotides at the differentially methylated region (DMR) of Mest that were associated with adiposity phenotype. The DNA methylation levels of the site-specific CpGs were quantified by targeted bisulfite pyrosequencing.

RESULTS: The Mest mRNA levels in the gWAT increased in a dose-dependent manner, compared to the BPS-unexposed control. Three CpG loci exhibiting significant differences in DNA methylation were identified through BSAS analysis of the Mest DMR. Consistent with BSAS data, each site-specific CpG at the Mest DMR was found to be differentially methylated among extreme groups with both gWAT/body weight ratio and the Mest expression levels.

CONCLUSIONS: Our study suggests that prenatal BPS and postnatal HFD might induce epigenetic influence, i.e., DNA methylation changes, on the Mest DMR, and consequently contribute to the gonadal adiposity in F1 male mice. Furthermore, the distinct epigenotype of Mest could be utilized as a biomarker of the exposure to potential adipogenic epigenotoxicants.

P-0980 Metabolomic Changes Associated With Chronic Arsenic Exposure in a Bangladeshi Population

Haotian Wu[1], Vrinda Kalia[1], Megan M. Niedzwiecki[2], Marianthi-Anna Kioumourtzoglu[1], Brandon Pierce[3,4,5], Jeff Goldsmith[6], Ana Navas-Acien[1], Vesna Ilievski[1], Vesna Slavkovich[1], Joseph H. Graziano[1], Dean P. Jones[7], Douglas I. Walker[2], Mary V. Gamble[1]

[1]Columbia University Mailman School of Public Health, New York, USA, [2]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Department of Public Health Sciences, University of Chicago, Chicago, USA, [4]Department of Human Genetics, University of Chicago, Chicago, USA, [5]Comprehensive Cancer Center, University of Chicago, Chicago, USA, [6]Department of Biostatistics, Mailman School of Public Health, Columbia University, New York, USA, [7]Division of Pulmonary, Allergy, Critical Care and Sleep Medicine, Department of Medicine, Emory University School of Medicine, Atlanta, USA

Our understanding of the pathways underlying the effects of arsenic (As) remains incomplete, in part because studies historically focused on individual targets. High-resolution metabolomics can capture changes more proximal to disease and integrates changes in multiple regulatory processes, providing a systems biology approach that will facilitate a more comprehensive understanding of the biological impacts of As exposure.

We selected 60 adults from the Folic Acid and Creatine Trial (FACT). Inorganic (AsIII, AsV) and organic (monomethylarsonous acid [MMAs], dimethylarsinous Acid [DMAs]) As species were measured in blood and urine collected at baseline and 12 weeks follow-up. Untargeted metabolomic profiles were measured by dual column liquid chromatography interfaced to a high-resolution mass spectrometer. We estimated the associations of blood and urinary As species with 170 confirmed metabolites and >26,000 untargeted metabolite features using a metabolome-wide association study (MWAS) approach. Models were adjusted for age, sex, visit, and BMI and corrected for multiple testing. Biological response was characterized using pathway enrichment analysis.

MWAS using identified metabolites detected 17 associated with ≥1 blood As species ($q<0.05$), the majority of which were fatty acids, neurotransmitter metabolites, and amino acids. Model results were consistent across As species and between blood and urine species. The full MWAS using all metabolite features identified 423 features associated with ≥1 blood As species. Unlike the confirmed metabolites, the results were not consistent across different As species, with AsV and DMAs showing distinct association patterns. Pathway analysis revealed 12 enriched metabolic pathways that overlap with the 17 identified metabolites, including one carbon metabolism, tricarboxylic acid cycle, fatty acid metabolism, and purine metabolism.

Our MWAS was able to recapitulate expected metabolomic alterations associated with As and identify novel metabolites and pathways not previously known to associate with As.

KEYWORDS: arsenic, metabolomics, one carbon metabolism, TCA, krebs, purine metabolism, uric acid, urate, neurotransmitter

P-0981 Maternal blood pressure associates with placental DNA methylation both directly and through alterations in cell-type composition

Lucile Broséus[1], Daniel Vaiman[2], Jörg Tost[3], Camino San Martin Ruano[2], Joel Schwartz[4], Rémi Béranger[3], Rémy Slama[1], Barbara Heude[5], Johanna Lepeule[1]

[1]Institute for Advanced Biosciences, INSERM, Grenoble, France, [2](b) From Gametes to Birth, Institut Cochin, INSERM, CNRS, Paris-Descartes University, Paris, France, [3](e) Univ. Rennes, CHU Rennes, INSERM, EHESP, IRSET (Institut de recherche en santé, environnement et travail), Rennes, France, [4]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [5](f) Univ. Paris, Centre for Research in Epidemiology and Statistics (CRESS), INSERM, INRAE, Paris, France

BACKGROUND AND AIM: Blood pressure levels are markedly affected by numerous environmental factors including temperature levels and drastic changes, ambient air pollution and noise. During pregnancy, maternal hypertension is associated with impaired placental development and an increased risk for children to suffer from cardiovascular and respiratory diseases later on. Alterations in placental state and functions, induced by the maternal and fetal environment, can be reflected by changes in DNA methylation levels and cell-type composition.
This study aims to discover epigenetic biomarkers of placental stress related to maternal blood pressure during pregnancy.

METHODS: Relying on a large cohort of 666 participants, we investigated the association between epigenome-wide DNA methylation in the placenta, measured using the Infinium HumanMethylation450 BeadChip, and maternal steady and pulsatile blood pressure indicators during pregnancy.

RESULTS: Our analyses highlighted 64 differentially methylated regions significantly associated with at least one blood pressure indicator which are enriched for genes implicated in lung development and diseases. Moreover, maternal blood pressure levels were significantly associated with placental cell-type composition. In particular, elevated blood pressure levels were associated with a decrease in the ratio between stromal cells and syncytiotrophoblasts. Further mediation analyses show that a significant part of the influence of steady blood pressure - but not pulsatile pressure - over placental methylation is mediated by perturbations in placental cell-type composition.

CONCLUSIONS: Our study provides the first evidence that maternal blood pressure during pregnancy has both direct and indirect effects, through cell-type composition alterations, on placental DNA methylation. These results could hint at molecular mechanisms linking maternal hypertension to lung development and early origins of childhood respiratory problems.

P-0985 Air Pollution Exposure and Human Endogenous Retrovirus Methylation in the School Inner-City Asthma Intervention Study

Aalekhya Reddam[1], Valentina Bollati[2], Haotian Wu[1], Chiara Favero[2], Letizia Tarantini[2], Mirjam Hoxha[2], Nicole Comfort[1], Diane R. Gold[3,4], Wanda Phipatanakul[5], Andrea A. Baccarelli[1]

[1]Department of Environmental Health Sciences; Mailman School of Public Health, Columbia University, New York, USA, [2]Department of Clinical Sciences and Community Health; University of Milan, Milan, Italy, [3]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, USA, [4]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [5]Asthma Clinical Research Center; Boston Children's Hospital, Boston, USA

BACKGROUND AND AIMS: Human endogenous retroviruses (HERVs) are transposable genomic elements. Usually repressed through DNA methylation, HERVs can be demethylated in response to environmental stimuli, and their expression may lead to dysregulation of the immune system. More research is needed to understand the influence of environmental exposures on HERV methylation, and as air pollutants are commonly linked with immune system dysregulation, our objective was to examine the association of air pollutant exposure with HERVs demethylation.

METHODS: The sample included 180 students with asthma from the School Inner-City Asthma Intervention Study (SICAS-2) recruited from 2015 to 2020. SICAS-2 is a controlled, group randomized trial evaluating the use of classroom HEPA air filters and school-wide integrated pest management (IPM) on air pollutant/allergen exposure and asthma outcomes. Air pollutants (CO2, NO2, PM2.5, coarse PM, and black carbon) were measured in classrooms before and after intervention. Buccal swabs were collected pre- and post-intervention, and methylation levels from 9 transposable genomic elements (HERV-E, -FRD, -K, -L, -R, -W, -9, and HRES and LINE1) were measured. Generalized estimating equations were used to estimate associations between HERV methylation and intervention. Multivariable linear regression analyses were run to assess associations with air pollutant exposure.

RESULTS: Neither intervention (HEPA/IPM), nor intervention-induced changes in air pollutants were associated with HERV methylation. However, after adjusting for intervention and plate number, pre-intervention PM2.5 was associated with a decrease in log-transformed post-intervention HERV-9 methylation (β =-0.22, 95% CI: -0.34, -0.11). Furthermore, pre-intervention black carbon (β = 0.87, 95% CI: 0.30, 1.4) and PM2.5 (β = 0.035, 95% CI: 0.004, 0.07) were associated with an increase in log-transformed post-intervention HERV-W methylation.

CONCLUSIONS: These results suggest that exposure to PM2.5 and black carbon may be associated with HERV methylation in children with asthma. This is the first report of air pollutant exposure on HERV methylation.

P-0986 Smoky coal exposure is associated with increased white blood cell DNA Alu retroelement copy number

Qing Lan[1], Batel Blechter[1], Richard Cawthon[2], Jason Wong[1], Lützen Portengen[3], George Downward[3], Wei Hu[1], Bryan Bassig[1], Mohammad Rahman[1], Wei Jie Seow[4,5], Dean Hosgood[6]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Rockville, USA, [2]University of Utah, Human Genetics, Salt Lake City, USA, [3]Division of Environmental Epidemiology, Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands, [4]Saw Swee Hock School of Public Health, National University of Singapore and National University Health System, Singapore, Singapore, [5]Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore and National University Health System, Singapore, Singapore, [6]Division of Epidemiology, Albert Einstein College of Medicine, New York, USA

BACKGROUND: The lung cancer rate for never-smoking women in Xuanwei, China, where coal is used extensively for home heating and cooking, is among the highest in the world. This excess is due almost entirely to household air pollution (HAP) from smoky (bituminous) coal used for home heating and cooking, which produces multiple toxic constituents including polycyclic aromatic hydrocarbons (PAHs). Alu retroelements, which are repetitive mobile DNA sequences that can multiply and affect genomic stability, have been associated with diesel engine exhaust exposure and prospectively linked to lung cancer risk. To explore the relationship between genotoxic carcinogens and Alu repeats, we assessed the association between HAP and Alu copy number.

METHODS: A cross-sectional study of 158 never-smoking women with repeat sampling of 48 subjects was conducted in Xuanwei, China. Quantitative PCR was used to measure Alu repeat copy number relative to albumin gene copy number (Alu/ALB ratio), reflecting the average quantity of Alu repeats per cell, in white blood cell DNA. Exposure models were used to predict levels of current exposure to 43 individual household air pollutants. Hierarchical clustering of the air pollutants was conducted to address collinearity, and generalized estimating equations were used to take into account Alu copy number measured in repeat samples.

RESULTS: A cluster of 31 PAHs was associated with increased Alu copy number (β:0.03(95% confidence interval:0.01,0.04) per SD;P-value=0.001). One compound within this cluster, 5-methylchrysene, which has been associated with lung cancer risk in Xuanwei and was selected a priori for analysis, was also associated with increased Alu copy number (P-value=0.0097).

CONCLUSIONS: Our findings suggest that exposure to PAHs from HAP due to household smoky coal combustion may contribute to genomic instability. Future work in larger studies and among those exposed to other types of coal, wood, and biomass combustion is warranted.

KEYWORDS: Solid fuel use, Alu, PAHs

P-0987 Associations between prenatal PM2.5 exposure and placental long non-coding RNA expression

Michael Hussey[1], Daniel Enquobahrie[1,2], James MacDonald[3], Theo Bammler[3], Fasil Tekola-Ayele[4], Kathleen Kerr[5], Alison Paquette[6,7], Christine Loftus[3], Nora Byington[7], Carmen Marsit[8], Adam Szpiro[5], Joel Kaufman[1,3], Kaja LeWinn[9], Qi Zhao[10], Catherine Karr[1,3,6], Sheela Sathyanarayana[3,6,7]

[1]Department of Epidemiology, School of Public Health, University of Washington, Seattle, USA, [2]Department of Health Systems and Population Health, School of Public Health, University ofWashington, Seattle, USA, [3]Department of Environmental and Occupational Health Sciences, School of Public Health, University of Washington, Seattle, USA, [4]Epidemiology Branch, Division of Population Health Research, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, USA, [5]Department of Biostatistics, School of Public Health, University of Washington, Seattle, USA, [6]Department of Pediatrics, School of Medicine, University of Washington, Seattle, USA, [7]Seattle Children's Research Institute, Seattle, USA, [8]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [9]Department of Psychiatry and Behavioral Sciences, School of Medicine, University of California, San Francisco, San Francisco, USA, [10]Department of Preventative Medicine, College of Medicine, University of Tennessee Health Science Center, Memphis, USA

KEYWORDS: PM2.5, placenta, lncRNA

BACKGROUND/AIM: Few studies have examined placental long non-coding RNA expression in relation to maternal PM2.5 exposure during pregnancy. We addressed this gap by investigating overall and infant sex-specific associations of placental lncRNA expression with prenatal maternal PM2.5 exposure during several exposure windows in two birth cohorts.

METHODS: Placental samples were collected from maternal-infant dyads recruited to the CANDLE (Memphis, TN) (n=776) and GAPPS (Seattle and Yakima, WA) (n=200) cohorts. Average PM2.5 exposure was estimated using a spatiotemporal model for six exposure windows: the first month, first, second and third trimesters, last month, and the full duration of each pregnancy. Cohort-specific linear models were fit by exposure window for >6,000 lncRNA transcripts and adjusted for potential confounders and experimental variables. We assessed infant sex interaction using interaction terms and sex-stratified models. All models used FDR<0.10.

RESULTS: No lncRNA transcripts were significantly associated with PM2.5 exposure in main or interaction models in GAPPS. In CANDLE, first trimester PM2.5 levels were associated with lower expression of AC113410.5 (logFC=-0.163, FDR=0.014) and higher expression of LINC00702 (logFC=0.108, FDR=0.093), and third trimester PM2.5 levels were associated with higher expression of LINC02280 (logFC=0.180, FDR=0.016). Additionally, offspring sex interacted significantly with final-month PM2.5 on ACO92268.2 expression and with full-pregnancy PM2.5 on LINC00339 (interaction FDR=0.002 and 0.012, respectively). Sex-stratified analysis indicated both transcripts were upregulated in male infants and downregulated in females with higher PM2.5 exposure, though associations were not statistically significant in these models.

CONCLUSIONS: PM2.5 exposure was not significantly associated with lncRNA expression in GAPPS. However, it was associated with altered expression of five lncRNA transcripts in CANDLE, including two associations that varied sex-specifically. While three of these transcripts (LINC00702, LINC02280 and LINC00339) are potentially linked to cancer etiology, further analysis is required to understand their functional significance in the placenta during pregnancy.

P-0988 Associations between metals and metabolomic profiles related to diabetes among adults in a rural region

Julia Debertin[1], Elizabeth Holzhausen[2], Douglas I. Walker[3], Katherine A. James[4], Tanya Alderete[2], Laura Corlin[1,5]
[1]Department of Public Health and Community Medicine, Tufts University School of Medicine, Boston, USA, [2]Department of Integrative Physiology, University of Colorado, Boulder, USA, [3]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [4]Department of Environmental and Occupational Health, Colorado School of Public Health, University of Colorado-Anschutz Medical Campus, Aurora, USA, [5]Department of Civil and Environmental Engineering, Tufts University School of Engineering, Medford, USA

BACKGROUND AND AIM: Exposure to metals is associated with increased risk of type 2 diabetes (T2D). Putative mechanisms involve oxidative stress and disruption of insulin-regulated glucose uptake. Here we present findings from a pilot study evaluating the hypothesis that the associations between metal exposure and diabetes are mediated by alterations in endogenous metabolite profiles.

METHODS: We analyzed urinary metal concentrations and plasma metabolites from 29 adults enrolled in the San Luis Valley Diabetes Study in rural Colorado. Concentrations of arsenic, cadmium, cobalt, lead, manganese, tungsten, and uranium were measured in urine, and plasma metabolites were analyzed using untargeted high-resolution mass spectrometry. To assess metabolic effects of metal exposure, we evaluated bivariate associations between each metabolite feature present in more than 50% of samples and metal levels with a 20% FUntargeted metabolite features were evaluated using Mummichog for pathway enrichment analysis for metabolites associated ($p < 0.05$) with each metal. Altered pathways were identified using a significance level < 0.05.

RESULTS: Participants had a mean age of 58.5 years (standard deviation = 9.20.), 48.3% were female, 48.3% were Hispanic, 13.8% were current smokers, and 65.5% had diabetes. Detected mass spectral signals included 786 metabolite features associated with at least one metal, including 133 associated with arsenic, 147 with cadmium, 7 with cobalt, 325 with lead, 92 with manganese, 5 with tungsten, and 77 with uranium. The metabolite features were linked to 35 pathways including butanoate metabolism, arginine and proline metabolism, aspartate and asparagine metabolism, lysine metabolism, and urea cycle/amino group metabolism. Several of these pathways have been previously associated with diabetes.

CONCLUSIONS: Our pilot results support the hypothesis that metals exposure may be associated with biological processes related to diabetes burden.

KEYWORDS: metabolomics, metals, diabetes, rural health, pathway enrichment

P-0989 Harnessing Extracellular Vesicle's for Elucidating Racial/Ethnic Disparity in Alzheimer's Disease and Related Dementia Risk in Light of Air Pollution Exposure

Stacia Nicholson[1], José F. Herrera-Moreno[1], Vrinda Kalia[1], Aalekhya Reddam Reddam[1], Diana Paredes-Céspedes[3], Andrea Baccarelli[1], José A. Luchsinger[2]

[1]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA, [2]Division of General Medicine, Center on Aging and Health Disparities, Columbia University, New York, USA, [3]Grupo de Salud Ambiental Laboral, Instituto Nacional de Salud, Columbia

BACKGROUND AND AIM: Extracellular Vesicle's (EVs) are involved in the physiological function of neurons in the brain, but also the pathological spread of proteins that contribute to neurodegeneration (ND) and Alzheimer's Disease (AD). Exposure to components of ambient air pollution has been associated with ND/AD and can alter EVs mechanisms. This study aims to determine whether racial/ethnic disparities in AD risk might be explained by differences in EVs production and neurotoxic protein cargo, and whether ambient air pollution exposure has a modifying effect.

METHODS: EVs isolated from plasma samples (NOMEM cohort) were immunoprecipitated to capture neuron-derived EVs (NDEVs). NDEVs Tau, Aβ42, apolipoprotein E (APOE), and TNF-α were quantified using single-molecule analysis or ELISA. Exposure to ambient NO2 and PM2.5 was assigned based on participant's residential address at the time of blood draw using US EPA AQI measurements. Data was analyzed using linear regression and Pearson correlations in R.

RESULTS: NDEVs concentrations didn't differ between racial/ethnic groups, but the relationship between EVs concentration and cargo did. Analysis of NDEVs concentration showed no association or correlation with NDEVs cargo, in Hispanics; a positive association and correlation with APOE and TNF-α, but a negative association and correlation with Aβ42, in Whites; and a negative association and correlation with tau, in African Americans. Preliminary analysis of air pollution exposure using NO2 did not modify these relationships, except the association between EV concentration and Aβ42 was lost in Whites. No significant differences in NO2 exposure were found, but NO2 comparison with NDEVs protein cargo displayed different patterns of association between groups.

CONCLUSION:

Functional differences in the clearance, via EVs, of proteins involved in the development of neurodegenerative disorders exist between racial/ethnic groups, which may influence brain response to air pollution exposure resulting in disparate AD outcomes.

P-0993 Prenatal exposure to di-2-ethylhexyl phthalate (DEHP) affects metabolic disorders: results of a novel strategy for integrative assessment of endocrine disrupters

Nafsika Papaioannou[1,2], Athanasios Papageorgiou[1,2], Catherina Gabriel[1,2], Normand Podechard[4], Sophie Langouet[4], Etienne Blanc[5,6], Karine Audouze[5,6], Spyros Karakitsios[1,2,7], Dimosthenis Sarigiannis[1,2,3]

[1]Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]HERACLES Research Center on the Exposome and Health, Centre for Interdisciplinary Research and Innovation, Aristotle University of Thessaloniki, Thessaloniki-Thermi, Greece, [3]Environmental Health Engineering, Institute of Advanced Study, Pavia, Italy, [4]Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail)-UMR_S 1085, University of Rennes, Rennes, France, [5]INSERM UMR-S 1124, Toxicité Environnementale, Cibles Thérapeutiques, Signalisation Cellulaire et Biomarqueurs, Paris, France, [6]University of Paris, Paris, France, [7]ENVE.X, Thessaloniki, Greece

BACKGROUND AND AIM: Endocrine-disrupting effects caused by exposure to chemicals represent one of the most critical public health threats. In line with the regulatory framework implemented within the European Union to reduce the levels of endocrine disruptors (EDs) for consumers, new and effective methods for ED testing are needed. Here we present an integrated approach for testing and assessment (IATA) that combines in vitro (3D HepaRG cells), in vivo (zebrafish at five days post fertilisation), epidemiological and human biomonitoring studies applied on di-2-ethylhexyl phthalate (DEHP).

METHODS: The effective concentrations of the chemical in vitro and in vivo were extrapolated from human biomonitoring data using the INTEGRA exposure modeling platform. Global untargeted metabolomics analysis was performed using an Agilent G6540A UHD Accurate-Mass Q-TOF LC/MS with 1260 HPLC System in positive and negative ionisation modes. Moreover, the samples were analysed using Reversed Phase (RP) and HILIC analytical columns to increase the coverage of the detected metabolites. Bioinformatics analysis, including spectra processing, statistical analysis, and metabolic pathway analysis, was performed using R/Bioconductor based packages.

RESULTS: Our study showed that the majority of the common metabolites between the three different systems (human, in vivo, and in vitro) are lipids, and more specifically, fatty acyls, glycerolipids, glycerophospholipids, sphingolipids, and sterol Lipids. Significant dysregulation of lipid and Sphingolipid metabolism was observed. Some of these metabolites are: 3-dehydroteasterone, lysoPC(15:0), PE(20:4(5Z,8Z,11Z,14Z)/0:0), PS(22:1(11Z)/0:0), PC(15:0/22:6(4Z,7Z,10Z,13Z,16Z,19Z)), PT(18:0/18:1(9Z)), PS(16:0/22:1(11Z)), and sphingosine 1-phosphate. Many experimental and clinical studies have described the importance of lipids, especially sphingolipids, in developing and pathogenesis of insulin resistance and metabolic syndrome. Still, our study provides mechanistic evidence regarding their (dys)regulation from endocrine disrupters and their effect on metabolism.

CONCLUSIONS: Data generated following our proposed integrated testing and assessment approach (IATA) will reveal the impact of EDs on metabolic disorders by developing novel Adverse Outcome Pathways (AOPs).

P-0998 Comparing and validating current methods for isolating and characterizing brain-derived extracellular vesicles as central nervous system biomarkers of environmentally linked neurodegenerative diseases

Tanya Butt[1], Roheeni Saxena[1], Cherine Jaafar[1,2], Lina Marcinczyk[1], Nicole Comfort[1], Mohammad Alayyoub[1], Madeline Strait[1], Eva Tipps[1], Diane B. Re[1]
[1]Columbia University, New York, USA, [2]Paris Saclay University, Paris, France

BACKGROUND AND AIM: Many environmental exposures (e.g., metals, pesticides) accumulate in central nervous system (CNS) tissues and are associated with adverse neurological outcomes. There is a great need for peripheral biomarkers that could provide insight into the CNS burden of these exposures to confirm the etiologic role of neurotoxic exposures. Our research group has observed CNS cells extruding toxicants via extracellular vesicles (EVs) and is characterizing the viability of CNS-derived EVs isolated from peripheral blood draws as potential biomarkers of environmental exposures. Several protocols for isolating EVs originating from the CNS via immunoprecipitation (IP) can be found in the literature, and these protocols are often replicated with only superficial validation. Here, we thoroughly validated and contrasted current EV isolation methods, tested optimal protease inhibition conditions, and compared IP efficiency and normalization techniques.

METHODS: We compared a one-step direct IP protocol with the widely used two-step Exoquick-based IP protocol for isolating CNS-EVs from human plasma using antibodies against CNS cell surface markers: EAAT1 for astrocytic EVs and L1CAM for neuronal EVs. EVs were characterized according to the Minimal Information for Studies of Extracellular Vesicles guidelines, including transmission election microscopy, nanotracking particle analysis, and protein ELISAs.

RESULTS: Our results show that a direct IP protocol is more effective for isolating CNS-derived EVs than commonly used Exoquick-based two-step protocols. These results demonstrate that EAAT1 antibodies are more effective than L1CAM in isolating-CNS-EVs even in conditions that are expected prevent L1CAM cleavage by metalloproteases. Results confirmed CD81 to be the best normalization factor for CNS-EV IP efficiency.

CONCLUSIONS: These data add to the ongoing controversy that L1CAM and Exoquick may not consistently isolate EVs of neuronal origin. This may be partly due to variability in immunoreagent quality. These data strongly demonstrate the importance of rigorous method validation before beginning cell-specific EV-based biomarker studies.

P-0999 Bringing TRAP and NLRP3 into focus to Save EJ Populations

Wig Zamore[1], Doug Brugge
[1]*Somerville Transportation Equity Partnership, Somerville, USA*

BACKGROUND AND AIMS:
Whole city studies, especially in cooler climates in advanced economies, have found profoundly large chronic health effects for those living short distances from large regional transportation related air pollution and noise sources, such as busy roadways, relative to similar populations living a kilometer or more from these exposures. (Oslo, Stockholm, Vancouver, Toronto, Boston, Copenhagen).
While primary pollutants like ultrafine particles and noise have steep gradients next to large TRAP sources, akin to these health effects, regional pollutants like PM2.5 and ozone have flat or inverse gradients. The spatiotemporal granularity of research required to show these TRAP relationships is more challenging than regional studies keyed on PM2.5 or Ozone (Six Cities vs CAFEH).

METHODS: We conducted a literature review of NLRP3 inflammasome and particulates.

RESULTS: and CONCLUSIONS: Both ambient particulate matter and NLRP3 inflammasome biology, specifically, have been shown to accelerate many major diseases of inflammation – sterile and pathogenic. Inflammasomes generate Interleukin 1 family cytokines such as IL-1beta. of the 21 human inflammasomes, only NLRP3 reacts strongly to exogenous and endogenous particles.
NLRP3 drives the health effects of a broad array of exogenous particles, including manufactured adjuvants, medical imaging agents, mineral fibres and ambient TRAP. and of endogenous particles such as crystalized uric acid, amyloid tau tangles, cholesterol and high molecular weight fatty acids.
Environmental justice (EJ) populations tend to concentrate in locations with high TRAP exposures. Without more focused research into environmental justice exposures, that integrates spatiotemporal knowledge of TRAP with NLRP3 immunology, we will be unable to protect these EJ populations. NLRP3 inflammasome biology may be the missing link between TRAP and EJ populations.

Near source exposures, transportation related air pollution, NLRP3 inflammasome biology, high exposure environmental justice populations

P-1000 Evidence of epigenetic age acceleration among adults with prenatal and early life arsenic exposure in Northern Chile

Anne Bozack[1], Philippe Boileau[2], Alan E Hubbard[2], Fenna C M Sillé[3], Catterina Ferreccio[4], Craig M Steinmaus[1], Martyn T Smith[1], Andres Cardenas[1]

[1]Division of Environmental Health Sciences, School of Public Health, University of California, Berkeley, Berkeley, USA, [2]Graduate Group in Biostatistics, University of California, Berkeley, Berkeley, USA, [3]Department of Environmental Health and Engineering, The Johns Hopkins University Bloomberg School of Public Health, Baltimore, USA, [4]Advanced Center for Chronic Diseases (ACCDiS), School of Medicine, Pontificia Universidad Católica de Chile, Santiago, Chile

BACKGROUND: Prenatal arsenic exposure influences epigenetic programming. The long-term influence on epigenetic age acceleration (EAA), a biomarker of morbidity and mortality, is unknown. We tested associations between prenatal and early-life arsenic exposure and epigenetic age acceleration in adulthood.

METHODS: Peripheral blood mononuclear cells (PBMCs) and buccal cells were collected from adults with high prenatal and early-life arsenic exposure (median = 555 µg/L in drinking water) and adults never exposed in Northern Chile (N = 40, age range: 44-53 years). Six measures of epigenetic age and EAA were calculated (Horvath age, Hannum age, PhenoAge, skin and blood age, GrimAge, and DNA methylation telomere length). Associations between high arsenic exposure or estimated water arsenic concentrations at birth and EAA were evaluated using linear models adjusted for sex and smoking.

RESULTS: In PBMCs, chronological age was strongly correlated with all epigenetic clocks (rPearson = 0.62-0.86) and DNA methylation telomere length (rPearson = -0.69); in buccal cells, correlations were significant but weaker. On average, adults with prenatal and early-life arsenic exposure had six-year greater PhenoAge acceleration in PBMCs [B (95% CI) = 6.01 (2.60, 9.42); adjusting for average lifetime water arsenic concentrations in adulthood: B (95% CI) = 6.65 (1.91, 11.38)]. Associations with Hannum EAA [B (95% CI) = 2.51 (-0.81, 5.83)] and extrinsic EAA [B (95% CI) = 3.66 (-0.91, 8.23)] in PBMCs, and with PhenoAge acceleration [B (95% CI) = 4.88 (-1.60, 11.36)] in buccal cells were positive but statistically significant. Associations with arsenic concentrations at birth were similar; PBMC PhenoAge increased by 0.32 (95% CI: 0.003, 0.63) years for each doubling in arsenic concentrations.

CONCLUSIONS: This study suggests that arsenic exposure limited to early-life stages is associated with accelerated epigenetic aging in adulthood, particularly biomarkers developed to predict morbidity and mortality. EAA might serve as a risk biomarker of early-life exposures.

P-0007 Epigenome-wide DNA methylation assists early intervention of Coronary Heart Disease with machine learning models

Yike Shen[1], Feng Gao[1], Arce Domingo-Relloso[1,2,3], Allison Kupsco[1], Marianthi-Anna Kioumourtzoglou[1], Karin Haack[4], Maria Tellez-Plaza[2], Jason G. Umans[5,6], Amanda M. Fretts[7], Ying Zhang[8], Shelley A. Cole[4], Haotian Wu[1], Andrea A. Baccarelli[1], Ana Navas-Acien[1]

[1]Department of Environmental Health Sciences, Columbia University, New York, USA, [2]Department of Chronic Diseases Epidemiology, Carlos III Health Institute, Madrid, Spain, [3]Department of Statistics and Operations Research, University of Valencia, Valencia, Spain, [4]Population Health Program, Texas Biomedical Research Institute, San Antonio, USA, [5]Department of Biostatistics, Columbia University, New York, USA, [6]Georgetown-Howard Universities Center for Clinical and Translational Science, Washington DC, USA, [7]Department of Epidemiology, University of Washington, Seattle, USA, [8]Department of Biostatistics and Epidemiology, The University of Oklahoma Health Sciences Center, Oklahoma City, USA

BACKGROUND AND AIM: Studies have shown American Indian communities have a disproportionally high rate of coronary heart disease (CHD) compared with other ethnic groups. Microarrays for epigenome-wide DNA methylation data have enabled researchers to model a large number of methylation sites to investigate their associations with incident CHD. However, accurate prediction of CHD from high-dimensional epigenome-wide DNA methylation data is challenging. We aim to develop a workflow to accurately predict CHD up to 30 years prior to diagnosis assist early disease intervention.

METHODS: The associations of CHD with epigenome-wide DNA methylation data were first screened using elastic-net penalized cox proportional hazard models based on a previous epigenome-wide association study to identify noteworthy CpG sites. The selected significant CpG sites were then input into our autoencoder deep learning model to learn the latent space representation (embeddings). The learned embeddings were then input to multiple machine learning models (i.e., logistic regression, support vector classifier, random forest, gradient boosted decision tree, and fully connected neural networks) to predict CHD. We also performed the same prediction on raw features.

RESULTS: Using our developed method, we achieved the state-of-the-art prediction accuracy of binary CHD outcome (best AUROC=0.872) with DNA methylation and clinical features using autoencoder combined with support vector classifier model (AE-SVC_DNAm+clinical), which is better than previous studies. Results showed that DNA methylation features alone had high prediction accuracy (best AUROC=0.867), clinical features alone had poor performance (best AUROC =0.692), and that AE-SVC_DNAm+clinical only increased the prediction results incrementally. Additionally, using the learned embedding increased the overall stability of our prediction results over raw input features.

CONCLUSIONS: Our data-driven method is highly effective in accurately predicting CHD up to 30 years in the Strong Heart Study population. We suggest using this workflow in future disease predictions from the high-dimensional DNA methylation data.

P-0022 Stratification score matching: Assessing the association of phthalates on asthma using the Human Health Exposure Analysis Resource (HHEAR) Data Repository

Stefanie Busgang[1], Matthew J. Mazzella[1], Moira Bixby[1], Parita Ratnani[1], Marissa Hauptman[2,3], Wanda Phipatanakul[2,4], Kelly Hunt[5], Susan L. Teitelbaum[1], Chris Gennings[1]

[1]Icahn School of Medicine at Mount Sinai, Department of Environmental Medicine and Public Health, New York, USA, [2]Harvard Medical School, Boston, USA, [3]Boston Children's Hospital, Division of General Pediatrics, Boston, USA, [4]Boston Children's Hospital, Division of Allergy and Immunology, Boston, USA, [5]Medical University of South Carolina, Charleston, USA

BACKGROUND AND AIM: The role of certain environmental exposures may be related to the onset, severity, or progression of disease, or any combination. The assessment of exposures in relation to severity may suggest unanticipated inverse associations, perhaps due to complex confounding issues. Such was the case when assessing phthalates on asthma control among children ages 4-14, all diagnosed with asthma. To better disentangle the potential role of phthalates on asthma, we sought to use stratification score (SS) methods to find comparable controls.

METHODS: Publicly available data from the HHEAR Data Repository were used to identify studies with 9 specified phthalates measured in children ages 4-14 between 2014-2018. Multivariate control charts (MCCs) were used to determine if phthalates measured in common quality control samples were comparable across studies. SSs were calculated as the probability of having asthma, conditioned on age, sex, race, ethnicity, and body mass index percentile. Controls were matched to cases using 1:1 SS matching and differences in log2 transformed specific-gravity corrected phthalate concentrations within pairs were assessed using paired t-tests. We repeated our matching algorithm 50 times and reported the distribution of effect estimates.

RESULTS: MCCs indicated phthalate measures from our studies of interest fell within acceptable bounds of variability and thus were combinable. On average, 101 of 139 eligible cases were matched across repetitions of matching. Compared to controls, cases had significantly higher concentrations for 7 phthalates, borderline significantly higher concentration for 1 phthalate and a significantly lower concentration for 1 phthalate. Consistent with the original study findings, differences between pairs tended to be higher or no different among well controlled asthmatics pairs compared to differences among poorly controlled asthmatics pairs.

CONCLUSIONS: Most phthalates were higher among asthmatic compared to non-asthmatic children. This study warrants further investigation into phthalate exposure sources used to reduce asthma symptoms.

KEYWORDS: phthalates, asthma, matching

P-0023 Exploring exposure-outcome relationships inside the VA Normative Aging Study using graph learning

Feng Gao[1], Marianthi-Anna Kioumourtzoglou[1], Pantel Vokonas[2,3], Avron Spiro III[2,4], Andrea Baccarelli[1], Yike Shen[1]
[1]Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [2]Normative Aging Study, VA Boston Healthcare System, Boston, USA, [3]Department of Medicine, Boston University School of Medicine, Boston, USA, [4]Department of Epidemiology, Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: Contemporary health sciences draw on large-scale longitudinal studies to understand the impact of lifestyle factors and environmental exposures on the risk of disease and identify potential underlying mechanisms. While there are extensive studies on associations between exposures and outcomes, the relationships among different studies within a single cohort are less studied. A database that summarizes those relationships is important towards unifying existing knowledge and inferring new information. In this study, we aim to construct an exposure-outcome network database across multiple publications in the Veterans Affairs Normative Aging Study (NAS) to explore its various applications including discovering core exposures/outcomes and hypothesis generation.

METHODS: NAS is a well-studied ongoing longitudinal study of aging in men followed since 1963. A network or a graph G can be constructed consisting of n nodes V and edges W, with each node representing an exposure E, or an outcome O. Two nodes are only connected by an edge w if their association has been studied. The core exposures/outcomes and communities of the network are retrieved with graph learning methods. Finally, we studied the dynamic changes of network structures.

RESULTS: We collected over 130 peer-reviewed exposure-outcome related publications in the last decade with title/abstract keyword “Normative Aging Study” in PubMed. We then constructed a network database describing the exposure-outcome relationship. We identified key exposures of interest, such as short- and long-term air pollution and its components, and key outcome nodes such as DNA methylation and lung function through network analysis. We also demonstrated the possibility of using the constructed network towards hypothesis generation.

CONCLUSIONS: We constructed a graph/network database to describe the relationship between exposures and outcomes across multiple studies inside the NAS cohort. Utilizing the graph learning methods, we demonstrated various applications including identifying key exposure/outcomes as well as hypothesis generation.

P-0026 The PFAS-Tox Database: A systematic evidence map of health studies on per- and polyfluoroalkyl substances

Julia Varshavsky[1], Anna Reade[2], Carol Kwiatkowski[3,4], Francheska M. Merced-Nieves[5], Haleigh Cavalier[6], Kim Schultz[7], Taylor Wolffe[8], Katherine E. Pelch

[1]Northeastern University, Boston, USA, [2]Natural Resources Defense Council, San Francisco, USA, [3]Green Science Policy Institute, Berkeley, USA, [4]North Carolina State University, Raleigh, Raleigh, [5]Icahn School of Medicine at Mount Sinai, New York, USA, [6]New York University School of Medicine, New York, USA, [7]Independent Consultant, [8]Lancaster University, Lancaster, UK, [9]University of North Texas Health Science Center, Fort Worth, USA

BACKGROUND AND AIM: PFAS (per-and polyfluoroalkyl substances) is a large class of synthetic chemicals used widely in consumer products and industrial processes. Health and toxicology literature on PFAS has increased dramatically in the last decade, and many key stakeholders could benefit from efficient access to the data. We aimed to create a systematic evidence map (SEM) of health and toxicological research on 29 PFAS that would be easily accessible for diverse audiences.

METHODS: We published a protocol a priori and conducted a PubMed database search of peer-reviewed literature through January 25, 2021. Studies were screened for inclusion and exclusion according to the Populations, Exposures, Comparators, and Outcomes (PECO) statement. Inclusion criteria were intentionally broad and included any human, animal, and/or in vitro study that investigated exposure to one of the 29 PFAS of interest and a human health or toxicological effect. Study details were extracted, with meta-data made freely available in the online, interactive SEM at https://pfastoxdatabase.org.

RESULTS: Over 15,000 studies were retrieved from the literature search. After manual screening, 1,067 studies (505 human, 385 animal, and 220 in vitro) were identified and included as investigating health or toxicological effects of one or more PFAS of interest. Most human studies were cross-sectional (48%) or cohort (39%), with body weight/size/growth (n=195), reproductive (n=158), endocrine (n=149), and metabolic/digestive systems (n=143) examined as the most common health outcome categories.

CONCLUSIONS: The PFAS-Tox Database is a useful tool for searching, filtering, and identifying peer-reviewed research on the health and toxicological effects of PFAS. The SEM provides examples of data gaps and clusters revealed by the database and will support scientists, regulatory agencies, and individuals with tools to advance future research efforts, systematic reviews, regulatory risk assessments, and cross-disciplinary coordination on the health effects of PFAS exposure.

P-0040 Longitudinal Associations of Air Pollution with Body Size and Composition in Midlife Women: The Study of Women's Health Across the Nation

Xin Wang[1], Carrie Karvonen-Gutierrez[1], Ellen Gold[2], Carol Derby[3], Gail Greendale[4], Xiangmei Wu[5], Joel Schwartz[6], Sung Kyun Park[1]

[1]University of Michigan, Ann Arbor, USA, [2]University of California, Davis, Davis, USA, [3]Albert Einstein College of Medicine, Bronx, USA, [4]University of California, Los Angeles, Los Angeles, USA, [5]California Environmental Protection Agency, Oakland, USA, [6]Harvard University, Boston, USA

BACKGROUND AND AIM: Exposure to air pollution has been suggested to be associated with obesity recently; however, epidemiologic evidence is still limited and has heavily focused on body mass index (BMI). We examined associations of fine particulate matters (PM2.5), nitrogen dioxide (NO2), and ozone (O3) with longitudinal measures of body size and composition including weight, BMI, waist circumference, fat mass, lean mass, and proportion fat mass in midlife women.

METHODS: The study population included 1,654 White, Black, Chinese and Japanese women from the Study of Women's Health Across the Nation, with the median age of 49.6 years and a total of 10,370 repeated observations followed from 2000 to 2008. Annual air pollution exposures were assigned by the residential addresses linked with hybrid estimates of air pollutant concentrations at 1-km2 resolution. Body size was measured objectively and body composition was measured using the dual-energy X-ray absorptiometry (DXA) at approximately annual visits. Linear mixed effects models were used to examine the associations between air pollution and body size and composition measures.

RESULTS: After adjusting for potential confounders, an interquartile range (IQR) increase in PM2.5 concentrations (4.5 μg/m3) was associated with 4.53% (95%CI:3.85%,5.22%) higher fat mass, 1.10% (95%CI:0.95%,1.25%) higher proportion fat mass, and 0.39% (95%CI:-0.77%,-0.01%) lower lean mass. An IQR increase in NO2 (9.5 ppb) was associated with 3.39% (95%CI:2.68%,4.10%) higher fat mass, 0.94% (95%CI:0.78%,1.10%) higher proportion fat mass, and 0.86% (95% CI:-1.26%,-0.45%) lower lean mass. Similar associations were also observed for O3. Physical activity was found to modify the associations of PM2.5 and NO2 with body size and composition: weaker associations were observed in participants who engaged in more physical activity.

CONCLUSIONS: PM2.5, NO2, and O3, are adversely associated with body composition, including higher fat mass, higher proportional fat mass, and lower lean mass, highlighting its potential role in contributing to obesity.

P-0043 Associations between traffic-related air pollution and cognitive function in Australian urban settings: the moderating role of diabetes status

Rachel Tham[1,2], Amanda J Wheeler[2,3], Alison Carver[2], David Dunstan[4,5], David Donaire-Gonzalez[2], Kaarin J Anstey[6,7], Jonathan E Shaw[5,8,9], Dianna E Magliano[5], Erika Martino[1], Anthony Barnett[2], Ester Cerin[2,5,10,11]

[1]University of Melbourne, Melbourne, Australia, [2]Australian Catholic University, Melbourne, Australia, [3]University of Tasmania, Hobart, Australia, [4]Deakin University, Melbourne, Australia, [5]Baker Heart and Diabetes Institute, Melbourne, Australia, [6]University of New South Wales, Sydney, Australia, [7]Neuroscience Research Australia, Sydney, Australia, [8]Monash University, Melbourne, Australia, [9]La Trobe University, Melbourne, Australia, [10]University of Hong Kong, Sandy Bay, Hong Kong, [11]The Arctic University of Norway, Tromso, Norway

BACKGROUND: Traffic-related air pollution (TRAP) is associated with poorer cognitive function and higher incidence of diabetes in older adults, but little is known about whether diabetes moderates the impact of TRAP on older adult cognitive function.

METHODS: We analysed cross-sectional data from 4141 adults who participated in the Australian Diabetes, Obesity and Lifestyle (AusDiab) study in 2011-2012. TRAP exposure was estimated using major and minor road density (100m/km²) within residential buffers: 200, 300, 500, 1000 and 1600 metres. Cognitive function was assessed with validated psychometric scales: California Verbal Learning Test (memory) and Symbol–Digit Modalities Test (processing speed). Diabetes status was measured using an oral glucose tolerance test. Missing data were imputed. Associations of TRAP with cognitive function and the moderating effects of diabetes on these associations were estimated using generalised additive mixed models adjusted for age, sex, English-speaking background, socioeconomic status, education, living arrangement, employment status, neighbourhood self-selection indices, urban density, neighbourhood greenspace and land-use mix. Results are reported as regression coefficients, β, per single unit increase in TRAP measures.

RESULTS: We observed positive associations between 200, 1000 and 1600m TRAP and memory (β=0.003, p=0.008; β=0.003, p=0.018; β=0.004, p=0.015 respectively) but not processing speed. Minor road density was not associated with cognitive function, while major road density showed positive associations with memory and processing speed among 1000 and 1600m buffers (β=0.010, p=0.038; β=0.014, p=0.026). Within a 300m buffer the relationship between TRAP and memory tended to be positive in people without diabetes (β=0.005; p=0.062), but negative in people with diabetes (β=-0.013; p=0.026); and negatively associated with processing speed in people with diabetes only (β=-0.047; p=0.059).

CONCLUSIONS: In Australian urban areas, higher TRAP exposure may be positively associated with cognitive function in urban dwelling people, but this benefit may not extend to people living with diabetes in urban settings.

P-0045 Short-term exposure to PM2.5 and daily all-cause dementia and Alzheimer´s disease mortality in Connecticut: a time-stratified case-crossover study

Chengyi Lin[1,2], Emily Goddard[2,3], Kevin Chan[4], Yiqun Ma[1,2], Qian Di[5], Carolyn A. Fredericks[6], Kai Chen[1,2]
[1]Department of Environmental Health Sciences, Yale School of Public Health, New Haven, USA, [2]Yale Center on Climate Change and Health, Yale School of Public Health, New Haven, USA, [3]Department of Social and Behavioral Sciences, Yale School of Public Health, New Haven, USA, [4]Yale College, New Haven, USA, [5]Vanke School of Public Health, Tsinghua University, Beijing, China, [6]Department of Neurology, Yale University, New Haven, USA

BACKGROUND: While emerging studies have examined long-term exposure to fine particulate matter ($PM_{2.5}$) and its association with various measures of morbidity of dementia and Alzheimer´s disease (AD), evidence on short-term $PM_{2.5}$ exposure and mortality caused by dementia or AD is sparse.

METHODS: We applied a time-stratified case-crossover design using conditional logistic regression to assess the association between ambient $PM_{2.5}$ concentrations and daily all-cause dementia and AD mortality in Connecticut between 2005 to 2016, while adjusting for mean air and dewpoint temperature. Our analysis included cases whose principal cause of death was all-cause dementia or AD. The daily 24-hour average $PM_{2.5}$ concentration was obtained from a well-validated model and the individual-level exposure was assigned based on the modeled $PM_{2.5}$ level in a 1 × 1 km^2 grid which contains the residential address. We also explored potential effect modification by age and sex groups.

RESULTS: A total of 28,736 all-cause dementia deaths occurred during our study period, among which 9,826 were specially coded as AD deaths. A 10 $\mu g/m^3$ increase in the 2-day moving average of ambient $PM_{2.5}$ was significantly associated with all-cause dementia (Odds Ratio [OR] =1.06, 95% confidence interval [CI]: 1.03, 1.09) and AD (OR=1.07, 95% CI: 1.02, 1.12). We did not find effect modification by age (<80 years vs. ≥ 80 years) in all-cause dementia or AD. The estimated effect of $PM_{2.5}$ was higher among the female subgroup compared to the male subgroup (P-value = 0.03) for mortality caused by all-cause dementia but not for AD.

CONCLUSIONS: Our study suggests a significant association between short-term exposure to $PM_{2.5}$ and an increase in mortality risks of all-cause dementia and AD. Further research is warranted on mechanisms that can explain the relationship between short-term $PM_{2.5}$ exposure and mortality risks of dementia.

KEYWORDS: $PM_{2.5}$; dementia; Alzheimer´s disease; mortality; short-term; case-crossover

P-0047 Para-dichlorobenzene exposure and serum α-Klotho levels among US participants in their middle and late adulthood

Yudan Wei[1], Jianmin Zhu[2]
[1]Mercer University School of Medicine, Macon, USA, [2]Fort Valley State University, Fort Valley, USA

BACKGROUND AND AIM: Para-dichlorobenzene (p-DCB) is a volatile compound commonly used as pest repellent and air deodorant in the home and public buildings. There has been an increasing concern about its metabolic and endocrine effects. The aim of the present study was to explore the relation between p-DCB exposure and serum levels of soluble α-Klotho, an anti-aging hormone, in US adults.

METHODS: A nationally representative subsample of 1485 adults 40-79 ages in the 2013-2016 National Health and Nutrition Examination Survey was analyzed for the association between urinary concentrations of 2,5-dichlorophenol (2,5-DCP), the major metabolite of p-DCB, and serum α-Klotho levels using multiple general linear models, adjusting for potential confounders. Age- and sex-specific analyses were further conducted.

RESULTS: The weighted geometric mean of urinary 2,5-DCP was 2.43 μg/L and the weighted mean of serum α-Klotho was 831.97 pg/mL in the study participants during 2013-2016. After adjusting for potential confounders, urinary 2,5-DCP was significantly associated with decreased serum levels of α-Klotho (regression coefficient β=-9.88; p=0.0133) in the total study population. When age- and sex-specific analyses being conducted, a significantly inverse association was found in older adults aged 60-79 years (β=-20.52; p<0.0001) and in males (β=-13.81; p=0.0097), but not in the middle ages (40-59 years) and in females. The strongest association was observed in older (60-79 years) male participants, with a 25.25 pg/mL reduction of α-Klotho levels per 1-unit increase of 2,5-DCP concentrations (p=0.0007). No statistically significant associations with α-Klotho levels were observed for urinary 2,4-dichlorophenol, another dichlorophenol pesticide.

CONCLUSIONS: Our study demonstrates a relation between p-DCB exposure, measured as 2,5-DCP, and decreased α-Klotho levels in older men. Additional studies would further explore these interactions and elucidate the pathogenesis of the potential effects of p-DCB exposure on aging.

KEYWORDS: 2,5-dichlorophenol, α-Klotho; middle and late adulthood, NHANES; para-dichlorobenzene exposure

P-0048 Associations between Air Pollution and Gait Speed in Older Adults

Boeun Kim, Anjum Hajat, Joel D. Kaufman, Cindy S. Leary, Erin Semmens, Annette Fitzpatrick
[1]*Johns Hopkins University, Baltimore, USA*

BACKGROUND AND AIM: Air pollution is widely recognized as a threat to public health, particularly among older adults. Long-term exposure to air pollution may impact gait speed trajectories over time, as gait speed is a marker of physical and cognitive decline. This study examined the relationship between long-term air pollution exposure and gait speed decline among older adults and evaluated whether cardiovascular disease (CVD) status modified the effect.

METHODS: We analyzed data from 3,022 older adults residing in the US followed from 2000 to 2008. Long-term exposure to fine particulate matter (PM2.5) and nitrogen dioxide (NO2) prior to study enrollment was estimated using state-of-the-art prediction models. Gait speed at usual and rapid pace was assessed annually using a 15-foot timed walk test. Mixed-effects models were fitted adjusting for sociodemographic variables overall and in those with and without CVD.

RESULTS: Greater long-term PM2.5 and NO2 exposure was related to faster gait speed decline. One interquartile range (IQR) higher 5-year PM2.5 exposure (2 μg/m3) prior to the study enrollment was related to 0.048 m/s decline in usual gait speed (95% CI: -0.084, -0.024) and an IQR higher 5-year NO2 exposure (6.5 ppb) was associated with 0.078 m/s decline in usual gait (95% CI: -0.120, -0.042) and 0.042 m/s decline in rapid gait (95% CI: -0.078, -0.006) over the 6-year period. Longitudinal association between air pollution (5- and 10-year average PM2.5 and NO2) and rapid gait speed decline was significant only in individuals with CVD.

CONCLUSIONS: Long-term exposure to air pollution appears to be associated with faster gait speed decline among older adults in the US. Policies to reduce the emission of air pollutants and interventions to avoid air pollution exposure could contribute to the reduction in the burden of preventable institutionalization and hospitalization.

KEYWORDS: Air pollutants, Walking speed, Aged, Dementia, cognitive decline

P-0050 Incident Dementia and Long-Term Exposure to Constituents of U.S. Fine Particle Air Pollution: A National Cohort Study

Liuhua Shi[1], Qiao Zhu[1], Yifan Wang[1], Hua Hao[1], Haisu Zhang[1], Joel Schwartz[2], Heresh Amini[3], Aaron van Donkelaar[4], Randall Martin[4], Kyle Steenland[1], Jeremy Sarnat[1], Tszshan Ma[1], Haomin Li[1], Howard Chang[1], Jeremiah Liu[2], Rodney Weber[5], Pengfei Liu[5]

[1]Emory University, Atlanta, USA, [2]Harvard T.H. Chan School of Public Health, Boston, USA, [3]University of Copenhagen, Copenhagen, Denmark, [4]Washington University at St. Louis, St. Louis, USA, [5]Georgia Institute of Technology, Atlanta, USA

BACKGROUND: Growing evidence suggests that PM2.5 likely increases the risks of neurological disorders, yet little is known about the relative contributions of different constituents. Understanding constituent-specific effects are critical to targeting emission reductions of specific sources with the greatest health protection.
METHOD: We conducted a nationwide population-based cohort study (2000-2017), by integrating the Medicare Chronic Conditions Warehouse database and two sets of high-resolution, multiple-species, air pollution datasets to investigate the impact of long-term exposure to PM2.5 constituents on incident dementia and Alzheimer's disease (AD). and home health-care claims. Hazard ratios for dementia and AD were estimated using single- and multi-constituent Cox proportional hazards models, and penalized splines were used to evaluate potential nonlinear concentration-response relationships.

RESULTS: of the 18.5 million dementia and 19.2 million AD individuals within these cohorts, 31.5% and 14.6% developed dementia and AD events, respectively. From the single-pollutant models, an interquartile range (IQR) increase in PM2.5 mass was associated with an increase in dementia incidence ranging between 6-7% using two exposure datasets. for different PM2.5 constituents, associations remained significant in black carbon (BC), organic matter (OM), sulfate (SO42−), and ammonium (NH4+). Incident dementia was observed to have the strongest association with increases in exposure to SO42− and BC (10-11% increase and 4-6% per IQR increase, respectively). Effect estimates for AD were even larger. for both endpoints, all constituents had largely linear concentration-response relationships in the low exposure range, but most tailed off at high exposure concentrations, particularly for AD.

CONCLUSIONS: Our study suggests that long-term exposure to PM2.5 is significantly associated with increased incident dementia and AD, and that the different PM2.5 constituents may elicit differential neurotoxicity. Reduction of PM2.5 emissions, especially for the main sources of BC and SO42−, may reduce the burden of dementia or AD in the aging US population.

P-0058 Long-term Ozone Exposure and Incident Frailty in Older Adults: Findings from a Prospective Cohort Study in Chinese Elderly

Yuebin Lv[1], Qingyang Zhu[2], Lihong Ye[1,3], Meijie Jiang[4], Jinhui Zhou[1], Yuan Wei[1,5], Chenfeng Li[1,6], Chen Chen[1], Yidan Qiu[1,7], Jun Wang[1], Juan Zhang[3], John S.Ji[8], Xu Gao[4], Yang Liu[2], Xiaoming Shi[1,9]

[1]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [3]School of Population Medicine and Public Health, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [4]Department of Occupational and Environmental Health Sciences, School of Public Health, Peking University, Beijing, China, [5]Department of Hygienic Inspection, School of Public Health, Jilin University, Jilin, China, [6]School of Public Health, Anhui Medical University, Anhui, China, [7]Department of Public Health, Zhejiang University, Zhejiang, China, [8]Vanke School of Public Health, Tsinghua University, Beijing, China, [9]Center for Global Health, School of Public Health, Nanjing Medical University, Jiangsu, China

BACKGROUND AND AIM: Studies have linked elevations in short-term ozone exposure to acute adverse health outcomes. In this study, we aimed to explore whether long-term ozone exposure was linked to the development of frailty in older adults.

METHODS: A total of 15,734 participants aged ≥65-year-old and were free of frailty were included in Chinese Longitudinal Healthy Longevity Survey (CLHLS) from 2005 to 2018. Frailty was defined by a frailty index (FI) ≥0.25, which was measured by 39 health deficits. Personal ozone exposures were estimated using full-composition annual ozone covering all of China at a 0.05° resolution. County-level ozone-related burden of frailty in China was calculated by warm season hazard ratio of frailty.

RESULTS: During 78,588 person-years follow-up, 3587 incident frailties were documented. In competing risk models, each 10-μg/m³ increase in baseline warm-season (May to October) and yearly ozone exposure corresponded to 6.9% and 12.1% higher risk of incident frailty, the hazard ratios were 1.069 (1.035-1.104) and 1.121 (1.063-1.182), respectively. Monotonically increasing dose-response of warm-season and yearly ozone exposure with incident frailty and FI score were observed. With the dramatic population aging and increasing ozone exposure simultaneously in China, it was estimated that the burden of warm season ozone related incident frailty among the population aged ≥65-year-old in China were 1,818,729 and 3,700,237 cases in 2010 and 2020, respectively, and there will be 4,806,037 incident frailties in 2030.

CONCLUSIONS: This nationwide prospective cohort study established that long-term ozone exposure was associated with incident frailty and contributed to an enormously significant and increased disease burden for the older adults, suggesting that controlling ozone exposure may be a priority area for air quality regulations in China in next decade that may yield substantial health benefits.

P-0059 Associations of peak season ozone with blood pressure among older adults without hypertension in a high exposure country: evidence from the Chinese Longitudinal Healthy Longevity Survey from 2005 to 2018

Jinhui Zhou[1], Qingyang Zhu[2], Lihong Ye[1,3], Yidan Qiu[1,4], Bing Wu[1,5], Chen Chen[1], Jun Wang[1], Yuan Wei[1,6], Xulin Zheng[1,5], Yuebin Lv[1], Yang Liu[2], Xiaoming Shi[1,5]

[1]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]Department of Environmental and Occupational Health, Emory University, Atlanta, USA, [3]School of population medicine and public health, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [4]Department of Public Health, Zhejiang University, Hangzhou, China, [5]Center for Global Health, School of Public Health, Nanjing Medical University, Nanjing, China, [6]School of Public Health, Jilin University, Changchun, China

BACKGROUND AND AIM: Evidence based on long-term prospective cohort studies is lacking to investigate the association between ambient ozone (O3) and blood pressure among older adults. We aim to evaluate the associations of peak season O3 with change of blood pressure in a long-term cohort study among older adults without hypertension.

METHODS: We included 5940 older adults aged ≥65 years and with repeated measurements of blood pressure from 2005 to 2018 in 23 provinces of China, estimated monthly O3 exposures at 0.05 ° ×0.05 ° resolution were matched to each participant. Peak season O3 exposure was measured as the average from April to September. Outcomes include blood pressure measurements of SBP, DBP, PP and MAP. Linear mixed models were performed to evaluate the associations between O3 exposures and blood pressure. Natural splines were applied to explore the potential non-linear concentration-response associations.

RESULTS: In this study, peak-season O3 ranges from 72.6 to 151.7 μg/m3 in China. In fully adjusted model, per 10 μg/m3 increase in peak season O3 was associated with increases of 2.46 mmHg (95% confidence interval [CI]: 1.85-3.06) in SBP, 2.46 mmHg (95%CI: 1.94-2.99) in PP and 0.74 mmHg (95%CI: 0.38-1.11) in MAP, but non-significant decrease in DBP. Female, ethnic minorities, and older adults who were not in marriage, underweight, with medium or low income levels were susceptible to O3 exposure. Non-linear curves indicated that the effect of O3 exposure on SBP, PP and MAP were monotone increasing, with faster increase in risk magnitude before WHO interim target 1 at 100 μg/m3, but slow down thereafter.

CONCLUSIONS: The study added evidence to support the World Health Organization interim targets for peak-season O3, however, lower interim targets should be set to maintain healthy blood pressure among populations in countries with high O3 concentrations.

KEYWORDS:Ozone; blood pressure; older adult; cohort study

P-0060 Association of blood mercury exposure with depressive symptoms in the Chinese oldest old

Jiahui Xiong[1,2], Yuebin Lv[1], Yuan Wei[1,3], Zuyun Liu[4], Xinwei Li[1,3], Yang Liu[1,3], Feng Zhao[1], Chen Chen[1], Heng Gu[1], Jun Wang[1], Xulin Zheng[1,5], Kai Xue[1,3], Yidan Qiu[1,4], Tong Shen[2], Xiaoming Shi[1,2]

[1]National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]Anhui Medical University, Hefei, China, [3]Jilin University, Changchun, China, [4]Zhejiang University, Hangzhou, China, [5]Nanjing Medical University, Nanjing, China

Background:Depressive symptoms have a significant impact on the quality-of-life among the oldest old. Current research on the association of blood mercury with depressive symptoms has mainly targeted the general population. However, it is unclear whether this association is present at the oldest old.

Objective:The aim of this study was to investigate the association of blood mercury exposure with depressive symptoms in the oldest old.

Methods:We used data from the Healthy Aging and Biomarker Cohort Study carried out in 2017-2018, with 1567 participants aged ≥80 years were eligible for analysis. Blood mercury levels were measured by inductively coupled plasma mass spectrometry (ICP-MS). The CES-D10 depression scale was used to assess depressive symptoms. Multivariable logistic regression models were used to examine the association between blood mercury levels and depressive symptoms. We also used restricted cubic splines (RCS) to assess the linear or nonlinear association of blood mercury with depressive symptoms.

Results:The mean age of the 1567 participants was 91.8 years, while the geometric mean concentration of blood mercury was 1.17 μg/L. Multivariable logistic regression analysis showed a statistically significant positive association of blood mercury with depressive symptoms after adjustment for covariates. The odds ratios of blood mercury for depressive symptoms in the second and third tertiles were 1.88 (1.37-2.56) and 1.51 (1.11-2.04), respectively, compared with that measured in the first tertile. The RCS model showed that there was a non-linear association between blood mercury level and depressive symptoms.

CONCLUSIONS: Among the oldest old, we found blood mercury levels are associated positively with depressive symptoms, highlighting the importance of appropriately managing their exposure to mercury.

KEYWORDS: depressive symptoms, blood mercury, the oldest old, restricted cubic splines, multivariate logistics

P-0061 Accelerated aging modifies impact of ozone on QT interval and markers of inflammation in healthy humans

William Weston[1], Marie-Abele Bind[2], Robert Devlin[1], Cavin Ward-Caviness[1]
[1]Center for Public Health and Environmental Assessment, USA Environmental Protection Agency, Chapel Hill, USA, [2]Department of Statistics, Harvard University, Cambridge, USA

BACKGROUND AND AIM: Older individuals often have increased health risks from environmental exposures, but this has been rarely investigated using molecular measurements of biological age. DNA methylation can be used to measure biological age and epigenetic age acceleration (EAA) in subjects. EAA accurately predicts mortality and chronic disease risk; however, it is unknown whether EAA modifies responses to environmental exposures. Here, we investigated whether cardiovascular and inflammatory responses to ozone are modified by EAA.

METHODS: LAMARCK was a controlled exposure study where 17 healthy participants were exposed to 0.3-ppm ozone or to clean air for two hours in a randomized single-blind crossover study design. Functional cardiopulmonary measures (n=3) and inflammation biomarkers (n=5) were collected immediately before and 24-hours after exposures. Epigenetic age was estimated using the Horvath method on cells that were collected from BALFs 24 hours after exposure. All outcomes were normalized to their pre-exposure values. We used mean and quantile regression to examine if EAA (calculated as epigenetic age – chronological age) measured during clean air exposure is associated with the estimated causal risk difference (CRD; Ozone – Clean Air) of cardiopulmonary and inflammatory outcomes. Regression models were evaluated with and without outliers to determine model consistency. Results are presented as percentage change relative to the mean value measured during air exposure.

RESULTS: Mean and median regression results were concordant. for mean regression, one-year higher EAA was associated with a 0.44% (95% confidence interval = 0.13%, 0.75%) increase in the CRD for QT interval in response to ozone exposure. One-year higher EAA was also associated with a -15.3% (95% confidence interval = -23.2%, -7.41%) change in the CRD for C-reactive protein in response to ozone. No other associations were observed.

CONCLUSIONS: Accelerated aging in the lung is associated with prolonged QT interval and depressed inflammatory response during short-term ozone exposure.

P-0064 Air Pollution and Trajectories of Positive and Negative Affect in Older Women

Andrew Petkus[1], Susan Resnick[2], Xinhui Wang[1], Lauren Salminen[1], Joshua Millstein[1], Daniel Beavers[3], Mark Espeland[3], Margaret Gatz[1], Joel Kaufman[4], Stephen Rapp[3], Jiu-Chiuan Chen[1]

[1]University of Southern California, Los Angeles, USA, [2]National Institute on Aging, Baltimore, USA, [3]Wake Forest School of Medicine, Winston-Salem, USA, [4]University of Washington, Seattle, USA

BACKGROUND AND AIM: Exposure to ambient air pollution, including PM2.5 (particulate matter <2.5 μm) and NO2 (nitrogen dioxide), is associated with depressive symptoms in older adulthood. Depression is characterized by low positive affect and high negative affect. Elucidating how exposure may differentially impact the emotional dimensions underlying depressive symptoms will deepen our understanding of the link between air pollution neurotoxicity and emotional health of older adults. Here we examined associations between air pollution and longitudinal trajectories of positive and negative affect in older women.

METHODS: Women (N=2,114; baseline age=73.3±3.8 years), enrolled in the Women's Health Initiative Study of Cognitive Aging (2000-2010), completed up to nine annual assessments with the Positive and Negative Affect Schedule (PANAS). Three-year average annual mean concentrations (scaled by interquartile range [IQR]) of ambient PM2.5 (in μg/m3; IQR=3.64 μg/m3) and NO2 (in ppb; IQR=10.35 ppb) before baseline were estimated at participants' addresses via spatiotemporal models. Latent-class mixture models were constructed to identify subgroups of women with similar trajectories of positive or negative affect over time. Multinomial logistic regressions were used to examine whether exposures predicted latent-class membership, adjusting for sociodemographic, lifestyle, and clinical characteristics.

RESULTS: Two latent trajectories of positive affect (PA) were identified: (high-stable PA: 95% and decreasing PA: 5%). Higher exposure to NO2 (OR = 1.55, p=.008), but not PM2.5 (OR=1.23, p=.212), was significantly associated with increased odds of being classified as having decreasing PA relative to high-stable PA. Four latent trajectories of negative affect (NA; minimal-stable: 27%; mild-stable: 46%; moderate-stable:21%; and moderate-decreasing: 6%) were identified. Neither NO2 nor PM2.5 was predictive of latent class membership of NA trajectories.

CONCLUSIONS: Exposure to NO2 may contribute to reduction of PA in older adulthood. Future studies should examine brain structures and neural networks as well as behavioral mechanisms underlying PA changes associated with air pollution neurotoxicity in late life.

P-0066 Narrative Review of Long-Term Exposure to Traffic-Related Air Pollution on Dementia and Related Outcomes in Older Adults

BACKGROUND AND AIM: As part of an extensive systematic review on the associations of important clinical health outcomes with exposure to traffic-related air pollution (TRAP), an independent Panel appointed by the Health Effects Institute considered the emerging literature on dementia-related outcomes and Parkinson's disease, two areas of significant public health interest.

METHODS: The Panel systematically searched the PubMed and LUDOK electronic databases for observational epidemiological studies from 1980 through 2019 on long-term exposure to TRAP and dementia-related outcomes and Parkinson's disease prevalence in the general population. Study selection and data extraction were conducted according to a defined protocol, and a novel framework was used to identify which studies provided information on TRAP exposure. Conclusions regarding the level of confidence in the presence of an association were based on a narrative assessment. The Panel decided a priori not to conduct formal confidence and risk of bias assessments and meta-analyses because this is an emerging area of research.

RESULTS: The Panel reviewed 15 studies on dementia-related outcomes and six studies of Parkinson's disease. Evidence for an association of dementia-related outcomes with TRAP was mixed; studies of cognition and incident dementia generally found adverse associations while findings on cognitive decline were null. Evidence for an association of TRAP with Parkinson's disease was inconsistent with some potential for systematic bias. Limitations of the body of literature included its small size, potential for bias due to outcome misclassification, selection and attrition bias, and adjustments for confounding that did not align with plausible pathways between TRAP exposure and outcomes.

CONCLUSIONS: The Panel's confidence in the association of TRAP with dementia-related outcomes was low to moderate, while confidence in the association with Parkinson's disease was low. Future systematic reviews will benefit from the continued growth in this literature.
KEYWORKS: narrative review, traffic-related air pollution, dementia, cognitive decline

P-0067 Long-Term Air Pollution Exposure and Loss of Independence in the U.S.

Boya Zhang[1], Carlos Mendes de Leon[1], Jennifer Weuve[2], Kenneth M. Langa[3,4,5,6], Jennifer D'Souza[1], Adam A. Szpiro[7], Jessica Faul[8], Jiaqi Gao[1], Joel Kaufman[9,10,11], Richard Hirth[12,13], Sara D. Adar[1]

KEYWORDS: Air pollution, personal help, disability

BACKGROUND AND AIM: Disabilities, especially those that result in lost independence, can result in high emotional and economic burdens to individuals and families. Although air pollution is a well-established risk factor for chronic disease, its impacts on disability are only recently being considered and current studies have not focused on lost independence. We examined associations between air pollution and receiving help for disability, in a nationally representative cohort, focusing on the highest degree of limitations.

METHODS: We used biennial self-reported data between 2006 and 2016 on receiving personal help with six activities of daily living (ADL) and five instrumental activities of daily living (IADL) or living in the nursing home due to health and memory problems from participants>50 years in the Health and Retirement Study. Using spatiotemporal models, we predicted 10-year average PM2.5, PM10-2.5, NO_2, and O_3 concentrations at participant addresses before each interview. Associations with first receipt of help due to disability were estimated with Cox models, adjusting for individual demographics, area-level characteristics, and temporal and geographic trends.

RESULTS: During 6.8±3.0 years of follow-up, 31.7% of our 20,800 participants reported newly receiving help due to disability. We observed a 4% (HR: 1.04 per 3.2 μg/m³, 95%CI: 0.99, 1.10) and 6% (HR: 1.06 per 6.73 ppb, 95%CI: 1.02, 1.11) greater rate of receiving help due to disability per inter-quartile range higher long-term PM2.5 and NO_2 concentrations, respectively. In contrast, PM10-2.5 and O_3 concentrations were not associated with increased rates of receiving help.

CONCLUSIONS: This prospective study of older U.S. adults provides evidence that air pollution is associated with an increased need for help due to disabilities, though this association varied across pollutants. Controlling air pollution might potentially divert or delay individuals from needing care in late life and prolong/enhance their ability to live independently.

P-0069 Heterogeneous impact of air pollution exposures on cognitive trajectories in Women's Health Initiative Memory Study in Younger Women

Xinhui Wang[1], Andrew Petkus[1], Lauren Salminen[1], Joshua Millstein[1], Daniel Beavers[2], Mark Espeland[2], Margaret Gatz[1], Susan Resnick[3], Joel Kaufman[4], Stephen Rapp[2], Jiu-Chiuan Chen[1]

[1]University of Southern California, Los Angeles, USA, [2]Wake Forest School of Medicine, Winston-Salem, USA, [3]National Institute on Aging, Baltimore, USA, [4]University of Washington, Seattle, USA

BACKGROUND AND AIM: Late-life exposure to ambient air pollutants is a risk factor for dementia, but little is known about the associations between midlife exposure and cognitive aging. We examined the effects on trajectories of general cognitive ability and episodic memory in older adulthood, comparing midlife and late-life exposures.

METHODS: Using regionalized universal kriging models applied to the residences of women (n=881; aged 62-71) enrolled in the Women's Health Initiative Memory Study in Younger Women (WHIMS-Y) in 2009, we estimated the annual PM2.5 (particulate matter<2.5μm) and NO2 (proxy for traffic-related pollutants) aggregated exposures to 3-year averages for midlife (aged 50-59, 12 years before WHIMS-Y inception) and late-life (at WHIMS-Y inception). General cognitive ability and episodic memory were assessed annually (2009-16) respectively by modified Telephone Interview for Cognitive Status (TICSm) and California Verbal Learning Test (CVLT). Linear mixed effect models were used to examine exposure effects adjusting for socio-demographic, lifestyle, and clinical covariates and time-varying propensity scores.

RESULTS: The average performance in TICSm and CVLT improved over time (both slope=0.15/year, p<0.001). Women with higher midlife exposures had worse baseline CVLT scores, with associations statistically significant for PM2.5 (β0,midlifePM2.5=-0.58 per IQR=3.43μg/m3, p=0.02), but not for NO2 (β0,midlifeNO2=-0.44 per IQR=9.23ppb, p=0.13). Women with higher midlife exposures had less improvement in CVLT performance over time, but the associations were non-significant. Associations between late-life exposures and CLVT trajectories and between both midlife or late-life exposures and TICSm trajectories were non-significant.

CONCLUSIONS: Among women aged 62-71 with positive trajectories suggesting considerable cognitive resilience, greater midlife PM2.5 exposure was associated with lower episodic memory with no appreciable impacts on trajectory afterwards. However, recent late-life exposures were not associated with cognitive trajectories. Results suggested the adverse midlife exposure effects may not contribute to the neuropathological processes underlying cognitive decline in late-life.

KEYWORDS: Air pollution, midlife exposure, cognitive trajectory

P-0071 Residential green space, air pollution, public facility and mortality among older adults in Beijing: a longitudinal cohort study

Hui Miao[1], Yucheng Wang[1], John Ji[1]
[1]*Tsinghua University, Beijing, China*

BACKGROUND AND AIM: Urban environment is influential towards healthy aging in China. We aimed to describe trends of greenness and air pollution in Beijing, and explore their association with mortality among the elderly.

METHODS: This study included 800 participants (mean age=88.7, SD=11.1) in China Longitudinal Healthy Longevity Survey (CLHLS) who entered the cohort in 2000, 2002, 2005 and 2008 and lived in Beijing. Residential greenness was measured as satellite-derived Normalized Difference Vegetation Index (NDVI) in 1250m-radius-buffer around individual residence; cumulative NDVI was used. Last-one-year residential PM2.5, NO2 and last-peak-season O3 were obtained from both monitors and estimating models. Counts of medical, recreational and sports facilities in 5km-radii-buffers around residence were calculated. We examined the association of NDVI, PM2.5, NO2, O3, and 10-year change in NDVI and PM2.5 with mortality using Cox models, adjusted for demographic, socioeconomic and lifestyle covariates, and counts of public facilities.

RESULTS: NDVI in Beijing increased from 0.38 in 2000 to 0.45 in 2019. PM2.5 and NO2 concentration showed an inverse-U trend, with a turning point in 2013. In fully-adjusted models, 0.1-unit increase of NDVI was associated with lower mortality (HR[95%CI]: 0.656[0.485,0.885]), and similar association was found with per 10μg/m3 increase of O3 (HR[95%CI]: 0.882[0.781,0.995]). Moreover, living with increasing NDVI in the past decade was beneficial for health (HR[95%CI]: 0.402 [0.231,0.698]). Living with decreasing PM2.5 had 88% lower mortality (HR[95%CI]: 0.121[0.039,0.372]), while increasing PM2.5 had an increase of risk by 783% (HR[95%CI]: 8.831[4.688,16.635]), comparing with those living with stable exposure in the past decade. PM2.5, NO2 and accessibility to facilities were inconsistently associated with mortality.

CONCLUSIONS: In Beijing, greenness increased over decades, and air pollution started to reduce in recent years. Besides level of residential greenness and air pollution, change in these factors also matter to elderly health.

KEYWORDS: greenness, PM2.5, healthy aging, urban environment

P-0073 Association of exposure to multiple essential trace elements with frailty in Chinese elderly

Lin Meng[1], Fanjia Guo[2], Yaoyao Lin[1], Mingjuan Jin[2], Jianbing Wang[3], Mengling Tang[1], Kun Chen[2]
[1]Department of Public Health, Fourth Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [2]Department of Public Health, Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [3]Department of Public Health, National Clinical Research Center for Child Health of Children's Hospital, Zhejiang University School of Medicine, China

BACKGROUND AND AIM: Deficiency and excessive intake of essential trace elements can cause a variety of adverse outcomes. This study aims to describe the levels of 6 essential trace elements, to analyze the combined and interactive effects of 6 essential trace elements on frailty and to evaluate the association between essential trace elements and frailty in the elderly in a community in Zhejiang province, China.

METHODS: Frailty was assessed by FRAIL Scale. Essential trace elements including chromium (Cr), manganese (Mn), iron (Fe), copper (Cu), zinc (Zn) and selenium (Se) were analyzed in whole blood after acid dilution pretreatment using inductively coupled plasma mass spectrometry (ICP-MS). Ordinal logistic regression models and restricted cubic spline (RCS) were used to analyze the independent association between elements and frailty. Bayesian kernel machine regression (BKMR) models was used to examine combined and interactive effects of 6 essential trace elements on frailty.

RESULTS: Participants were determined following inclusion and exclusion criteria, and 4.2% of them were considered frail. Ordinal logistic regression models indicated that Se was inversely associated with frailty while Cu was positively associated with it. RCS showed U-shaped association between Cr, Mn and Zn and frailty, showed L-shaped association between Se and frailty, while the risk of frailty increased in a Cu dose-dependent manner, decreased in a Fe dose-dependent manner. BKMR models showed similar results, the inverse association between Cr and frailty was stronger when the remaining at lower levels. Exposure to all 6 trace elements was negatively associated with frailty.

CONCLUSIONS: Deficiency and excessive intake of Mn and Cr would increase the risk of frailty, and all 6 essential trace elements mixed exposure was negatively associated with frailty.

KEYWORDS: Essential trace elements, frailty, BKMR, multiple-exposure

P-0074 Associations of cumulative exposure to metal mixtures with metabolic dysfunction-associated fatty liver disease in a Chinese aged population

Fanjia Guo[1], Lin Meng[2], Yaoyao Lin[2], Mingjuan Jin[1], Jianbing Wang[3], Mengling Tang[2], Kun Chen[1]
[1]Department of Public Health, Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [2]Department of Public Health, Fourth Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [3]Department of Public Health, National Clinical Research Center for Child Health of Children's Hospital, Zhejiang University School of Medicine, Hangzhou, China

BACKGROUND AND AIM: Few studies have demonstrated the potential effects of metal mixtures on metabolic dysfunction-associated fatty liver disease (MAFLD). Here, we examined the associations between whole blood metal mixtures and prevalence of MAFLD among an aged population in China.

METHODS: a cross-sectional study of community-dwelling elderly adults were conducted in China. Whole blood concentrations of fourteen metals were measured by inductively coupled plasma mass spectrometry (ICP-MS). MAFLD was ascertained based on ultrasonographic evidence of hepatic steatosis and the presence of overweight/obesity, type 2 diabetes mellitus, or metabolic dysregulation. We performed logistic regression and restricted cubic spline (RCS) models to independently estimate the associations between metal concentrations and MAFLD prevalence. Environmental Risk Score (ERS) constructed by adaptive elastic net (AENET) and Bayesian kernel machine regression (BKMR) analysis were utilized to examine joint effects of metal mixtures and metal interactions on MAFLD.

RESULTS: In the models adjusting for multiple covariates, lower blood copper and higher selenium, iron and mercury were significantly associated with the elevated prevalence of MAFLD. Non-linear effects of copper, iron, magnesium, manganese and selenium on MAFLD were observed in RCS models. Similar metals (copper, selenium, zinc, iron, cadmium and mercury) were selected as crucial predictors for MAFLD prevalence by AENET and BKMR models. The association between ERS and MAFLD was estimated and the ERS was significantly associated with the elevated OR for MAFLD.

CONCLUSIONS: Our findings provide evidence that exposure to blood copper, iron, selenium and mercury are associated with the prevalence of MAFLD. Multiple metals exposure may adversely affect MAFLD, with copper, selenium, zinc, iron, cadmium and mercury being the major contributors. Further researches are needed to clarify the cumulative effects of metal mixture in a larger population.

KEYWORDS: Metals; Mixture; Metabolic dysfunction-associated fatty liver disease; ERS; BKMR analysis

P-0075 Association between whole blood essential trace elements and cognitive function in the elderly

Yaoyao Lin[1], Lin Meng[1], Fanjia Guo[2], Mingjuan Jin[2], Jianbing Wang[3], Mengling Tang[1], Kun Chen[2]
[1]Department of Public Health, Fourth Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [2]Department of Public Health, Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [3]Department of Public Health, National Clinical Research Center for Child Health of Children's Hospital, Zhejiang University School of Medicine, Hangzhou, China

BACKGROUND
Essential trace elements (ETEs) are important for keeping nervous system function. The evidence of associations between ETEs and cognitive function among the elderly was limited. Therefore, we aimed to investigate the individual and joint association between ETEs and cognitive function among the elderly.

METHODS: An elderly population from Yiwu cohort in China was available for this study. Whole blood chromium (Cr), manganese (Mn), copper (Cu), and selenium (Se) concentrations were measured by inductively coupled plasma mass spectrometry (ICP-MS). Cognitive function was assessed using the Mini-Mental State Examination (MMSE), consisting of five specific-cognitive domains of orientation, registry, attention and calculation, recall, and language and praxis. Linear regression, restricted cubic spline (RCS) analysis, and Bayesian kernel machine regression (BKMR) were performed to explore the individual and joint associations between ETEs and cognitive function.

RESULTS: Linear regression showed that high-level Cr was positively associated with MMSE score compared to the lowest quartile, especially with recall. Further RCS analysis found an inverted-U-shaped association between Cr and MMSE score. Se was positively associated with MMSE score and particularly with registry. BKMR model showed that ETEs mixture was positively associated with cognitive function, and Se was the most important contributor within the mixture. Therefore, Se demonstrated a positive additive effect on the associations for other ETEs with cognitive function.

CONCLUSIONS: Low and high levels Cr were associated with poor cognitive function, indicating that exploring an appropriate range of Cr concentration is important. Se was positively associated with cognitive function and was the most important contributor to the association between ETEs mixture and cognitive function. Moreover, Se presented the additive effect for other ETEs. Thus, it should be considered the joint effect of ETEs mixture. Our findings provided the evidence to protect cognitive function by supplementing ETEs.

P-0076 The Interactive Effects of Ambient Air Pollution and Residential Greenness on Overweight and Obesity in Older Adults: Findings from the Chinese Longitudinal Healthy Longevity Survey

Lihong Ye[1], Yuebin Lv[2], Jinhui Zhou[2], Juan Zhang[1], Xiaoming Shi[2]

[1]School of Population Medicine and Public Health, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [2]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, China

BACKGROUND AND AIM: Air pollution [e.g., Fine particulate matter < 2.5 μm (PM2.5)] is a risk factor for frailty, while there were limited ways to overcome it. Currently, cross-sectional studies of the European population found an inverse association of residential greenness with body mass index (BMI). However, in older Chinese adults, there was inconsistent evidence regarding the association between residential greenness and overweight/obesity. Additionally, the interaction of residential greenness and PM2.5 concentration on overweight/obesity remains unknown. This cohort study aimed to evaluate the interactive effects of normalized difference vegetation index (NDVI) and PM2.5 exposure on overweight/obesity among older Chinese adults.

METHODS: The study included a total of 23,431 participants aged ≥65-year-old from 2000 to 2018 wave of the Chinese Longitudinal Healthy Longevity Survey. The baseline NDVI for each participant was calculated, based on a region within 1000 m radius around their residence. PM2.5 concentration was calculated using 3-year average concentrations in 1 km×1 km grid resolution. The overweight/obesity was defined based on BMI ≥24.0 during follow-up. Cox proportional hazards models were used to estimate the effects of NDVI, PM2.5, and their interaction on overweight/obesity.

RESULTS: During 117,240 person-years follow-up, 2622 incidents of overweight/obesity were documented. The hazard ratio of overweight/obesity was 0.95 [95% confidence interval (95% CI): 0.92~0.99] for each 0.1-unit increase in baseline NDVI, 1.16(1.13~1.19) for each 10 μg/m³ increase in 3-year average PM2.5, and 1.04 (1.02~1.06) for the interaction term. In the sensitivity analyses, the interaction of NDVI and PM2.5 on BMI remained significant.

CONCLUSIONS: This nation-wide prospective cohort study revealed the interaction effect of greenness and air pollution on overweight/obesity, which deserve the potential to lead to the lobbying of governments to determine new ways to reduce the burden of PM2.5 air pollution for older Chinese adults.

P-0081 Multiple air pollutants co-exposure and health among the older adults in China

John Ji[1], Linxin Liu[1], Yi Zeng[2,3]
[1]Tsinghua University, Beijing, China, [2]Peking University, Beijing, China, [3]Duke University, Durham, USA

BACKGROUND AND AIM: We aim to examine the association between ambient air pollutants defined by the WHO guideline AQG (PM2.5, NO2, O3) and mortality, cognitive function, and activities of daily living (ADL) disability in Chinese older adults.

METHODS: We used the 2008-2018 cohort of the Chinese Longitudinal Healthy Longevity Study (CLHLS). We included 11 835 participants, covering 23 provinces of China. We ran the Cox proportional hazards model to examine the association between the ambient air pollutants exposure and all-cause mortality, generalized estimating equation to test the association between air pollutants and repeatedly measured cognitive function and ADL disability.

RESULTS: The participants had a mean age of 87 (SD:11) and 57% were females. The annual average PM2.5, NO2, and O3 were higher in northern China than in southern China. The proportion exposed under the AQG level in the last year was 0% for PM2.5, 23.7% for NO2, and 0.7% for O3. Each 10 μg/m3 increase in PM2.5 was associated with higher mortality risk in both the single-pollutant and three-pollutant model [hazard ratio: 1.17, 95% confidence interval (CI): 1.15-1.19]. NO2 was not significantly associated with mortality risk and O3 was protective for mortality in three-pollutant model. Each 10 μg/m3 increase in O3 was associated with higher odds of cognitive impairment [Odds ratio (OR): 1.04, 95% CI: 1.01-1.07] in three-pollutant model. Each 10 μg/m3 increase in PM2.5 and NO2 were both associated with higher odds of ADL disability [OR (95% CI): 1.03 (1.01, 1.06) and 1.24 (1.20, 1.28) respectively] in three-pollutant model.
CONCLUSION: China has diverse air pollution levels depending on geographical areas, and do not meet WHO AQG in the majority of regions. PM2.5 was dominant for mortality outcome, while O3 and NO2 were dominant for cognitive impairment, and ADL disability outcomes, respectively.

KEYWORDS: Air pollution, mortality, cognitive function, ADL, China

P-0082 Interactive effects of physical activity and air pollution on incident dementia

Wei Xu[1], Jason Fletcher[1], Kristen Malecki[1], Ozioma Okonkwo[1]
[1]*University of Wisconsin Madison, Madison, USA*

BACKGROUND AND AIM: Accumulating evidence suggests that physical activity reduces dementia risk, but the extent to which this can be offset by residential air pollution is unknown. The aim is to determine whether residential air pollution attenuates the beneficial effects against the risk of incident dementia induced by regular physical activity.

METHODS: A population-based longitudinal study that included adults aged between 40 and 74 years without dementia at baseline. Participants were recruited to the UK Biobank study between 2006 and 2010 and followed up for an average of 9.0 years. Physical activity was categorized into regular and non-regular and residential overall air pollution with Q1 (lowest quartile, 25.6-43.6 µg/m3) to Q4 (highest quartile, 60.8-280.1 µg/m3) exposure categories. Associations between physical activity and air pollution and risk of incident dementias were assessed using Cox proportional hazards regression models.

RESULTS: 502 222 individuals (mean [SD] age, 56.5 [8.1] years; 45.6% were women) were included in the study, among which 2 502 individuals were subsequently diagnosed with all-cause dementia. Results of main effects indicate that not engaging in regular physical activity was associated with a 15% increase in dementia risk (adjusted hazard ratio, 1.15; 95%CI, 1.05-1.26) while exposure to the highest level of air pollution was associated with a 29% increase in the risk (adjusted hazard ratio, 1.29; 95%CI, 1.14-1.46). Hazard ratios associated with no regular physical activity decreased as air pollution increased; however, there was no significant interaction between the two factors (p = .05).

CONCLUSIONS: Among mid-age adults without dementia, regular physical activity was significantly associated with lower dementia risk and higher air pollution were significantly associated with higher risk. Although the benefit of physical activity was smaller among participants exposed to higher air pollution, we found no significant interaction effects.

KEYWORDS: air pollution; physical activity; incident dementia

P-0083 Mapping the complex systems that connects the urban environment to cognitive decline in older adults: a group model building study

Ione Avila-Palencia[1], Leandro Garcia[1], Claire Cleland[1], Bernadette McGuinness[1], Conor Meehan[2], Ruth F. Hunter[1]
[1]*Centre for Public Health, School of Medicine, Dentistry and Biomedical Sciences, Queen's University Belfast, Belfast, UK,* [2]*Innovation Lab of the Northern Irish Civil Service, Belfast, UK*

BACKGROUND AND AIM: The number of people living with dementia and Mild Cognitive Impairment (MCI) is increasing. A supportive urban environment can prevent or delay the progress of cognitive decline. There is evidence for the existence of mechanistic pathways between the urban environment and cognitive decline, but the interrelations between these pathways are unclear. In this study, we aimed to map the mechanistic pathways by which urban environment factors impact cognitive decline in older adults.

METHODS: This study was part of the Supportive environments for Physical and social Activity, healthy ageing and CognitivE health (SPACE) project. A 2-day workshop with the SPACE investigators was conducted based on the Group Model Building (GMB) methodology. The workshop aimed to create a causal-loop diagram (CLD) that identifies established and potential urban environment, lifestyle, health, and physiological determinants of cognitive decline in older adults. A facilitation team guided the activities. The workshop was held online following appropriately adapted scripts. After the workshop, the modelling team reviewed the CLD to ensure that main potential causal pathways and mechanisms were captured.

RESULTS: During the workshop, 12 experts from 10 different disciplines identified 83 factors and 221 connections between them. After review, the CLD presented 50 factors and 154 connections. All factors were classified in 10 main groups: urban design, social environment, travel behaviours, urban design by-products, lifestyle, disease/physiology, mental health conditions, exogenous factors, and cognitive decline outcomes. The main output was a CLD of the complex system of how the urban environment can influence cognitive decline in older adults.

CONCLUSIONS: The CLD detailed the plausible causal pathways between the urban environment and cognitive decline. Our findings suggested that GMB can engage experts and help them view problems through the lens of complex systems.

KEYWORDS: cognitive decline, urban environment, group model building

P-0085 Air pollution protective measures at personal-level affecting health outcomes: A systematic review and meta-analysis

Surabhi Shah[1], Eunji Kim, Kyoung-Nam Kim, Eunhee Ha
[1]*Ewha Womans University College of Medicine, Seoul, Republic of Korea*

BACKGROUND: Evidence for the effect of health-protective measures from air pollution at the individual level is relatively scarce. We performed a systematic review and meta-analysis to investigate the effect of personal protective measures for air pollution on various health outcomes.

METHODS: We searched PubMed, Scopus, and Web of Science to find randomized controlled trial studies investigating the effect of personal protective measures for air pollution on health outcomes. Two authors independently searched and selected studies, extracted information, and assessed each study's quality and risk of bias. Meta-analyses were performed when three or more studies were available for specific pair of protective measure and health outcome.

RESULTS: Lung function was higher in groups applying air purifiers than control groups with sham/no filter: forced expiratory volume in 1 second (FEV1) by 0.25 L [95% confidence intervals (CI): 0.01, 0.49]. The application of air-purifying respirators was associated with increased heart rate variability: the root mean square of successive differences between normal heartbeats (rMSSD) by 0.36 (95% CI: 0.13, 0.59). for other pairs of measures and health outcomes, evidence was insufficient.
CONCLUSION: Our findings suggest that air purifiers and air-purifying respirators can serve as an efficient protective measure for respiratory and cardiovascular health, respectively.

KEYWORDS: air pollution, personal-level protective measures

P-0092 Association between Long-Term Ambient PM2.5 Exposure and Cardiovascular Outcomes among U.S. Hemodialysis Patients

Yuzhi Xi[1,2,3], David Richardson[3], Abhijit Kshirsagar[4,5], Timothy Wade[6], Jennifer Flythe[4,5], Eric Whitsel[3,5], Ana Rappold[6]
[1]Emory University, Atlanta, USA, [2]Oak Ridge Institute for Science and Education at the USA Environmental Protection Agency, National Health and Environmental Effects Research Laboratory, Environmental Public Health Division, Research Triangle Park, USA, [3]Department of Epidemiology Gillings School of Global Public Health UNC Chapel Hill, Chapel Hill, USA, [4]University of North Carolina Kidney Center, Division of Nephrology and Hypertension, Department of Medicine, Chapel Hill, USA, [5]Department of Medicine,School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, USA, [6]USA Environmental Protection Agency, Center for Public Health and Environmental Assessment, Research Triangle Park, USA

BACKGROUND AND AIM: Ambient PM2.5 is a ubiquitous air pollutant with established adverse cardiovascular (CV) effects. However, quantitative estimates of PM2.5 exposure associations on CV outcomes in susceptible populations are limited. This study assessed the impact of long-term PM2.5 on CV events and cardiovascular disease (CVD)-specific mortality among patients receiving maintenance in-center hemodialysis (HD).

METHODS: We conducted a retrospective cohort study with 314,079 adult kidney failure patients initiating HD between 2011 and 2016 identified from the United State Renal Data System. Estimated daily ZIP code-level PM2.5 concentrations were used to calculate each participant's annual-average PM2.5 exposure based on the dialysis clinics visited during the 365 days prior to the outcome. CV event and CVD-specific mortality were ascertained based on ICD-9/ICD-10 diagnostic codes and recorded cause of death from form 2746. Discrete time hazards models were used to estimate hazards ratios (HRs) per 1 µg/m3 in annual-average PM2.5 adjusting for temperature, humidity, day of the week, season, age at baseline, race, employment status, and geographic region. Effect measure modification was assessed for age, sex, race, and baseline comorbidities.

RESULTS: Annual-average PM2.5 of 1 µg/m3 was associated with increased hazard rates in CV events (HR: 1.02, 95% CI: 1.01, 1.02) and CVD-specific mortality (1.02, 95% CI: 1.02, 1.03). The association was more pronounced for people who initiated dialysis at an older age, had COPD at baseline, or were Asian. Evidence of effect modification was also observed across strata of race, and other baseline comorbidities.

CONCLUSIONS: Long-term ambient PM2.5 exposure was positively associated with CV outcomes among patients receiving maintenance in-center HD. Patients who had advanced age, COPD, or reported to be Asian, appeared to be more susceptible to long-term PM2.5 adverse effects.

KEYWORDS: Air pollution, long-term, vulnerable population, dialysis patients

P-0095 Short-Term Coarse Particulate Exposure and Daily Cardio-Respiratory Hospital Admissions in the Helsinki Capital Region

Enembe Okokon[1], Pekka Tiittanen[2], Timo Lanki[2,3]
[1]University of Calabar, Calabar, Nigeria, [2]Finnish Institute for Health and Welfare, Kuopio, Finland, [3]University of Eastern Finland, Kuopio, Finland

BACKGROUND AND AIM: Short-term exposure to coarse inhalable particles (2.5 µg/m3>PMcoarse<10 µg/m3) has been suggested to increase the risk of respiratory disease independently of fine particles, but studies present mixed findings which are even less clear for other outcomes.
This study aims to assess the relationship between short-term exposure to PMcoarse and total admissions for cardio-pulmonary diseases.

METHODS: We conducted a seventeen-year (01/2001-12/2017) time-series study of the daily admissions for cardio-respiratory disease in relation to the mean levels of coarse particles. We obtained air pollution data from the Helsinki Region Environmental Services Authority, meteorological data from the Finnish Meteorological Institute, and hospital exit records from the Finnish Institute for Health and Welfare. We modelled the association between particles and cardiorespiratory admissions using log-linked quasi-Poisson regression. Penalised splines were used to adjust for the time-trend and the meteorological variables. These models were also adjusted for the weekday, pollen concentration, and influenza outbreaks. Different lag structures were explored in both single-pollutant and multipollutant models. The multipollutant models were simultaneously adjusted for PM2.5, NO2, and O3.

RESULTS: The mean(standard deviation) concentration of PMcoarse was 6.6(5.9) (µg/m3), while the mean (standard deviation) daily numbers of cardiovascular and respiratory admissions were 25.9(7.3) and 21.3(7.4), respectively. A 10 µg/m3 increase in the same day PMcoarse was associated with a 1.7% (95% CI, 0.4%—3.1%) and a 1.9% (95% CI, 0.5%—3.4%) excess daily risk of respiratory admissions in the single-pollutant and multipollutant models, respectively; same-day excess cardiovascular admissions risks were 0.6% (95% CI, -0.5%—1.7%) and 0.3% (95% CI, -0.9%—1.4%) in similar models.

CONCLUSIONS: Short-term exposure to PMcoarse can increase respiratory admission risks independently of co-pollutants but has a less determinate effect on cardiovascular admissions. A guideline framework should be considered for PMcoarse.

KEYWORDS: Coarse Particles, Cardiovascular Admissions, Respiratory Admissions, Time-Series, Fine Particles

P-0096 Particulate matter, albumin/creatinine ratio, and chronic kidney disease in a prospective cohort study

Ta-Yuan Chang[1], MS Ai-Hua Lee[1], MS Zhi-Ling Lin[1], Tsai-Chung Li,[1], Chiu-Shong Liu[2], Cheng-Chieh Lin[1]
[1]China Medical University, Taichung, Taiwan, [2]China Medical University Hospital, Taichung, Taiwan

BACKGROUND: Many studies have investigated the association between exposure to particulate matter (PM) and kidney dysfunction, but the relationship is inconsistent due to the variations in exposure assessment, the use of renal-function indices, and study design.
OBJECTIVES: This study elucidated the associations between exposure to PM10, PM2.5, and PM1 with albumin/creatinine ratio (ACR) and the incidence of chronic kidney disease (CKD) in a community-based cohort in Taiwan.

METHODS: A total of 704 residents living in Taichung were recruited as study subjects at the baseline of 2004 and followed up to the end of 2018. Questionnaire and health examination was used to collect personal information and renal-function indices at baseline and follow-up. Land-use regression models were established to predict individual levels of PM10, PM2.5, and PM1 annually during studying periods. The multivariable linear regression and Cox regression were conducted to investigate the associations between PM exposures, ACR, and the incident CKD (creatinine-based estimated glomerular filtration rate, [eGFRcr] < 60ml/min/1.73m2).

RESULTS: We found that an increase of 1 μg/m3 in PM10, PM2.5, and PM1 was associated with the decreased ACR of 1.10±1.14 mg/g (p=0.080), 4.66±2.17 mg/g (p=0.032), and 6.05±2.82 mg/g (p=0.032), respectively. The similar associations were identified for the cumulative exposure of 1 μg/m3-year to PM10, PM2.5, and PM1, which decreased the ACR of 0.14±0.10 mg/g (p=0.157), 0.55±0.27 mg/g (p=0.040), and 0.72±0.35 mg/g (p=0.040), respectively. Per 1 μg/m3 increase in PM10, PM2.5, and PM1 was associated with the elevated risk of 1.07-fold (95% confidence interval [CI]=1.00-1.15, p=0.055), 1.19-fold (95% CI=1.04-1.37, p=0.011), and 1.26-fold (95% CI=1.05-1.50, p=0.011) in the incident CKD, respectively.

CONCLUSIONS: The present study showed that exposure to PM2.5 and PM1 was associated with the decreased renal function to increase the risk of developing CKD.

P-0097 Fine particulate matter infiltration at skilled nursing facilities during wildfire season in the Western USA

Ethan Walker[1], Luke Montrose[2], Curtis Noonan[1]
[1]*Center for Population Health Research, University of Montana, Missoula, USA,* [2]*Department of Public Health and Population Science, Boise State University, Boise, USA*

BACKGROUND AND AIM: Wildfire air pollution is a growing public health concern as wildfires increase in size, intensity, and duration in the USA (US). Residents of skilled nursing facilities (SNFs) are vulnerable to wildfire smoke due to common pre-existing health conditions and advanced age of these populations. We assessed the impact of wildfire smoke on SNFs by estimating ambient fine particulate matter ($PM_{2.5}$) infiltration into SNFs during wildfire season.

METHODS: We measured continuous outdoor and indoor $PM_{2.5}$ concentrations from July-October 2021 at six SNFs in the US states of Idaho and Montana using PurpleAir monitors. We calculated infiltration efficiency (range 0-1; higher values indicate more ambient $PM_{2.5}$ infiltration to the indoor environment) at each facility using paired outdoor/indoor $PM_{2.5}$ samples in a validated recursive modeling approach. Analyses were conducted separately for each facility, by time of day (8am-5pm work hours versus after hours), and by days impacted by wildfire smoke.

RESULTS: Median outdoor $PM_{2.5}$ at the SNFs ranged from 7.9 μg/m³ (25th percentile=4.4, 75th percentile=21.6) to 16.0 μg/m³ (25th percentile=7.4, 75th percentile=30.6). Median indoor $PM_{2.5}$ at the SNFs ranged from 2.1 μg/m³ (25th percentile=1.7, 75th percentile=3.9) to 8.4 μg/m³ (25th percentile=2.0, 75th percentile=15.8). Infiltration efficiency at the facilities ranged from 0.13 (95% Confidence Interval: 0.10, 0.18) to 0.74 (95% Confidence Interval: 0.64, 0.85). Infiltration efficiency was similar during work hours versus after hours, but was higher during wildfire-impacted days than non-wildfire-impacted days for all but one facility.

CONCLUSIONS: The high variability of indoor $PM_{2.5}$ and infiltration efficiency across the facilities suggests that indoor exposures to wildfire smoke may be a modifiable risk factor for SNF residents. Future work will assess building characteristics and behavioral factors among residents and staff that may be related to wildfire smoke infiltration.

KEYWORDS: smoke, wildfires, indoor air pollution, vulnerable populations, infiltration efficiency, $PM_{2.5}$

P-0099 Educational intervention to promote air pollution knowledge and personal exposure mitigation strategies using wearable sensors

Trang VoPham[1,2], Eric S. Kim[3,4,5], Francine Laden[6,7,8], Jaime E. Hart[6,8]

[1]Epidemiology Program, Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, USA, [2]Department of Epidemiology, University of Washington, Seattle, USA, [3]Department of Psychology, The University of British Columbia, Vancouver, Canada, [4]Human Flourishing Program, Harvard Institute for Quantitative Social Science, Harvard University, Cambridge, USA, [5]Lee Kum Sheung Center for Health and Happiness, Harvard T.H. Chan School of Public Health, Boston, USA, [6]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [7]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [8]Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA

BACKGROUND AND AIM: Although strategies to reduce air pollution have focused on policy regulations and population-level controls, personal exposure mitigation is an approach that has not been well-explored. The aim of this study was to determine the feasibility of conducting an educational intervention to promote knowledge regarding air pollution, its health effects, and preventive behaviors.

METHODS: We recruited participants from Seattle, Washington from September-November 2021 for a 5-week study. Participants were asked to use Plume Labs Flow 2 wearable air pollution sensors, watch educational videos (intervention at week 3), and receive Air Quality Index (AQI) alerts. Questionnaires were administered pre- and post-intervention to assess air pollution knowledge and Health Belief Model (HBM) constructs for perceived susceptibility, severity, benefits, barriers, cues to action, and self-efficacy. McNemar and signed-rank tests were used to determine pre- and post-intervention differences.

RESULTS: A total of n=20 participants were included in this study (n=18 were never-smokers). Participants were knowledgeable regarding air pollution (≥35% of participants responded correctly to any given knowledge item at baseline). There was an increase in knowledge of AQI (of the 7 participants who answered incorrectly at pre-intervention, 6 answered correctly at post-intervention; p=0.01). There were no differences in HBM constructs, although pre-intervention responses showed participants perceived air pollution as a personal health threat (perceived severity mean score 8.7 ± 1.3; score range 1-10). Post-intervention personal NO2 levels (mean 11.62 ppb ± 5.89) were lower compared to pre-intervention levels (mean 13.49 ppb ± 3.00) (p=0.02). There were no differences in VOCs, PM1, PM2.5, or PM10 exposures at post-intervention.

CONCLUSIONS: This study demonstrated high feasibility in conducting an educational intervention to promote air pollution knowledge and reduce NO2 exposure. Future research could scale this intervention to subgroups disproportionately impacted by air pollution (e.g., vulnerable populations).

KEYWORDS: intervention; air pollution; sensors; wearables; behavioral science

P-0107 A hybrid model for estimating number concentrations of ultrafine particles in central Taiwan

Li-Hao Young[1], Wei-Ting Chen[2], Chau-Ren Jung[3,4]

[1]Department of Occupational Safety and Health, China Medical University, Taichung, Taiwan, [2]Department of Atmospheric Sciences, National Taiwan University, Taipei, Taiwan, [3]Department of Public Health, China Medical University, Taichung, Taiwan, [4]Japan Environment and Children's Study Programme Office, National Institute for Environmental Studies, Tsukuba, Japan

BACKGROUND AND AIM: The epidemiological studies for assessing ultrafine particles (UFP) and health effects are scarce. The reasons are that the instrument for measuring UFP is expensive and the previous studies generally relied on a small number of fixed monitoring stations or short-term measurements. Modeling is a cost-effective measure to precisely estimate personal concentration in large-scale epidemiological studies, while the previous UFP estimation generally relied on the land-use regression model (LUR) and lacked temporal resolution. In this study, we conducted in-situ measurements for UFP in Taichung city, Taiwan, and developed a UFP estimation model by using machine learning algorithms.

METHODS: A scanning mobility particle sizer (SMPS Model 5.500, GIMM Aerosol Technik, Gmbh, Germany) was used to measure UFP number concentrations hourly in two sites (urban and rural sites) from 2017 to 2021. Random forest, XGBoost, and deep neural network were used to build the model. Ten-fold cross-validation was used to evaluate model performance. Coefficient of determination (R^2) and normalized root mean square error (nRMSE) were utilized to compare models.

RESULTS: A total of 1488 observations were collected. The average number concentrations of UFP was 23505.4±14643.9 (mean±sd). The XGBoost model had the best performance with a fitting R^2 of 1.00 (nRMSE: 0.20%) and a cross-validation R^2 of 0.63 (RMSE: 3.84%). The top important variables were temperature, surface pressure, Julian date, nitrogen dioxide, wind direction (X direction), fine particulate matter, sulfur dioxide, relative humidity, ozone, year, and aerosol optical depth (AOD).

CONCLUSIONS: Our results provided basic descriptions of UFP in Taiwan and identified several important features for UFP. Although the XGBoost model displayed overfitting, it still outperformed the previous models and provided accurate estimates. These estimates can be used to assess both the short-term and long-term effects of UFP on health outcomes.

KEYWORDS: Aerosol optical depth, estimation model, machine learning, ultrafine particles

P-0113 Household Cooking Fuel Choices and Associated Factors in a Rural and Peri-Urban Community in Western Kenya

Judith Mangeni[1], Diana Menya[1], James Mwitari[2], Matt Shupler[3], Rachel Anderson de Cuevas3[3], ms Edna Sang[1], Esilaba Anabwani[1], Noelle Sutton[1], Emily Nix[3], Sarah Ronzi[3], Dan Pope[3], Elisa Puzzolo[3], Kwaku Poku Poku Asante[4]
[1]Moi University, Eldoret, Kenya, [2]Kenya Medical Research Institute, Nairobi, Kenya, [3]University of Liverpool, Liverpool, UK, [4]Kintampo Health Research Centre., Kintampo, Ghana

BACKGROUND AND AIM
Polluting fuels such as biomass and kerosene are used for cooking by approximately 85% of the population in sub-Saharan Africa (SSA) despite the well-known associated adverse health effects. Many governments across SSA aim to scale up domestic use of liquefied petroleum gas (LPG), a cleaner-burning fuel in terms of black carbon and fine particulate matter emissions, to promote public health and protect the environment by reducing deforestation. We sought to determine factors associated with household fuel choice in-order to make recommendations that could promote uptake of LPG in rural and peri-urban settings within Uasin Gishu County.

METHODS: The study was part of the CLEAN-Air(Africa) project designed to address barriers to transitioning populations way from reliance on polluting biomass for cooking. A quantitative survey was administered to over 2000 households in peri-urban and rural sub-counties of Uasin Gishu County, West Kenya, to determine cooking characteristics and factors associated with the primary cooking fuel choice (biomass versus LPG).

RESULTS: We found that the majority (72%) of the households still use biomass as a primary fuel while about one third use clean fuels. Predictors for use of clean fuel include; residing in a peri-urban area (aOR 2.5,C.I: 1.933-3.162), education (aOR: 1.9, C.I 1.095-3.602), connection to electricity (aOR: 2.2, C.I: 1.649 -3.189), regular income (aOR:1.4,C.I: 1.117-1.886). Supply factors such as the ease of accessing refills affects duration of LPG use.

CONCLUSIONS: Urbanization at a sub-county level may lead to increases in the use of LPG for cooking. Socio-economic factors and LPG supply factors also predict LPG use. Policies that would increase the availability of LPG to rural communities need to be enacted in order to reduce the time and transportation costs that are likely to affect access and hence low usage.

KEYWORDS: Cooking fuel, factors associated, peri-urban and rural, Western Kenya

P-0121 Particle Radioactivity: A potential driving factor for PM2.5 toxicity

Rebecca Stern[1], Petros Koutrakis[1], Haroula Baliaka[2], Man Liu[1], Choong Min Kang[1], Spyros Pandis[2], Athanasios Nenes[2], Carol Zilli Vieira[1], Longxiang Li[1]
[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]University of Patras, Patras, Greece

BACKGROUND AND AIM: Fine particulate matter (PM2.5) is associated with adverse human health outcomes. However, little is known about the mechanism(s) for the toxicity or which components of the PM2.5 cause the health effects. The ability of particles to cause oxidative damage may play a role.

METHODS: We evaluated the associations between the oxidative potential (OP) of PM2.5 particles (N=60) as measured by the dithiothreitol (DTT) assay, and different properties of these particles, including α- and β-activity, PM2.5 mass, and chemical components.

RESULTS: We found that Pearson correlation coefficients (r) between OP and the different variables were the strongest for α- and β-activities (Pearson's r=0.49 and 0.47, respectively), with a weaker correlation for PM2.5 mass (Pearson's r=0.33). Correlations between OP and the 25 PM2.5 elemental concentrations were weaker, ranging from 0.32 for Zinc to -0.21 for Barium. Bivariate regression models including radiation (either α- or β-activity) and one other variable (mass or chemical component) showed that only the radiation component was a significant predictor ($p<0.001$). None of the PM2.5 mass and elemental concentrations were significant.

CONCLUSIONS: The findings here suggest that radionuclides play a role in the toxicity of the particles. Gross α- and β-activity may help explain the association found between PM2.5 and detrimental health outcomes. This is the first study to link particle radioactivity to an oxidative stress assay.

P-0124 Causal relationship between PM 2.5 and diabetes mellitus: Two sample Mendelian Randomization using MR-Base platform

Eunji Kim[1], Joyce Mary Kim[1], Whanhee Lee[1], Jongmin Oh[1], Eunhee Ha[1]
[1]*Ewha Womans University, Seoul, Republic of Korea*

BACKGROUND AND AIM: Many studies have shown air pollution has emerged as one of the major environmental risk factors for diabetes mellitus; however, studies on the causal relationship between air pollution and diabetes mellitus based on genetic approaches are scarce. The study estimated the causal relationship between diabetes and fine particulate matter (PM2.5) using Mendelian randomization (MR).

METHODS: We collected genetic data from European ancestry publicly available genome wide association studies (GWAS) summary data through the MR-BASE repository. The IEU GWAS information output (PM2.5) from the Single nucleotide polymorphisms (SNPs) GWAS pipeline using pheasant-derived variables (Consortium=MRC-IEU, sample size: 423,796). The annual estimates of PM2.5 (2010) were modeled for each address using a Land Use Regression model developed as part of the European Study of Cohorts for Air Pollution Effects. Diabetes GWAS information (Consortium=MRC-IEU, sample size: 461,578) were used, and the genetic variants were used as the instrumental variables (IVs). We performed three representative MR

METHODS: Inverse Variance Weighted regression (IVW), Egger, and Weighted median for causal inference using genetic variants. Furthermore, we used a novel method called MR Mixture to identify outlier SNPs.

RESULTS: From the IVW method, we revealed the causal relationship between PM2.5 and diabetes (Odds ratio [OR]: 1.041, 95% CI: 1.008-1.076, p=0.016), and the finding was substantiated by the absence of any directional horizontal pleiotropy through MR-Egger regression (β=0.016, p=0.687). From the IVW fixed-effect method (i.e. one of the MR Mixture methods), we excluded outlier SNP (rs1537371) and showed the best predictive model (AUC=0.72) with a causal relationship between PM2.5 and diabetes (OR: 1.028, 95% CI: 1.006-1.049, p=0.012).

CONCLUSIONS: We identified the hypothesis that there is a causal relationship between PM2.5 and diabetes in the European population, using MR methods.

P-0125 Short-term effects of fine particulate matter constituents on pulmonary function among adolescents

Yoshiko Yoda[1], Hiroshi Takagi[2], Takeshi Ito[2], Junko Wakamatsu[2], Ryohei Nakatsubo[3], Yosuke Horie[3], Takatoshi Hiraki[3], Satoru Kobayashi[1], Masayuki Shima[1]

[1]Hyogo Medical University, Nishinomiya, Japan, [2]National Institute of Technology, Yuge College, Kamijima, Japan, [3]Hyogo Prefectural Institute of Environmental Sciences, Kobe, Japan

BACKGROUND: Expose to fine particle matter (PM2.5) has been associated with adverse effects on pulmonary function. Especially, it has been recently focused on the effects of PM2.5 constituents on human health. However, it is unclear whether healthy adolescents are affected by the expose to PM2.5 constituents in daily life. We investigated the association between PM2.5 constituents and pulmonary function in healthy adolescents.

METHODS: We conducted a panel study for about one month, in every spring and fall from 2014 to 2016, in Yuge Island, Japan. Pulmonary function measurements were conducted every morning in 48 healthy adolescents. PM2.5 samples were collected every 24 h during the study period, and the concentrations of 27 constituents in PM2.5 were analyzed. Mixed effects model were used to estimate the associations of pulmonary function with the average concentrations of PM2.5 constituents for 24h before a pulmonary function measurements.

RESULTS: The mean (SD) of PM2.5 mass concentration was14.9 (7.5) µg/m3 during the study period. A total of 4155 pulmonary function measurements were conducted by 48 healthy students. The peak expiratory flow (PEF) decreased significantly in relation to increases in concentrations of 12 constituents in PM2.5. The largest decrease of PEF with an interquartile range increase was observed for potassium (-4.01L/min [95% confidence interval: -6.07, -1.94]). The force expiratory volume in 1 s (FEV1) also decreased significantly in relation to increases in 11 constituents in PM2.5, and potassium had the most prominent effects among the constituents in PM2.5.

CONCLUSIONS: Our results suggest that many constituents in PM2.5 were associated with significant reduction in pulmonary function among healthy adolescents. Further studies are needed to clarify the source of the constituents in PM2.5 that affect respiratory system, and the reduction of the substances is desired to prevent the health effects of PM2.5.

P-0128 Triggering of ST-elevation myocardial infarction by ultrafine particles in New York: changes following Tier 3 vehicle introduction

Catherine Yount[1], Philip K Hopke, Mark Utell, Sally W Thurston, Frederick Ling, Yunle Chen, David Chalupa, Shao Lin, Xinlei Deng, David Q Rich
[1]*University of Rochester, Rochester, USA*

BACKGROUND AND AIM: Previously, we found increased rates of ST-elevation myocardial infarction (STEMI) associated with increased ultrafine particle (UFP; <100nm) concentrations in the previous few hours in Rochester, New York. Rates were higher after air quality policies and a recession reduced pollutant concentrations (2014-2016 versus 2005-2013), suggesting PM composition had become more toxic. Tier 3 light duty vehicles, which should produce less primary organic aerosols and oxidizable gaseous compounds, likely making PM less toxic, were introduced in 2017. Because of this, we hypothesized we would observe a lower relative STEMI rate in 2017-2019 than 2014-2016.

METHODS: Using STEMI events treated at the University of Rochester Medical Center (2014-2019), local UFP and other pollutant concentrations, a case-crossover design, and conditional logistic regression models, we separately estimated the rate of STEMI associated with increased UFP and other pollutants in the previous hours and days in the 2014-2016 and 2017-2019 periods.

RESULTS: An increased rate of STEMI was associated with each 3121 particles/cm3 increase in UFP concentration in 2014-2016 (lag hour 0: OR=1.23; 95% CI = 1.08, 1.41), but not in 2017-2019 (OR=0.93; 95% CI = 0.79, 1.09). There were similar patterns for black carbon, UFP11-50nm, and UFP51-100nm. In contrast, increased rates of STEMI were associated with 0.6ppb increases in SO2 concentrations in the previous 120 hours in both periods (2014-2016: OR=1.25, 95% CI = 1.00, 1.36; 2017-2019: OR=1.22, 95% CI = 0.88, 1.68).

CONCLUSIONS: Greater rates of STEMI were associated with short term increases in concentrations of UFP and other motor vehicle related pollutants before Tier 3 introduction (2014-2016), but not afterwards (2017-2019). This change may be due to changes in PM composition, to increased exposure misclassification and greater underestimation of effects from 2017-2019, and/or changes in therapeutic approaches such as preventive aspirin use.

KEYWORDS: myocardial infarction, air pollution, ultrafine particles, case-crossover

P-0129 Ambient fine particulate matter exposure and risk of incident breast cancer in the NIH-AARP Diet and Health Study

Alexandra White[1], Jared Fisher[2], Neal Freedman[3], Joel Kaufman[4], Debra Silverman[2], Rena Jones[2]
[1]Epidemiology Branch, National Institute of Environmental Health Sciences, Research Triangle Park, USA, [2]Occupational and Environmental Epidemiology Branch, National Cancer Institute, Rockville, USA, [3]Metabolic Epidemiology Branch, National Cancer Institute, Rockville, USA, [4]Environment and Occupational Health Sciences, University of Washington, Seattle, USA

BACKGROUND AND AIM: Fine particulate matter (PM2.5) has been inconsistently associated with breast cancer risk, however few studies have considered historic exposure levels which may be more relevant given the long latency of breast cancer.

METHODS: Outdoor residential PM2.5 concentrations were estimated using a nationwide spatiotemporal model for women in the NIH-AARP Diet and Health Study, a cohort located in 6 states (California, Florida, Louisiana, New Jersey, North Carolina, and Pennsylvania) and 2 metropolitan areas (Atlanta, Georgia, and Detroit, Michigan) and enrolled in 1995-1996. Annual average PM2.5 concentrations were estimated for a 5-year historical period 10 years prior to enrollment (1980-1984). We used Cox regression to estimate adjusted hazard ratios (HRs) and 95% confidence intervals (95% CIs) for the association between a 10µg/m3 increase in PM2.5 and incident breast cancer risk overall and by estrogen receptor (ER) status and extent of the tumor (invasive vs. ductal carcinoma in situ (DCIS)). Models were adjusted for age, body mass index, race/ethnicity, smoking status and catchment area. We also conducted analyses stratified by catchment area.

RESULTS: With follow-up through 2011, 13,246 breast cancer cases were diagnosed. A 10ug/m3 increase in PM2.5 was significantly associated with overall breast cancer risk (HR=1.07, 95% CI:1.01-1.13). No significant differences were observed between invasive tumors and DCIS (p-for-heterogeneity=0.40). The association was evident for ER+ tumors (HR=1.09, 95% CI:1.02-1.17), but not ER- tumors (HR=0.97, 95% CI:0.80-1.17; p-for-heterogeneity=0.31). Overall breast cancer HRs were >1 across all cohort catchment areas; ranging from a HR=1.47 (95%CI: 0.73-3.00) for Georgia to a HR=1.04 (95% CI:0.97-1.11) for California (p-for-heterogeneity=0.66).

CONCLUSIONS: In this large U.S. cohort with historical air pollutant exposure, PM2.5 was associated with ER+ breast cancer risk. Future work should consider region-specific associations and the potential contribution of PM2.5 chemical constituency in modifying the observed association with breast cancer.

KEYWORDS: breast cancer, outdoor air pollution

P-0135 Source apportionment of ambient PM2.5 using positive matrix factorization (PMF) model in Cape Town, South Africa

Anna Alfeus[1], Adewale Adeyemi[2], Joyce Shirinde[2], Peter Molnar[3], Johan Boman[4], Philip Hopke[5], Janine Wichmann[2]
[1]University of Namibia, Oshakati, Namibia, [2]School of Health System and Public health, University of Pretoria, Pretoria, South Africa, [3]Department of Occupational and Environmental Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, SE-405 30 Götenborg, Sweden, [4]Department of Chemistry and Molecular Biology, University of Gothenburg, SE-412 96 Götenborg, Sweden, [5]Department of Public Health Sciences, University of Rochester School of Medicine and Dentistry, Rochester, USA

BACKGROUND AND AIM: Particulate matter (PM) with an aerodynamic diameter <2.5µm (PM2.5) is an indicator of air pollution that threatens global population health. In 2017, exposure to PM2.5 was attributed to 2.9 million premature deaths and 83 million DALYs globally. The dearth of data on PM2.5 sources and quantification presents a significant gap in knowledge for Africa and South Africa in particular. This study identified the sources and their contributions to ambient PM2.5 in Cape Town, South Africa.

METHODS: PM2.5 samples were collected every third day for 121 days in an urban background site in the Kraaifontein suburb in Cape Town. Filters were analyzed for black carbon, organic carbon, and trace elements using Model OT21 Optical Transmissometer and a Xepos 5 Energy-dispersive x-ray fluorescence (EDXRF) spectrometer, respectively. Concentration and uncertainty data for PM2.5, BC, OC, and trace elements (S, Cl, Si, K, Ca, Ti, V, Fe, Ni, Cu, Zn, As, Se, Br, Sr, Sb, Ba, Pb, U) were used in the PMF, version 5.0 from the US Environmental Protection Agency to identify sources by markers.

RESULTS: The mean PM2.5 concentration was 13.4 ± 8.2 µg/m3 (1.2 to 39.1µg/m3) above the stipulated WHO air quality guideline of 5µg/m3. The PM2.5 mean seasonal concentration were 17.37µg/m3 (spring), 16.1 µg/m3 (winter), 11.25 µg/m3 (autumn) and 9.12 µg/m3 (summer). Sulfur had the highest mean concentration of 346.95ng/m3 followed by chlorine (288.21ng/m3) then silicon (204.52ng/m3). Uranium had the lowest mean concentration of 0.62ng/m3. Seven sources of PM2.5 were quantified including point source emission (24.6%), biomass burning (22.3%), traffic emission (16.8%), secondary sulphate (13.1 %), sea salt (9.3%), diesel combustion (8.4%) and crustal sources (5.5%).

CONCLUSIONS: The main PM2.5 emitters are combustion sources. Therefore abatement strategies should focus on improving the combustion processes.

P-0139 Chronic exposure to air pollution and semen quality in an Asian population

Yiqian Zeng[1], Cui Guo[1], Jinjian Chen[1], Xianglin Wei[1], Xiangqian Lao[1,2]
[1]The Chinese University of Hong Kong, Hong Kong, China, [2]Shenzhen Research Institute of the Chinese University of Hong Kong, Shenzhen, China

BACKGROUND AND AIM: Evidence concerning the association between air pollution and semen quality is sparse, and findings in previous studies remain inconsistent. This study aims to investigate the associations between exposure to ambient air pollution and semen quality in Asia.

METHODS: A cross-sectional study was conducted among 7,658 male participants (aged ≥15 years) who participated in a standard medical examination program in Taiwan and Hong Kong between 2000 and 2018. The 2-year average concentration of $PM_{2.5}$, NO_2, and O_3 was estimated at each participant's address using satellite-based spatial-temporal models. Semen quality was assessed according to the WHO 1999 guidelines, including sperm concentration, total motility, progressive motility, and morphology. Generalized linear mixed models were used to examine the association between air pollution and sperm quality, with a region-level random intercept used in all models to control within-region clustering effects.

RESULTS: Every 10 ug/m^3 increase in NO_2 was associated with a decrease of -1.72% [95% confidence interval (CI): -2.68% to -0.75%] in sperm concentration. However, each 10 ug/m^3 increase in $PM_{2.5}$ and O_3 was associated with an increase of 3.13% (95%CI: 0.76% to 5.55%] and 2.88% (95%CI: 0.75% to 5.05%) in sperm concentration, respectively. In addition, each 10 ug/m^3 increase in $PM_{2.5}$ was associated with a lower percentage of normal sperm morphology, with a coefficient of -1.54 (95%CI: -2.41 to -0.68). There were no consistent associations between air pollution and other semen parameters.

CONCLUSIONS: We found that exposure to ambient NO_2 was associated with a lower level of sperm concentration and exposure to ambient $PM_{2.5}$ was associated with a lower level of normal sperm morphology. Further studies are warranted to validate our findings.

KEYWORDS: Air pollution, ozone, male infertility, semen quality

P-0145 Associations between long-term air pollution exposure and physical function in older adults

Tzu-Hsuan Liu[1], Yuan-Ting C. Lo[1], Yann-Yuh Jou[2], Han-Bin Huang[1]
[1]School of Public Health, National Defense Medical Center, Taipei, Taiwan, [2]Health Promotion Administration, Ministry of Health and Welfare, Taipei, Taiwan

BACKGROUND AND AIM: Epidemiological studies concerning the relations between exposure to air pollutants especially in ozone and disability in older adults were limited. Thus, this study aims to investigate the associations between exposure to long-term air pollution and the risk of disability among the community-dwelling older adults.

METHODS: Study participants were adopted from the third to sixth wave surveys (1996, 1999, 2003 and 2007 year) in Taiwan Longitudinal Study on Aging (TLSA) (n=2241). We estimated 1-year and 2-year exposure window for ozone levels from 1994 to 2007 by using daily concentration data at air quality monitoring stations in the administrative zone of participants' residences. The status of disability for each participant was evaluated on the activities of daily living scale (ADLs) and instrumental activities of daily living scale (IADLs). Generalized linear mixed models were used to investigate the associations between long-term ozone exposure and disability after adjusting for covariates.

RESULTS: We found that long-term (1-year moving average or 2-year moving average) ozone exposure was positively associated with the risk of disability in the elderly. for example, when the average concentration of ozone increased 1 ppb in 1-year exposure window, the risk of disability for ADL scores ≥1 and IADL scores ≥7 in the elders increased 5.4% (OR=1.054, 95% CI:1.022-1.086) and 4.3% (OR=1.043, 95%CI:1.016-1.071), respectively. As compared to quartile 1 (Q1) of 1-year moving average for ozone levels, quartile 4 (Q4) of ozone exposure was significantly associated with the risk of disability for ADL scores ≥1 and IADL scores ≥7 in older adults (OR=1.858, 95% CI:1.404-2.459 for ADL scores ≥1; OR=1.700, 95%CI:1.331-2.171 for IADL scores ≥7).

CONCLUSIONS: Our results indicated that the long-term exposure to ozone could be a risk factor of disability in older adults. More researches on the biological mechanism of ozone-disability associations are required in the future.

P-0146 Adoption of innovative energy efficiency pots to enhance sustained use of clean cooking with gas in resource-poor households in Kenya: perceptions from participants of a randomized controlled trial

Willah Simiyu[1], Elisa Puzzolo[2,3], Stephen Clayton[2], James Mwitari[1], Arthur Gohole[1], Elizabeth Muchiri[3], Dan Pope[2]
[1]Amref International University (AMIU), Nairobi, Kenya, [2]Department of Public Health, Policy and Systems, University of Liverpool, Liverpool, UK, UK, [3]The Global LPG Partnership (GLPGP), 654 Madison Avenue, New York, USA

BACKGROUND AND AIM: Initial equipment purchase and recurrent fuel costs, as well as cultural cooking preferences (including perceived fuel wastage for long cooking duration foods) are recognized barriers to adoption and use of gas and electricity for clean cooking. Scaling clean cooking is now a priority for many sub-Saharan African countries to address the substantial health burden from exposure to household air pollution from reliance on polluting solid fuels.
METHOD: To facilitate transition to clean cooking with liquefied petroleum gas (LPG) innovative cooking pots with a revolutionary new fuel saving design were tested by LPG using cooks in an informal settlement in Nairobi, Kenya who currently also used polluting fuels for their cooking. Semi-structured interviews (SSIs) were conducted with 22 of 200 cooks who took part in a randomized control trial of the pots to test the impacts of the pots on exclusive clean cooking with LPG. The SSIs explored positive and negative perceptions of the technology in aiding clean cooking and potential time savings.

RESULTS: Universal appreciation of the benefits of the pots for cooking, fuel and time saving and prestige were reported by the cooks with all cooks reporting advantages over their traditional locally available pots (Sufurias). Willingness to pay for the pots and the potential for scale in the local community was a key outcome from the thematic analysis.

CONCLUSIONS: This study highlights the potential role for energy-efficient pots as a solution to sustained /exclusive clean cooking with LPG in resource poor settings. The documented positive impacts on time and fuel savings are substantiated and contextualized through the results of this qualitative study. In addition, the findings are directly relevant to scale of the cooking pots in local markets through both import and local manufacturing.

KEYWORDS: Household Air pollution, energy-efficient pots, LPG, adoption, enhanced cookware, gas.

P-0150 Malodour and health risks in the surroundings of an animal rendering plant

Eleni Sazakli[1], Michalis Leotsinidis[1]
[1]*Lab of Public Health, Medical School, University of Patras, Patras, Greece*

BACKGROUND AND AIM. Volatile Organic Compounds (VOCs) emitted from animal rendering processes, may be hazardous and/or malodorous. This study was conducted in the vicinity of a rendering plant in Southwest Greece, during operation and after its compulsory cessation. The aim was to assess the odour annoyance and the possible carcinogenic and toxic risks, derived from VOCs in ambient air.

METHODS: VOCs were absorbed onto Tenax TA/Sulficarb sorbents via active sampling and analyzed by Thermal Desorption-Gas Chromatography-Mass Spectrometry. Odour Activity Values (OAVs) were calculated for odorants. Health risks were determined by probabilistic risk assessment. Past and present odour nuisance perceived by residents was assessed through a questionnaire.

RESULTS: A substantial reduction in ambient air concentrations of VOCs (47 %) was found after closure of the plant. Seventeen compounds totally disappeared, of which four (propanoic and butanoic acids, dimethyl trisulfide, 2-nonenal) were immensely malodorous. The total odour burden, as expressed by the sum of OAVs, decreased by 70 %. Residents reported a definite drop in the frequency, intensity, duration and annoyance of the odour. Non-specific health symptoms (nausea, respiratory problems, etc.) that participants were experiencing in the past, no longer occur. During the operation period, the cumulative Lifetime Cancer Risk (LCR) for the general population was calculated to be 10 times higher than the acceptable risk. The cumulative mean Hazard Quotient (HQ = 3.3), indicated a high risk of adverse health effects. After activity termination, LCR decreased by 3-fold, while HQ remained almost the same.

CONCLUSIONS: Three major issues, odour disturbance, cancer and toxic risks were imposed on the surrounding population by a rendering plant, which was not operating under the Best Available Techniques framework. A significant amelioration of life quality was reported by residents after activity termination.

P-0156 Pregnant women's exposure to 1-hydroxypyrene predicted by airport-related source indicators in an area with low ambient air pollution

Emily Craig[1], Yan Lin[1], Xiaodong Liu[1], Yihui Ge[1], Xiangtian Wang[1], Zhenchun Yang[1], Jessica Brunner[2], Philip Hopke[2], Sally Thurston[2], Susan Murphy[1], Emily Barrett[3], Thomas O'Connor[2], Dave Rich[2], Junfeng Zhang[1]
[1]Duke University, Durham, USA, [2]University of Rochester, Rochester, USA, [3]Rutgers University, Newark, USA

BACKGROUND: Gestational exposures to polycyclic aromatic hydrocarbons (PAHs) are associated with adverse health effects among mothers and infants. Although outdoor air pollution is a known contributor to the general population's exposures to PAHs, it is unclear whether residential proximity to local pollution sources predict PAH exposure in pregnant women, especially in areas with low-level pollution.
AIM: To determine the associations of residential proximity to vehicular traffic and a nearby airport with urinary 1-hydroxypyrene (1-OHP) among pregnant women living in Rochester, New York.

METHODS: We used 743 urine samples measured for 1-OHP (once per trimester) from a pregnancy cohort study of 313 women. We calculated the distance between participants' residences and the Rochester Airport and annual average daily traffic volumes (AADT) within different buffer distances from the residence (100m increments). Associations between 1-OHP and these proximity measures were examined using linear regressions, adjusting for age, body mass index, and smoking status.

RESULTS: Residential proximity to the airport and AADT within a 300m buffer distance were associated with 1-OHP concentrations. One IQR increase in log-distance (i.e., from 6.3 to 14.0 km) was associated with an 11.0% increase in 1-OHP concentration (95%CI: 4.4%, 17.2%), while each IQR increase in the square root of AADT was associated with an 8.3% increase in 1-OHP concentration (95%CI: 1.41%, 15.73%). We found greater increases in 1-OHP levels associated with IQR increases in residential proximity to the airport when participants lived downwind (15%) than upwind (12%) of the airport, suggesting a substantial contribution of airport-related sources to PAH exposures.

CONCLUSIONS: Emissions from an airport and local traffic activities likely contributed to increased PAH exposures among pregnant women living in a Northeastern US city with low air pollution levels (average participant exposure PM2.5 = 6.1 μg/m3).

KEYWORDS: PAH, 1-hydroxypyrene, pregnant women exposure

P-0161 Hospital admission risks and costs for neuropsychiatric disorders attributable to fine particulate matter in New York State: a community-level cross-sectional study

Jieun Min[1], Whanhee Lee[1,2], Soo In Kim[3], Eunhee Ha[1,2]

[1]Department of Environmental Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [2]Institute of Ewha-SCL for Environmental Health (IESEH), Ewha Womans University College of Medicine, Seoul, Republic of Korea, [3]Department of Psychiatry, Ewha Womans University Mokdong Hospital, Ewha Womans University College of Medicine, Seoul, Republic of Korea

BACKGROUND AND AIM Neuropsychiatric disorders are a huge and growing public health concern during the recent years. However, evidence is limited for air pollution and related excess medical costs for neuropsychiatric disorders. We aimed to investigate excess risks and costs of hospital admission for neuropsychiatric disorders associated with long-term exposure to fine particulate matter (PM2.5) in New York State and examine disproportionate impact of PM2.5 on neuropsychiatric disorders by individual characteristics.

METHODS: We collected non-elective annual hospital admission counts and costs for six neuropsychiatric disorders—fatigue, headache, behavior disorder, mood disorder, Parkinson's diseases, and epilepsy— from the Statewide Planning and Research Cooperative System (SPARCS) database from 2010 to 2016. We also obtained county-level annual average of PM2.5 from the high-quality prediction model. We performed a generalized linear mixed model to estimate the association between annual average PM2.5 and the number of annual hospital admissions for neuropsychiatric disorders and calculated the excess medical costs attributable to PM2.5 based on the estimated association.

RESULTS: We found that higher exposure to PM2.5 was associated with higher hospital admission risks of neuropsychiatric disorders, and the risk was more evident in behavior disorder and Parkinson's disease, RRs: 1.08 (95% CI: 1.02, 1.16) and 1.08 (95% CI: 1.00, 1.17). Meanwhile, the excess medical cost attributable to annual PM2.5 was the highest in mood disorder (309.8 million dollars with 95% CI: -48.4, 599.4 million dollars) and epilepsy (255.5 million dollars with 95% CI: 55.9, 405.2 million dollars).

CONCLUSIONS:This study provides the excess hospital admission risks due to exposure to long-term PM2.5 for neuropsychiatric disorders, together with the excess costs attributable to PM2.5 which have a different pattern from the estimated risks.

KEYWORDS: Fine particulate matter, PM2.5, Neuropsychiatric disorders, Economic burden.

P-0167 Individual and regional vulnerability for hospitalization with cardiovascular and respiratory diseases in association with short-term ambient PM2.5 exposure

Hyungryul Lim[1], Jonghyuk Choi[1], Sanghyuk Bae[2], Kyung-Hwa Choi[1], Xue Han[1], Mina Ha[1], Ho-Jang Kwon[1]
[1]Department of Preventive Medicine, College of Medicine, Dankook University, Cheonan, Republic of Korea, [2]Department of Preventive Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

BACKGROUND AND AIM: Short-term effect of ambient $PM_{2.5}$ exposure on cardiovascular and respiratory hospitalization has a high scientific evidence. However, further evaluation for the vulnerability in terms of individual and regional characteristics is still needed.
METHOD: We covered 166 municipalities, in which has ambient $PM_{2.5}$ monitoring sites, in Republic of Korea from 2015 to 2019. We used daily means of $PM_{2.5}$ concentration, temperature, relative humidity data, and daily hospitalization [ischemic heart disease (IHD), stroke, chronic obstructive pulmonary disease (COPD), and asthma] count data from the National Health Insurance Sharing Service. Quasi-Poisson generalized additive models for overall population and the strata [individually identified; sex, age, social economic status (SES)] in each municipality and meta-analyses using regional-level variables (over aged 65, obesity, current smoker, and greenspace rate, Gross Regional Domestic Product(GRDP) per capita, employment rate, and untreated medical need rate) were implemented.

RESULTS: The pooled risk according to increase of 10 $\mu g/m^3$ of $PM_{2.5}$ concentration was increased by 0.62% (95%CI, 0.44–0.81), 0.16% (95%CI, -0.09–0.40), 0.75% (95%CI, 0.49-1.02) and 0.59% (95%CI, 0.32–0.86) based on the model with 0-1 lag day exposure, for IHD, stroke, COPD, and asthma, respectively. We found higher risks in female for IHD (0.76%), male for COPD (1.19%), in lower SES for IHD (0.88%) and stroke (0.47%), and in older group aged 65 or more for IHD (0.97%), stroke (0.36%), COPD (1.31%), and asthma (1.85%). In the regions with higher rates of older group over aged 65, obesity,and GRDP per capita, the higher risks were shown for IHD, stroke, and asthma, while in the regions with lower employment rate, those were for IHD, stroke, and COPD.

CONCLUSIONS: We explored to identify the vulnerable factors in terms of individual and regional characteristics.

KEYWORDS: Short-term exposure, $PM_{2.5}$, susceptibility, multi-city time-series, meta-regression

P-0171 Impact of the wood-burning Justa stove on Fractional Exhaled Nitric Oxide: A stepped-wedge randomized trial in Honduras

BACKGROUND: In 2019, household air pollution from combustion related to household energy needs (e.g., cooking) was estimated to be responsible for 2.3 million premature deaths globally, including nearly 400,000 from chronic respiratory diseases. In rural Honduras, we demonstrated substantially reduced personal fine particulate matter [PM2.5] concentrations following a 3-year wood-burning Justa stove (engineered combustion chamber and chimney) intervention (e.g., 24-hour PM2.5 median [25th, 75th percentiles]: Justa, 43 [27, 73]; traditional stove, 81 [50, 141] µg/m3). We evaluated the impact of the intervention and PM2.5 and black carbon (BC) concentrations on fractional exhaled nitric oxide (FeNO), a noninvasively collected biomarker of eosinophilic airway inflammation previously associated with exposure to ambient air pollution.

METHODS: With 6 visits per household over 3 years, the individual-level, stepped-wedge randomized controlled trial was conducted among 230 primary female cooks aged 24-59 years and using traditional stoves at baseline. In addition to 24-hour gravimetric personal and kitchen PM2.5 and BC concentrations, we longitudinally assessed FeNO levels with the NIOX Vero device at each visit in a random sample of 90 participants. Among participants reporting no use of anti-inflammatory medications, we explored FeNO impacts of the intervention in intent-to-treat (adjusted for time trends) and exposure-response (adjusted for potential confounders) linear mixed effect models (n=414 observations).

RESULTS: We did not observe an effect of the intervention on FeNO levels (3% higher geometric mean among those assigned to the Justa compared to the traditional stove, 95% confidence interval [CI]: -12%, 21%). Associations between pollution concentrations and FeNO were consistent with the null association (e.g., we observed a difference of 4% lower FeNO per 1-unit higher log-transformed personal PM2.5, 95% CI: -9%, 1%).

CONCLUSIONS: Evidence from ambient and HAP studies regarding associations with FeNO is inconsistent, and may be attributable to differing study populations, exposures, and FeNO measurement procedures.

P-0173 Long-term trends in mortality risks associated with short-term exposure to air pollution in 10 Japanese cities between 1977 and 2015

Hironori Nishikawa[1,9], Xerxes Tesoro Seposo[1,2], Lina Madaniyazi[1], Yoonhee Kim[3], Aurelio Tobías[1,4], Makiko Yamagami[5], Satbyul Estella Kim[6], Akinori Takami[7], Seiji Sugata[7], Yasushi Honda[1,8], Kayo Ueda[2], Masahiro Hashizume[9,10], Chris Fook Sheng Ng[1,9]

BACKGROUND AND AIM: Short-term associations between air pollution and mortality have been well reported in Japan, but the historical changes of mortality risks remain unknown while Japan undergoes rapid aging. We examined temporal changes in the mortality risks associated with short-term exposure to four criteria air pollutants in selected Japanese cities.

METHODS: We collected daily mortality data for non-accidental causes (n=5,748,206), cardiovascular (n=1,938,743) and respiratory diseases (n=777,266), and air pollutants – SO_2, NO_2, suspended particulate matter (SPM) and oxidants (Ox) – of 10 cities from 1977 to 2015. We performed a two-stage analysis with 5-year stratification to estimate the relative risk (RR) of mortality per 10 unit increase in 2-day moving average of air pollutant concentrations. In the first stage, city-specific associations were assessed using a quasi-Poisson generalized linear regression model. In the second stage, the city-specific estimates were pooled using a random-effects meta-analysis. Ratio of relative risks (RRR) was computed to examine temporal changes.

RESULTS: Average concentrations in each stratified period decreased for SO_2, NO_2, and SPM (14.2–2.3 ppb, 29.4–17.5 ppb, 52.1–20.6 μg/m³, respectively) but increased for Ox (29.1–39.1 ppb), over the study period. When stratifying the analysis by every 5 years, the estimated risks of non-accidental mortality with these pollutants remained positive but did not show any clear trend. Meanwhile, the risk of respiratory mortality with SPM had increased (RRR of the latest period to that of the earliest period: 1.008, 95% CI: 1.002–1.015). The risks posed by these pollutants were slightly to moderately heterogeneous for the different cities.

CONCLUSIONS: The respiratory mortality risk per 10 unit increase of SPM concentration was significantly higher in the latest period than in the earliest period. Other pollutant–mortality associations indicated either decrease or non-significant risk change in Japan between 1977 and 2015.

KEYWORDS: air pollution, daily mortality, time-varying effects, long-term trend

P-0174 Long-Term Association of Air Pollution and Incidence of Lung Cancer in American Elderly Population: A National Study in Medicare Cohort

Cristina Su Liu[1], Mahdieh Danesh Yazdi[1], Xinye Qiu[1], Edgar Castro[1], Yaguang Wei[1], Qiao Zhu[2], Haomin Li[2], Joel D. Schwartz[1], Liuhua Shi[2]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [2]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA

BACKGROUND AND AIM: Despite growing evidence of the association of fine particulate matter [PM2.5] to an increased risk of lung cancer mortality, few studies have investigated associations of multiple pollutants simultaneously. We aim to investigate the long-term effects of PM2.5, nitrogen dioxide [NO2], and warm-season (i.e. May to October) ozone [O3] on lung cancer incidence in a large national cohort.

METHODS: We conducted a prospective study in a nationwide cohort with Medicare beneficiaries (aged ≥ 65 years) enrolled in the fee-for-service program in the contiguous US from 2000 to 2016. Air pollution exposure was averaged across three years and assigned to each subject based on their ZIP code of residence. We fitted single-, bi-, and tri-pollutant Cox proportional hazards models to estimate the hazard ratios (HRs) for lung cancer incidence, adjusted for potential confounders.

RESULTS: Over the study period, we identified 172,371 lung cancer cases (n= 12,827,068). We found a significant increase in lung cancer risk for all three pollutants in the single-pollutants model. HRs associated with 1 μg/m3 increase in PM2.5 (μg/m3) was 1.015 (1.013, 1.018), and with 1 ppb increase in NO2 and O3 was 1.013 (1.012, 1.014) and 1.007 (1.006, 1.009) respectively. In bi- and tri-pollutant models, we observed potential confounding by NO2 on PM2.5¬, which was no longer significantly associated with lung cancer incidence. Subgroup analysis revealed significantly stronger effects for PM2.5 for those who were men, aged ≥ 75 years, black, eligible for Medicaid, and living in neighborhoods at the lowest quartile of median household income.

CONCLUSIONS: Long-term exposure to elevated concentrations of PM2.5, NO2, and O3 was significantly associated with an increased risk of lung cancer incidence among the Medicare population. Improving air quality in the US could yield substantial health benefits for the aging American population.

KEYWORDS: air pollution, lung cancer, Medicare

P-0177 Estimate High-Spatial Resolution of Ground-Level Ozone in Korea during 2001-2020 using Ensemble Model

Dohoon Kwon[1], Whanhee Lee[2,3], Cinoo Kang[1], Insung Song[1], Jieun Min[1], Jieun Oh[1], Jeongmin Moon[1], Jinah Park[1], Ho Kim[1]

[1]Graduate School of Public Health, Seoul National University, Seoul, Republic of Korea, [2]Departmemt of Environmental Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [3]Institute of Ewha-SCL for Environmental Health (IESEH) College of Medicine, Ewha Womans University, Seoul, Republic of Korea

BACKGROUND AND AIM: Estimating ground-level ozone concentrations with high spatial resolution is crucial to assess the adverse health effects associated with exposure to ozone. Despite its importance, there is no study estimating high spatial resolution of ozone concentration in Korea. This study aims to estimate monthly average of daily maximum 8 hours (8 h) ozone at a resolution of 1 km × 1 km across Korea from 2001 to 2020.

METHODS: This study used an ensemble model that integrated multiple machine learning algorithms (random forest, light gradient boosting, and neural network) to estimate monthly average of daily maximum 8 h ozone at a resolution of 1 km × 1 km across the contiguous Korea. We used a generalized additive model that accounted for geographic difference to combine ozone estimates from random forest, light gradient boosting, and neural network. The three machine learning models include multiple predictors with satellite data, meteorological variables, spatially weighted ground-level air pollutants, land-use variables, reanalysis datasets for meteorological variables, and others.

RESULTS: Total number of monitoring stations for ozone was 480 during the period 2001-2020. In the total area, our ensemble model showed a 10-fold cross-validated R2 of 0.840 during the entire study period. Urban areas showed the better prediction performance (R2 of 0.842), compared to the non-urban areas (R2 of 0.764).

CONCLUSIONS: This study can provide the high-resolution ozone prediction estimates with excellent performance, and our estimates can be used to estimate the more precise health impacts attributable to ozone.

P-0178 Long-term and short-term exposures to ambient ozone and sleep quality in China

Yao Zhang[1], Limei Ke[1], Xindong Ma[1], Qian Di[1]
[1]*Tsinghua University, Beijing, China*

BACKGROUND: Compelling evidence has documented that ground-level ozone has various adverse health impacts, causing elevated mortality and morbidity. However, few studies have focused on the effect of ozone on sleep quality.
METHOD: We assessed the causal relationship between short-term and long-term exposure to ozone and sleep quality in a national representative sample from the China Family Panel Study, using a difference-in-difference study design. We further followed ninety healthy Chinese adults from September 2020 to June 2021, ascertained their daily ozone exposure, and measured average daily accelerometer-based sleep architecture and resting-state EEG signals in 4 one-week-long sessions.

RESULTS: In the national sample, we found that every 1-□g/m3 increase in yearly and monthly ozone exposure was causally associated with 0.0047 (p = 0.047) and 0.0021 (p = 0.014) hours decline in night-time sleep duration, respectively. In the small sample with objective sleep measurements, we found that every 1-□g/m3 increase in daily ozone exposure was associated with 0.19 minutes decrease in night-time sleep duration (p = 0.031), 0.058 percentage decrease in sleep efficiency (p < 0.001), 0.071 minutes increase in sleep latency (p = 0.007) and 0.20 minutes increase in wake after sleep onset (p = 0.0016) in a quasi-linear pattern. Interestingly, we also found that short-term ozone exposure was directly associated with altered EEG pattern, with sleep quality playing as a potential mediating role.

CONCLUSIONS: This study indicates that long-term and short-term ozone exposure has adverse impact on sleep health and might impair brain functioning. More hidden adverse health effects of ozone are worth exploring.

P-0179 Exposure to outdoor $PM_{2.5}$ and Risk of Upper Gastrointestinal Cancers in a Large Prospective U.S. Cohort

Natalie Prtichett[1,2], Jared Fisher[1], George Gray[3], Joel Kaufman[2], Debra Silverman[1], Sandy Dawsey[1], Rena Jones[1]
[1]National Cancer Institute (U.S.), Rockville, USA, [2]University of Washington, Seattle, USA, [3]George Washington University, Washington, USA

BACKGROUND AND AIM: Studies of outdoor air pollution and upper gastrointestinal (UGI) cancers are limited, and few have evaluated heterogeneity in effects by histologic subtype. We investigated the relationship between ambient fine particulate matter ($PM_{2.5}$) and UGI cancer risk in a large prospective cohort.

METHODS: Our analysis included 456,472 participants of the NIH-AARP Diet and Health Study in 6 U.S. states (California, Florida, Louisiana, New Jersey, North Carolina, and Pennsylvania) and 2 metropolitan areas (Atlanta, Georgia and Detroit, Michigan). We used annual estimates from a historical spatiotemporal model to assess average residential $PM_{2.5}$ concentrations during a 15-year period (1980-1994) prior to enrollment in 1995-1996. We used Cox regression to estimate hazard ratios and 95% confidence intervals (HR [CI]) for risk of incident UGI (esophageal and gastric) cancers overall and by histologic subtype per 10µg/m3 increase in $PM_{2.5}$. Models were adjusted for age, smoking, alcohol intake, body mass index (BMI), race/ethnicity, and catchment area and separately adjusted for residential nitrogen dioxide (NO_2) concentrations. We ran models stratified by smoking status, sex, and BMI, and evaluated statistical interaction via Wald tests.

RESULTS: We found no overall $PM_{2.5}$-UGI cancer association in follow-up through 2011 (N=2,352 cases). Increased risk of esophageal squamous cell carcinoma (N=244) was suggested (HR:1.50 [0.95-2.37] per 10µg/m^3) and stronger among men (HR=1.80 [1.06-3.07]) than women (HR=1.01 [0.50-2.09]), although the interaction was non-significant (p-interaction=0.4). There was no association with esophageal adenocarcinoma (n=774). We observed a small, nonsignificant increased risk for gastric noncardia adenocarcinoma (n=898; HR=1.06 [0.84-1.35]); risk of gastric cardia adenocarcinoma (N=577) was increased only among never smokers (p-interaction=0.01). There were no differences in relationships by BMI, and NO_2 adjustment did not change associations.

CONCLUSIONS: Our novel investigation provides evidence of a relationship between $PM_{2.5}$ and specific UGI cancer subtypes. Stratified findings suggest important areas for future research.

KEYWORDS: gastrointestinal cancer, air pollution

P-0184 Long-term air pollution exposure and the incidence of cardiovascular diseases among American elderly population

Tingfan Jin[1], Qian Di[2], Weeberb J. Réquia[3], Mahdieh Danesh Yazdi[1], Edgar Castro[1], Qiao Zhu[4], Yifan Wang[4], Haisu Zhang[4], Liuhua Shi[4], Joel Schwartz[1]

[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Vanke School of Public Health, Tsinghua University, Beijing, China, [3]School of Public Policy and Government, Fundação Getúlio Vargas, Brazil, [4]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA

BACKGROUND AND AIM: Numerous studies have linked PM2.5, NO2, and ozone with cardiovascular diseases. Fewer studies have examined the multi-pollutant effects and effects at low pollutant levels, as well as potential effect modifications.

METHODS: Our study population included all Medicare enrollees continuously enrolled in the fee-for-service (FFS) program and both Medicare part A and part B in the contiguous U.S. from 2000 to 2016. We looked at the association between population-weighted ZIP code level annual average PM2.5, NO2, and warm-season ozone (May-October) and the first diagnosis of atrial fibrillation (AF), congestive heart failure (CHF), and stroke using Cox proportional hazards models. We adjusted for individual demographic characteristics and area-level covariates. We further examined these associations at low pollutant levels (PM2.5: <10 µg/m3¬, <8 µg/m3; NO2: <25 ppb, <18 ppb; warm-season ozone: <50 ppb, <40 ppb) and potential modifications by race and comorbidities (diabetes, hypertension, hyperlipidemia).

RESULTS: In the full cohorts, elevated PM2.5 and NO2 levels were associated with increased incidence of AF, CHF, and stroke. for each µg/m3 increase in annual PM2.5, HRs were 1.0059 (95%CI: 1.0054, 1.0064), 1.0260 (95%CI: 1.0256, 1.0264), and 1.0279 (95%CI: 1.0274, 1.0284), respectively. for each ppb increase in annual NO2, HRs were 1.0057 (95%CI: 1.0056, 1.0059), 1.0112 (95%CI: 1.0110, 1.0113), and 1.0095 (95%CI: 1.0093, 1.0096), respectively. Each one ppb increase in warm-season ozone was associated with an increased risk of CHF (HR=1.0035, 95%CI: 1.0033-1.0037) and stroke (HR=1.0026, 95%CI: 1.0023-1.0028). The effect estimates were stronger when we restricted the analyses to low pollutant levels. We also found generally higher risks for enrollees who are black or have diabetes.

CONCLUSIONS: Long-term exposure to PM2.5, NO2, and warm-season ozone were associated with risks of cardiovascular diseases, even at low pollutant levels. These associations were modified by race and several comorbidities.

KEYWORDS: Air Pollution, PM2.5, NO2, Ozone, Cardiovascular Diseases

P-0187 Fine particulate matter (PM2.5) levels in Brits, North West province, South Africa

Boitshoko Lekwe[1], Adewale Adeyemi[1], Janine Wichmann[1]
[1]*University of Pretoria, Pretoria, South Africa*

BACKGROUND AND AIM: Air pollution is a major threat to human health globally. In 2021, the World Health Organization (WHO) reported that 7 million premature deaths, mainly from non-communicable diseases are due to air pollution. Air quality studies on PM2.5 and its composition are lacking in South Africa and Africa. In order to find ways to reduce PM2.5 sources and its associated health impact in Brits, South Africa, it is necessary to determine PM2.5 levels and its chemical composition, followed by a source apportionment study.

METHODS: 24-hour PM2.5 filter samples were collected on the roof of a home in Brits every sixth day. In total, 61 samples and 10 duplicate samples were collected during 10 May 2020 and 5 May 2021. GilAir5 pumps and PM2.5 cyclones were used in the sampling. PM2.5 levels were determined with gravimetric analysis at the Air Quality Laboratory, School of Health Systems and Public Health, University of Pretoria. The yearly average was compared to the Averages were compared across seasons.

RESULTS: The average PM2.5 level during the sampling period was 17.7 µg/m³ (range: 3.6 -52.7 µg/m³), which is higher than the yearly WHO guideline (5 µg/m³), but lower that the yearly South African standard (20 µg/m³). The 24-hour PM2.5 levels exceeded the daily WHO guideline (15 µg/m³) and daily South African standard (40 µg/m³) on 17 and 2 occasions, respectively. The highest PM2.5 levels were observed during dusty spring season (52.7 µg/m³: September 2021) and winter (43.4 µg/m³: June 2021). Possible outdoor sources include industrial and mining activities. The lowest PM2.5 level (3.6 µg/m ³) was observed in May 2021 (autumn).

CONCLUSIONS: The PM2.5 levels in Brits exceeded the yearly and daily WHO guidelines on several occasions. This may pose a public health risk to the population.

KEYWORDS: PM2.5, outdoor air pollution, South Africa.

P-0188 Source apportionment of PM2.5 and PM2.5-bound trace elements in Pretoria, South Africa

Nandi Mwase[1], Peter Molnar[2], Johan Boman[2], Janine Wichmannn[1]
[1]University of Pretoria, Pretoria, South Africa, [2]University of Gothenburg, Gothenburg, Sweden

BACKGROUND AND AIM: Source apportionment studies are an important step in understanding primary sources and contributions of fine particulate matter (PM2.5). However, there is still research needed on the topic in South Africa. The aim of this study was to identify the possible sources of PM2.5 in Pretoria, during a 46-month study period.

METHODS: PM2.5 samples were collected on the roof of the School of Health Systems and Public Health (SHSPH), University of Pretoria in Pretoria from 18 April 2017 to 12 February 2021. Gravimetric analysis was done at the SHSPH Air Quality Lab. The trace element composition was determined with X-ray fluorescence at the University of Gothenburg, Sweden. Source apportionment was conducted using the US EPA 5.0 software.

RESULTS: The average PM2.5 concentration during the 46-month study period was 21.8±17.9 µg/m3 (range 0.29–138.9 µg/m3). The identified sources and their contribution to PM2.5 were mining (43.2%), biomass/coal burning (14.2%), secondary sulphur (12.1%), road traffic (11.3%), industry/base metal (8.7%), resuspended dust (8.5%) and vehicle exhaust (2.0%). Mining and biomass burning contributed to over half of the PM2.5 and higher contributions were observed during cold winter months. South Africa primarily depends on fossil fuel burning (i.e. coal) for energy through mining and production.

CONCLUSIONS: Reduction of PM2.5 at both local level in Pretoria can be implemented through the adjustments of the national air quality management act. Particularly introducing more safe national air quality standards that could lead to lower PM2.5 levels in Pretoria.

P-0192 Patterns of fuel use, cooking practices and factors associated with the use of LPG for cooking in peri-urban Cameroon

Esong Miranda Baame[1], Humphrey Atongno[1,4], Andre Pascal Goura[1], Emmanuel Betang[1], Mathew Shupler[2], Emily Nix[2], Elisa Pozzolo[2], Daniel Pope[2], Bertrand Hugo Ngahane Mbatchou[1,3]

[1]Douala General Hospital, Douala, Cameroon, [2]University of Liverpool, Department of Public Health, Policy and Systems., Liverpool, UK, [3]University of Douala, Faculty of Medicine and Pharmaceutical Sciences., Douala, Cameroon, [4]University of Buea, Faculty of Health Sciences, Department of Public Health, Buea, Cameroon

BACKGROUND AND AIM: Over three billion people, mostly living in low and middle income countries (LMICs), are exposed to household air pollution from reliance on polluting fuels (e.g. wood, charcoal). There is a dearth of information on barriers to adoption and sustained use of clean cooking fuels, (e.g. liquefied petroleum gas (LPG)) in remote locations in sub-Saharan Africa.

METHODS: A cross-sectional demographic and fuel use survey was completed by approximately 1500 household cooks from peri-urban Mbalmayo in Central Cameroon. Stratified random sampling was conducted to identify approximately 200 clean (LPG) and 200 polluting (e.g. wood) cooking fuel users who completed in-depth surveys on individual and household characteristics that were potentially associated with cooking behavior and fuel choice.

RESULTS: Among households using solid fuels (n=196), the main reported barrier to LPG adoption included the initial cost of LPG equipment (n=87; 59%). Concerns over LPG safety were a significant concern in both users and non-users of LPG (n=366; 83.6% perceived LPG to be dangerous). Decision making over choice of cooking fuel was approximately equally split between the main cook (typically women) and the head of household (usually men); men were in charge of decision making regarding cooking fuel adoption among 41.4% (n=121) LPG users and 56.2% (n=82) of biomass users. Stacking was universal (100%) amongst LPG users, with 70% LPG use. Free secondary fuel and a distance 20-30minutes from retail point reduced LPG use by 20% and 10% respectively. Household head unemployed (O.R 2,057, p-value .000), No formal education (O.R 15.200,p-value .006), and Cost (O.R 2.489, p-value 0.000) were all associated with the non-adoption of LPG.

CONCLUSIONS: Addressing safety concerns through education, and financially supporting households (e.g. through microfinance) will considerably scale LPG adoption in peri-urban Cameroon. Policies to facilitate LPG adoption should be targeted to both genders.

KEYWORDS: LPG, clean cooking, adoption

P-0193 Long-term Total and Source-specific PM2.5 in Relation to Incident Dementia in the U.S.

Boya Zhang[1], Jennifer Weuve[2], Kenneth M. Langa[3,4,5,6], Adam A. Szpiro[7], Carlos Mendes de Leon[1], Jessica Faul[8], Jiaqi Gao[1], Joel Kaufman[9,10,11], Richard Hirth[12,13], Jennifer D'Souza[1], Sara D. Adar[1]

[1]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, USA, [2]Department of Epidemiology, 715 Albany Street, Boston University School of Public Health, Boston, USA, [3]Institute for Social Research, University of Michigan Medical School, Ann Arbor, USA, [4]University of Michigan Medical School, Ann Arbor, USA, [5]Institute for Healthcare Policy and Innovation, University of Michigan, Ann Arbor, USA, [6]Veterans Affairs Center for Clinical Management Research, Ann Arbor, USA, [7]Department of Biostatistics, University of Washington, Seattle, USA, [8]Survey Research Center, University of Michigan, Ann Arbor, USA, [9]Department of Epidemiology, School of Public Health, University of Washington, Seattle, USA, [10]Departments of Environmental and Occupational Health Sciences, and Epidemiology, University of Washington School of Public Health, Seattle, USA, [11]Department of Medicine, School of Medicine, University of Washington, Seattle, USA, [12]Department of Health Management and Policy, University of Michigan School of Public Health, Ann Arbor, USA, [13]Department of Internal Medicine, University of Michigan, Ann Arbor, USA

BACKGROUND AND AIM: Emerging, but sometimes inconsistent, associations have been observed between PM2.5 and incident dementia. One possible explanation for differing associations across studies could be differing toxicity by source. We investigated the associations of long-term exposures to total and source-specific PM2.5 with incident dementia in a national, population-based cohort.

METHODS: We used biennial data between 1998 and 2016 from participants >50 years in the Health and Retirement Study. Incident dementia was identified using a validated algorithm based on cognitive testing and informant information. We predicted 10-year average total PM2.5 at participant residences before each interview using spatiotemporal modeling. Then, we derived source-specific PM2.5 by leveraging spatially refined fractions of PM2.5 from agriculture, traffic, energy, industry, open-fire and windblown dust as estimated by GEOS-Chem. Associations with incident dementia were estimated with Cox models, adjusting for individual demographics, area-level characteristics, time, and geographic trends.

RESULTS: Among 27,857 participants, 4,105 (15%) developed dementia during follow-up. Mean PM2.5 levels were 11.5+3.7 µg/m3 overall, with the largest contributing individual sectors of agriculture (1.6+0.6) and the smallest of windblown dust (0.2+0.4). In single-source models, we observed a hazard ratio of 1.16 (95% CI: 1.05 to 1.29), 1.20 (1.01 to 1.41), 1,65 (0.98 to 2.77), 1.07 (0.94 to 1.22) and 1.07 (1.02 to 1.13) for incident dementia per 1-µg/m³ greater PM2.5 from agriculture, road traffic, non-road traffic, energy coal, and open fires, respectively. These associations remained after adjustment for the sum of PM2.5 from other sources. Associations corresponding to PM2.5 from other sources were inconsistent with adverse effects.

CONCLUSIONS: We found evidence that specific emission sources may be more important in the relationship between PM2.5 and dementia risk, suggesting the possibility of targeted interventions to reduce the burden of dementia in the future.

KEYWORDS: Air Pollution, Source-specific PM2.5, Dementia

P-0195 Forecasting greenhouse gas emissions from road traffic in 2040 across the Greater Montreal Region of Canada

Ying Liu[1], Marianne Hatzopoulou[2], Arman Gangi[2], Audrey Smargiassi[1]
[1]*University of Montreal, Montreal, Canada,* [2]*University of Toronto, Toronto, Canada*

BACKGROUND AND AIM: Road traffic is a major source of ambient air pollution and greenhouse gas (GHG) emissions in urban areas and is linked with human health impacts and climate change. Urban land-use planning and travel behavior greatly influence on-road traffic. The aim of this study was to map the spatial distributions of on-road traffic and its associated GHG emissions across the Greater Montreal Region (Canada) for the year 2040 under different population growth and land-use scenarios.

METHODS: A random forest model was developed to estimate the annual average daily traffic (AADT) for each road segment based on the 2018 traffic count data collected from in-situ monitoring stations and Google aerial images, an origin-destination travel survey, points of interest from OpenStreetMap, and sociodemographic census data. The spatial distribution of the population in 2040 was then predicted under three population growth scenarios. According to the forecasted population distributions in 2040, we modified the population-related predictors in the 2018 random forest model to map AADT distributions for 2040. Finally, vehicle induced GHG emissions in 2040 were estimated based on AADT.

RESULTS: Our random forest model performed well for AADT prediction, resulting in an R2 of 0.66 in leave-one-out cross-validation. Vehicle induced GHG emissions will increase 13.28% in 2040 compared to 2018 if population growth maintains past trends. GHG emissions will only increase 4.30% and 2.36% with 60% of the new population located within one kilometer of subway stations and with telecommuting increasing by 12.5% and 40% respectively.

CONCLUSIONS: Allocating new population in areas with transportation infrastructure and increasing telecommuting can reduce traffic-associated GHG emissions. Our modelling work demonstrates the potential influences of travel behaviors and land use planning on human health and climate change.

KEYWORDS: greenhouse gas emission, traffic count, air pollution, population, land use.

P-0197 A Review of studies using Air Q software for prediction of Air Pollution Health effects in Iran

Narges Khanjani[1], Mohammad Amin Farahmand[1], Marzieh Eslahi[1]
[1]*Kerman University of Medical Sciences, Kerman, Islamic Republic of Iran*

BACKGROUND AND AIM: Exposure to air pollutants may lead to various health effects and is a major public health issue. Concerns about these effects exist in both developed and developing countries. The Air Q software was developed to estimate the health impacts of air pollution based on reported levels of air pollutants in real world studies. In Iran several studies have been conducted to estimate human morbidity and mortality based on this software. We conducted this review to summarize articles which have predicted the effects of air pollution on human health in Iran using Air Q.

METHODS: We conducted a systematic search for relevant studies published until 24 April 2021 in Web of Science, PubMed, Scopus and SID (Scientific Information Database which includes articles in Farsi language). We applied no time or language restrictions.

RESULTS: 44 studies out of 525 identified articles met our inclusion criteria. The main air pollutants under investigation were particulate matter (PM), NO2, O3 and SO2. Most studies were conducted in metropolitan areas, such as Ahvaz (9 studies), Tehran (9 studies), and Shiraz (7 studies). In all studies the levels of most air pollutants were higher than the 2005 WHO guideline levels and were predicted to be related to considerable health effects. However, it was not possible to aggregate the results and report the total number of casualties during these years, because studies were done in different cities with fluctuating levels of multiple pollutants and in different years and time frames.

CONCLUSIONS: This systematic review showed that air pollution remains at unacceptably high levels resulting in substantial detrimental health effects in various Iranian cities. Using clean renewable energies, increasing human capital and increasing green spaces and vegetation can help improve air pollution and decrease human casualties in Iran.

KEYWORDS: Air Pollution, Air Q, Iran

P-0200 Ambient air pollutants and pulmonary function in children after COVID-19 pandemic

I-Jen Wang[1,2,3]

[1]Department of Pediatrics, Taipei Hospital Ministry of Health and Welfare, Taipei, Taiwan, [2]School of Medicine, National Yang-Ming University, Taipei, Taiwan, [3]College of Public Health, China Medical University, Taichung, Taiwan

BACKGROUND AND AIM: The acute effects of air pollutants on pulmonary function remain unclear. After COVID-19 spreads, fear drives patients away from hospitals. Smartphone applications may help asthma care. This study investigated the acute effects of ambient air pollution on pulmonary function among asthma in children by smartphone applications.

METHODS: We designed a smartphone app to provide timely support for patients with asthma. Peak expiratory flow (PEF) recordings were made twice daily and was corrected by age and gender. The severity of asthma by GINA guideline and asthma control test (ACT) test score were also monitored. Ambient air pollution parameters of particulate matter (PM), ozone(O3), oxides of nitrogen (NO2),carbon monoxide (CO), and sulfur dioxide (SO2) were measured from each nearby air monitoring station at each time while PEF recordings by linking to Global Positioning System. Allergen-specific IgE were also measured by MAST. Effects of exposure to pollutants on PEF were assessed in person-days of observations by GEE model.

RESULTS: In lag 0 (the same day), PM10, NO2, CO, and SO2 were negatively correlated with PEF (p=0.030, 0.031, 0.008, 0.017). In lag1 (one day before), NO2, CO, and SO2 were found to be correlated PEF (p=0.005, 0.010, 0.025). In lag2, PM2.5, PM10, NO2, and SO2 were associated with PEF (p=0.031, 0.023, 0.031, 0.005). Analyses stratified by mite allergen sensitization revealed that PM10, NO2, CO, and SO2 air pollutant levels negatively correlated with PEF only in mite sensitization children.

CONCLUSIONS: Exposure to air pollutants can lead to acute effects on the pulmonary function in children with asthma. Pollutants may reduce lung function and have different effects over time. Mite sensitization might modify the effect of air pollutant exposures on lung function on asthma. Smartphone applications are readily available tools to help individual air monitoring and asthma care after COVID-19 pandemic.

P-0202 Measurement of indoor and outdoor SO2 and NO2 and indoor BTEX/VOC concentrations at pre-schools in Mabopane Township, Tshwane Metropolitan Municipality, Gauteng Province, South Africa

Joyce Shirinde[1], Mandla Bhuda[1], Matome Rapatsa[1], Sean Patrick[1], Janine Wichmann[1]
[1]*University of Pretoria, Pretoria, South Africa*

INTRODUCTION: Children spend approximately 7 hours a day at pre-schools, mostly indoors. The aim of the study was to assess indoor and outdoor SO2 and NO2 and indoor BTEX/VOC at pre-schools situated in Mabopane, Tshwane Metropolitan Municipality, Gauteng Province, South Africa
Methodology: Six pre-schools in the study area were purposively selected to participate in the study. Indoor and outdoor levels of SO2 and NO2, and indoor BTEX/VOC were assessed over 24hrs for two weeks using Radiello passive samplers. Indoor temperature and relative humidity were also monitored using temperature data loggers. The outdoor temperature and relative humidity data was provided by South African Weather Services.

RESULTS: The indoor and outdoor SO2 median levels were 0.22 µg.m-3 and 1.12 µg.m-3 The indoor and outdoor NO2 median levels were 21.10 µg.m-3 and 17.22 µg.m-3, respectively. The indoor/outdoor ratios for NO2 and SO2 were 0.20 and 1.07, respectively. The infiltration factor parameter estimates of NO2 and SO2 were 0.48 and 0.01. The indoor and outdoor temperature and relative humidity levels were 2.11 °C and 22.4 °C, and 43.14% and 57%. The median concentrations of BTEX ranged from 0.5µg/m3 to 43.19µg/m3. The Kruskal-Wallis test showed that the level of benzene in the six schools differed significantly - $\chi^2=13.87$,p-value=0.016. The levels of toluene at the six school did not differ significantly - $\chi^2=5.96$,p-value=0.310. There was no statistically significant difference between the six schools in terms of ethylbenzene - $\chi^2=6.30$,p-value=0.2710. The p-value for Xylene showed there was no statistically significant difference between the six schools - $\chi^2=6.01$,p-value=0.2967..

CONCLUSIONS: The levels of outdoor NO2, SO2 and BTEX/VOC were below the South African National Ambient Air Quality Standards and WHO Air Quality Guidelines. However, they still pose a health risk for children attending pre-school in the area.

KEYWORDS: Air pollution; SO2, NO2, BTEX/VOC, Temperature; Relative humidity; South African

P-0203 Health Risk Assessment and Projection of Municipal Solid Waste Disposal in China

Jianxun Yang[1], Yunqi Liu[2], Yanyan Qiu[1], Qi Zhou[1], Miaomiao Liu[1], Jun Bi[1]
[1]Nanjing University, Nanjing, China, [2]Nanjing Foreign Language School, Nanjing, China

BACKGROUND: China's Municipal solid waste (MSW) is growing rapidly. Incineration and landfill are two main approaches of MSW disposal and both of them emit different types of ambient pollutants and threaten human health. There lacks systematic health risk assessment and projections of MSW incineration and landfill in China.

METHODS: We established the historical MSW incineration and landfill emission inventories from 2015 to 2017 and used the Gaussian Diffusion Model to simulate the spatial distribution of ambient pollutants. We then used Risk Quotients Model to assess the non-carcinogenic and carcinogenic health risks through inhalation exposure. Besides, we set seven possible MSW incineration development scenarios to predict health risk levels in 2035, considering the effect of population growth, incineration rate, waste classification and recycling, and technology progress.

RESULTS: The results show that non-carcinogenic risk caused by MSW incineration from 2015 to 2017 was lower than landfill at the national level. Both of them were meet the maximum acceptable level (HI ≤ 1). From 2015 to 2017, carcinogenic risks caused by landfill were 9.42 × 10-6, 9.40 × 10-6, 9.37 × 10-6, nine times larger than the maximum acceptable level (CR ≤ 1×10-6). Carcinogenic risks caused by incineration were 5.71 × 10-6, 7.92 × 10-6, 9.44 × 10-6, five to nine times larger than the maximum acceptable level. Projection results show that compared to the baseline scenario, through classification and recycling, changing incinerator furnace, and improving, national health risk levels will be decreased by 24%, 94% and 97%.

CONCLUSIONS: We assessed the health risks caused by MSF disposal and found MSF incineration a relatively low risk alternative disposal approach compared to waste landfill. In the future, local government should reduce MSF disposal health risks by optimizing the selection of incinerators locations, improving the garbage sorting recycling system, and strengthening information disclosure and communications.

P-0214 Demonstration project to transition from gas to electric induction stoves in affordable housing units: the 'Out of Gas' pilot study

Ashlinn Quinn[1], Annie Carforo[2], Michelle Feliciano[3], Francis Rodriguez[3], Heather Miller[1], Ricardo Piedrahita[1], Misbath Daouda[4], Darby Jack[4], Michael Johnson[1]

[1]Berkeley Air Monitoring Group, Fort Collins, USA, [2]We Act for Environmental Justice, New York, USA, [3]Association for Energy Affordability, New York, USA, [4]Columbia Mailman School of Public Health, New York, USA

BACKGROUND: Natural gas-fueled stoves are a major source of indoor residential NO_2, which has been associated with asthma exacerbations. WE ACT for Environmental Justice launched 'Out of Gas' in 2021 to investigate the feasibility of transitioning from fossil fuels to renewable energy in affordable housing. 20 families in New York City Housing Authority units in the Bronx, New York City were selected to receive electric induction stoves to replace existing gas stoves. Air pollution (primarily NO_2 and PM2.5) and stove usage are being monitored before and after the transition. The pilot will be repeated in Buffalo, NY.

METHODS: In-kitchen stationary monitoring of NO_2, PM2.5, CO_2, and CO was conducted for 7 days at baseline and after stove switch-out using the Home Health Box (Access Sensor Technologies, Fort Collins, CO). Cooking events were identified using temperature loggers (Wellzion Electronics Technology Co, China). Pollutant concentrations were analyzed during cooking vs. non-cooking times and compared to ambient levels from nearby New York Department of Environmental Conservation stations.

RESULTS: Mean (SD) [median] NO_2 kitchen concentrations at baseline (before appliance switch-out) were 47.0 (60.6) [34.6] ppb, 27.8 ppb higher than ambient levels during the monitoring period. PM2.5 concentrations were 17.2 (40.1) [7.3] $\mu g/m^3$, 7.9 $\mu g/m^3$ higher than ambient levels. Levels of both pollutants were higher during cooking, with NO_2 averaging 117.5 (125.5) [82.3] ppb during cooking versus 35.5 (25.8) [32.5] ppb otherwise. The corresponding values for PM2.5 were 33.4 (63.7) [11.5] $\mu g/m^3$ during cooking and 14.5 (33.8) [7.0] $\mu g/m^3$ otherwise. On average, cooking was associated with an increase of 63.3 ppb NO_2 and 18.3 $\mu g/m^3$ PM2.5 above baseline levels.

CONCLUSIONS: Cooking with gas stoves contributes substantially to indoor residential NO_2 and PM2.5 concentrations. Switching to efficient electric induction stoves could reduce the exposure of potentially vulnerable populations to these pollutants.

KEYWORDS: NO_2, PM2.5, cookstoves

P-0217 “[Classes] are highly affected because of the smoke”: Impacts of cooking on air pollution and health among three schools in Nairobi, Kenya

Emily Nix[1], Willah Simiyu, Arthur Gohole[2], James Mwitari[2], Matthew Shupler[1], Elisa Puzzolo[1], Federico Lorenzetti[1], Serena Saligari[1], Rachel Anderson de Cuevas[1], Margaret Nyongesa[2], Daniel Pope[1]
[1]University of Liverpool, Liverpool, UK, [2]Amref International University, Nairobi, Kenya

BACKGROUND AND AIM: Links between cooking with polluting fuels (e.g., wood, charcoal), air pollution and health are well-established. However, few studies have been conducted in schools that rely on such fuels for catering. This study presents the first investigation of air pollution, cooking, and health in schools in Nairobi, Kenya.

METHODS: We carried out an in-depth study in three schools (two primary schools and a college) in an informal settlement using wood and/or charcoal for catering. 24-hour air pollution measurements (particulate matter (PM2.5) and carbon monoxide (CO)) were collected to assess concentrations in the main kitchen and a nearby classroom, and personal exposure of the main cook. Surveys with catering staff collected data on the health impacts on air pollution. Focus groups with catering staff, teachers and senior management were used to understand impacts on health and the school environment, perspectives, and pathways for clean fuel transitions.

RESULTS: Mean 24-hr PM2.5 cook exposures ranged from 97.6 -343.7 µg/m3, and 24hr concentrations ranged from 64.9-171.7 µg/m3 and 66.3-903.9 µg/m3 in classrooms and kitchens, respectively –all exceeding WHO 24-hr air quality guidelines. Reported impacts from the pollution by catering staff included eye irritation, wheezing and headaches, leading to the frequent avoidance of smoke. Focus groups highlighted disturbance to teaching from smoke and how students experienced coughing and sneezing. While the impact of cooking with polluting fuels was understood, opportunities for fuel transitions were limited by catering needs and external organisations’ agendas.

CONCLUSIONS: Despite cooking not occurring in classrooms, minimum concentrations were similar to kitchens, suggesting students are exposed to unhealthy air pollution levels. Transitions in schools to clean fuels can likely advance health and minimize disturbances to teaching. Building awareness on links between cooking, air pollution and health and developing solutions that support schools catering needs is vital to support transitions.

P-0221 Correlation between extreme/unusual ozone events and corona effect from electric power transmission & distribution grids. Assessing the health and environmental impact of high-voltage direct current (HVDC) grid on ozone ground levels in Sao Paulo metropolitan area, Brazil.

Pedro Diaz Peralta[1], Claudia Ribeiro Pereira Nunes[1]
[1]*Yale School of the Environment- Michelle L. Bell´s Research Group, New Haven -CT, USA*

BACKGROUND AND AIM: 1- Ozone ground levels pose a risk for public health
2- The increasing ozone levels measured in parts of the metropolitan area of Sao Paulo have brought the attention of researchers. Proposed mechanisms do not provide a clear outcome for establishing root causes, and for clarifying sources of ozone. Spatial distribution of ozone also depends on wind patterns.
3- As an alternate hypothesis for explaining unusual high levels of ozone, the corona discharge from electric transmission grid, known as corona effect, can play a significative role in the absence of, or in coincidence with other concomitant factors, to explain ozone (O3) and nitric oxide (NO) unusual levels. Negative coronas emits more ozone than Positive coronas.
4- The Environmental Protection Agency- EPA, found in a report of 1973 (EPA-650/4-73-003), following a research carried out in areas of high concentration of transmission lines that "under minimal wind conditions, such transmission line concentrations can produce sizeable local ozone levels."
5- Research applies geospatial and statistical analysis with the aim of better understanding correlations between exposures and ozone levels.

METHODS: Geographic Information System (GIS)-based systems with average grid cell edge length of 10 km minimum. Global InMAP (Intervention Model for Air Pollution) with a variable resolution grid (4 km horizontal grid cell widths) in combination with GEOS- Chem simulations. Data analysis by machine-learning model.

RESULTS: Applying Predictive Machine Learning algorithm as regression models, research found that coronas could generate significant ozone levels downwind of the power line.

CONCLUSIONS: Evidence of correlation between unusual ozone measurements and location of key power electric grid transmission lines and distribution centers with potential for corona effect are found in Sao Paulo state and Sao Paulo city metropolitan area.

KEYWORDS: Corona effect, ozone, electric grids, spatial simulation, wind patterns, air pollution

P-0222 Exposure to Household Air Pollution (HAP) and measures of central hemodynamic parameters among Bangladeshi population- A cross-sectional study.

Mohammad Shahriar[1], Mahbubul Eunus[2], Shyfuddin Ahmed[3,5], Muhammad Ashique Haider Chowdhury[6], Shirmin Kader[3], Bilkis Begum[7], Rabab Shams[3], Golam Sarwar[3], Tariqul Islam[3], Dewan Alam[8], Faruque Parvez[4], Rubhana Raqib[3], Habibul Ahsan[1], Muhammad Yunus[3]

[1]Institute for Population and Precision Health, The University of Chicago, Chicago, USA, [2]UChicago Research Bangladesh (URB), Dhaka, Bangladesh, [3]icddr,b, Dhaka, Bangladesh, [4]Mailman School of Public Health, Columbia University, NY, USA, [5]Robert Stempel College of Public Health and Social Work, Florida International University, Miami, USA, [6]Department of Public Health Sciences, Biological Science Division, The University of Chicago, Chicago, USA, [7]Chemistry Division, Atomic Energy Center, Dhaka, Bangladesh, [8]School of Kinesiology and Health Science, Faculty of Health, York University, Toronto, Canada

Household Air Population (HAP) has been linked to an array of adverse health hazards, including cardiovascular mortality and morbidity. We have assessed whether household air pollution (HAP) is associated with hemodynamic parameters as part of the Bangladesh Global Environmental and Occupational Health (GEO Health) project.

We assessed central hemodynamic parameters-Systolic Blood Pressure (SBP), Diastolic Blood Pressure (DBP), and Heart rate (HR) using a standard cuff sphygmomanometer (Omron) and Mean Arterial Pressure (MAP) and Pulse Pressure (PP) using the standard formula. The exposures to particulate matter < 2.5µm (PM2.5) and Black Carbon (BC) from biomass fuel were measured for 24 hours using a personal monitor, RTI MicroPEM (RTI International, NC), among healthy, non-smoking women (n=400) and men (n=200). A multiple linear regression model adjusted for potential confounders was used to examine the association between HAP exposures and hemodynamic outcomes.

The average 24-hour PM2.5 concentration was 167.7 µgm-3 for females and 98.0µgm-3 for males. The average 24-hour concentration of BC was 14.1µgm-3 for females and 10.3µgm-3 for males. In the adjusted multivariable regression model, an 1% increase in BC resulted in a 1.6 mm of Hg reduction in MAP (95% CI: -3.24, -.03 mm of Hg, P=0.04), 2.8 mm of Hg increase in PP (95% CI: 1.55, 4.22 mm of Hg, P=0.00) and 2.6 mm of Hg reduction in DBP (95% CI: -4.09, -1.10 mm of Hg, P=0.00). No association was observed between BC and SBP as well as BC and HR. PM2.5 was not associated with any of the hemodynamic parameters even after adjusting for age, cooking duration, household income, and Body mass index (BMI).

This population-based study provides evidence that exposure to HAP (BC) is linked with central hemodynamic parameters, especially MAP and PP, which have negative implications for cardiovascular health when they become high and low.

HAP, Hemodynamics, Bangladesh

P-0228 Fine particulate matter shown to influence cytokine and chemokine levels during pregnancy

Amanda Goodrich[1], Chelsea Kelland[1,2], Heather Volk[3], Judy Van De Water[1,2], Rebecca Schmidt[1,2]
[1]University of California, Davis, Davis, USA, [2]UC Davis MIND Institute, Sacramento, USA, [3]Johns Hopkins University, Baltimore, USA

BACKGROUND AND AIM: Pregnancy is a period vulnerable to environmental exposures like air pollution that disrupt immune regulation or induce inflammatory responses.

METHODS: Participants were 148 mother–child pairs from MARBLES (Markers of Autism Risk in Babies – Learning Early Signs), a high familial risk ASD cohort. Self-reported maternal address history was obtained for the entire pregnancy period and the 3 months prior to pregnancy. Daily PM2.5 (particulate matter < 2.5 μm in diameter) exposure values were spatially interpolated from the U.S. Environmental Protection Agency's (EPA) Air Quality System (AQS) monitoring stations' locations to the residence locations using inverse distance-squared weighting. Trimester-specific PM2.5 averages were assigned. Maternal plasma samples from each trimester were quantified for 29 cytokines and chemokines using Luminex multiplex analysis technology. Cytokines and chemokines were natural log transformed and standardized. Betas and 95% confidence intervals (CIs) for an interquartile range (IQR) change in PM2.5 were estimated using confounder-adjusted linear regression.

RESULTS: Pre-pregnancy PM2.5 was associated with a statistically significant increase in first trimester IL-8, IL-1β, MIP-1β, and TNFα values and in second trimester IL-7 and EGF values, and with a statistically significant decrease in third trimester IL-10. Trimester 2 PM2.5 was associated with a statistically significant decrease in second trimester IL-12 (p40) and EGF and with third trimester GM-CSF, IL-10, and IL-15. Trimester 3 PM2.5 was associated with a statistically significant decrease in third trimester IFN-γ, IL-2, IL-1ra, and IL-5.

CONCLUSIONS: PM2.5 appears to be associated with a shift from typical cytokine and chemokine levels that differs by trimester. Future studies should examine the ramification of such changes in cytokine and chemokine profiles associated with air pollution exposure.

P-0229 Ultrafine particulate matter exposure during second year of life associated with increased risk of autism spectrum disorder in mixtures model

Amanda Goodrich[1], Michael Kleeman[1], Daniel Tancredi[1], Yunin Ludeña[1], Deborah Bennett[1], Irva Hertz-Picciotto[1,2], Rebecca Schmidt[1,2]

[1]University of California, Davis, Davis, USA, [2]UC Davis MIND Institute, Sacramento, USA

BACKGROUND AND AIM: Prenatal and early life exposure to air pollution has been shown to be associated with autism spectrum disorder (ASD) risk, but the results have been mixed and to our knowledge, no study has reported on effects of combined exposures to multiple air pollutants using a mixtures approach. We applied a multidomain, multipollutant approach to assess the association between ASD and air pollution.

METHODS: The study consisted of 484 TD children and 707 children with ASD from the CHARGE case-control study. Air pollution exposures for NO2, and Ozone, fine (PM2.5) and ultrafine (PM0.1) particles were predicted using a chemical transport model with statistical bias adjustment based on ground-based monitors. Averages were calculated for each pregnancy period (pre-pregnancy, each trimester of pregnancy, and first and second year of life) for all births between the year 2000 and 2016. The air pollution (AP) variables were natural log transformed and then standardized. We estimated individual and joint effects of AP exposure with ASD and evaluated potential interactions among AP variables for each pregnancy period, using component-wise and hierarchal Bayesian Kernel Machine Regression (BKMR) models.

RESULTS: In component-wise BKMR models that included PM0.1, NO2, and Ozone, we found a strong increasing risk of ASD in year 2 of life with increasing PM0.1 (Posterior inclusion probability, PIP, = 0.99). This held true in hierarchal models when grouped by time or by pollutant. In component-wise BKMR models that included PM2.5, NO2, and Ozone, we found that NO2 and Ozone in years 1 and 2 were associated with ASD in an inverted U shape. No robust associations were observed in the prenatal or pregnancy periods.

CONCLUSIONS: PM0.1 appears to be associated with an increased risk of ASD in year 2 of life. Future research should examine ultrafine particulate matter in relation to ASD.

P-0231 Evaluation of adult and pediatric burns from domestic fuel use at the Douala General Hospital, Cameroon

Lifafa Kange[1], Frederico Lorenzentti[2], Humphrey Atongno[1,4], Emmanuel Betang[1], Elisa Puzzolo[2], Daniel Pope[2], 1,3 Bertrand Hugo Mbatchou Ngahane[1,3]

[1]Douala General Hospital, Douala, Cameroon, [2]University of Liverpool, Department of Public Health, Policy and Systems, Liverpool, UK, [3]University of Douala, Faculty of Medicine and Pharmaceutical Sciences., Douala, Cameroon, [4]University of Buea, Faculty of Health Sciences, Department of Public Health, Buea, Cameroon

BACKGROUND AND AIM: Burns have a significant contribution to the global burden of death and disability accounting for over 300,000 deaths occurring yearly, with majority in low-and middle-income countries where solid fuels are widely used for cooking. The aim of this study was to characterize burns from domestic fuel among burns patients received at the Douala General Hospital (DGH), Cameroon

METHODS: A descriptive study involving adult and paediatric burn patients admitted in the burn unit during a 6 months period at the DGH was conducted. A consecutive sampling was used to include the participants. The Global burn registry data collection tool with closed and open ended questions was used for data collection between September 2021 and February 2022.

RESULTS: A total of 61 patients participated, with a mean age of 25.8±20.3 years; majority were aged 1 to 10 years (31.1%) and 31 to 40 years (24.6%). Majority of the participants were males with 41(67.2%) participants. Majority of the burns were due to electrical causes (n=21; 34.4%) while flame from cooking were involved in 10 subjects (16.4%). The main parts of the body involved were the trunk (75%), arms (67.2%) and legs (67.2%). Among the participants with burns from cooking, the main sites were head (90%), arms (80%) and legs (70%). The total body surface was less than 20% in 29 participants (47.5%) and 21-40% in 16 (26.2%). The mortality rate was 24.6%, although insignificant (P=0.21), this rate was higher for burns from flame cooking than burns of other causes.

CONCLUSIONS: Burn injuries are frequent in Cameroon, with cooking fuels being responsible for 16.4% of them. The related mortality rate remains very high. It is therefore necessary to create awareness and reinforce strategies to reduce the burden of burn accidents.

P-0244 Multiple Air Pollutants Exposure and Leukemia Incidence in Tehran, Iran

Zahra Khorrami[2], Mohsen Pourkhosravani[3], Marzieh Eslahi[1], Maysam Rezapour[4], Mohammad Esmail Akbari[2], Heresh Amini[5], Seyed Mahmood Taghavi-Shahri[5], Nino Künzli[6], Koorosh Etemad[2], Narges Khanjani[1]

[1]Kerman University of Medical Sciences, Kerman, Islamic Republic of Iran, [2]Shahid Beheshti University of Medical Sciences, Tehran, Iran, [3]Shahid Bahonar University of Kerman, Kerman, Iran, [4]Mazandaran University of Medical Sciences, Sari, Iran, [5]University of Copenhagen, Copenhagen, Denmark, [6]University of Basel, Basel, Switzerland

BACKGROUND AND AIM: Leukemia is one of the most common cancers and may be associated with exposure to environmental carcinogens, especially outdoor air pollutants. The objective of this study was to investigate the association of ambient air pollution and leukemia in Tehran, Iran.

METHODS: In this ecological study, data about the residential district of leukemia cases diagnosed from 2010 to 2016 were inquired from the Ministry of Health cancer database. Data from a previous study was used to determine long-term average exposure to different air pollutants in 22 districts of Tehran. Latent profile analysis (LPA) was used to classify pollutants in two exposure profiles. The association between air pollutants and leukemia incidence was analyzed by negative binomial regression.

RESULTS: The districts with higher concentrations for all pollutants were near the city center. The incidence rate ratio (IRR) was positive but non-significant for most of the air pollutants. However, annual mean NOx was directly and significantly associated with total leukemia incidence in the fully adjusted model (IRR (95% CI): 1.03 (1.003, 1.06) per 10 ppb increase). Based on LPA, districts with a higher multiple air-pollutants profile were also associated with higher leukemia incidence (IRR (95% CI): 1.003 (0.99, 1.007) per 1 ppb increase).

CONCLUSIONS: Our study shows that districts with higher air pollution (nitrogen oxides and multi-pollutants) have higher incidence rates of leukemia in Tehran, Iran. This study warrants conducting further research with individual human data and better control of confounding.

KEYWORDS: Air pollution; multiple pollutants; pollutant profile; Leukemia; Latent profile analysis

P-0253 Association between historical redlining and neighborhood deprivation in North Carolina

Monica Jimenez[1], Danielle T Lobdell[2], Alison K Krajewski[2], Kristen M Rappazzo[2], Lynne C Messer[3], Thomas J Luben[2]
[1]Oak Ridge Institute for Science and Education (ORISE) Postdoctoral Fellow at US EPA, Chapel Hill, USA, [2]US Environmental Protection Agency, Center for Public Health and Environmental Assessment, Research Triangle Park, USA, [3]OHSU-PSU School of Public Health, Portland, USA

BACKGROUND AND AIM: In the late 1930s, the Home Owners' Loan Corporation created maps that ranked neighborhoods considered high risk for mortgage lending; these ratings denied residents, usually racial, ethnic, and religious minorities, the opportunity to become homeowners and accumulate wealth. We explored whether historical designation as a redlined neighborhood predicted contemporary (2010) neighborhood-level deprivation in North Carolina (NC) cities (Asheville, Charlotte, Durham, Greensboro, Winston-Salem).

METHODS: We examined 142 NC census tracts with historical redlining data. Because neighborhoods can be disadvantaged in many ways, a composite index representing poverty, occupation, housing, employment, and education was used for determining the relationship between neighborhood deprivation and having been previously redlined. To create the exposure, we overlayed a census tract shapefile layer on high-resolution digital maps of historical redlining, assigning a redlining rating of Best (N=15), Still Desirable (N=14), Declining (N=73), or Hazardous (N=40). The ratings were further combined to create exposure categories as follows: Best or Still Desirable (BSD, referent), Declining, Hazardous, and a combined redlined areas category that included both Declining and Hazardous (DH). Linear models estimated the associations between historical redlining ratings and contemporary neighborhood deprivation.

RESULTS: Neighborhood deprivation scores ranged from -1.78 to 2.72, with a higher score indicating worse neighborhood deprivation. When comparing the combined redlined areas (DH) to BSD areas, we observed increasing neighborhood deprivation (1.34 increase in index score [95% CI: 1.01, 1.67]). We observed increasing neighborhood deprivation score when comparing Declining or Hazardous ratings individually to BSD areas (1.24 increase in score [95% CI: 0.93, 1.55]; 1.57 increase in score [95% CI: 1.15, 1.98], respectively).

CONCLUSIONS: Results suggest that redlined neighborhoods are associated with increased neighborhood deprivation 70 years later and may contribute to disparities in exposure to detrimental environments and associated effects on health and well-being.

P-0261 Reduction of noise-induced change in cardiovascular functions and subjective sensations when using passive and active hearing protection devices

Yi-Chun Lin[1], Ai-Luen Tsai[1], Chen-Peng Chen[1]
[1]*China Medical University Department of Occupational Safety and Health, Taichung City, Taiwan*

Impulse and continuous noise occur frequently in the workplace and harm the physiological and psychological capability of the workers. This study investigated how the exposure to noise of varying acoustic pressure and frequency influenced cardiovascular functions and subjective sensations of people and how the use of passive and active hearing protection devices (HPDs) reduced the impacts.
Twenty participants (10 males and 10 females) were exposed to three levels of sound for 5 min each level in the order of ascending acoustic pressure, 65, 85, or 100 dBA. The participants used either foam earplugs or electronic earplugs that compressed noise while allowing transmission of speech. The experiment was first conducted at a noise frequency of 200 Hz and repeated at 1,000 Hz. Changes in cardiovascular functions (blood pressures, heart rate, and metabolic rate) and those potentially involved in local hemodynamics (skin capillary blood flow and transepidermal water loss) of the participants were measured intermittently. Subjective perceptions of noise intensity, harshness, annoyance, and reduction in attention and short-term memory were also evaluated.
The noise exposure significantly increased the blood pressures and heart rate and the sensations of noise intensity, annoyance and sharpness. The most prominent increase was observed in the first 5 min of exposure, even though the acoustic pressure during this stage was the same as that of the background (white noise). The cardiovascular functions of the participants returned to the baseline 15 min after the exposure ended. The foam earplugs provided better reduction in sounds of low frequency whereas the electronic plugs performed better against those of high frequency.
The physiological impacts of noise exposure were determined by the physical characteristics of the noise. On-site evaluation of the acoustic environment and job requirements should be performed before HPDs were selected to manage the exposure.

KEYWORDS: Noise exposure, hearing protection devices.

P-0279 Heat Policies and AC Availability in US Prison Systems

Marjorie Segule[1], Jessica Lin[1], Joseph Allen[1], Monik Jimenez[2,3]
[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Harvard Medical School, Boston, USA, [3]Brigham and Women's Hospital, Boston, USA

BACKGROUND AND AIM: Climate change will increase the number of hot days and heatwaves leaving incarcerated populations particularly vulnerable to extreme heat due to their lack of agency and control over their heat exposure. Previous prison heat policy analysis has not utilized Heat Index to provide context for the implementation of policies or had access to air-conditioning data. We aimed to examine the coverage and gaps of US prison system heat policies and air-conditioning access.

METHODS: Prison heat policies were identified using 52 prison system (50 states, DC, and Federal Bureau of Prisons) websites and complemented by state legislation. Heat policies were analyzed using the National Weather Service's (NWS) Heat Index Calculator on maximum reported temperature values. Facility-level air-conditioning data for 18 prison systems were public or received through public records requests by UCLA's COVID-19 Behind Bars, with facility function, capacity, and heat risk collected from federal, state, and the Intercept's Climate and Punishment datasets.

RESULTS: Half of the prison systems had publicly-available heat policies (n=52), of which 81% included temperature values (n=21). 64% of heat indices using maximum indoor temperature (n=14) would be classified as "caution" and 63% of heat indices using temperatures when respite resources would be provided (e.g. extra water) (n=8) were classified as "extreme caution" by the NWS assuming 50% relative humidity. 18% of facilities (n=374) lacked AC access completely. Among these, 55% of non-air-conditioned facilities (41,000 operational capacity) are at "severe or extreme heat risk". Overall, 23% of facilities whose function includes serving heat-sensitive populations (n=202), lack any air-conditioning despite their heat risk.

CONCLUSIONS: This study emphasizes the need for national correctional temperature policies and air-conditioning requirements to protect the thermal health of those who live and work in carceral facilities.

P-0287 Modeling energy and exposure benefits through integrated ventilation upgrades and rooftop gardens in a high school in Boston, MA

Catherine Connolly[1], Sarabeth Buckley[2], Pamela Templer[3], Jacqueline Ashmore[4], Luis Carvalho[5], Nathan Phillips[6], Jonathan Levy[1], M. Patricia Fabian[1]

[1]Boston University School of Public Health, Boston, USA, [2]University of Cambridge, Cambridge, UK, [3]Boston University Department of Biology, Boston, USA, [4]Borrego Solar, San Diego, USA, [5]Boston University Department of Mathematics and Statistics, Boston, USA, [6]Boston University Earth and Environment Department, Boston, USA

BACKGROUND AND AIM: Many U.S. schools have poor indoor ventilation, impacting air quality (IAQ), which is associated with adverse learning outcomes for children (e.g. reduced cognition, academic performance). However, increased ventilation results in increased energy consumption, which conflicts with goals to lower utility bills and carbon emissions. Addressing these challenges requires innovative and sustainable solutions. We propose a novel approach to simultaneously implement indoor ventilation upgrades and rooftop gardens, and model the impacts on energy use, financial costs, and carbon cycling in a Boston, MA high school.

METHODS: We measured CO2 concentrations continuously for a week in 13 classrooms and at exhaust rooftop vents during a two-month period in Spring 2019. We calculated baseline school-level average ventilation rates and estimated the energy needed to increase indoor ventilation to reduce CO2 to recommended indoor values (i.e. <1000 ppm). We then compared to yearly modeled energy savings and carbon emissions reductions occurring through plant carbon capture at a rooftop garden.

RESULTS: The baseline median classroom CO2 concentration was 840 ppm and exceeded 1000 ppm 33% of the school day. The estimated ventilation rate during occupancy was 4 L/s/person, below the recommended 7 L/s/person. Increasing ventilation to recommended levels would increase yearly total energy, cost, and carbon emissions (1-4%). A rooftop garden would provide net decreases of energy (12%), cost (13%), and carbon emissions (23-46%) with the higher end of this range attributed to plant growth enhancement.

CONCLUSIONS: Our analyses demonstrated the potential for integrated interventions in school buildings that can improve IAQ while capturing carbon through rooftop gardens. We found that CO2 levels of concern persist in schools, but could be vented to rooftops to reduce exposures and benefit plant growth. Future studies should evaluate alternative rooftop garden configurations that yield maximal energy and carbon reduction benefits.

KEYWORDS: Schools, CO2, energy, rooftops

P-0292 The changes of lipid profiles among Chinese adults may be associated with legacy and emerging per- and polyfluoroalkyl substances: Evidence from China National Human Biomonitoring

Bing Wu[1], Yuebin Lv[1], Xiaoming Shi[1]
[1]*National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND AND AIM: In the past decade, the levels of cholesterol and lipid profiles have drastically changed. Whether these changes may be associated with legacy and emerging PFASs is worth exploring. In this study, we aimed to explore the associations of single and mixed exposure to legacy and emerging PFASs with lipid profiles in general Chinese adults.

METHODS: A total of 10855 adults aged 18 and older from China National Human Biomonitoring (CHBNM) were recruited. Weighted multiple linear regression was used in single-pollutant models to explore the associations of PFAS with lipid profiles. Qgcomp was used to explore the joint associations of 8 PFAS mixtures (PFOA, PFNA, PFDA, PFUnDA, PFHxS, PFHpS, PFOS, 6:2Cl-PFESA) with lipid profiles.

RESULTS: Single and multiple pollution models showed that legacy and emerging PFASs were positively associated with lipid profiles. The adjusted β (95% confidence intervals: CI) of log(10) transformed PFOA, PFOS, PFNA and 6:2 Cl-PFESA with TC were 0.123 (0.058, 0.187), 0.214 (0.151,0.277), 0.227 (0.159, 0.295) and 0.115 (0.066, 0.164). The adjusted estimated changes (95%CI) of PFAS mixtures with TG, TC, LDL-C, HDL-C, and non-HDLC were 0.023 (0.009, 0.037), 0.253 (0.225,0.281), 0.149 (0.125,0.174), 0.081 (0.07,0.092), and 0.172 (0.145,0.199), respectively. Qgcomp model showed that PFNA (67.7%) contributed the most to TG, PFUnDA (30.2%) contributed the most to TC, PFHpS (36.7%) contributed the most to LDLC, PFUnDA (74.8%) contributed the most to HDLC, and PFHpS (38.6%) contributed the most to non-HDLC. However, compared with legacy PFASs, 6:2 Cl-PFESA contributed less to the lipid profiles.

CONCLUSIONS: The changes of lipid profiles among Chinese adults may be associated with legacy and emerging PFASs. Compared to legacy PFASs, emerging PFASs such as 6:2 Cl-PFESA may be less harmful to lipids.

KEYWORDS: Per- and polyfluoroalkyl substances, Lipid profiles, Joint effects, emerging PFAS.

P-0297 Greenspace exposure and depressive symptoms: findings from the French CONSTANCES cohort

Mohammad Javad Zare Sakhvidi[1], Antoine Lafontaine[2], Emeline Lequy[3], Claudine Berr[4], Payam Dadvand[5,6,7], Kees de Hoogh[8,9], Danielle Vienneau[8,9], Marcel Goldberg[3], Marie Zins[3], Cédric Lemogne[10], Bénédicte Jacquemin[2]

[1]Occupational Health Department, School of Public Health, Shahid Sadoughi University of Medical Sciences, Yazd, Islamic Republic of Iran, [2]Univ Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) – UMR_S 1085, F-35000, Rennes, France, [3]Université Paris Cité, Unité "Cohortes en Population" INSERM, Université Paris Saclay, UVSQ, UMS 011, Paris, France, [4]INM, Univ Montpellier, Inserm, Montpellier, France, [5]ISGlobal, Doctor Aiguader 88, 08003, Barcelona, Spain, [6]Universitat Pompeu Fabra (UPF), Doctor Aiguader 88, 08003, Barcelona, Spain, [7]CIBER Epidemiología y Salud Pública (CIBERESP), Melchor Fernández Almagro, 3-5, 28029, Madrid, Spain, [8]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [9]University of Basel, Basel, Switzerland, [10]Service de Psychiatrie de l'adulte, AP-HP, Hôpital Hôtel-Dieu, F-75004, Paris, France

BACKGROUND AND AIM: The association between greenspace exposure and different dimensions of depression is yet to be established. We aimed to explore this association in a large population-based cohort.

METHODS: Data from the enrollment phase of the French CONSTANCES cohort (2012-2020) were analyzed cross-sectionally. Depressive symptoms were measured by the Centre of Epidemiologic Studies Depression (CES-D) questionnaire allowing to compute a total CES-D score (≥19 used as a cutoff score to identify individuals at risk for clinical depression), and including four dimensions (depressed affect, disturbed interpersonal relations, low positive affect, somatic complaints). Residential surrounding greenspace exposure was quantified using the satellite-based Normalized Difference Vegetation Index (NDVI) at 300m buffer during the enrollment year. Adjusted multiple logistic and linear regression models were developed, reported as odds ratio [OR] for dichotomized total depressive symptoms, and ß for dimension-scores, with a 95% confidence interval [CI] for an interquartile range [IQR] increase in exposure. Analyses stratified by personal and socioeconomic variables were performed.

RESULTS: In total 185,781 participants were included (age: 46.80±13.61 years, 53.5% women). Residential surrounding greenness (average NDVI: 0.53; IQR=0.28) was significantly associated with lower odds of having depressive symptoms (OR [95%CI]: 0.94 [0.90-0.99]). This exposure was also associated with a lower scores for all dimensions (ß [95% CI]: -0.043 [-0.053: -0.033]; -0.016 [-0.026:-0.006]; -0.020 [-0.030:-0.010]; and -0.019 [-0.029:-0.009] for depressed affect, disturbed interpersonal relations, low positive affect, and somatic complaints, respectively). We found suggestions for potentially stronger protective associations in men and participants with lower income.

CONCLUSION: Residential surrounding greenspace was associated with lower depressive symptoms in general, and all four dimensions especially depressed affect and somatic complaints. Considering depression prevalence, its burden, and the increasing trend of urbanization, our finding is of importance for policymakers.

P-0302 Comparing greenspace metrics and buffer methods in Metro Vancouver, Canada: Implications for environmental health research

Katherine White[1], Kate Weinberger[1], Connor Wolff[2], Trevor Dummer[1], Lawrence Frank[1,3]
[1]School of Population and Public Health, University of British Columbia, Vancouver, Canada, [2]School of Community and Regional Planning, University of British Columbia, Vancouver, Canada, [3]Urban Studies and Planning, University of California San Diego, San Diego, USA

BACKGROUND AND AIM: Access and exposure to greenspace has been shown to promote mental and physical health; however, not all studies have found these benefits, with some studies reporting no association and others reporting associations with adverse health outcomes. It has been suggested that the use of diverse greenspace metrics, the varied quality of these metrics, and the specific methods used to quantify exposure or access, may contribute to these inconsistent findings. This project sought to compare the results of using different metrics in Metro Vancouver, Canada.

METHODS: Greenspace metrics were calculated from the centroid of each 6-digit postal code. Average buffer normalized differences vegetation index (NDVI), green landcover, tree canopy cover, and park count were calculated using circular and network buffers, at both 400m and 1000m. Pearson's correlation coefficients were calculated to compare the results for each metric and method.

RESULTS: The number of parks was only weakly positively correlated with each of the other three greenspace metrics for 1000m circular buffers (NDVI $r = 0.12$; green land cover $r = 0.07$; tree canopy $r = 0.14$, $p < .01$). for 1000m network buffers (NDVI $r = -0.34$; green landcover $r = -0.12$; tree canopy $r = 0.05$, $p < .01$) two of the correlations became negative. Circular and network buffer were most highly correlated for the tree canopy (1000m $r = 0.92$; 400m $r = 0.86$, $p < .01$), whereas park count had the weakest correlation (1000m $r = 0.66$; 400m $r = 0.66$, $p < .01$).

CONCLUSIONS: The associations between greenspace metrics vary. Selection of buffering method may be particularly influential when using park count data. These findings support the importance of intentional selection of greenspace metric and measurement method in environmental epidemiological research.

P-0311 Source tracking swine fecal waste on household surfaces proximal to swine concentrated animal feeding operations in southeastern North Carolina, USA

Kathleen Kurowski[1], Kristoffer Spicer[1], Carolyn Gigot[1], Nora Pisanic[1], Devon Hall[2], Devon Hall Jr[2], Margaret Carr[2], Arika Miller[2], Unique Hall[2], Ana M. Rule[1], Kate Kruczynski[1], Christopher D. Heaney[1]

[1]Johns Hopkins University, Department of Environmental Health and Engineering, Baltimore, USA, [2]Rural Empowerment Association for Community Help, Warsaw, USA

BACKGROUND AND AIM: In North Carolina, swine industrial livestock operations (ILOs) are located disproportionately in low-income and communities of color. Swine ILO neighbors have raised concerns about emissions from ILOs. We aim to compare the detection frequency and quantity of a swine-specific Bacteroides fecal microbial source-tracking marker (pig-2-bac DNA) contamination on outdoor and indoor household surfaces at ILO worker (ILO) compared to ILO neighbor (ILO-N) and metropolitan resident (metro) homes in North Carolina.

METHODS: at enrollment, ILO, ILO-N, and metro participants collected 2 outdoor and 2 indoor household surface settled dust samples wiping a Copan flocked swab across a 10 cm2 area. Using quantitative real-time PCR, pig-2-bac DNA copy number per area was estimated in household samples. We used logistic and linear regression to evaluate differences in pig-2-bac prevalence and quantity between the three household groups and on outdoor compared to indoor surfaces.

RESULTS: Ninety-one households (354 swabs) were sampled: 30 ILO (113 swabs), 31 ILO-N (119 swabs) and 30 metro (122 swabs). Prevalence of Pig-2-bac detection on >=1 household surface was 33%, 39%, and 0% among ILO, ILO-N, and metro households, respectively. Compared to metro households, higher log-10 pig-2-bac DNA copy number per 10 cm2 was observed at ILO (beta=0.5; 95% confidence interval [CI]=0.2, 0.7) and ILO-N households (beta=0.2; 95% CI=0.06, 0.4). Compared to indoor surfaces, higher log-10 copy number per 10 cm2S was observed on outdoor surfaces (beta = 0.181, 95% CI=0.02, 0.3).

CONCLUSIONS: Swine-specific fecal contamination was detected at a higher prevalence in ILO-N compared to ILO workers and metro resident homes. Both ILO and ILO-N groups had statistically significant increases in copy number compared to the metro group.

KEYWORDS: microbial contamination, pig-2-bac, industrial livestock operations, concentrated animal feeding operations

P-0312 Trends and Patterns in Industrial and Commercial Sources of Lead (Pb) in the US

Nichole Kulikowski[1], Stephanie DeFlorio-Barker[1], Rogelio Tornero-Velez[1], Archana Lamichhane[1]
[1]*US EPA, Durham, USA*

BACKGROUND AND AIM: Lead (Pb) exposures in the US have declined over the last 40 years due to phaseout of Pb in gasoline, residential paint, and plumbing. However, Pb still circulates in commerce (batteries, ammunition, glass, pigments, e-waste). While the Environmental Protection Agency (EPA) tracks large industrial movements of Pb (>25,000lbs), modest Pb movements are not identified and may translate to substantial cumulative exposure and public health significance due to proximity to residences, schools, or places of work. This research aims to identify and evaluate trends in commercial sources of Pb in the US.

METHODS: Peer-reviewed literature was used to identify relevant commercial sources of Pb and link to corresponding Standard Industrial Classification (SIC) codes. Counts of each SIC code were calculated per census tract, using geolocations from Dun and Bradstreet (D&B) from 1990-2018. Data capturing measurable Pb emissions (Toxics Release Inventory (TRI)) and area-level socioeconomic measures (CDC's Social Vulnerability Index) were further linked by census tract. Data were analyzed using R and ArcGIS.

RESULTS: A total of 31 unique SIC codes were identified, corresponding to >1,300 potential Pb-emitting businesses in 1,265 census tracts. The most common commercial businesses represented shooting ranges (n=838) and refuse systems (n=221). Preliminary analyses data indicate widespread current Pb-emitting industries are widespread but further socioeconomic and Pb-emission data will be analyzed. Preliminary data show a decline in some identified industries over time.

CONCLUSIONS: Preliminary results show the number of Pb-emitting industries has decreased over time in the US. However, certain geographic areas of the USA yield higher densities of Pb-emitting industries and commercial businesses, which could have a profound public health significance. The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.

KEYWORDS: Lead (Pb) exposure, environmental justice

P-0320 Case-cohort study of the association between PFAS and cancers of the kidney and bladder among participants in the American Cancer Society's Cancer Prevention II cohort

Andrea Winquist[1], James Hodge[2], W. Ryan Diver[2], Lauren Teras, Juan Rodriguez[1], Johnni Daniel[1]
[1]U.S. Centers for Disease Control and Prevention, Atlanta, USA, [2]American Cancer Society, Atlanta, USA

BACKGROUND AND AIM: Some per- and polyfluoroalkyl substances (PFAS), including perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS), have been associated with genitourinary system cancers in some, but not all previous studies. Many studies did not consider histology. We examined associations between PFAS exposure and risk of histologic subtypes of kidney and bladder cancer.

METHODS: We conducted a case-cohort study within the American Cancer Society's prospective Cancer Prevention Study II (CPS-II) LifeLink cohort for which serum specimens were collected during 1998-2001 (ages ≥54 years). This study included a subcohort (500 men, 499 women) randomly selected from cohort members without prior cancer diagnoses at serum collection, and all persons with incident (after serum collection) first cancers of the kidney (n=158, including 109 renal cell carcinoma/adenocarcinomas [RCC] and 47 transitional cell carcinomas [TCC]) and bladder (n=401, including 390 TCC). Concentrations of PFOA, PFOS, perfluorohexane sulfonic acid, perfluorononanoic acid, perfluorooctane sulfonamide and perfluoroheptanoic acid were measured in stored serum. Multivariable Cox proportional hazards regression was used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for associations between PFAS concentrations and risk of RCC and TCC. Models accounted for the study design and controlled for sex (using stratification), age and year at blood draw, education, race/ethnicity, smoking and alcohol use, and occupational exposures (coal dust/tar, dyes, and diesel/gasoline; TCC only).

RESULTS: Serum PFOA concentrations were positively associated with RCC among women [HRs (95% CIs) for PFOA quartiles 2-4, respectively, vs. quartile 1: 1.33 (0.42-4.19), 1.66 (0.54-5.13), 3.14 (1.02-9.65)] but not men. TCC (bladder or kidney) was not significantly associated with the measured PFAS, although PFOS-TCC HRs were elevated among men.

CONCLUSIONS: This study provides additional evidence for an association between PFOA and RCC. Consideration of histologic types might help clarify inconsistencies in the literature on PFAS exposure and cancer.

KEYWORDS: PFAS, cancer

P-0321 Biomonitoring Legacy and Emerging Contaminants and Local Fish Consumption in Susceptible Great Lakes Populations, 2010-2020

Zheng Li[1], Tara Serio[1], Susan Manente[2], Deanna Scher[3], Elizabeth Lewis-Michl[4], Jonanthan Meiman[5], Elizabeth Irvin[1], Angela Ragin-Wilson[1]

[1]Centers for Disease Control and Prevention/Agency for Toxic Substances and Disease Registry, Atlanta, USA, [2]Michigan Department of Health and Human Services, Lansing, USA, [3]Minnesota Department of Health, St. Paul, USA, [4]New York State Department of Health, Albany, USA, [5]Wisconsin Department of Health Services, Madison, USA

BACKGROUND AND AIM: Over the past century, the Great Lakes, the world's largest fresh surface water system, has been contaminated with numerous chemical pollutants. From 2010 to 2020, the Agency for Toxic Substances and Disease Registry conducted the Biomonitoring of Great Lakes Populations program to assess exposure to legacy and emerging contaminants in susceptible populations who consumed fish caught in contaminated waterbodies.

METHODS: The Program consists of a series of cross-sectional studies conducted collaboratively with health departments in Michigan, Minnesota, New York, and Wisconsin. The target populations–including various angler and refugee populations in different areas with known contamination–were sampled and recruited independently using sampling strategies that were tailored for the specific populations. Participants completed questionnaires focusing on fish consumption and provided biological samples. Selected blood metals and polychlorinated biphenyls (PCBs) were measured in all participants. Some chemicals of emerging concern, such as per- and polyfluoroalkyl substances (PFAS), were also measured in several studies.

RESULTS: Body burden levels of mercury, lead, and perfluorooctane sulfonic acid (PFOS) in most target populations were elevated compared to the U.S. population. Locally caught fish consumption was associated with blood mercury and serum PFOS in most cohorts. Serum PCB was elevated only in the Detroit shoreline angler cohort and was associated with eating locally caught fish.

CONCLUSIONS: Most target populations in this program had higher exposures to some metals and PFOS, and the exposures were generally associated with eating fish caught in local, contaminated waterbodies. The results generated from this program helped guide public health actions to reduce chemical exposures in vulnerable Great Lakes populations, including updated fish advisories and targeted education and outreach on risk and benefit of fish consumption.

P-0326 Exposure to four metals and depressive symptom in adults: NHANES epidemiological study

Jiyoung Shin[1], Yuan Luo[1]
[1]*Dept. of Preventive Medicine, Feinberg School of Medicine, Northwestern University, Chicago, USA*

BACKGROUND AND AIM: Although some of the heavy metal are known to have an adverse effect on neurobehavioral symptoms, studies on the exposure to multiple metal and depression are limited. This study purposed to evaluate the association between individual and multiple heavy metal and depression in the adult population by using National Health and Nutrition Examination Survey (NHANES) dataset.

METHODS: This study used the data from the U.S. NHANES between 2007 to 2014 to examine cross-sectional relationships between metal exposure and depression in adult over 20 years. After applying exclusion criteria, 6021 subjects were included in the final analysis. We used four urinary metals including mercury, cadmium, lead, and arsenic as exposure variables. Patient Health Questionnaire (PHQ-9) was used to assess the depression symptom of the participants. Multivariate linear regression (MLR) for each heavy metal exposure and quantile g-computation model for multiple exposure to four heavy metals were applied. Stratification analysis according to the alcohol habit of the subjects was also performed.

RESULTS: MLR models indicated that urinary cadmium was positively associated with continuous depression score (β = 0.39, 95% confidence interval (CI): 0.24-0.53). Other urinary metals showed positive relationship with continuous depression score, but it was not significant. In the quantile g-computation model, statistically significant positive association were found between the mixture of urinary metals and depression score (Difference in PHQ-9 score increase: 0.32, 95% CI: 0.14-0.50). When stratified the model by alcohol consumption habit, a stronger association was found in a heavy alcohol consumption group.

CONCLUSIONS: When comparing the results from different models, not only individual urinary heavy metal was related to depression score, but also four heavy metals mixture was positively associated with a depression. Future cohort studies are needed to clarify the effect of metal mixture.

KEYWORDS: Heavy metal, depression, quantile g-computation, alcohol consumption

P-0330 Predicting Cumulative Lead (Pb) Exposure Using the Super Learner Algorithm

Xin Wang[1], Kelly Bakulski[1], Bhramar Mukherjee[1], Howard Hu[2], Sung Kyun Park[1]
[1]University of Michigan, Ann Arbor, USA, [2]University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Chronic lead (Pb) exposure causes long term health effects. While recent exposure can be assessed by measuring blood lead (half-life 30 days), chronic exposures can be assessed by measuring lead in bone (half-life of years to decades). Bone lead measurements, in turn, have been measured non-invasively in large population-based studies using x-ray fluorescence techniques, but the method remains limited due to technical availability, expense, and the need for licensing radioactive materials. Thus, we developed prediction models for bone lead concentrations using a flexible machine learning approach--Super Learner, which combines the predictions from a set of machine learning algorithms for better prediction performance.

METHODS: The study population included 695 men in the Normative Aging Study, aged 48 years and older, whose bone (patella and tibia) lead concentrations were directly measured using K-shell-X-ray fluorescence. Ten predictors (blood lead, age, education, job type, weight, height, body mass index, waist circumference, cumulative cigarette smoking (pack-year), and smoking status) were selected for patella lead and 11 (the same 10 predictors plus serum phosphorus) for tibia lead using the Boruta algorithm. We implemented Super Learner to predict bone lead concentrations by calculating a weighted combination of predictions from 8 algorithms based on selected predictors.

RESULTS: In the nested cross-validation, the correlation coefficients between measured and predicted bone lead concentrations were 0.58 for patella lead and 0.52 for tibia lead, which has improved the correlations obtained in previously-published linear regression-based prediction models. We evaluated the applicability of these prediction models to the National Health and Nutrition Examination Survey for the associations between predicted bone lead concentrations and blood pressure, and positive associations were observed.

CONCLUSIONS: These bone lead prediction models provide reasonable accuracy and can be used to evaluate health effects of cumulative lead exposure in studies where bone lead is not measured.

P-0331 Interactions between chemical mixtures and the overall antioxidant and inflammatory capacity of the diet in the association between dietary exposure to chemical mixtures and mortality risk in the E3N French prospective cohort

Chloé Marques[1], Pauline Frenoy[1], Thibault Fiolet[1], Gianluca Severi[1,2], Francesca Romana Mancini[1]
[1]*Université Paris-Saclay, UVSQ, Inserm, Gustave Roussy, "Exposome and Heredity" team, CESP UMR1018, Villejuif, France,* [2]*Department of Statistics, Computer Science, Applications "G. Parenti", University of Florence, Florence, Italy*

Since food is contaminated by many chemicals which may interact, resulting in additive, synergistic or antagonistic effects, it is necessary to study the exposure to chemical mixtures. These mixtures can interact with nutrients by targeting the same molecular signalling pathways and biological functions. Chemicals and nutrients may impact oxidative stress and chronic systemic inflammation, both associated with non-communicable diseases.
Our objective was to investigate the association between dietary exposure to chemical mixtures and mortality risk in the E3N (Etude Epidémiologique auprès de femmes de l'Education Nationale) prospective cohort, and to study the interactions between these mixtures and nutrients.
We considered 72585 women from the E3N cohort who completed a food frequency questionnaire in 1993. Using sparse non-negative matrix under-approximation, we identified the six main chemical mixtures to which these women were exposed through the diet. We analysed the association between dietary exposure to these mixtures and all-cause and cause-specific mortality with Cox proportional hazard models. We investigated the interactions between these exposures and the overall antioxidant and inflammatory capacity of the diet.
During the follow-up (1993-2014), 6441 deaths occurred. We observed statistically significant interactions between some chemical mixtures and the overall antioxidant and inflammatory capacity of the diet which modified the relationship between dietary exposure to the mixtures and mortality. for example, when considering a mixture characterised by the exposure to persistent organic pollutants, no association was highlighted with all-cause mortality for women with an anti-inflammatory diet (HR 1.02, CI 0.90-1.15), while a positive association was found for women with a pro-inflammatory diet (HR 1.16, CI 1.02-1.31).
This study highlighted for the first time the existence of interactions between chemical mixtures and the overall antioxidant and inflammatory capacity of the diet in a human-based study. More studies are needed to clarify the underlying biological mechanisms.

P-0333 Positive association between dietary exposure to polybrominated diphenyl ethers and breast cancer risk in the French E3N cohort: the role of vegetable oil consumption

Pauline Frenoy[1], Chloé Marques[1], Thibault Fiolet[1], German Cano-Sancho[2], Gianluca Severi[1,3], Francesca Romana Mancini[1]

[1]Paris Saclay University, Inserm CESP UMR1018, "Exposome and Heredity" team, Paris, France, [2]LABERCA, Oniris, INRAE, Nantes, France, [3]University of Florence, Department of Statistics, Computer Science, Applications "G. Parenti", Florence, Italy

BACKGROUND AND AIM: Exposure to endocrine-disrupting chemicals, like Polybrominated diphenyl ethers (PBDE), is suspected to play a role in the occurrence of breast cancer. Moreover, there is growing evidence that food chemical contaminants could interact with different components of the diet, especially lipophilic ones, such as PBDE. In an in-vitro study, vegetable oil has been shown to increase the bioaccessibility of PBDE. The objective of the present study was to assess the association between dietary intake of PBDE and breast cancer risk in the French E3N cohort study, and to investigate the potential modification of this association by vegetable oil consumption or lipid intake.

METHODS: The study included 67 879 women. Intake of individual PBDE were estimated using food consumption data from a validated semi-quantitative food frequency questionnaire. Hazard Ratios (HR) and 95% Confidence Intervals (CI) were estimated for the association between total PBDE dietary intake and breast cancer risk. Interaction measures for vegetable oil consumption were estimated on both additive and multiplicative scales.

RESULTS: The women were followed for a maximum of 21.4 years, and 5 686 developed an incident breast cancer. A positive linear trend was highlighted between dietary intake of PBDE in quintile groups and breast cancer risk, borderline with statistical significance (p-trend=0.06, HRQ5vsQ1 and 95%CI: 1.09 [0.99;1.20]). Interaction measures for vegetable oil consumption were significant both in additive and multiplicative scales. Higher effect sizes of the association were highlighted in high consumers of vegetable oil, i.e. ≥4.6 g/day (HRQ5vsQ1 and 95%CI: 1.23 [1.08; 1.40]), and almost no effect were found in low consumers (HRQ5vsQ1 and 95%CI: 0.97 [0.86; 1.10]).

CONCLUSIONS: Highlighting such interactions between nutrients and chemicals is crucial to develop efficient dietary recommendations to limit the negative health effects associated to exposure to food chemical contaminants.

P-0335 Ovarian volume mediates associations of phthalate metabolites with anti-Mullerian hormone in midlife women

Maria Kloboves[1,2,3], Diana Pacyga[1,3], Elnur Babayev[4], Francesca Duncan[4], Paige Williams[5,6], Jodi Flaws[7], Rita Strakovsky[1,3]

[1]Department of Food Science & Human Nutrition, Michigan State University, East Lansing, USA, [2]Department of Epidemiology & Biostatistics, Michigan State University, East Lansing, USA, [3]Institute for Integrative Toxicology, Michigan State University, East Lansing, USA, [4]Department of Obstetrics and Gynecology, Northwestern University, Chicago, USA, [5]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [6]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, USA, [7]Department of Comparative Biosciences, University of Illinois, Urbana-Champaign, USA

BACKGROUND AND AIM: We previously reported positive associations of phthalates with anti-Mullerian hormone (AMH), a biomarker of ovarian reserve, in midlife women. Growing follicles produce AMH, so we evaluated associations of phthalates with ovarian volume (indicating folliculogenesis), considering whether this relationship explained associations of phthalates with AMH.

METHODS: Midlife women had a transvaginal ultrasound of right and left ovaries to calculate ovarian volume. Women provided one blood sample for AMH quantification and up-to-four urine samples across one menstrual cycle, which we pooled to quantify nine phthalate metabolites. We assessed AMH as a binary variable (above/below the level of detection). Covariate-adjusted linear regression models were used to evaluate associations of phthalates with mean left/right ovarian volumes (both ln-transformed). Using a formal mediation analysis, we estimated the proportion of overall associations between phthalates and high AMH (total association) explained by relationships of phthalates and mean ovarian volume (indirect association).

RESULTS: In 666 midlife women, 65% were non-Hispanic White, 67% were premenopausal, and 33% perimenopausal. Only mono(3-carboxypropyl) phthalate (MCPP) and monobenzyl phthalate (MBzP) were positively associated with mean ovarian volume. In adjusted models, each two-fold increase in MCPP and MBzP was associated with 4.13% (95%CI: -0.75, 9.01) and 7.12% (95%CI: 0.83, 13.40) larger ovarian volume, respectively. These relationships partially explained associations of MCPP or MBzP with high AMH. The indirect association between MCPP and ovarian volume (β=0.03, 95%CI: 0.00, 0.07) explained 19% of the total association between MCPP and high AMH (OR=1.16; 95%CI: 0.96, 1.37). Similarly, the indirect association between MBzP and ovarian volume (β=0.06, 95%CI: 0.00, 0.13) explained 17% of the total association between MBzP and high AMH (OR=1.37; 95%CI: 1.05, 1.70).

CONCLUSIONS: Phthalates may induce folliculogenesis, with implications for midlife hormone production. Future prospective studies are needed and could consider mediation approaches using complex chemical mixtures.

KEYWORDS: phthalates, ovarian volume, AMH

P-0336 Urinary phthalate metabolites and melamine are linked to early renal injury in pregnant mothers in Taiwan

Chia-Fang Wu[1], Ming-Tsang Wu[2]
[1]International Master Program of Translational Medicine, National United University, Miaoli, Taiwan, [2]Research Center for Environmental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan

BACKGROUND: Pregnant women exposed to two regularly encountered toxicants, melamine and phthalate, could potentially be at risk of kidney damage.
AIM
This study investigated the effects of melamine and phthalates, specifically di-(2-ethylhexyl) phthalate (DEHP), alone and interactively, on early renal injury in a nationwide cohort of pregnant women during their third trimester, participants in Taiwan's Maternal and Infant Cohort Study (TMICS).

METHODS: Participants received questionnaires, physical examinations, and blood and one-spot overnight urine tests during regular routine checkups their third trimester between October, 2012 and May, 2015. The specimens were analyzed for melamine, eleven phthalate metabolites, microalbumin and N-acetyl-beta-D-glucosaminidas (NAG), two markers of renal injury. We calculated estimated daily DEHP intake using measurements of three urinary DEHP metabolites. If a participant was found to have urinary albumin/creatinine ratio (ACR) higher than 3.5 mg/mmol, she was defined as having microalbuminuria.

RESULTS: In total, we analyzed data collected from 1433 pregnant women, who were found to have a median urinary melamine value of 0.63 μg/mmol Cr and estimated DEHP intake of 1.84 μg/kg/day. Compared to those in the lowest quartile of estimated DEHP intake, those belonging in the highest quartile had significantly increased urinary ACR ($\beta = 0.095$, $p = 0.043$) and microalbuminuria (adjusted OR = 1.752, 95% confidence interval = 1.118–2.746). A significant interactive effect between urinary melamine and estimated DEHP intake on urinary ACR and NAG was also found.

CONCLUSIONS: There is a strong association between exposure to these two pervasive toxicants, both independently and interactively, and the urinary indicators of early kidney injury we measured in this nationwide birth cohort of pregnant women.

P-0340 Urinary biomonitoring of glyphosate exposure among male farmers and non-farmers in the Biomarkers of Exposure and Effect in Agriculture (BEEA) study

Vicky C. Chang[1], Maria Ospina[2], Shuai Xie[1], Gabriella Andreotti[1], Melissa C. Friesen[1], Danping Liu[3], Nathaniel Rothman[1], Debra T. Silverman[1], Laura E. Beane Freeman[1], Antonia M. Calafat[2], Jonathan N. Hofmann[1]

[1]Occupational and Environmental Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, USA, [2]National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA, [3]Biostatistics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, USA

BACKGROUND AND AIM: Glyphosate is the most widely applied herbicide worldwide. Despite potential health effects of glyphosate, biomonitoring data of glyphosate exposure in agriculture and other settings are limited. We measured urinary glyphosate concentrations and assessed their determinants among male farmers and non-farmers from Iowa and North Carolina in the BEEA study.

METHODS: Based on questionnaire-assessed pesticide exposure histories, we selected four groups of BEEA participants: recently exposed farmers with occupational glyphosate use in the last 7 days (n=98), farmers with high cumulative lifetime days of glyphosate use (>80th percentile) but no use in the last 7 days (n=70), farmers with minimal lifetime glyphosate use (n=100), and non-farmers with no occupational pesticide exposure (n=100). We quantified glyphosate in first-morning void urine samples using ion chromatography isotope-dilution tandem mass spectrometry. We estimated geometric mean urinary glyphosate concentrations across groups and evaluated associations with potential determinants using linear regression.

RESULTS: Glyphosate was detected in urine of most recently (91%), high-lifetime (93%), and low-lifetime (88%) exposed farmers, as well as non-farmers (81%); geometric mean concentrations were 0.86, 0.58, 0.44, and 0.37 µg/L, respectively. Compared to non-farmers, urinary glyphosate concentrations were significantly elevated among recently exposed farmers (P<0.0001), particularly those who used glyphosate within 1 day of urine collection [age- and creatinine-adjusted geometric mean ratio (GMR)=6.4, 95% confidence interval (CI)=4.3-9.3] and those not wearing gloves during glyphosate application (GMR=2.6, 95% CI=2.0-3.4).

CONCLUSIONS: Preliminary results suggest that a high proportion of both farming and non-farming populations may be exposed to glyphosate. Substantial exposure contrast between those with and without recent occupational glyphosate use was detectable in urine. Given the short elimination half-life of glyphosate, the exposure differences between groups may be even greater than those reflected by measured urine concentrations. Continued biomonitoring of glyphosate in various settings is warranted.

KEYWORDS: Glyphosate, exposure assessment, pesticide biomonitoring

P-0346 Hazard and risk assessment for indoor air pollutants: dimethylsiloxanes, glycols, butanediol, hydrocarbons, trimethylbenzenes, benzene, naphthalene, and ethyltoluene

Kenichi Azuma[1], Hideto Jinno[2,4], Toshiko Tanaka-Kagawa[3,4], Shinobu Sakai[4]

[1]Kindai University Faculty of Medicine, Osakasayama, Japan, [2]Meijo University Faculty of Pharmacy, Nagoya, Japan, [3]Yokohama University of Pharmacy, Yokohama, Japan, [4]National Institute of Health Sciences, Kawasaki, Japan

Individuals living in an indoor environment are typically exposed to a greater variety of air pollutants than in an outdoor environment. Numerous sources of chemical emissions are found in the indoor environment, depending on the building materials as well as the lifestyle of the occupants. The quality of the indoor environment considerably impacts public health. Japan has established indoor air quality guidelines for 13 chemicals, including formaldehyde, acetaldehyde, xylene, ethylbenzene, styrene, 1,4-dichlorobenzene, and toluene. However, the types and concentrations of indoor pollutants have not been consistent over time due to alterations in lifestyle and development of novel household products and building materials. Therefore, a comprehensive approach and action plan for the overall reduction of health risks caused by indoor air pollutants are required for public health protection. To determine the high-risk indoor air pollutants that should be reduced, we conducted a preliminary risk assessment using data from nationwide exposure assessments and existing hazard data. In this assessment, identifications of the critical effects and the reference values obtained from reviewing the hazard or toxicological data are crucial. We identified indoor air pollutants that appeared with high frequency and high concentration in the nationwide exposure assessments. We previously reported the critical effects and reference values for acute and chronic effects of eight indoor air pollutants, including ethyl acetate, butyl acetate, propylene glycol monomethyl ether, 3-methoxy-3-methylbutanol, diethylene glycol methyl ether, diethylene glycol ethyl ether, propylene glycol monomethyl ether acetate, and methyl isobutyl ketone. In this study, the critical effects and the reference values of nine indoor air pollutants, including octamethyl cyclotetrasiloxan, decamethyl cyclopentasiloxan, propylene glycol, 1,3-butanediol, aliphatic saturated hydrocarbons (C8–C16), trimethylbenzenes, benzene, naphthalene, and ethyltoluene and the results of risk assessment are reported.

P-0348 Acetylcholinesterase activity and serum lead concentrations in pregnant women enrolled in the Rio Birth Cohort pilot Study, Brazil

Aline Santos[1], Liliane Silva[1], Isabella Giannini[1], Armando Meyer[1]
[1]*Federal University of Rio de Janeiro, Rio de Janeiro, Brazil*

BACKGROUND AND AIM: Lead (Pb) is considered one of the main chemicals of interest to public health, given its potential for neurotoxicity, especially in vulnerable populations such as pregnant women (WHO, 2020). One of the mechanisms proposed for Pb toxic effects on the nervous system is the acetylcholinesterase enzyme inhibition (AChE), considering that this metal mimics and inhibits the action of calcium in this enzyme (Breslller et al. 1991). Despite evidence from experimental studies, little is known about the effects of lead on AChE in humans (Nwobi et al. 2019). We evaluated the association between blood levels of Pb and erythrocyte AChE activity in pregnant women in an urban area of Rio de Janeiro.

METHODS: Cross-sectional study with 139 pregnant women enrolled in the Rio Birth Cohort Pilot Study in the third trimester of pregnancy. Socioeconomic and lifestyle data were obtained from a structured questionnaire. AChE activity was measured by the Ellman (1961) method modified by Oliveira-Silva (2000). Lead concentrations were measured in whole blood using inductively coupled plasma mass spectrometry (ICP-MS). Linear regression and Spearman correlation were used to assess the association between lead levels and erythrocyte AChE activity.

RESULTS: The median of lead concentrations in the whole blood of pregnant women was 3.9ug/dL (n=119). A weak negative correlation was observed between lead levels and AChE activity (rho= -0.289; p= 0.002). Elevated levels of lead seems to inhibit erythrocyte AChE activity (β= -0.30; 95%CI: -0.54, -0.06) in age-adjusted models.

CONCLUSIONS: Our results suggest that lead can inhibit erythrocyte AChE activity in pregnant women. This evidence reinforces the need to investigate a relationship little explored in the literature may indicate mechanisms of lead toxicity in humans.

P-0349 Persistent organic pollutant levels in maternal blood, umbilical cord blood, and breast milk: Results from the Rio Birth Cohort pilot Study, Brazil

Aline Santos[1], Josino Moreira[2], Antonio Azeredo[1], Ana Rosa[2], Volney Câmara[1], Carmen Asmus[3], Armando Meyer[1]
[1]Occupational and Environmental Health, Public Health Institute, Federal University of Rio de Janeiro., Rio de Janeiro, Brazil, [2]Center for Studies of Human Ecology and Worker's Health, National School of Public Health, Oswaldo Cruz Foundation., Rio de Janeiro, Brazil, [3]of Medicine, Maternity School Hospital, Federal University of Rio de Janeiro., Rio de Janeiro, Brazil

BACKGROUND AND AIM: Environmental exposure to 11 polychlorinated biphenyls (PCB) and 17 organochlorine pesticides (OCP) were evaluated in maternal blood, umbilical cord blood, and breast milk of women living in Rio de Janeiro, Brazil.

METHODS: The concentration of PCBs 28, 31, 52, 101, 105, 118, 128, 138, 153, 156, 180 and the OCPs DDT, chlordane, HCH, dicofol, dieldrin, endosulfan, metoxichlor, mirex, and pentacloroanisol, as well as some isomers and metabolites, were measured in 135 samples of maternal blood, 116 samples of umbilical cord blood, and 40, 47 and 45 breast milk samples during 1st, 3rd, and 6th follow-up months using gas chromatography triple quadrupole mass spectrometry (GC-MS/MS). Women were also asked to answer an enrollment questionnaire that included reproductive, lifestyle, residential, and sociodemographic questions.

RESULTS: The most commonly detected OCPs metabolites in the maternal blood were 4,4'-DDE (22.2%); β (8.9%); ɣ-HCH (7.4%); PCB 28 (4.4%); and PCB 153 (2.2%). In the umbilical cord blood, the most frequently found compounds were 4,4'-DDE (15.6%); 4,4'-DDT (10.4%); 4,4'-DDD (7.9%); β-HCH (11.2%), PCB 28 (4.3%); and PCB 153 (5.2%). In addition, p,p'-DDE was detected in 45, 47, and 13% of breast milk samples of the 1st, 3rd, and 6th follow-up months. Although not statistically significant, ∑DDT levels were higher among women with a pregestational BMI ≥30, non-white, and those older than >40 years. On the other hand, newborns with an Apgar score ≤8 at minute 5 of life showed significantly higher levels of ∑DDT in the umbilical cord blood.

CONCLUSIONS: Several persistent OCPs and PCBs were detected in the umbilical cord and maternal blood, and only p,p'-DDE was quantified during the three follow-ups. Although the concentrations of OCPs and PCBs were relatively low, they still pose a risk to the mothers' health, the pregnancy outcome, and the infants' post-natal development.

P-0350 The role of epidemiology studies in chemical risk assessment to inform risk characterization of vulnerable populations in Canada

Sareena McDonald[1]
[1]*Health Canada, Cornwall, Canada*

BACKGROUND AND AIM: The enhanced protection of vulnerable populations through the assessment of chemicals was a commitment made by the Government of Canada in 2018. Health Canada considers vulnerable populations in the assessment of existing chemical substances under the Canadian Environmental Protection Act (CEPA) (1999). Vulnerable populations include those in the general population with greater levels of exposure levels and/or increased biological susceptibility, resulting in the need for additional risk characterization. The populations considered in Screening Assessment Reports (SAR) may include infants and children, pregnant females, Indigenous communities and communities in close proximity to point source exposures, including commercial or industrial facilities. The aim of this abstract is to summarize and highlight the use of epidemiology data in risk characterization of chemical substances in vulnerable populations.

METHODS: An exploratory review of both draft and final SARs published by Health Canada and Environment and Climate Change Canada, as well as special publications was conducted. This review investigated the use of epidemiology data in chemical risk assessment, highlighting the use of epidemiology data in the assessment of vulnerable populations.

RESULTS: Several reports were identified that used observational data such as Zinc and Selenium. Observational data is used in numerous ways in these reports including characterizing exposure (concentrations of exposure, identification of exposure scenarios), informing the hazard of a substance (outcomes that cannot be assessed in animal models, populations with increased susceptibility), and characterizing risk (clarifying the mechanism of action, supporting the relevance of animal data to humans).
CONCLUSION: The consideration of epidemiological data in the risk assessment of chemical substances is an emerging area that requires further evaluation and research efforts to address the needs of vulnerable populations.

P-0353 Exposure to mercury and associated factors in Portuguese adolescents

Sónia Namorado[1,2,3], Diogo Gomes[4], Diogo Iria[4], Federico Cestelli[4], Afonso Mota[4], Bernardo Alves[4], João Leal[4], Andreia Luz[4], João Gomes[4], Rafael Barros[5,6], M. Ramiro Pastorinho[6,7,8], Ana C. Sousa[8,9]

[1]Department of Epidemiology, National Institute of Health Doutor Ricardo Jorge, Lisboa, Portugal, [2]NOVA National School of Public Health, Public Health Research Centre, Universidade NOVA de Lisboa, Lisbon, Portugal, [3]Comprehensive Health Research Center, Universidade NOVA de Lisboa, Lisbon, Portugal, [4]Colégio Valsassina, Lisbon, Portugal, [5]Health Sciences Research Centre (CICS), Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal, [6]NuESA - Health and Environment Study Unit, Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal, [7]Department of Medical and Health Sciences, School of Health and Human Development, University of Évora, Évora, Portugal, [8]Comprehensive Health Research Centre (CHRC), University of Évora, Évora, Portugal, [9]Department of Biology, School of Science and Technology, University of Évora, Évora, Portugal

Due to its well-known neurotoxicity and endocrine disrupting potential mercury has been recognized as a chemical of concern by governments and citizens alike, leading to the adoption of the Minamata Convention on Mercury in 2017 by 127 countries. This work aimed to evaluate exposure to mercury in Portuguese adolescents and simultaneously to increase their knowledge and awareness about the possible effects of mercury exposure and ways to reduce it. for that, the research team together with a group of teenagers from a school in Lisbon and their teachers developed and implemented a human biomonitoring survey.

Students from the 11th and 12th grades performed recruitment at the school under the supervision of their biology teachers and after having received training from researchers. Hair samples and data on possible mercury exposure sources (e.g. seafood consumption, dental amalgams) were collected. Atomic absorption spectrometry with thermal decomposition and gold amalgamation was used to analyse samples, alongside with human hair certified reference material. The study was approved by the school's Pedagogical Board and the National Data Protection Authority.

A total of 92 students were recruited. They were aged 12-18 years, 56.5% were females, most lived in urban areas (91.3%) and the majority (97.8%) didn't have dental amalgam fillings nor used hair dye. Participants' BMI ranged from 15.1 to 28.4 kg/m2, with a mean of 20.6 ± 2.6 kg/m2. Total mercury in hair ranged from 0.01 to 3.32 µg/g, with a mean of 1.09 ± 0.66 µg/g. Around 40% of the students had mercury levels higher than US-EPA reference limit (1 µg/g), while 9.8% exhibit levels higher than WHO reference dose (2 µg/g). Higher mercury levels were significantly associated with higher consumption of fish, namely seawater fish, and with having dental amalgam fillings, but not with shellfish or seaweed consumption.

P-0358 Low-level cadmium exposure and atherosclerosis in the carotid arteries: results from the Swedish population-based cohort SCAPIS

Florencia Harari[1], Lars Barregard[1], Gerd Sallsten[1], Niklas Forsgard[2], Margaretha Persson[3], Thomas Lundh[4], Björn Fagerberg[5], Gunnar Engström[3], Göran Bergström[6]

[1]Occupational and Environmental Medicine, University of Gothenburg and Sahlgrenska University Hospital, Gothenburg, Sweden, [2]Department of Clinical Chemistry, Sahlgrenska University Hospital, Sweden, [3]Department of Clinical Sciences in Malmö, CRC, Lund University and Skane University Hospital, Sweden, [4]Division of Occupational and Environmental Medicine, Department of Laboratory Medicine, Lund University and Skane University Hospital, Sweden, [5]Department of Molecular and Clinical Medicine, Wallenberg Laboratory for Cardiovascular and Metabolic Research, University of Gothenburg and Sahlgrenska University Hospital, Sweden, [6]Department of Molecular and Clinical Medicine, University of Gothenburg, and Department of Clinical Physiology, Sahlgrenska University Hospital, Sweden

BACKGROUND AND AIM: Cadmium exposure is associated with atherosclerosis and cardiovascular mortality. Few studies have, however, examined how cadmium affects the atherosclerotic burden. We investigated the association between cadmium exposure and atherosclerotic burden in a Swedish population-based cohort.

METHODS: We performed a cross-sectional study using data from the Swedish CardioPulmonary bioImage Study (SCAPIS), including 5622 middle-aged men and women, enrolled 2013-2018. Cadmium was measured in whole blood (B-Cd) using inductively coupled plasma mass spectrometry. Presence of atherosclerotic plaque (yes/no, uni-/bilateral), total plaque area (mm²) and presence of large plaques (>25 mm²), all measured in the carotid arteries by high-resolution ultrasonography, were used as outcomes. Associations between B-Cd (in quartiles, Q1-4) and the different outcomes were analyzed using Poisson (for dichotomized outcomes) and linear (for continuous outcomes) regression and adjusted for cardiovascular risk factors and confounders.

RESULTS: Atherosclerotic plaques were present in 57% of the individuals, for whom the median total plaque area was 16 mm² (range: 0.2-222). The median B-Cd concentration was 0.24 µg/L (range: 0.01-8.5). In multivariable-adjusted models, individuals in the fourth quartile of B-Cd (Q4) had a prevalence ratio (PR) for plaque of 1.10 (95%CI: 1.01, 1.19) when compared with the first quartile (Q1). Individuals in Q4 had on average 3.8 mm² larger plaques (95%CI 0.78, 6.7) and a 27% increased risk of having large plaques (95%CI 0.93, 1.74) compared with individuals in Q1. The PR for bilateral plaques for individuals in Q4 vs Q1 was larger than that for unilateral plaques [PR 1.21 (95%CI 1.06, 1.4) and PR 1.09 (95%CI: 0.96, 1.24), respectively]. Estimates were larger for men and for current smokers.

CONCLUSIONS: Our study shows that increasing cadmium exposure is associated with a larger atherosclerotic burden and reinforces the urgent need of public health measures to reduce cadmium exposure in the general population.

KEYWORDS: cadmium, atherosclerosis.

P-0359 Tattoos: a new ancient carcinogen?

Milena Foerster[1], Khaled Ezzedine[2], Céline Ribet[3], Marie Zins[3], Marcel Goldberg[3], Joachim Schüz[1]
[1]International Agency for Research on Cancer (IARC), Lyon, France, [2]Université Paris Est Créteil (UPEC), Paris, France, [3]French Institute of Health and Medical Research (INSERM), Paris, Lyon

Tattoo prevalence has been rising steeply during the last decades, a development seen worldwide mostly in the younger age groups. However, only few are aware that tattoo inks may contain harmful environmental and chemical contaminants classified as (probably) carcinogenic to humans. Amongst them are polycyclic aromatic hydrocarbons, primary aromatic amines and metals. However, as studies underlying this classification did not consider subcutaneous exposure, it remains to decipher whether tattoos might cause cancer in humans.
As it is known that the largest part of the nano- and microparticle sized injected tattoo pigments travels to the local lymph node and, from there, potentially to other organs, the systemic exposure is not restricted to the skin. Especially in young individuals exposure to tattoo ink is worrisome as they will have a long-term exposure to these substances. To understand the potential relationship of tattoos and certain kinds of cancer, epidemiological studies are needed, which are scarce worldwide. A sound study design needs to assure a long-term follow-up of (young) tattooed cohort participants, prospective and objective recruitment of medically confirmed cancer outcomes and the inclusion of major sociodemographic, medical and lifestyle confounders.
This in mind, the first longitudinal population based cohort study on tattoos and cancer is currently being set-up in the framework of the French national cohort “Constances”. The CRABAT (Cancer Risk Associated with the Body Art of Tattooing) study is led by the International Agency for Research on Cancer (IARC) and leverages the infrastructure of the French national cohort “Constances”. Here we present its conceptual framework, study design and exposure assessment.

P-0360 Detection of 4-hydroxychlorothalonil in human serum

Annette Krais[1], Emelie Rietz Liljedahl[1], Elin Wallstedt[1], Annelise Blomberg[1], Anna Rönnholm[1], Marie Bengtsson[1], Christel Nielsen[1], Christian Lindh[1]
[1]*Division of Occupational and Environmental Medicine, Lund University, Lund, Sweden*

BACKGROUND AND AIM: Chlorothalonil (CHT) is an organochlorine fungicide that has been widely used, e.g. in agriculture but also as wood protectant and paint additive. It has recently been banned in the European Union due to its potential impact on the environment and human health. The transformation product 4-hydroxychlorothalonil (4-OH-CHT) was recently identified using nontargeted analysis in human serum and breastmilk samples. Large knowledge gaps exist, but there are indications that 4-OH-CHT is more toxic and has a higher environmental persistency than CHT. Our aim was to investigate serum levels of 4-OH-CHT in a large human population.

METHODS: We developed a quantitative method for 4-OH-CHT analysis using liquid chromatography-triple quadrupole mass spectrometry (LC-MS/MS). We measured 4-OH-CHT in 1,815 serum samples collected from pregnant women between 1997-2015, which were originally stored in the Swedish Rubella Screening Program Biobank and analyzed as part of the NIH R01 funded Autism and Prenatal Endocrine Disruptors study. Linear regression models were used to assess time trends of 4-OH-CHT.

RESULTS: The validated analytical method performed well and the LOD was 0.1 ng/ml. 4-OH-CHT was detected in all serum samples with a median concentration of 4.1 ng/ml (range: 0.16-38 ng/ml). Concentrations showed clear seasonality, with higher concentrations in the first half of each year. A linear regression of log-transformed 4-OH-CHT by year showed no linear trend.

CONCLUSIONS: To the best of our knowledge, this is the first study to quantify a chlorothalonil metabolite in human serum. 4-OH-CHT does not seem to degrade after 25 years of storage. Concentrations of 4-OH-CHT were higher than expected and suggest a widespread and continuous chlorothalonil exposure in the general Swedish population. More research is needed to explore possible sources of exposure to CHT and 4-OH-CHT, as well as their persistency.

KEYWORDS: Chlorothalonil, emerging chemicals of concern, human biomonitoring

P-0362 The Use of Potentially Toxic Skin Bleaching Products Among Women In Urban and Rural Areas In Lagos State and Investigation of Active Chemicals In Selected Skin Lightening Products

Chidinma Gab-Okafor[1], Antoinette Ofili[2], Tanimola Akande[3], Kofoworola Odeyemi[4], Babatunde Salako[5]
[1]Department of Biochemistry and Nutrition, National Institute of Medical Research, Yaba, Nigeria, [2]Department of Community Health, University of Benin, Benin, Nigeria, [3]Department of Epidemiology and Community Health, University of Ilorin, Ilorin, Nigeria, [4]Department of Community Health and Primary Care, College of Health Sciences, University of Lagos, Idi-Araba, Surulere, Nigeria, [5]Clinical Sciences Department, National Institute of M edical Research, Yaba, Nigeria

BACKGROUND AND AIM: The prevalence of skin lightening SL is higher in African nations especially Nigeria and it cuts across all socio-demographic and geographical characteristics. Studies have reported various regulatory failures that remains unabated. This study was aimed at determining the use of SL products among women in urban and rural areas in Lagos state of Nigeria and assessment of SL compounds in selected SL products.
Methodology:
A comparative cross-sectional study carried out in Lagos State, among 1100 women within the age range 18-65 years who resided in rural and urban areas . Respondents were selected using a multi-stage sampling technique and data was collected using exploratory parallel mixed method. The study also involved laboratory analysis of SL compounds in SL products.

RESULTS: Knowledge of SL was significantly higher among rural (83.1%) than urban (87.9%) women ($p<0.05$). Conversely, about half of the respondents in the urban area (45.8%) had positive attitude to SL than rural respondents (36.2%; $p<0.05$). The reported prevalence (82.9%) was significantly higher in rural area than the urban area.
There were very elevated levels of the SL compounds in all categories of SL products. About 90% of the SL chemical compounds analysed were not declared on the ingredient list of the SL products. Similarly, 75% of the SL products had SL chemicals greater than the permissible limits on laboratory analysis.

CONCLUSIONS: There is outstanding gap in the knowledge and attitude to SL in both rural and urban areas of Lagos though there is a shift in the demography of users of SL products. The reported prevalence however is still higher among the rural women. The study highlights huge regulatory failure in cosmetic products. Advocacy, health information literacy and regulatory reinforcement can contribute to the control of SL in Nigeria.

P-0368 Per- and polyfluoroalkyl substances (PFAS) exposure and sleep health in U.S. adults, NHANES 2005-2014

Zhihao Jin[1], Pengfei Guo[1,2], Jiajun Luo[1,2], Kosuke Inoue[3], Krystal G. Pollitt[1,2], Nicole C. Deziel[1,2], Zeyan Liew[1,2]
[1]Department of Environmental Health Sciences, Yale School of Public Health, New Haven, USA, [2]Yale Center for Perinatal, Pediatric, and Environmental Epidemiology, Yale School of Public Health, New Haven, USA, [3]Department of Social Epidemiology, Graduate School of Medicine, Kyoto University, Kyoto, Japan

BACKGROUND AND AIM Per- and polyfluoroalkyl substances (PFAS) are synthetic chemicals that may induce oxidative inflammatory responses and disrupt the endocrine and the central nervous systems, all of which can influence sleep. This study aims to investigate the association between PFAS exposure and sleep health in adults using the U.S. National Health and Nutrition Examination Survey (NHANES).

METHODS: We analyzed serum concentrations of four PFAS [perfluorooctane sulfonic acid (PFOS), perfluorooctanoic acid (PFOA), perfluorohexane sulfonic acid (PFHxS), and perfluorononanoic acid (PFNA)] in 8,015 adults enrolled in five waves of NHANES between 2005 and 2014. Self-reported outcomes include diagnosis of sleep disorder (e.g., apnea, insomnia), insufficient sleep (<6 hours/day), and excessive sleep (>9 hours/day). Weighted multivariate logistic regression was utilized to estimate the association between the sleep outcomes and PFAS (individual compounds and mixtures) modeled continuously (log2) or in exposure tertiles, adjusting for potential confounders. A quantile g-computation was used to estimate the joint effects of PFAS mixtures on the sleep outcomes.

RESULTS: Overall, 8.4% (N=674) of participants had sleep disorder diagnosis, and 14.7% (N=1,177) and 2.8% (N=227) were classified as insufficient or excessive sleep, respectively. A doubling of serum-PFOS concentrations (ng/ml) was associated with lower odds of having diagnosed sleep disorder (OR=0.87, 95%CI: 0.81, 0.93) and experiencing insufficient sleep (OR=0.92, 95%CI: 0.85, 0.99). These inverse associations were also observed for PFAS mixtures, but only among male adults aged 60 and above. Adults with higher exposure tertiles of PFOS, PFOA, and PFNA were associated with higher odds of excessive sleep compared to those in the lowest tertiles.

CONCLUSIONS:PFAS exposure was linked to sleep outcomes in NHANES, but the effect direction varied by the chemical and outcome assessed. Potential influence from reverse causation and selection bias due to pre-existing sleep conditions needs to be considered.

P-0369 Association between lead and cadmium exposure and kidney function and mediation effects of atherosclerosis

Carl Guldbrand[1], Huiqi Li[2], Niklas Forsgard[3], Florencia Harari[1]

[1]Occupational and Environmental Medicine, Department of Public Health and Community Medicine, University of Gothenburg and Sahlgrenska University Hospital, Gothenburg, Sweden, [2]School of Public Health and Community Medicine, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, [3]Department of Clinical Chemistry, Sahlgrenska University Hospital, Gothenburg, Sweden

BACKGROUND AND AIM: Environmental lead and cadmium exposure has been associated with reduced kidney function and chronic kidney disease as well as with a higher risk of atherosclerosis. The role of atherosclerosis in the associations between these metals and kidney function has not been studied before. The aim of this study is therefore to assess the associations between lead and cadmium exposure and kidney function and the role of atherosclerosis as a mediating factor.

METHODS: This cross-sectional study used data from the population-based Swedish CArdioPulmonary bioImage Study (SCAPIS) and involved 4804 men and women (50-65 years old), recruited in 2013-2017. Blood cadmium (B-Cd) and lead (B-Pb) concentrations, analyzed using inductively coupled plasma mass spectrometry, were used as exposure biomarkers. Estimated glomerular filtration rate (eGFR) based on serum creatinine and Cystatin C was used as marker of kidney function. Associations between B-Cd and B-Pb (in quartiles, Q1-4) and eGFR was assessed using linear regression models adjusted for known risk factors of renal disease and confounders. Mediation analysis was conducted to evaluate the indirect effect (via atherosclerosis) of lead and cadmium on kidney function.

RESULTS: The median B-Pb and B-Cd was 14µg/L (range: 0.75-178) and 0.24 µg/L (range: 0.0098-8.5), respectively. The median eGFR was 88 ml/min/1.73m2 (range: 17-122). In multivariable-adjusted models, individuals in Q4 of B-Pb had a -1.26 ml/min lower eGFR (95%CI: -2.24, -0.28) compared to those in Q1. This estimate remained unchanged after adjustment for cadmium. In stratified analyses, the effect size was similar for both never and current smokers. The mediation analyses showed that the effect of lead on eGFR is not mediated by atherosclerosis. There were no associations between eGFR and B-Cd.

CONCLUSIONS: Increased lead exposure was associated with a reduced eGFR. This association does not seem to be mediated by atherosclerosis.

KEYWORDS: heavy metals, kidney function, atherosclerosis

P-0370 The association of urinary nickel concentrations with type 2 diabetes and fasting blood glucose levels: A cross-sectional study from the China National Human Biomonitoring

Yingli Qu[1]

[1]*National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND AND AIM: Epidemiological studies on the effect of nickel exposure on the prevalence of type 2 diabetes (T2D) in the general population are scarce and remain controversial. We aimed to assess the association of nickel exposure with the odds of T2D and fasting blood glucose (FBG).

METHODS: The study included a total of 10,890 adults aged 18 years or older from the China National Human Biomonitoring conducted in 2017-2018. The urinary nickel concentrations and FBG were measured and lifestyle and demographic data were collected. Weighted multiple regression analyses were used to estimate the associations of urinary nickel concentrations with the odds of T2D and increased FBG.

RESULTS: The weighted median concentration (interquartile range) of urinary nickel was 1.74 μg/L (0.85-3.37 μg/L). After adjusting for potential confounding factors, the urinary nickel concentrations were correlated positively with the prevalence of T2D, and the odd ratios of T2D associated with the highest quartile of nickel concentrations were 1.84 (95% confidence interval (CI), 1.33-2.54) when compared to the lowest quartile. Elevated urinary nickels were associated with higher FBG, each one-unit increase in log10-transformed urinary nickel concentration was associated with a 0.39 (95%CI: 0.20-0.58) mmol/L elevation in FBG in the most adjusted categorical model. In addition, restricted cubic spline analysis showed a significant linear association between nickel exposure and the odds of T2D and FBG levels.

CONCLUSIONS: Our findings suggested that elevated urinary nickel levels may be related to an increase in FBG levels and T2D prevalence in Chinese adults.

KEYWORDS: Urinary nickel levels; type 2 diabetes; fasting blood glucose; China National Human Biomonitoring

P-0377 Exposure to perfluoroalkyl substances, incident Type 2 Diabetes risk and associated metabolic pathway dysregulation in a multiethnic population

Vishal Midya[1], Elena Colicino[1], Dinesh Barupal[1], Chris Gennings[1], Ruth J. F. Loos[2,3], Ryan W. Walker[1], Douglas I. Walker[1], Damaskini Valvi[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]The Charles Bronfman Institutes for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Novo Nordisk Foundation Center for Basic Metabolic Research, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark

BACKGROUND AND AIM: Growing experimental and epidemiology evidence suggests that exposure to perfluoroalkyl substances (PFAS) increase type 2 diabetes (T2D) risk; however, effects of PFAS-mixtures and underlying mechanisms are unclear. We examined associations of exposure to PFAS-mixture with incident T2D-risk and underlying plasma metabolic-pathways using untargeted metabolomics.

METHODS: We conducted a nested case–control study within BioMe, an electronic health record-linked biobank of >60,000 patients seeking primary care at Mount Sinai Hospital, New York, since 2007. A total of 180 incident T2D cases (33% African Americans, 33% Hispanics, 33% Whites) were matched to 180 controls by age, sex and ancestry. We used liquid-chromatography with high-resolution mass spectrometry, to quantify seven PFAS (PFOS, PFOA, PFHxS, PFHpA, PFDA, PFHpS and PFNA) and measured untargeted metabolomic profiles in prediagnostic plasma. Cases had an average of ~6 years between blood draw and T2D diagnosis. We used (1)Weighted Quantile Sum(WQS) regression to evaluate the PFAS-mixture association with incident T2D risk; (2)performed metabolome-wide association analysis using Hierarchical-Bayesian WQS and logistic regression to separately analyze PFAS-mixture and T2D associations with 656 annotated metabolites, adjusting for confounders. Pathway enrichment analyses were performed using Mummichog. We used inverse probability weighting to account for nested case-control design in PFAS-metabolites analysis. Multiple comparisons were accounted by calculating q-values.

RESULTS: Each tertile increase in PFAS-mixture(ng/mL) was associated with increased odds of incident T2D (OR[95%CI]=1.45[1.01, 2.09]) with PFOS and PFHpA having highest contributions to PFAS-mixture. T2D risk and PFAS-mixture associated top metabolites were aminoadipic acid, cortisol, gamma-glutamylglytamine, sulfolithocholylglycine, n-acetylaspartic acid and top pathways were alanine and aspartate metabolism, C21-steroid hormone biosynthesis and metabolism, androgen and estrogen biosynthesis and metabolism(p-value<0.05;q-value >0.2).

CONCLUSIONS: Exposure to PFAS mixtures may dysregulate pathways of amino acid metabolism and steroid-hormone biosynthesis and metabolism, increasing risk of T2D diagnosis in multiethnic populations.

P-0379 The Breast Milk Perfluorome is Associated with Infant Growth in the First Year of Life

Tanya Alderete[1], Jesse Goodrich[2], Hongxu Wang[2], Elizabeth Holzhausen[1], Maximilian Bailey[1], Xiangping Lin[3], Zoe Coates Fuentes[3], Douglas Walker[3], David Conti[2], Leda Chatzi[2], Michael Goran[4]
[1]University of Colorado Boulder, USA, [2]University of Southern California, USA, [3]Icahn School of Medicine at Mount Sinai, USA, [4]Children's Hospital of Los Angeles, USA

BACKGROUND AND AIM: Early life exposure to poly- and perfluoroalkyl substances (PFAS) has significant obesogenic effects that are manifested in early life. However, PFAS examined do not include the wide range of PFAS used in commercial applications.

METHODS: This pilot included 56 Hispanic mother-child pairs from Southern California. Maternal and infant characteristics were assessed, including infant weight, length, and fat mass. All mothers were breastfeeding, and breast milk was collected at 1-month postpartum. The perfluorome was characterized using untargeted high-resolution mass spectrometry. Organofluorine compounds were identified using the EPA CompTox Dashboard. Multivariable linear and logistic regression analyses were used to examine associations between PFAS with growth measures (12-months, change in first year, rapid growth) after adjusting for infant age, sex, pre-pregnancy BMI, gestational age, and formula feedings. Results are reported for associations with $p<0.05$ and were considered statistically significant using a false discovery rate (FDR) of 20%.

RESULTS: 484 suspect PFAS compounds were detected in ≥75% of samples. PFAS were associated with 12-month weight [n(%): 10(2.1%) positive, 12(2.5%) negative], change in weight [10(2.1%) positive, 22(4.5%) negative], 12-month length [21(4.3%) positive, 17(3.5%) negative] change in length [22(4.5%) positive, 25(5.2%) negative], 12-month fat mass [9(1.9%) positive, 12(2.5%) negative], and change in fat mass [18(3.7%) positive, 21(4.3%) negative]. Additionally, 12(2.5%) and 13(2.7%) of PFAS compounds were associated with an increased (OR=2.0-3.8) and decreased odds (OR=0.28-0.47) of rapid growth in the first, respectively. After FDR, three compounds, each detected in >98% of samples, were associated with change in length ($q=0.01$; n=2 positive, n=1 negative). Tentative annotations of these compounds identified novel PFAS, including methyl 4,4,5,5,5-pentafluoropent-2-ynoate3,4,4,5,5-Pentafluoro-2-methoxycyclopent-2-en-1-one, ethyl [5-(heptafluoropropyl)-1-methyl-1H-pyrazol-3-yl]acetate, and ethyl 2-acetyl-4,4,5,5,5-pentafluoro-3-oxopentanoate.

CONCLUSIONS: Results from this pilot suggest that a wide range of PFAS are present in human breast milk, which may impact infant growth in the first year of life.

KEYWORDS: breast milk, PFAS, infants

P-0380 Lindane use and the incidence of thyroid cancer in the USA; an ecological study

Mathilda Alsen[1], Vikram Vasan[1], Catherine Sinclair[1], Maaike Van Gerwen
[1]*Icahn School of Medicine at Mount Sinai, New York, USA*

INTRODUCTION: The increased thyroid cancer incidence rate may potentially be partially attributable to exposure to chemicals with endocrine disruptive properties. Lindane is an organochlorine pesticide with endocrine disruptive properties that has been classified as carcinogenic to humans. The aim of this ecological study was to evaluate potential correlation between Lindane exposure and thyroid cancer incidence in the USA (US).

METHODS: Data on age-adjusted thyroid cancer incidence rate (per 100,000 people) was obtained from the Centers for Disease Control and Prevention for all US states for 2018. Lindane use was obtained from the US Geological Survey and presented in quintiles for the years 1992 and 2007 to consider latency period. Trend of Lindane use between 1992 and 2007 was calculated using Mann Kendall correlation test. Lindane use estimates per cropland (kg/acres cropland) were overlaid on the map of age-adjusted thyroid cancer incidence rate using ArcGIS. Correlation between statewide Lindane use and age-adjusted thyroid cancer incidence rates was calculated using Spearman correlation.

RESULTS: Overall Lindane use decreased significantly between 1992 and 2007 ($T = -0.617$; $p < 0.001$). Statewide differences in the patterns of Lindane use as well as thyroid cancer were found, with high rates of thyroid cancer and Lindane use reported in several states including Delaware and Georgia. There was no statistically significant correlation between thyroid cancer incidence rates in 2018 and Lindane use in 1992 ($r=0.075$; $p=0.689$) nor Lindane use in 2007 ($r=0.01$; $p=0.935$), among males and females combined.

CONCLUSIONS: Restrictions clearly seem to be effective in reducing Lindane use. While, overall, there was no evidence of a correlation between thyroid cancer and Lindane use, more research is needed to explore this further specifically in highly exposed populations (e.g. rural areas) with longitudinal studies that assess the effects of long-term exposure to Lindane and other organochlorine pesticides.

P-0385 Exposure of adults aged 18 to 44 years to personal care products (PCPs) in Beijing, China: urinary levels, exposure patterns and risk evaluation.

Linxue Han[1], Xiao Lin[1], Xu Zhang[1], Ying Zhu[1]

[1]*China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND AND AIM: PCPs, including parabens, benzophenones and antimicrobials, are a group of typical EDCs that widely applied in various consumer products and industrial applications. Concern for adverse effects on human health arises from results of in vitro and in vivo experiments. The purpose of this study was to assess the characteristics of exposure to PCPs and to provide a preliminary assessment of exposure levels and health risks within typical PCPs in the target population in combination with estimated daily intake (EDI) and risk entropy (HQ).

METHODS: 15 PCPs were measured in 127 spot urine samples collected from Beijing residents aged 18 to 44 years from November 2021 to January 2022. Individual specific gravity (SG) was used to correct for urinary dilution. Since distributions of PCPs concentration were right skewed, non-parametric statistics were used. The relationships between different parabens and benzophenones were determined using the Spearman correlation coefficient. The difference of PCPs concentration in various demographic characteristics, such as gender and age, were compared by Mann-Whiney test.

RESULTS: We found that PCPs were ubiquitous in all urine samples, with methyl paraben(MP), ethyl paraben(EP) and propyl paraben(PP) being the main compounds with median concentrations of 27.08 μg/L, 0.76 μg/L and 1.16 μg/L, respectively. Non-parametric tests showed statistically significant differences in gender for 8 PCPs. There was a significant positive correlation between MP and PP concentrations, Benzophenone-1、Benzophenone-3 and Benzophenone-4 concentrations. The median EDI-urine values of PCPs varied in the range of 20.01~88,295 ng/kg-bw/day. More than 5% of the target population exhibited greater HQs > 1 for individual PCPs.

CONCLUSIONS: The high correlation between the different PCPs suggests that they may have the same and/or similar original sources. Exposure to PCPs might be a critical factor contributing to adverse health effects in Beijing residents.

KEYWORDS: PCPs, EDI, risk assessment

P-0386 Persistent Organic Pollutants and Dysregulation of microRNAs Expression in Humans and Animals - A Systematic Literature Review

Yijie Li[1], Brittney O. Baumert[1], Elizabeth Costello[1], Sarah Rock[1], Nikos Stratakis[2], Jesse Goodrich[1], Yinqi Zhao[1], Sandrah P. Eckel[1], Douglas I. Walker[3], Damaskini Valvi[3], Michele A. La Merrill[4], Rob McConnell[1], Victoria K. Cortessis[1], Max Aung[1], Haotian Wu[5], Andrea Baccarelli[5], David Conti[1], Lida Chatzi[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [2]Barcelona Institute for Global Health, ISGlobal, Barcelona, Spain, [3]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [4]Department of Environmental Toxicology, University of California, Davis, USA, [5]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA

BACKGROUND: MicroRNAs (miRNAs) are key regulators in many physiological processes. Evidence suggests that exposure to persistent organic pollutants (POPs) is associated with miRNA dysregulation. Exposure to POPs is ubiquitous and these chemicals are characterized by their environmental persistence. It is therefore of public health concern to understand the relationship between POPs and miRNA as it relates to health outcomes.
OBJECTIVES: The objective of this systematic review is to evaluate the relationship between exposure to POPs including per- and polyfluoroalkyl substances (PFAS), polychlorinated biphenyls (PCBs), dichloro-diphenyl-trichloroethane (DDT), hexachlorobenzene (HCB), and polybrominated diphenyl ethers (PBDEs), with miRNA expression in both human and animal studies.

METHODS: The systematic search of the literature was conducted in PubMed and Embase. Search results of human and animal studies were included if they included at least one POP of interest in relation to at least one miRNA. Data were synthesized to determine the direction and statistical significance of associations between POPs and miRNA. Finally, a review of disease pathways was conducted for miRNAs that were consistently associated with POPs.

RESULTS: Our search identified 35 studies, 8 of humans and 27 of model organisms. PFAS were associated with decreased expression of miR-144, miR-19 and miR-193, and increased expression of miR-26b, miR-199a-3p, miR-122 and miR-128 across studies. PCBs were associated with increased expression of miR-15a, miR-21, miR-1537 and decreased let-7b in both humans and animals. Pathway review suggested that PFAS-associated miRNAs are all involved in prostate cancer, hepatocellular carcinoma and nonalcoholic fatty liver disease, while PCB-associated miRNA are associated with gastric cancer.

CONCLUSIONS: This is the first systematic review of the association of POPs with miRNAs in humans and model organisms. Large-scale prospective human studies are now warranted to examine the role of miRNAs as mediators between POPs and health outcomes.

KEYWORDS: persistent organic pollutants, miRNAs, systematic review

P-0388 Associations of blood lead and cadmium co-exposure and hepatic dysfunction: A cross-sectional study among Chinese adults aged 18 and older

Xiao Lin[1], Linxue Han[1], Master Xu Zhang[1], Master Qi Sun[1], Master Tian Qiu[1], Ying Zhu[1], Yuebin Lv[1], Xiaoming Shi[1]
[1]*China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND AND AIM: Lead (Pb) and cadmium (Cd) were once toxic metals of occupational importance, but are now more harmful as environmental pollutants. Current evidence on the relationship between Pb and Cd co-exposure on liver function are still limited and findings remain conflicting. This study focused on studying the effects of Pb and Cd alone and co-exposure on liver function among Chinese adults aged 18 years and older.

METHODS: The study used data from the China National Human Biomonitoring (CNHBM) in 2017-2018. Pb and Cd levels were measured in whole blood. Alanine aminotransferase (ALT), Aspartate aminotransferase （AST） and γ-glutamyl transpeptidase （γ-GT） were selected as the hepatic function biomarkers. Combined effect of blood Pb and Cd were assessed using logistic regression.

RESULTS: The median of blood lead and blood cadmium in the population were 23.38 μg/L and 0.83 μg/L, respectively. In the joint association analyses of blood Pb and Cd, significant p-interaction values were found in all elevated hepatic biomarkers, indicating there was an interaction between these two metals. for biomarker ALT, in full adjusted model, the ORs of subjects with low Pb and high Cd, and high Pb/Cd were 1.37(1.03, 1.84) and 1.55 (1.16, 2.07), compared to those with low Pb/Cd, respectively. Similar results were exhibited in the biomarker AST. for biomarker γ-GT, the ORs of subjects with high Pb and low Cd, and high Pb/Cd, were 2.02(1.26, 3.23) and 1.97(1.27, 3.05) after adjusting for confounders.

CONCLUSIONS: Co-exposures of Pb and Cd were associated with hepatic dysfunction, efforts should be made to further reduce environmental Pb and Cd exposure in order to weaken the interaction effect.

KEYWORDS: lead, cadmium, co-exposure, liver, Chinese adults

P-0392 Relationships between urinary phthalate metabolites and lipidomic profile in a Taiwanese elderly population

Ming-Chieh Li[1], Chi-Hsien Chen[2,5], Ching-Yu Lin[3], Tzu-Chieh Chou[4], Yue Leon Guo[5,6,3]

[1]Department of Health Promotion and Health Education, College of Education, National Taiwan Normal University, Taipei City, Taiwan, [2]Department of Environmental and Occupational Medicine, National Taiwan University Hospital Hsin-Chu Branch, Hsinchu City, Taiwan, [3]Institute of Environmental and Occupational Health Sciences, College of Public Health, National Taiwan University, Taipei City, Taiwan, [4]Department of Public Health, College of Public Health, China Medical University, Taichung City, Taiwan, [5]Department of Environmental and Occupational Medicine, College of Medicine, National Taiwan University (NTU) and NTU Hospital, Taipei City, Taiwan, [6]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli County, Taiwan

BACKGROUND AND AIM: Phthalate exposure has been associated with circulating lipid composition. However, limited epidemiological study has been carried out in elderly people. Therefore, we conducted a cross-sectional study to examine the associations between urinary phthalate exposure and lipidomic profile in Taiwanese elderly people.

METHODS: A cross-sectional survey of the elderly (age >= 65 years) was conducted in Taipei city, New Taipei City, Hualien County, Chiayi County, and Kaohsiung City in Taiwan. A total of 11 urinary phthalates metabolites and 86 lipids (phosphatidylcholines (PCs) and sphingomyelins (SMs)) were assessed. Demographic information was obtained by a structured questionnaire. Serum lipidomic profile was identified using principal component analysis (PCA). A two-step analysis was performed. We first performed multiple linear regressions to evaluate whether urinary phthalate metabolites were related to the PCA-derived components of serum lipid concentrations. Then we performed multiple linear regressions to investigate each of the lipids that were suggestively correlated with some of the phthalates in PCA. Urinary concentrations of phthalate metabolites were log-transformed to normalize distributions.

RESULTS: A total of 886 participants (58.9% women) were included in the final analysis. There were ten components identified by PCA, which accounts for 63.2% of total variance. After adjusting for age, sex, body mass index, urinary creatinine, urinary phthalate metabolites were correlated with 6 components. Among them, component 7 was correlated with the most phthalates metabolites (Bonferroni corrected p-value < 0.007). Monomethyl phthalate (MMP) and monobutyl phthalate (MnBP) were negatively correlated with component 7, whereas monoisobutyl phthalate (MiBP), monobenzyl phthalate (MBzP), and monoisononyl phthalate (MiNP) were positively correlated with component 7. Among component 7, PC(16:0/16:0), PC(16:0/17:1), PC(16:0/18:1), PC(16:0/19:5), PC(16:0/20:5), PC(16:0/22:4), PC(38:0), PC(P-16:1/22:5), PC(P-40:4), and PC(P-40:5) were highly loaded.

CONCLUSIONS: Urinary phthalate metabolites were correlated with the lipidomic pattern. Most of them were diacyl-phosphatidylcholines, which might play a role in hepatic lipid metabolism.

P-0401 Exploratory Analysis of Relationship of Trihalomethane Levels in Water for Human Consumption and Health Profile in Municipalities of Sao Paulo State in Brazil

Marcio Ribeiro Barbosa[1], Telma de Cassia dos Santos Nery[2], Paulo Junior Paz de Lima[3]

[1]Universitary Hospital of University of São Paulo - USP - Department of Health of Government, São Paulo, Brazil, [2]Divisao de Pneumologia do INCOR HC FMUSP, Sao Paulo, Brazil, [3]Associacao Brasileira de Pesquisadores pela Justica Social, Sao Paulo, Brazil

Presence of chemicals, heavy metals (such as lead, arsenic) and agrochemicals in various regions are causing environmental and human health impacts. Water used for human consumption has been seen as a serious public health problem in Brazil, like in several countries. High levels of sanitary higienization products have been dumped into our effluents, with chlorine as the main halogen in its composition. The degradation of chlorine with the formation of trihalomethanes has been the object of study in several regions of Brazil, especially for its potential in carcinogenesis. The state of SP has a population of about 50 million people and has the best levels of sanitation in the country. Nevertheless, it does not analyze the relationships between levels of trihalomethanes and their impacts on public health. The objective of this study was to analyze the database referring to the presence of trihalomethanes in water for human consumption in 645 municipalities in the state of São Paulo in the last decade. The information was with exploratory analysis associated to the main pathologies responsible for the mortality profile in each municipality. The information banks of the national health system - DATASUS and the national water information system - SISAGUA were used. In the results we founded specific clusters of some specific groups of pathological, as compared to the international ICD 10 classification. Conclusion : In Brazil, the legislation is in a process of recent change with the confrontation of the current databases, contributing in the discussion on preventive measures in public health

KEYWORDS: Chemicals, Trihalomethanes, Water, Public Health

P-0403 Astrocyte-derived extracellular vesicles: novel biomarkers of CNS metal exposure and elimination with applications in discerning the pathogenesis of neurodegenerative diseases

Roheeni Saxena[1], Tanya Butt[1], Mohammad Alayyoub[1], Cherine Jaafar[2], Lina Marcinczyk[1], Madeleine Strait[1], Nicole Comfort[1], Eva Tipps[1], Ronald Glabonjat[1], Kathrin Schilling[1], Diane Re[1]

[1]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA, [2]Paris Saclay University, Paris, France

BACKGROUND AND AIM: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative condition, and though environmental exposure to metals has been associated with ALS, there are no existing biomarkers for these potentially causal environmental exposures – a biomarker for toxicant load in the central nervous system is greatly needed. Upon exposure to toxic metals in vitro, central nervous system (CNS) astrocytes, critical in metallohomeostasis, were observed to produce extracellular vesicles loaded with metals, potentially as a cellular elimination pathway. Metals are known to bioaccumulate in the CNS; EVs originating from the CNS (CNS-EVs) are readily found in peripherally drawn blood and can be isolated using cell-specific surface proteins. This study examines whether blood-borne CNS-EV metal cargoes can serve as reliable biomarkers of CNS metal exposure and reveal a link between metal metabolism and neurodegenerative disease (i.e., ALS).

METHODS: Precautions were undertaken to ensure EV protocols were completed under metal-free conditions. CNS-EVs were isolated from human whole blood and plasma samples via direct immunoprecipitation using biotinylated antibodies for proteins expressed on astrocytes. Once EVs were isolated, ELISA analysis generated protein concentrations, ViewSizer Nanoparticle Tracking analysis quantified abundance, and Transmission Electron Microscopy visualized particles. EVs were analyzed for metal contents using a Perkin-Elmer NexION 350S via an ICP-MS/MS dynamic reaction cell method.

RESULTS: Results demonstrate that it is feasible to quantify the small quantities of metals within these CNS-derived EVs, particularly in terms of toxic metals known to be associated with neurodegenerative disorders, including copper, zinc, lead, aluminum, manganese, and iron.

CONCLUSIONS: CNS-derived EVs isolated from peripheral blood draws show promise as a potential biomarker of metal exposure and/or elimination in the brain and spinal cord, with promising applications in understanding the potential environmental pathogenesis of neurodegenerative disorders (i.e., ALS) among patients with relevant elevated CNS metal loads.

P-0404 Determinants of exposure to phenols, phthalates, parabens and triclosan in pregnant women, Colombia

CA Gómez-Mercado[1], Gregory Mejía- Sandoval[2], Albino Barraza-Villareal[3], Liliana Acevedo-Saenz[4], Damaskini Valvi[5], Cathrine Thomsen[6], CM Arango-Álzate[1], AK Sakhi[6], AM Segura-Cardona[1]

[1]CES University, Graduate School, Medellín, Colombia, [2]CES University, MVZ Faculty, Medellin, Colombia, [3]National Institute of Health of Mexico, Cuernavaca, Mexico, [4]CES University, Faculty of Nursing, Medellin, Colombia, [5]Icahn School of Medicine at Mount Sinai, Department of Environmental Medicine and Public Health, New York, EEUU, [6]Norwegian Institute of Public Health, Oslo, Norway

INTRODUCTION: Phenols, phthalates, parabens and triclosan are endocrine disruptors (1) and human beings are exposed daily through contact with skin, water, food and the air they breathe, these compounds are measured in urine (2).
OBJECTIVE: to determine the sources of exposure to phenols, phthalates, parabens and triclosan in pregnant women.

METHODS: study carried out in 400 women with ≤12 weeks of pregnancy from two institutions in Medellín. Demographic, nutritional and environmental exposure characteristics were investigated and 37 metabolites in urine were quantified at the Norwegian Institute of Public Health (NIPH), by means of ultra-high resolution liquid chromatography coupled to tandem mass spectrometry (UPLC-MS- MS) and dilution correction for specific gravity. Using t-student, differences were observed in the geometric measurements according to exposure determinants.

RESULTS: significant differences were found in the geometric means of Propyl Paraben (PRPA) according to the use of floor cleaners (yes: 7.94ng/mL 95% CI: 4.70-13.43; no: 18.76ng/mL 95% CI :9.21-38.21), Mono-iso-butyl phthalate(MiBP) given exposure to second-hand tobacco (yes:12.56ng/mL 95% CI:10.00-15.78; no:19, 94ng/mL 95% CI:14.86-26.76) and from exposure to the use of cosmetics, the GM of some phthalates were, Mono-4-methyl-7-oxooctyl phthalate(oxo-MiNP) [si:3, 03ng/mL 95% CI: 2.35-3.92; no:5.58ng/mL 95% IC:2.28-13.67], Mono-4-methyl-7-carboxyoctyl-phthalate(cx-MiNP) [yes:7.08ng/mL 95% IC:6.24- 805; no:11.28ng/mL 95% CI:5.57-23.26], 6-Hydroxy-Monopropylheptylphthalate(OH-MPHP) [yes:1.68 ng/mL 95% CI:1.51-1.86; no: 2.18ng/mL 95% CI: 1.39-3.41].

CONCLUSIONS: the determinants of exposure to phenols, phthalates, parabens and triclosan in pregnant women in the study were the use of floor cleaners, second-hand tobacco and the use of cosmetics.

KEYWORDS: phenols, parabens, triclosan, endocrine disruptors, urine

P-0405 Descriptive analysis of victims of poisoning, suicide attempts and deaths from pesticides in Brazil between 2010 and 2020

Paulo Junior Paz De Lima[1], Dra. Telma de Cassia dos Santos Nery[2]
[1]Brazilian Association of Researchers for Social Justice – ABRAPPS, Brazil, São Paulo, Brazil, [2]Divisao de Pneumologia do INCOR HCFMUSP, Sao Paulo, Brazil

Between 2010 and 2021, 3,474 new pesticides were registered and authorized in Brazil, of which 76.5% were only between 2016 and 2021. An increase of 540% in registrations of new pesticides when compared to 2010. As a result of this policy and with the approval in the first vote, in 2022, by the Brazilian Congress of the so-called poison package, this scenario could be even worse in the short and long term, with incalculable impacts on the health of the population and the environment. OBJECTIVES: To describe and analyze the profile of victims of pesticide poisoning, suicide attempts and deaths from agricultural, domestic, public health, rodenticide and veterinary pesticides between 2010 and 2020.

METHODS: Descriptive cross-sectional study. Data were collected from the Ministry of Health database – DATASUS.

RESULTS: There were 135,803 cases of intoxication, 73.2% of intoxications were not due to exposure at work; 71,009 suicide attempts and 3,944 deaths from poisoning, with 48.8% of the deaths being between black/brown and 36% white; 74.6% of intoxications were in urban residents and 21.9% in rural areas and 94.5% of deaths were not related to work. 712 of the victims of attempted suicides were younger than 1 year and 4 years old, 10,834 of the victims were between 10 and 14 years old.

CONCLUSIONS: The results point to higher rates of poisoning, suicide attempts and deaths from pesticide poisoning among black/brown children, with low schooling and, for the most part, living in urban areas and belonging to black/brown color/ethnicity. and no exposure to work.

KEYWORDS: Pesticides, intoxications, deaths, suicide, ethnicity.

P-0407 Mixture effects of gestational synthetic phenol and phthalate exposures on the neuro-behavior of children in the Healthy Start cohort

Dorothy Nakiwala[1], Wei Perng[1], Deborah Glueck[1], Dana Dabelea[1], Anne P. Starling[1,2]
[1]*Center for Lifecourse Epidemiology of Adiposity and Diabetes, University of Colorado, Anschutz Medical Campus, Aurora, USA,* [2]*Department of Epidemiology, University of North Carolina-Chapel Hill, Chapel Hill, USA*

BACKGROUND: Simultaneous exposure to multiple endocrine disruptors may be harmful even when individual exposures for which individual effects may be below observable levels. We sought to assess the effects of prenatal exposure to a mixture of phthalates and phenols on the neuro-behavior of preschool-aged children.
METHODOLOGY: In a sample of 293 mother-infant pairs from the Healthy Start pre-birth cohort, sixteen phthalate metabolites and phenols were assessed in maternal spot urine samples from mid-pregnancy. Behavioral outcomes in preschool children (4-5 years) were assessed using the child behavior check list (CBCL). We computed 3 composite scales for total behavioral, externalizing and internalizing problems. Covariate-adjusted weighted quantile sum (WQS) regression was used to estimate associations between the mixture of phenols and phthalates and the behavioral scales.

RESULTS: WQS regression indicated a positive trend with the externalizing scale. We observed a 0.15 points (95% CI: -0.02; 0.33, p-value = 0.09) increase in the externalizing problems' score for one tertile increase in the WQS index. The major contributors to this mixture effect were Di-isononyl phthalate (DiNP) (with a weight of 24%), Benzophenone-3 (22%), triclosan, methyl paraben (11%), MEP (7%) and bisphenol A (6%). No statistically significant (p-values > 0.1) associations were observed with the total (beta = 0.06(CI 95% -0.04; 0.16)) and internalizing (beta = -0.09(CI 95% -0.29; 0.11)) composite scores.

CONCLUSIONS: Exposure to mixtures of phenols and phthalates in utero may induce behavioral problems during early childhood. Future policy guidelines on exposure limits to these compounds should consider mixture effects as they are increasingly being reported in epidemiological studies.

P-0410 The effects of combined exposure of lead and stress during pregnancy on cognitive development in offspring

Xiangrong Guo[1,2], Shiwei Jiang[1], Jian Xu[2], Ying Tian[1], Fengxiu Ouyang[1], Xiaodan Yu[1], Chonghuai Yan[1], Junxia Liu[1], Jun Zhang[1]

[1]Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]The International Peace Maternity & Child Health Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

BACKGROUND AND AIM: To assess the current exposure levels of lead and stress during pregnancy, and compared the effects of prenatal combined exposure of lead and stress during different stages of pregnancy on the neurodevelopment of offspring.

METHODS: A total of 5270 mother-child pairs were assessed in the Shanghai Birth Cohort, maternal blood lead in early pregnancy and umbilical cord blood lead were measured. Assessments of prenatal maternal stress, the Center for Epidemiological Studies-Depression Scale and the Self-Rating Anxiety Scale during mid-pregnancy, postnatal maternal stress using the Edinburgh Postnatal Depression Scale were conducted, and groups of prenatal single exposure to lead/stress and combined exposure were therefore formed. The Ages-Stages-Questionnaires (at 6- and 12-months-of-age) and the Bayley-III (at 24-months-of-age) were performed to assess the offspring neurodevelopment.

RESULTS: The geometric means of maternal blood lead in early pregnancy and umbilical cord blood lead were 1.45 μg/dL and 1.53 μg/dL, respectively. A total of 1.86% and 0.18% of the mothers were screened positive for depression and anxiety. Adjusting for related confounders, the prenatal combined exposure in early pregnancy was associated with more deficits in infant communication skills and social-emotional skills, especially in social-emotional at 24-month-old (P=0.016); the prenatal combined exposure around birth was adversely associated with infant neurodevelopment levels in multiple domains.

CONCLUSIONS: The prenatal combined exposure to lead and stress may affect offspring neurodevelopment more profoundly (especially on social-emotional development), and the combined exposure in early pregnancy may induce more deficits in offspring social-emotional development than the combined exposure around birth.

P-0412 Early life organophosphate ester exposures and bone health at age 12 years: The Health Outcomes and Measures of the Environment (HOME) Study

Jordan Kuiper[1], Ann Vuong[2], Bruce Lanphear[3], Antonia Calafat[4], Maria Ospina[4], Kim Cecil[5], Yingying Xu[6], Kimberly Yolton[6], Heidi Kalkwarf[6], Joseph Braun[7], Aimin Chen[8], Jessie Buckley[1]

[1]Department of Environmental Health and Engineering, Johns Hopkins University Bloomberg School of Public Health, Baltimore, USA, [2]Department of Epidemiology and Biostatistics, School of Public Health, University of Nevada, Las Vegas, USA, [3]Faculty of Health Sciences, Simon Fraser University, Vancouver, Canada, [4]Division of Laboratory Sciences, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA, [5]Department of Radiology, Cincinnati Children's Hospital Medical Center, University of Cincinnati College of Medicine, Cincinnati, USA, [6]Department of Pediatrics, Cincinnati Children's Hospital Medical Center, University of Cincinnati College of Medicine, Cincinnati, USA, [7]Department of Epidemiology, Brown University, Providence, USA, [8]Department of Biostatistics, Epidemiology and Informatics, University of Pennsylvania Perelman School of Medicine, Philadelphia, USA

BACKGROUND AND AIM: No human studies have evaluated early life organophosphate ester (OPE) exposures with bone health outcomes, despite evidence of osteotoxicity. We assessed associations of urinary OPE metabolites measured across early life with bone mineral content (BMC) and areal bone mineral density (aBMD) at age 12 years.

METHODS: Among 223 mother-child dyads enrolled in the Health Outcomes and Measures of the Environment (HOME) Study, we quantified concentrations of bis-2-chloroethyl phosphate (BCEP), bis-(1,3-dichloro-2-propyl) (BDCIPP), di-n-butyl phosphate (DnBP), and diphenyl phosphate (DPHP) in urine collected from mothers during pregnancy and children at ages 1, 2, 3, 5, and 8 years. at age 12 years, we performed dual energy x-ray absorptiometry and calculated BMC and aBMD z-scores at six skeletal sites. Using a multiple informants framework, we estimated overall and sex-stratified BMC/BMD z-score differences per interquartile range (IQR) increase in OPE concentrations at multiple exposure timepoints: gestation (average) and 1–3 (average), 5, and 8 years.

RESULTS: In adjusted models, overall associations of BCEP and BDCIPP with total hip and 1/3rd distal radius aBMD varied significantly by exposure timepoint, as did BDCIPP with whole body aBMD. for example, differences (95% CI) in total hip aBMD z-score per IQR increase in BDCIPP were 0.33 (0.01, 0.65), -0.10 (-0.34, 0.14), -0.17 (-0.40, 0.05), and 0.14 (-0.09, 0.38) for concentrations during gestation and at 1–3, 5, and 8 years, respectively. Overall DnBP and DPHP associations were generally null at all timepoints. We observed sex-specific associations for some timepoints and skeletal sites. for example, an IQR increase in 8-year DPHP was associated with a 0.24 (0.08, 0.39) greater total hip aBMD z-score among females and a -0.15 (-0.39, 0.08) lower z-score among males.

CONCLUSIONS: Early life OPE exposures may be associated with sex- and exposure period-dependent alterations in early adolescent bone mineral accrual and strength.

P-0422 Prenatal exposure to emissions from a coalmine fire and childhood lung function

Emily Hemstock[1,2], Rachel Foong[3,4], Graham Hall[3,4], Amanda Wheeler[1,5], Shyamali Dharmage[6], Marita Dalton[1], Grant Williamson[1], Michael Abramson[7], Fay Johnston[1], Graeme Zosky[1,8]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]Centre for Air pollution, energy and health Research, NHMRC CRE, Glebe, Australia, [3]Children's Lung Health, Wal-yan Respiratory Research Centre, Telethon Kids Institute, Nedlands, Australia, [4]School of Allied Health, Curtin University, Bentley, Australia, [5]Mary McKillop Institute for Health Research, Australian Catholic University, Melbourne, Australia, [6]School of Population and Global Health, University of Melbourne, Melbourne, Australia, [7]School of Public Health & Preventive Medicine, Monash University, Melbourne, Australia, [8]Tasmanian School of Medicine, University of Tasmania, Hobart, Australia

BACKGROUND AND AIM: Studies linking early life exposure to air pollution and impaired lung health have focused on chronic, low-level exposure in urban settings. We have previously shown that early post-natal exposure to an acute, high-intensity air pollution episode was associated with mild impairments in peripheral lung mechanics. We aimed to determine whether in utero exposure to the same pollution event impaired lung function 7-years later.

METHODS: We conducted a prospective study in a cohort of children who lived in the vicinity of a coalmine fire that burned for 6 weeks in 2014. Individual exposure to $PM_{2.5}$ from the fire were estimated using dispersion and chemical transport modelling. Respiratory function was measured in children who were in utero during the fire, or conceived after the fire (unexposed), using the forced oscillation technique. Z-scores for resistance at 5Hz(R5), reactance at 5Hz(X5) and area under the reactance curve(AX) were calculated. Regression models were fitted to compare Z-scores of unexposed and in utero exposed children, and to examine the relationship between in utero $PM_{2.5}$ exposure and lung function.

RESULTS: of the 72 children, 22 who were unexposed and 50 exposed in utero, and had acceptable lung function measurements. Medians (interquartile ranges) for daily average and peak $PM_{2.5}$ for the children exposed in utero were 9.2(7.6–20.2) and 124(74–252) $\mu g/m^3$. There were no statistically significant differences between mean R5, X5 or AX Z-scores of unexposed and in utero exposed children. There were no associations between R5, X5 or AX Z-scores and in utero exposure to daily average or peak $PM_{2.5}$. This lack of association was maintained after inclusion of covariates in the models.

CONCLUSIONS: There was no detectable effect of in utero exposure to $PM_{2.5}$ from a local coalmine fire on post-natal lung function 7-years later.

P-0426 The impact of heat waves on children’s kidney health: Systematic review and meta-analysis

Youngrin Kwag[1], Eunhee Ha[1]
[1]*Ewha Women's University College of Medicine and Graduate School of Medicine, Seoul, Republic of Korea*

BACKGROUND: Children are known to be particularly sensitive to heat waves, but still there has been little research interest in this area . In particular, a systematic review and meta-analysis is needed to identify the relationship between climate change-related heatwaves and children's kidney health.
METHOD: Papers published between 2000 and 2022 was identified using keywords in PubMed. 320 of 2406 publications searched for "climate change", "heat wave", "children", "kidney" met the selection criteria.
RESULT: In our study we included kidney stones and urolithiasis as kidney disease. This study lists the consistent definitions of heatwaves in each literature from the perspective of children's health impact. Our study explores detailed outcome measures to quantify the effects of heatwaves on children's kidney health, and analyzes the literature to evaluate the effects of heatwaves

CONCLUSIONS: Through this study, the effect of heat wave on children's kidney health, with regards to age, gender and income, and vulnerability to heat wave between countries can be understood. In addition, it will be helpful in predicting the burden of children's kidney disease due to heat wave with respect to climate change, and developing effective heat wave damage mitigation and adaptation strategies.

P-0427 Comparative Analysis of Health Patterns and Gaps due to Environmental Influences in South Korea and North Korea, 2000-2017

Yoorim Bang[1], Jongmin Oh, Eun Mee Kim, Ji Hyen Lee, Minah Kang, Miju Kim, Seok Hyang Kim, Jae Jin Han, Hae Soon Kim, Oran Kwon, Hunjoo Ha, Harris Kim, Hye Won Chung, Eunshil Kim, Young Ju Kim, Yuri Kim, Younhee Kang, Eunhee Ha

[1]*Institute for Development and Human Security, Ewha Womans University, Seoul, Korea, Republic of Korea*

BACKGROUND AND AIM: Children's metabolism is immature and vulnerable to environmental stressors creating a larger burden of diseases. South Korea and North Korea have been isolated from each other and while sharing the same ethnicity and early history, this provides a rich ground for comparative research. The study aims to conduct a comparative study of children's health in South Korea versus North Korea with a focus on air pollution.

METHODS: The study used mortality rate, prevalence, and environmental indicators data from 2000 to 2017 from the World Bank and World Health Organizations. Comparative analysis and trend analysis of the two Koreas were conducted to evaluate changes in health status over time. Spearman's correlation analysis was used to find out the correlation between environmental indicators and children's health status.

RESULTS: The study found a distinct gap in children's health status. While North Korea reported a higher death rate of children than South Korea, it showed a decreasing trend and the gap in children's health status between them narrowed from 2000 to 2017. The prevalence of overweight and obesity increased and that of thinness decreased in both Koreas. Except for PM2.5 exposure, South Korea reported much higher figures in most indicators of air pollutant emissions (South Korea, mean (SD) = 28.3 (2.0); North Korea, mean (SD) = 36.5 (2.8), p-value=0.002).

CONCLUSIONS: The study empirically discovered the gaps and patterns of children's health between South Korea and North Korea. The findings imply epigenetic modification caused by environmental stressors affects children's health in the two Koreas despite sharing similar genetic characteristics. Considering the gaps in children's health between them, more attention and resources need to be directed towards North Korea because the necessary commodities and services to improve children's health are lacking in North Korea.

P-0428 Indoor coal ash and school and social competency among children aged 6-14 years old

Kristina M Zierold[1], John V Myers[2], Guy N Brock[2], Clara G Sears[3], Charlie H Zhang[4], Lonnie Sears[5]
[1]University of Alabama at Birmingham - Dept of Environmental Health Sciences, Birmingham, USA, [2]The Ohio State University - Center for Biostatistics, Columbus, USA, [3]University of Louisville - Dept of Environmental Medicine, Louisville, USA, [4]University of Louisville - Dept of Geographical and Environmental Sciences, Louisville, USA, [5]University of Louisville - Dept of Pediatrics, Louisville, USA

BACKGROUND AND AIM: Coal ash, a waste product generated when burning coal for energy, is comprised of small particles with neurotoxic heavy metal(loid)s found to be risk factors for learning and social problems in school. The purpose of this novel study was to assess the association of coal ash in children's homes with school and social competency.

METHODS: We recruited children aged 6-14 years old from communities located within 10 miles of two coal-burning power plants. In homes of the participants, coal ash was collected on polycarbonate filters using personal modular impactors. We measured school competency and social competency using the validated Child Behavioral Checklist. Using Tobit and linear regression we investigated the relationship of indoor coal ash with school and social competency.

RESULTS: Forty-three percent of children in the study had coal ash in their homes. In Tobit models that were adjusted for age, sex, self-reported race, mother's education, and traffic exposure, children with coal ash in their homes scored on average 2.5 (-4.9 to -0.1) points lower on the school competency scale than peers without ash in their homes (p=0.04). We did not observe that coal ash in homes was related with lower social competency.

CONCLUSIONS: Children with coal ash in their homes had poorer performance in the school setting, compared to peers without coal ash in homes. Coal ash consists of small particles, that contains neurotoxins and may be a contributing factor to poor school performance, which potentially impairs children's academic achievement. There are limited regulations on the storage of coal ash and this study provides impetus for more research.

KEYWORDS: coal ash, fly ash, school competency, social competency, school performance, environmental exposure

P-0441 Early life exposure to coal smoke and hospital visitation: findings from a data linkage cohort study

Myriam Ziou[1], Caroline Gao[2], Amanda Wheeler[1,3], Graeme Zosky[1,4], A/Prof Nicola Stephens[4], A/Prof Luke Knibbs[5], Shannon Melody[1], Alison Venn[1], Marita Dalton[1], Shyamali Dharmage[6], Fay Johnston[1]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia, [3]Mary MacKillop Institute for Health Research, Australian Catholic University, Melbourne, Australia, [4]Tasmanian School of Medicine, University of Tasmania, Hobart, Australia, [5]Sydney School of Public Health, The University of Sydney, Sydney, Australia, [6]Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia

BACKGROUND AND AIM: The extent to which air pollution exposure in early life could engender modifications of immune responses with long-term health consequences is still largely unknown. The aim of this study was to analyse emergency department (ED) visits and hospitalisations following prenatal and postnatal exposure to severe smoke from the Hazelwood coal mine fire (9 Feb-25 Mar 2014).

METHODS: The Victorian Emergency Minimum Dataset and the Victorian Admitted Episodes Dataset were linked to the Victorian Perinatal Data Collection to obtain ED visits and hospitalisations of children born in the Latrobe Valley, Australia from March 2012 to December 2015. Exposure to fire-related PM2.5 was assigned from gridded modelled estimates based on residential address at birth. Children exposed in utero and in infancy (<1 year old) were investigated separately. Associations between exposure to fire-related PM2.5 and ED presentations and hospitalisations for any cause, respiratory outcomes, respiratory-related infections, any infections, and allergies/skin rash in the first year of life (in utero) or in the year following the end of the fire (infant) were estimated with logistic regression models. Adjustment for potential confounders was performed through multiple regression in the dose-response analysis, and with propensity score weighting when comparing exposure groups.

RESULTS: A dose-response relationship was found between prenatal exposure to PM2.5 and ED presentations for allergies/skin rash (OR=1.14, 95%CI=1.01-1.27 per 100µg/m³) in the first year of life. A cumulative exposure >25 µg/m³ in infancy was associated with higher risks of presenting to the ED for respiratory causes (OR=1.39; 95%CI=1.06-1.81), respiratory-related infections (OR=1.41, 95%CI=1.07-1.86), and any infections (OR=1.21, 95%CI=0.98-1.49) in the year following the fire.

CONCLUSIONS: Exposure to large concentrations of smoke in early life could be associated with allergic and infectious conditions up to one year after return to normal levels of ambient air pollution.

KEYWORDS: Particulate matter; Long-term exposure; Infections; Allergies;

P-0442 Prenatal and early postnatal exposure to air pollution associations with primary care and prescription usage

Myriam Ziou[1], Caroline Gao[2], Amanda Wheeler[1,3], Graeme Zosky[1,4], A/Prof Nicola Stephens[4], A/Prof Luke Knibbs[5], Shannon Melody[1], Alison Venn[1], Marita Dalton[1], Shyamali Dharmage[6], Fay Johnston[1]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia, [3]Mary MacKillop Institute for Health Research, Australian Catholic University, Melbourne, Australia, [4]Tasmanian School of Medicine, University of Tasmania, Hobart, Australia, [5]Sydney School of Public Health, The University of Sydney, Sydney, Australia, [6]Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia

BACKGROUND AND AIM: Health consequences of air pollution in early life have been mostly studied in hospital settings, with less focus put on primary care and prescribed medications. The aim of this study was to investigate general practitioner (GP) consultations and prescriptions dispensed following exposure in utero and in the first year of life to the Hazelwood coal mine fire, a severe air pollution episode lasting six weeks.

METHODS: The Victorian Perinatal Data Collection was linked to the Medicare Benefits Schedule and the Pharmaceutical Benefits Scheme for a cohort of children born in the Latrobe Valley, Australia between March 2012 and December 2015. Modelled estimates of fire-related PM2.5 exposure were assigned at the residential address at birth. The total numbers of GP visits and of prescriptions of antibiotics, asthma inhalers and steroid skin creams dispensed in the first year of life or in the year following the fire were extracted for children exposed in utero and in infancy (<1 year old), respectively. Negative binomial regression models estimated associations between each outcome and exposure to fire-related PM2.5, with adjustment made for potential confounders.

RESULTS: Higher levels of PM2.5 in utero were associated with increased asthma inhalers dispensed (IRR=1.07, 95%CI=1.00-1.14 per 100µg/m³ of cumulative PM2.5; IRR=1.27, 95%CI=1.01-1.58 per 50µg/m3 of peak 24-h PM2.5) in infancy. Surprisingly, a cumulative exposure >25 µg/m³ in infancy was linked to fewer GP visits (IRR=0.83, 95%CI=0.68-0.99) in the year following the fire.

CONCLUSIONS: Our findings indicate that prenatal exposure to time-limited severe air pollution could be linked with increased need of asthma medications in infancy. They also suggest that such exposure in infancy could be associated with less GP consultations following extreme events, which could be due to increased needs of specialised and hospital care.

KEYWORDS: Particulate matter; Long-term exposure; Infections; Asthma;

P-0443 Associations of Prenatal First-Trimester Metal Mixtures and Childhood Adipokines in the Project Viva Cohort

Anna Rose Smith[1], Pi-I Debby Lin[2], Sheryl L. Rifas-Shiman[2], Robert O. Wright[3], Brent Coull[4], Marie-France Hivert[2,5], Emily Oken[2], Andres Cardenas[1]

[1]Division of Environmental Health Sciences, School of Public Health and Center for Computational Biology, University of California, Berkeley, Berkeley, USA, [2]Division of Chronic Disease Research Across the Lifecourse, Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA, [3]Department of Environmental Medicine and Institute for Exposomic Research, Icahn School of Medicine at Mount Sinai, New York City, USA, [4]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Harvard University, Boston, USA, [5]Diabetes Unit, Massachusetts General Hospital, Boston, USA

BACKGROUND AND AIM: The adipokines leptin and adiponectin, mainly produced in adipose tissue, are involved in energy homeostasis and insulin sensitivity. Lower adiponectin and higher leptin correlate with older childhood and adult adiposity, while the relationship in young children is less clear. Higher prenatal heavy metals and lower nonessential metals have been associated with childhood adiposity, but it is unclear if prenatal metals influence childhood adipokines.

METHODS: Six nonessential (As, Ba, Cd, Cs, Hg, Pb) and four essential (Mg, Mn, Se, Zn) metals were measured in first trimester red blood cells from pregnant participants in the Boston MA-area Project Viva cohort. Blood leptin and adiponectin were measured in early-childhood (N=527-526; mean 3.3 (SD 0.3) years), mid-childhood (N=426; 8.0 (0.8) years), and early-adolescence (N=477; 13.1 (0.9) years). Linear regression and quantile g-computation models estimated associations between individual and mixtures of metals and adipokines, adjusting for confounders.

RESULTS: Mean (SD) leptin was 1.9 (1.9) ng/ml in early-childhood, 5.6 (6.8) ng/ml in mid-childhood and 11.9 (14.7) ng/ml in early-adolescence. Mean (SD) adiponectin was 22.4 (5.5) µg/ml in early-childhood, 15.7 (8.5) µg/ml in mid-childhood and 6.4 (2.8) µg/ml in early-adolescence. A doubling in arsenic was associated with lower adiponectin at the early-childhood visit (β=-0.40 µg/ml, 95% CI: -0.73, -0.07), while cesium was associated with higher leptin at the early-adolescence visit (β=2.76 ng/mL, 95% CI: 0.22, 5.30). In mixture analyses, adjusting for metals not in the mixture, a quartile increase in nonessential metal mixture was associated with lower adiponectin (β=-0.18 µg/ml, 95% CI: -0.33, -0.03) at the mid-childhood visit.

CONCLUSIONS: Our findings suggest that certain prenatal metals are associated with adipokines in childhood, which might influence cardiometabolic risk. Future work will evaluate if adipokines mediate associations of prenatal metals with adiposity and cardiometabolic risk.

KEYWORDS: Heavy metals, Mixtures analysis, Children's environmental health

P-0444 Newborn Metabolomics linking prenatal air pollution exposure and autism spectrum disorder risk in children

Ni Kang[1], Lauren Petrick[2], Jiawen Liao[1], Md Mostafijur Rahman[1], Sarah Carter[4], Nathan Pavlovic[5], Frederick Lurmann[5], Ting Chow[4], Mayra Martinez[4], Xin Yu[3], Jane Lin[4], Sandrah Eckel[1], Joel Schwartz[6,7], Jiu-Chiuan Chen[1], Rob McConnell[1], Anny Xiang[4], Zhanghua Chen[1]

[1]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, USA, [2]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Spatial Science Institute, University of Southern California, Los Angeles, USA, [4]Department of Research & Evaluation, Kaiser Permanente Southern California, Pasadena, USA, [5]Sonoma Technology, Inc, Petaluma, USA, [6]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [7]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA

KEYWORDS: Metabolomics, Autism spectrum disorder, air pollution exposure, pregnancy, oxidative stress.

BACKGROUND: Prenatal PM2.5 and near-roadway air pollution (NRAP) exposures, particularly nonfreeway NRAP, have been associated with increased autism spectrum disorder (ASD) risk in children. However, the underlying biological mechanism is unclear.

Aim: To investigate neonatal metabolic pathways altered by prenatal PM2.5 and NRAP exposures that increase ASD risk.

METHOD: Using electronic medical records, 50 ASD cases diagnosed before age 5 and 50 controls matched on birth year, medical center, sex, and race/ethnicity were randomly selected from all children born at Kaiser Permanente Southern California between 2007-2009. Weekly PM2.5 and monthly nonfreeway NRAP exposures during pregnancy were estimated based on residential history using spatiotemporal prediction and California line-source dispersion models, respectively. Untargeted, high-resolution metabolomics was analyzed in archived newborn dry blood spots, resulting in 26,578 HILIC-positive and 27,614 C18-negative metabolomic features.

Conditional logistic regression was used to identify metabolomic features associated with ASD diagnosis. Linear regression was used to investigate associations between prenatal air pollution exposure and metabolomic features. Beyond matching factors, maternal age, education level and household income categories were adjusted in the analyses. Mummichog pathway analysis was performed to identify metabolic pathways associated with prenatal air pollution exposure and ASD.

RESULTS: Dysregulated aspartate and asparagine metabolism was associated with increased ASD risk($p=0.01$) and higher PM2.5 exposure during the 1st trimester and the entire pregnancy($p<0.001$). Glutamate metabolism was associated with PM2.5 during pregnancy($p=0.028$) and increased ASD risk($p=0.03$). Prenatal nonfreeway NRAP was associated with altered nitrogen ($p=0.027$) and sialic acid metabolism($p=0.038$), while nitrogen metabolism was also associated with increased ASD risk($p=0.02$).

CONCLUSIONS: Dysregulated metabolism reflected in aspartate, asparagine and glutamate was associated with both prenatal air pollution exposure, particularly PM2.5, and increased ASD risk, suggesting newborn oxidative stress and inflammation may be pathways of effects of prenatal air pollution exposure.

P-0445 Neonicotinoid, pyrethroid and organophosphate urinary metabolites in relation to neurobehavioral performance in Ecuadorian adolescents

Jessica Yen[1], Kun Yang[1], Ana Skomal[1], Xin Tu[1], Sheila Gahagan[1], Jose Suarez-Lopez[2]
[1]School of Medicine, University of California-San Diego, La Jolla, USA, [2]Herbert Wertheim School of Public Health, University of California-San Diego, La Jolla, USA

BACKGROUND AND AIM: Insecticides, including organophosphates and pyrethroids, have been found to affect the neurobehavioral development of children, but limited evidence exists among adolescents. These insecticides have been slowly replaced by neonicotinoids, but there is little epidemiological data regarding their effects on neurobehavior. We examined the associations between urinary insecticide concentrations and neurobehavioral performance amongst adolescents living in agricultural communities in Ecuador.

METHODS: This study included 522 participants aged 11-17 years who were examined in 2016. Urinary insecticide metabolites were measured using mass-spectrometry and neurobehavior was assessed using the NEPSY-II (domains: Attention/Inhibitory Control, Language, Memory/Learning, Visuospatial Processing, Social Perception). Associations were adjusted for creatinine and demographic, anthropometric, and socioeconomic characteristics. Multiple imputation was used for values below the level of detection.

RESULTS: The mean(SD) neurobehavior scores ranged from 7.03(2.04) to 8.69(2.28). Among organophosphate metabolites, 3,5,6-Trichloro-2-pyridinol (TCPy) was inversely associated with Language (score difference per 50% increase in metabolite concentration [β] = -0.11 [95%CI: -0.50, -0.02]) and para-Nitrophenol (PNP) was inversely associated with Social Perception (β = -0.26 [95%CI: -1.07, -0.20]). There was also evidence of a threshold: TCPy and PNP had significant inverse associations with Attention/Inhibitory Control only at concentrations above the 60th percentile (β = -0.22 [95%CI: -0.43, -0.00] and β = -0.29 [95%CI: -0.54, -0.04], respectively). The pyrethroid, 3-phenoxybenzoic acid (3-PBA), was inversely associated with Language (β = -0.11 [95%CI: -0.48, -0.05]) and had a negative quadratic association with Attention/Inhibitory Control ($p<0.01$). The neonicotinoid, 5-Hydroxy imidacloprid (OHIM), was positively associated with Memory/Learning (β = 0.21 [95%CI: 0.12, 0.93]). These associations did not differ by gender.

CONCLUSIONS: Organophosphate and pyrethroid metabolites were associated with lower performance on Language, Social Perception and Attention/Inhibitory Control, while neonicotinoids were associated with better Memory/Learning scores. These findings highlight the importance of limiting environmental insecticide exposures during developmental years.

P-0448 Urinary metabolites of volatile organic compounds and polycyclic aromatic hydrocarbons increases the risk of nonalcoholic fatty liver disease in Korean adolescents: A Korean National Environmental Health Survey (KoNEHS) 2015-2017 analysis

Yun-Hee Choi[1,2], Yun-Hee Choi[1,2,3]

[2]*BK21 FOUR R & E Center for Learning Health System, Korea University, Anam-ro 145, Seongbuk-gu, Seoul, Republic of Korea,*
[3]*Department of Health and Environmental Science, Korea University, Anam-ro 145, Seongbuk-gu, Seoul, Republic of Korea*

Non-alcoholic fatty liver disease (NAFLD) is one of the most common liver diseases in adolescents and is an urgent public health issue. Several animal studies have suggested that volatile organic compounds (VOCs) and polycyclic aromatic hydrocarbons (PAHs) led to NAFLD. However, few epidemiological studies have confirmed the associations of VOCs and PAHs with NAFLD in the general adolescent population. Therefore, we analyzed 798 adolescents from the Korean National Environmental Health Survey (KoNEHS) 2015-2017 to examine the associations of urinary metabolites for VOCs and PAHs with serum alanine aminotransferase (ALT) activity and NAFLD prevalence. We employed linear, logistic regression, and Bayesian kernel machine regression (BKMR) to evaluate the association of urinary VOCs and PAHs metabolites with ALT activity and NAFLD. After adjusting for all covariates, urinary benzylmercapturic acid level and 2-hydroxyfluorene level increased serum ALT activity and NAFLD prevalence. Additionally, the BKMR analyses showed a significantly positive overall effect on ALT activity and NAFLD prevalence with urinary concentrations of VOCs and PAHs metabolites, and 2-hydroxyfluorene contributed the most. Our study suggests that exposure to low-level VOCs and PAHs may have a detrimental effect on NAFLD risk in adolescents. Given the increasing prevalence of NAFLD in adolescents, future cohort studies are warranted to understand these chemicals' impact on NAFLD risk.

KEYWORDS: volatile organic compounds (VOCs), polycyclic aromatic hydrocarbons (PAHs), adolescents, Non-alcoholic fatty liver disease, Korean National Environmental Health Survey (KoNEHS)

P-0450 Effect of prenatal PM2.5 and its constituents exposure and fetal growth pattern on children's accelerated growth in the first three years

Shuang Zhou[1], MS. Tiantian Li[2], MS. Na Han[3], MS. Yi Zhang[2], Yuelong Ji[1], Qin Li[1], MS. Jue Liu[1], MS. Hui Wang[1], Jianlin Hu[4], MS. Ting Liu[4], Hai-Jun Wang[1]

[1]Department of Maternal and Child Health, School of Public Health, Peking University, Beijing, China, [2]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [3]Tongzhou Maternal and Child Health Care Hospital of Beijing, Beijing, China, [4]Jiangsu Key Laboratory of Atmospheric Environment Monitoring and Pollution Control, Collaborative Innovation Center of Atmospheric Environment and Equipment Technology, Nanjing University of Information Science & Technology, Nanjing, China

BACKGROUND: No study investigated the effect of prenatal exposure to PM2.5 and its constituents on accelerated childhood growth, with consideration of fetal growth pattern in utero. We aimed to examine the effect of prenatal PM2.5 and its constituents exposure, fetal growth pattern on children's accelerated growth in the first three years.

METHODS: The study was embedded in a population-based birth cohort in China, including 5,424 mother-child pairs. Prenatal PM2.5 and its constituents [organic carbon (OC), elemental carbon (EC), sulfate (SO42-), nitrate (NO3-), and ammonium (NH4+)] concentrations were estimated. Estimated fetal weight (EFW) Z-score by fetal ultrasound examination in second and third- trimester was calculated and then K-means algorithm was used to cluster the fetal growth pattern. Children's accelerated growth was defined as the change of BMI Z-score from birth to three years >0.67. Generalized logistic regression was used to analyze the effect of prenatal PM2.5 and its constituents exposure and fetal growth pattern on children's accelerated growth.

RESULTS: Compared with higher fetal growth, children with lower fetal growth had 1.706 (95%CI: 1.520, 1.915) times higher risk of children's accelerated growth from birth to three years old. An IQR increase in PM2.5, OC, NH4+, and SO42- was associated with 1.147 (95%CI:1.012, 1.300), 1.360 (95%CI:1.113, 1.662), 1.127 (95%CI:1.017, 1.248), and 1.257 (95%CI:1.012, 1.561) times higher risk of children's accelerated growth, respectively. Prenatal PM2.5 and its constituents exposure and fetal growth had joint effect on children's accelerated growth from birth to three years old, especially for OC (RERI:0.485, 95%CI: 0.018,0.952).

CONCLUSIONS: The study suggested that prenatal PM2.5 and its constituents exposure and fetal growth in utero had individual and joint effect on children's accelerated growth from birth to three years old.

KEYWORDS: PM2.5, constituents, accelerated childhood growth, fetal growth

P-0456 Systematic review in 2000-2020 on early childhood developmental conditions of environmental noise exposure

Elisa Herrera[1], Leticia Hernández[1], Ma Maricela Piña[1]
[1]*National Institute of Public Health, Cuernavaca, Mexico*

BACKGROUND AND AIM: Early childhood is a crucial stage of human development. Exposure to noise can alter their development and affect their health, reducing their quality of life. Information to facilitate decision making in this regard is still scarce in several countries, so the aim of this study was to characterize the developmental conditions in early childhood that have been related to environmental exposure to noise based on population-based studies.

METHODS: An exhaustive systematic review was carried out using Cochrane methodology during the period 2000-2020. Publications were included without restriction of language, country or publication type, with information on adverse developmental outcomes in early childhood (0-8 years of age) due to prenatal or concurrent exposure to environmental noise.

RESULTS: Thirty-four studies were selected that addressed early childhood with prenatal or postnatal exposure, grouping the effects into three groups: fetal period (malformations and miscarriage), neonatal period (premature birth, low birth weight, small for gestational age and physiological alterations) and childhood (physiological, constitutional, learning and behavioral alterations). Information sources for both, outcome and exposure events varied between direct and indirect measurements. Five articles address biological plausibility mechanisms. In Eight articles, no significant findings are reported, and in no study the impact on the quality of subsequent life stages was investigated.

CONCLUSIONS: Sufficient evidence was found to support the presence of conditions in early childhood due to prenatal and concurrent environmental exposure to environmental noise. The need to generate policies that allow routine monitoring of noise levels and their regulation to mitigate exposure and protect children's health is evident.

KEYWORDS: environmental noise, child development, early childhood, child developmental impairment, noise pollution.

P-0470 Multiple air pollutants and renal health in children and adolescents: An 18-year longitudinal study in Asia

Cui Guo[1], Xianglin Wei[1], Yiqian Zeng[1], Xiang Qian Lao[1]
[1]*The Chinese University of Hong Kong, Shatin, Hong Kong*

BACKGROUND AND AIM: Few studies have examined the effects of multi-pollutant air pollution on renal health, especially in children and adolescents. This study investigated the association between long-term ambient air pollution exposure and renal health in Asian children and adolescents.

METHODS: This study included 10,942 children and adolescents aged ≤ 25 years from Taiwan and Hong Kong from 2000 to 2017. PM2.5, NO2 and O3 concentrations were estimated using satellite-based spatiotemporal regression models. Two-year average concentrations, those of the year of visit and the preceding year, were used. Linear mixed models were used to examine the association between air pollution and yearly changes in estimated glomerular filtration rate (eGFR). Cox regression models with time-dependent covariates were used to examine the association between air pollution and the development of chronic kidney disease (CKD). Both single- and multi-pollutant models were used.

RESULTS: for the single-pollutant models, each 10μg/m3 increase in PM2.5 was associated with a 0.45μL/min/1.73 m2 [95% confidence interval (CI): 0.28−0.63] reduction in the yearly increase in eGFR and 53% [hazard ratio (HR): 1.53 (95%CI: 1.07–2.2)] greater risk of CKD. Each 10μg/m3 increase in NO2 was associated with a 7% [HR (95%CI): 1.07 (1.00–1.15)] higher risk of CKD, while an equivalent increase in O3 was associated with a 19% [HR (95%CI): 0.81 (0.67–0.98)] lower risk of CKD. for multi-pollutant models, the air pollution–CKD associations were slightly attenuated.

CONCLUSIONS: Long-term exposure to ambient PM2.5 and NO2 was associated with a slower growth of eGFR and a higher risk of CKD in children and adolescents. Our findings suggest that air pollution control in early life is imperative to improve lifelong renal health and alleviate the CKD burden.

P-0471 Prenatal air pollution exposure and infant weight trajectories from 3rd trimester to 2 years of age

NAN Ji[1], Mark Johnson[1], Sandrah Eckel[1], William Gauderman[1], Thomas Chavez[1], Dema Faham[1], Fred Lurmann[2], Nathan Pavlovic[2], Brendan Grubbs[1], Deborah Lerner[3], Rima Habre[1], Shohreh Farzan[1], Theresa Bastain[1], Carrie Breton[1]

[1]University of Southern California, Los Angeles, USA, [2]Sonoma Technology, Inc., Petaluma, USA, [3]Eisner Health, Los Angeles, USA

BACKGROUND AND AIM: Prenatal exposure to air pollution is increasingly viewed as harmful to fetal development and leads to childhood obesity. However, few studies have evaluated in utero growth measures and postnatal weight trajectories along a continuum in statistical models. This study aims to evaluate associations between prenatal air pollution and weight trajectories from the 3rd trimester through 2 years of life among infants in the Maternal and Development Risks from Environmental and Social Stressors (MADRES) pregnancy cohort, which comprises a low-income, primarily Hispanic population in Los Angeles, California.

METHODS: Fetal weights during the 3rd trimester were abstracted from maternal ultrasound records. Infant weight measures were abstracted from medical records and measured by staff at study visits. Ambient particulate matter ≤2.5 µm and ≤10 µm in diameter (PM2.5 and PM10) concentrations were assigned using spatial interpolation from the regulatory air monitoring stations. Piecewise linear spline models were used to assess non-linear associations between prenatal air pollution exposure and infant weight trajectories.

RESULTS: Weight increased most rapidly from 3 months prior to birth through 3 months of age, slowing thereafter. Pregnancy-averaged PM2.5 and PM10 were associated with a slower rate of growth from the 3rd trimester until age 2 years. A one IQR increase in PM2.5 (1.65 ug/m3) and PM10 (7.48 ug/m3) exposure were associated with a 0.28 kg and 0.38 kg lower weight at 2 years of age, respectively. In sex-stratified models, the effects of PM2.5 and PM10 were only significant in females.

CONCLUSIONS: Our findings suggest that prenatal exposure to PM2.5 and PM10 could impact infant weight gain trajectories and thus, impact childhood obesity, with potentially more pronounced impacts among females.

KEYWORDS: prenatal air pollution, growth trajectory

P-0480 The Season of Conception and Cerebral Palsy Risk in California

Haoran Zhuo[1,2], Beate Ritz[3,4], Zeyan Liew[1,2]

[1]Department of Environmental Health Sciences, Yale School of Public Health, New Haven, USA, [2]Yale Center for Perinatal, Pediatric and Environmental Epidemiology, Yale School of Public Health, New Haven, USA, [3]Department of Epidemiology, Fielding School of Public Health, University of California, Los Angeles, Los Angeles, USA, [4]Department of Neurology, School of Medicine, University of California, Los Angeles, Los Angeles, USA

BACKGROUND AND AIM: Cerebral palsy (CP) is the most prevalent, severe, costly neuro-motor disability in children, and it is permanent. The majority of CP cases have an unknown etiology. This is the first study to investigate whether season of conception is associated with CP in California.

METHODS: We analyzed a California birth cohort of 5,089,216 children born in 2005-2015. A total of 5,508 children diagnosed with CP were identified by linking their California birth records with the diagnostic records from the California Department of Developmental Services. We used multivariate logistic regression analyses to estimate the odds ratio (OR) and 95% confidence interval (CI) for CP according to the month and season of conception, controlling for maternal characteristics (age, race/ethnicity, education), child's sex, and the year of conception. Month of conception was estimated from the child's date of birth and length of gestation and was grouped into seasons (winter: Jan-March, spring: April-June, summer: July-Sept, fall: Oct-Dec). We performed stratified analyses by child's sex (females, males), disease subtypes (spastic, ataxic, hypotonic, other), limb involvement (unilateral, bilateral), and geographical locations of birth (Northern, Central, Southern) in California.

RESULTS: Having been conceived in winter and spring was associated with 9% higher odds of having CP (OR=1.09, 95% CI winter: 1.01-1.18, spring: 1.01-1.17) compared to summer conceptions. When considering months, consistent increases of CP with >10% higher odds were observed for each month from January to June compared to September, except for March. We observed no apparent differences in the stratified analyses.

CONCLUSIONS: This is the first study to show winter and spring conceptions to be associated with higher CP occurrence in the offspring. Environmental factors and/or infections that predominate in winter/spring in California may underly this increased CP risk and need to be further explored.

KEYWORDS: Cerebral Palsy, Seasonal Variation, Environment, Neurodevelopment, Birth cohort

P-0482 Congenital malformations of the male genital system and risk of attention deficit hyperactivity disorder

Ran Rotem[1,2], Gabriel Chodick[2], Marc Weisskopf[1]
[1]Harvard TH Chan School of Public Health, Boston, USA, [2]Maccabi Healthcare Services, Tel Aviv, Israel

BACKGROUND: Accumulating evidence suggests that gestational exposure to environmental anti-androgenic endocrine disrupting chemicals has important neurodevelopmental effects. Specifically, androgens have extensive influence on brain development in regions that are relevant for attention deficient hyperactivity disorder (ADHD), yet their specific involvement in the etiology of this common disorder remains unclear. Hypospadias (abnormal positioning of the urethral opening) and cryptorchidism (undescended testes) are two common male birth defects that are strongly associated with deficiencies in prenatal androgen exposure. Thus, having cryptorchidism or hypospadias is a proxy indicator of atypical gestational androgen exposure, yet the association between these disorders and ADHD has not been extensively studied.

METHODS: We analyzed singleton live births (boys=203,728; girls=199,065) born in 1999-2012 in a large Israeli healthcare organization. Boys with cryptorchidism (n=3,945) or hypospadias (n=2,860) were identified via a validated algorithm based on diagnosis and medical procedure records. ADHD cases (n=59,272) were identified through diagnosis records and verified through review of medication dispensing data. Analyses were conducted using Cox proportional hazard models with robust standard error to account for family clusters.

RESULTS: In multivariable-adjusted analyses, the hazard ratio (HR) for ADHD among boys with cryptorchidism was 1.10 (95% CI:1.02-1.18) and among boys with hypospadias was 1.16 (95% CI:1.07-1.25) compared with boys without these conditions. ADHD hazard was also higher among reproductive condition-free brothers of cryptorchidism cases (aHR=1.15, 95% CI:1.06-1.25) and sisters of hypospadias cases (aHR=1.14, 95% CI:0.99-1.30).

CONCLUSIONS: Boys with cryptorchidism or hypospadias had an elevated ADHD hazard compared with boys without these conditions. Results among unaffected siblings suggest that these associations were potentially partly driven by parental or environmental factors present outside of the pregnancy period. Understanding the links between these congenital malformations, androgen homeostasis, and ADHD could shed light on the etiology of the disorder and allow for early detection and intervention.

P-0490 Early-life exposure to phthalates among infants in Italy: characterization and time trends

Elena Righi[1], Lucia Palandri[1], Angela Ferrari[1], Riccardo Barbieri[1], Camilla Lugli[1], Viola Trevisani[2], Erica Passini[2], Fabio Facchinetti[2], Laura Lucaccioni[2]

[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, [2]Department of Medical and Surgical Sciences for Mothers, Children and Adults, University of Modena and Reggio Emilia, Modena, Italy

BACKGROUND AND AIM: Human exposure to phthalates, endocrine disruptors, and reproductive toxicants,is ubiquitous. Urine is the matrix of choice for biomonitoring and in utero exposure is well documented. Evidence of early life exposure to phthalates is scarce.
The aim of this study is to assess phthalate exposure and its changes over time in a cohort of healthy infants in the province of Modena, Italy.

METHODS: In this prospective birth-cohort study, we assessed phthalate exposure(8 metabolites of 6 phthalates)in urine samples collected from mothers just after delivery and in infants at birth, 3 and 6 months using phthalate-free bags. Mother-infant pairs were enrolled in a university hospital in Modena(Italy)between January 2019 and May 2020. After solid-phase extraction, samples were analyzed by triple Quad LC/MS Mass Spectrometry.

RESULTS: 188 mother-infant pairs were enrolled. MEP was always detectable and showed the highest levels, increasing over time. MMP and DEHP metabolites showed as well an increasing trend, however, they were detected at lower levels, while MnBP and MBzP showed intermediate concentrations and decreasing trends over time.
Significant associations between mother-infant pairs at birth were found only for a few metabolites(MMP, MEP, and MnBP). Infant levels at 3 and 6 months appeared more related, suggesting a continuative exposure to these chemicals inside the indoor environment.

CONCLUSIONS: Phthalate exposure appears wide and extended over time. Infants were exposed to several phthalates, including those more toxic and strictly regulated in infant toys, personal care products and food contact materials in the European Union. Their unregulated use in other consumers'products, building and decorating materials or home furniture may explain the potential exposure of at-risk groups, such as infants or pregnant women. To effectively protect the most vulnerable subjects, public health preventive and regulatory actions should address this specific issue as well.

KEYWORDS: Phthalates, Biomonitoring, Urine, Newborns, Postnatal Exposure.

P-0491 Prenatal exposure to poly- and perfluoroalkyl substances and serum concentrations of vaccine antibodies in early childhood

Lauren Zell-Baran[1,2], Jill M. Norris[1], Deborah H. Glueck[3,4], John Adgate[5], Jared Brown[6], Dana Dabelea[1,3,4], Kylie K. Harrall[1,3], Anne P. Starling

[1]Department of Epidemiology; Colorado School of Public Health; University of Colorado Anschutz Medical Campus, Aurora, USA, [2]Division of Environmental and Occupational Health Sciences; National Jewish Health, Denver, USA, [3]Lifecourse Epidemiology of Adiposity and Diabetes (LEAD) Center; Colorado School of Public Health; University of Colorado Anschutz Medical Campus, Aurora, USA, [4]Deparment of Pediatrics; University of Colorado Anschutz Medical Campus, Aurora, USA, [5]Department of Environmental and Occupational Health; Colorado School of Public Health; University of Colorado Anschutz Medical Campus, Aurora, USA, [6]Department of Pharmaceutical Sciences; University of Colorado Anschutz Medical Campus, Aurora, USA, [7]Department of Epidemiology; Gillings School of Global Public Health; University of North Carolina at Chapel Hill, Chapel Hill, USA

BACKGROUND AND AIM: Prenatal exposure to certain poly- and perfluoroalkyl substances (PFAS) have been associated with a reduced humoral response to tetanus and diphtheria vaccines. Whether this is observed for other childhood immunizations is unknown.

METHODS: In a sample of 120 children in the Healthy Start cohort, we measured semi-quantitative antibody titers to measles, mumps, rubella, and varicella in child serum at 4-6 years old. We employed separate Cox proportional hazards models to estimate associations between maternal serum concentrations of five PFAS and the risk of a non-protective antibody titer, based on time since most recent dose (stratified by number of doses received).

RESULTS: Maternal PFAS concentrations were generally at or below the US median. Most children had protective vaccine titers (rubella 100%, measles 98%, mumps 90%, varicella 80%). Unadjusted associations between individual PFAS and the hazard of non-protective antibody titers had wide confidence intervals including the null [e.g. after two doses, lnPFOA HR, 95% CI: mumps 1.09 (0.21, 5.54); varicella 1.09 (0.33, 3.61): lnPFOS mumps 1.87 (0.22, 16.12); varicella 2.12 (0.55, 8.23): lnPFNA mumps 1.63 (0.21, 12.64); varicella 1.68 (0.36, 7.79): lnPFHxS mumps 6.05 (0.86, 42.75); varicella 1.36 (0.59, 3.13): lnPFDA mumps 1.71 (0.27, 10.84); varicella 2.74 (0.83, 9.07)]. Sensitivity analyses adjusting for the potential confounders of child sex or age at collection did not meaningfully change the effect estimates. We were unable to estimate associations with measles and rubella antibodies due to the small number of children with non-protective titers.

CONCLUSIONS: In this cohort of young children with background levels of PFAS exposure, higher prenatal PFAS concentrations were not significantly associated with greater risk of non-protective mumps and varicella antibody titers. This study demonstrates the utility of time-to-event models for examining associations between environmental chemicals and loss of disease protection.

P-0495 Air Pollution Exposures and Executive Function in Middle Childhood: A U.S. Multi-Cohort Study

Yu Ni[1], Alexis Sullivan[2], Adam Szpiro[1], Christine Loftus[1], Ruby Nguyen[3], Shanna Swan[4], Sheela Sathyanarayana[1,5], Emily Barrett[6], Nicole Bush[2], Catherine Karr[1], Kaja LeWinn[2]

[1]University of Washington, Seattle, USA, [2]University of California, San Francisco, San Francisco, USA, [3]University of Minnesota, Minneapolis, USA, [4]Icahn School of Medicine at Mount Sinai, New York, USA, [5]Seattle Children's Research Institute, Seattle, USA, [6]Rutgers University, Piscataway, USA

BACKGROUND AND AIM: Prior studies examining the association between spatiotemporally resolved air pollution and child executive function (working memory, inhibitory control, and cognitive flexibility) are limited. We aimed to fill this gap using data from the ECHO-PATHWAYS Consortium.

METHODS: We included 1,241 children from three U.S. pregnancy cohorts (CANDLE, TIDES, and GAPPS). Exposure to particulate matter ≤2.5µm in aerodynamic diameter ($PM_{2.5}$), nitrogen dioxide (NO_2), and ozone (O_3) at age 0-4 were derived from spatiotemporal models. at age 8-9, child working memory and inhibitory control were assessed using the Digit Span subtest from the Wechsler Intelligence Scale for Children, 5th Edition and the NIH Toolbox Flanker Inhibitory Control and Attention test, respectively. Cognitive flexibility was quantified by percent accuracy and mean latency of the Hearts and Flowers Task mixed block condition. We fitted linear regression models adjusted for sociodemographic, behavioral, and maternal psychological factors, and examined potential modification by child sex, maternal education, and neighborhood education quality.

RESULTS: Mean $PM_{2.5}$, NO_2, and O_3 were 8.9 (SD:1.7) µg/m³, 9.2 (SD:2.8) ppb, and 25.7 (SD:2.8) ppb, respectively. Overall, each 2-ppb increase of NO_2 was associated with a 1.1% lower percent accuracy in cognitive flexibility (95%CI: -1.8%, -0.3%), whereas other associations were all null. We found sex-specific inverse associations of NO_2 with working memory (Pinteraction: 0.019) and cognitive flexibility (Pinteraction: 0.017), and between $PM_{2.5}$ and inhibitory control (Pinteraction: 0.022), only in boys. The positive association between $PM_{2.5}$ and mean latency was stronger in children whose mothers completed high school or less (Pinteraction: 0.045). The protective association between $PM_{2.5}$ and cognitive flexibility was shown exclusively in children residing in neighborhoods with better education quality (Pinteraction: 0.004).

CONCLUSIONS: Our study contributes to a nascent literature on common air pollution exposures, notably NO_2, and child executive function.

KEYWORDS: Air pollution exposures, executive functions, child health

P-0499 Residential green space as a positive influencer on early childhood bone mineral density

Hanne Sleurs[1], Ana Inês Silva[1], Esmée M. Bijnens[1,2], Yinthe Dockx[1], Leen Rasking[1], Tim S. Nawrot[1,3], Michelle Plusquin[1]

[1]Centre for Environmental Sciences, Hasselt University, Diepenbeek, Belgium, [2]Department of Human Structure and Repair, Ghent University Hospital, Ghent, Belgium, [3]Centre for Environment and Health, Department of Public Health, Leuven University, Leuven, Belgium

BACKGROUND AND AIM The most crucial contribution to lifelong bone health is attained during the first decades of life by achieving the highest possible peak bone mass. Besides a solid genetic impact, this process is sensitive to environmental and behavioral influences. We explored whether exposure to the surrounding residential green space is related to a change in bone density in young children.

METHODS Within the ongoing Belgian ENVIRONAGE (Environmental influence on Ageing in Early Life) birth cohort, we followed up 471 children aged 4-to-6-years and assessed their radial bone mineral density with ultrasonic speed of sound measurements. Green spaces surrounding their residence were calculated based on high-resolution land cover data within multiple radii (50m to 3000m). Multivariable linear regression modelling was used to explore the association between green space exposure and children's bone density adjusted for relevant confounders.

RESULTS Children's radial bone mineral density was on average (SD) 3682 (112.4) m/sec, and the mean total green space for a 50 to 3000m radius around the residence ranged from 46.20% to 60.02%, respectively. An interquartile range (IQR) increment in high growing (>3m) and total (sum of <3m and >3m) residential green space in a 500m radius was associated with a corresponding increase of 19 m/sec (95% C.I.: 4.3 – 33.0 m/sec) and 17 m/sec (95% C.I.: 3.0 – 31.9 m/sec) in bone density. Moreover, significant results were noted within extended radii with long-term exposure to the surrounding green space, viewed in a subgroup of children who did not relocate between birth and follow-up phase.

CONCLUSIONS We found a positive association between children's bone mineral density and the surrounding residential green space exposure. These results contribute to unravelling factors increasing peak bone mass in early life and improving lifelong bone health.

KEYWORDS: Green Space, Bone Mineral Density, Bone Health, Childhood

P-0502 Study on the concentration of polybrominated diphenyl ethers in serum of teenagers in Zibo, China

Yifu Lu[1], Mengmeng Wang[1], Linna Xie[1], Ying Zhu[1]
[1]*China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND: Polybrominated diphenyl ethers (PBDEs) can lead to thyroid dysfunction. Teenagers are in a critical period of growth and development. So we should pay more attention to the concentration of PBDEs in the serum of teenagers.
AIM: This study is to evaluate the distribution and concentration of PBDEs in the serum of teenagers and to gain a preliminary understanding of the exposure of PBDEs in teenagers.

METHODS: The 255 serum samples of teenagers (age=15 years) were collected from Zibo in 2018. The 14 PBDEs (including BDE17, 28, 47, 66, 71, 85, 99, 100, 138, 153, 154, 183,190,209) were analyzed with high resolution gas chromatography-high resolution mass spectrometry (HRGC-HRMS) based on CDC method.

RESULTS: The results showed that the PBDEs concentrations were higher in males than in females. The mass concentration of PBDEs in serum was in the range of 2.4-123.9 ng/g lipid, the median concentration of ∑PBDEs was 12.4 ng/g lipid and the geometric mean concentration was 19.2 ng/g lipid. BDE-47 was detected in the serum samples with a relatively high detection frequency, followed by BDE-28 and BDE-99. Although the BDE-209 detection rate was relatively low but contribute the most abundant to the total concentration of PBDEs. There is a correlation between ∑PBDEs and each component, as well as between the components of PBDEs. BDE-28 was correlated to BDE-99 (r=0.558), BDE-47 was correlated to BDE-99 (r=0.599), and BDE-28 was correlated to BDE-47 (r=0.477). ∑PBDEs was correlated to BDE-28, BDE-47, and BDE-99 (r=0.471, 0.423, and 0.484), respectively.

CONCLUSIONS: Compared with other studies, the serum ∑PBDEs levels were close to the level in South China, lower than in America, slightly higher than in Japan and Switzerland. The results imply that there had some PBDEs exposure to teenagers in this region.

KEYWORDS: polybrominated diphenyl ethers, serum, teenagers

P-0504 Launching of CHildren's Environmental health Clinic in Korea (CHECK) and Institute of Ewha-Seoul Clinical Laboratories for Environmental Health (IESEH): The first clinic to research model of pediatric environmental health in South Korea

Hanna Kim[1,2], Whanhee Lee[1,3], Yi-Jun Kim[1,3], Ji Hyen Lee[2,4], Jung Won Lee[2,4], Hae Soon Kim[2,4], Kyoung-Ryul Lee[5], SaeYun Baik[5], Eunhee Ha[1,3,6]

[1]Department of Environmental Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [2]CHildren's Environmental health Clinic in Korea (CHECK), College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [3]Institute of Ewha-SCL for Environmental Health (IESEH), College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [4]Department of Pediatrics, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [5]Department of Laboratory Medicine, Seoul Clinical Laboratories, Gyeonggi-do, Republic of Korea, [6]Graduate Program in System Health Science and Engineering, Ewha Womans University, Ewha Medical Research Institute, College of Medicine, Seoul, Republic of Korea

BACKGROUND: In recent years, environmental hazards affecting children's health have been a public health concern. Since the 1990s, the Pediatric Environmental Health Specialty Units (PEHSUs) in the USA have provided rigorous research, clinical care, and public health interventions; nevertheless, this systematic network is scarce globally, especially in Asia. Thus, we established South Korea's first integrated "clinic to research" network for protecting children's health.

METHOD

The first children's health and environmental clinic in South Korea, CHildren's Environmental health Clinic in Korea (CHECK), was established. CHECK aims to develop 1) a pediatric-environmental medical examination system with a biobank, 2) a consultation system by specialized pediatricians, 3) medical guidelines for pediatric-environmental diseases, and 4) clinic operation models in this field. Subsequently, we founded the Institute of Ewha-Seoul Clinical Laboratories for Environmental Health (IESEH) to perform multidisciplinary pediatric-environmental research in collaboration with CHECK and medical departments, including Pediatrics, Internal Medicine, Obstetrics and Gynecology, and Environmental Medicine.

RESULTS: CHECK promotes pediatric patients' health by providing medical examinations, laboratory tests (including heavy metals, volatile organic compounds, and endocrine-disrupting chemicals), and specialized counseling and education for patients and parents concerned about environmental risks. IESEH will build a big-data resource by integrating data systematically collected from CHECK, Korea's national health insurance, and the Korean CHildren's ENvironmental health Study (Ko-CHENS)—a nationwide birth cohort. Through this, IESEH undertakes divergent pediatric-environmental studies ranging from data science-based epidemiology to genetics and validation studies for clinical intervention.

CONCLUSION: CHECK is the first pediatric environmental health clinic in Korea. IESEH performs research on pediatric-environmental health in collaboration with multidisciplinary experts, utilizing integrative data from CHECK and national cohorts. CHECK and IESEH will provide a gold standard for pediatric environmental health clinics and laboratories as a standardized and specialized "clinic to research" model.

KEYWORDS: CHECK; IESEH; children; environmental health; clinic to research model.

P-0505 A joint analysis of school neighbourhoods' exposure to urban environment factors in Greater London

Niloofar Shoari[1], Sean Beevers, Michael Brauer, Marta Blangiardo
[1]*Imperial College London, London, UK*

BACKGROUND AND AIM: Schools and their immediate neighbourhoods are places where children spend the most time outside their homes. Depending on the school location, there are variations in exposure to multiple urban environment features that can create and widen health inequality among children. Our aim was to identify and characterize clusters of schools with similar exposure profiles within 400 m (5-10 minutes walking distance) of schools in Greater London. We then explored association between clusters characteristics, ethnicity, and socioeconomic status.

METHODS: We modelled joint exposure to air pollution (NO2 and PM2.5), access to public greenspace, food environment, and road safety for 2,929 schools, employing a Bayesian non-parametric approach based on the Dirichlet Process Mixture (DPM) modelling. We identified clusters with similar exposure profiles, computed the summary statistics for each cluster, and uncovered urban features that were dominant contributory factor to each cluster.

RESULTS: We identified 12 clusters of schools with similar exposure profiles and were able to make probabilistic statements on the magnitude of exposures. We found that schools with relatively high exposures to harmful factors and a low exposure to beneficial factors (greenspace) were located in the most deprived areas.

CONCLUSIONS: Schools have a crucial role in providing equitable and healthy environment for children. We provided a tool to help schools, public health officials, and policy-makers to understand schools joint exposure to specific urban environment features. Our study highlighted the presence of distinct subgroups of schools with respect to exposure. This helps prioritize interventions and design local policies, with the aim of targeting the schools most in need.

KEYWORDS: Air quality; greenspace; food environment; pedestrian child crash; school exposure; Bayesian nonparametrics

P-0506 The association between per-/polyfluoroalkyl substances in serum of teenagers and thyroid function parameters near a Chinese fluorochemical industrial plant: A cross-sectional study

Linna Xie[1], Xiaochen Wang[1], Shasha Hou[1], Zhenhuan Li[1], Ying Zhu[1]
[1]*China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

As the global pollutant, per-/polyfluoroalkyl substances (PFASs) are widely detected in population, inducing some adverse health effects, such as endocrine disruption. However, there are few studies on the exposure characteristics and health effects of PFASs on population with relatively high internal exposure of PFASs. In the current study, 906 teenagers (11-15 years old) living near an industrial plant were included, the concentrations of 18 PFASs had been determined, and the association between PFAS concentrations and thyroid function was explored. PFOA was found to be the predominant PFAS with a median concentration of 138 ng/mL, followed by PFOS (2.08 ng/mL), PFBA (1.12 ng/mL) and 6:2 Cl-PFESA (1.08 ng/mL). for the thyroid function parameters of participants, the abnormal rates of FT3 (29.7%) and FT4 (19.7%) were relatively high, but those of TSH (2.2%), TPO-Ab (2.1%) and TG-Ab (3.3%) were relatively low. Furthermore, logistic regression analysis showed that abnormal FT4 was significantly correlated with higher concentrations of PFOA. Results of multiple linear regression analysis showed that levels of FT4 were significantly and negatively correlated with concentrations of PFOA and PFHpA, and positively correlated with concentrations of PFHxA ($p < 0.05$) by adjusting gender, age, BMI, outdoor activity time and average sleep time. and there was a significantly positive correlation between FT3 levels and concentrations of PFHxA and PFHxS. for TSH, the levels of which were significantly and negatively correlated with PFOA concentrations, but positively correlated with PFHxS concentrations. In conclusion, PFOA may be the risk factor for decreased FT4 for the participants, but the evidence is not enough to demonstrate that other PFASs are the risk factor of thyroid function, local government should pay more attention to the above findings and take measures to reduce the PFASs external exposure of local residents. The present study is of great significance for the epidemiological findings.

P-0509 Clusters of small-scale sources of air carcinogens emissions increase the risks of acute lymphoblastic leukemia (ALL) in children and teenagers at a small area level in urban areas

Lizet Jarquin-Yanez[3], Luis E. Reyes-Arreguin[1], Monica Martinez-Acuna[3], Jaqueline Calderon, MSP Karla I. Lara-Rojas[1]

[1]UNIVERSIDAD AUTONOMA DE SAN LUIS POTOSI, San Luis Potosi, Mexico, [2]Boston College, Newton, USA, [3]Universidad Autonoma de Zacatecas, Zacatecas, Mexico

Vehicle exhaust emissions, small-scale commercial business (gasoline, paints, or pigments distributers), manufacturing of brick kilns, use of wood or coal for cooking, and hazardous waste management (incinerators, crematories), are some contributors to air carcinogens. Air exposure to benzene, polycyclic aromatic hydrocarbons (PAHs), fine respirable matter, and nitrogen dioxide have been associated with an increased risk of acute lymphoblastic leukemia (ALL) in children. The aim of this study was to identify clusters of ALL cases and examine possible relationships between clustered small-scale sources of carcinogens emissions in the metropolitan area of San Luis Potosi, Mexico.

METHODS: Hospital based-cancer registry (2010-2020) of ALL cases < 19 years old were geocoded. An inventory of fixed sources of air carcinogens emissions was created from governmental data sources. Also, information on air pollutants was taken from community air monitoring stations. ALL clusters' cases were identified through the Kernel density scan test. Multivariable spatial modeling assessed the effect of fixed urban sources and air pollutants controlling for socioeconomic status on ALL risk.

RESULTS: We identified five ALL clusters with excess risk (ranging from 1.1 to 2.3). The downtown area, brick kilns neighborhood, high-density vehicle areas, and vicinity to industrial sites. Clustered sources of brick kilns, crematories, incinerators, municipal landfills, and/or wood-coal commercial businesses were located close to ALL cases (less than 500 meters). Fine respirable matter (PM 2.5), nitrogen dioxide and wood use were contributing sources to the incidence of ALL cases.

CONCLUSIONS: Cumulative and aggregate environmental carcinogens from diverse sources increase the risk for ALL for the youth population. The gaps in our knowledge of the environmental ALL causes pose a major challenge for designing prevention strategies. Until now, pollution reduction has received scant attention in programs for cancer control and has been largely absent from prevention guidelines, which have focused almost exclusively on treatment.

P-0511 Prenatal exposure to Nitrogen Oxides and Waist-to-Height Ratio (WHtR) as a cardiovascular risk factor in school-aged children participants of the POSGRAD Cohort

Priscila Ceja Esparza[1]
[1]*The National Institute of Public Health of Mexico (INSP), Mexico City, Mexico*

BACKGROUND AND AIM: Prenatal exposure to NOx may increase the risk of obesity and cardiovascular risk factors in children. This study aims to evaluate the relationship between prenatal exposure to NOx and its effect on the behavior of the WHtR in school-aged children from the ages of 7 to 12 years old and to determine if the prenatal supplementation with docosahexaenoic acid (DHA) influences the outcome.

METHODS: We included 642 mother-child from the POSGRAD cohort. Land use regression models were performed to estimate exposure to NOx (NO, NO2 and NOx) using the results of passive outdoor monitoring from a representative sample of participant households. Child anthropometrics were taken yearly and WHtR was calculated. The association between prenatal exposure to NOx and WHtR was measured through a logistic random-effects model by tertiles of exposure and considering the prenatal supplementation status.

RESULTS: We found a significant difference in the risk of having a WHtR >= 0.5, on the second tertile of exposure for NOx between the supplemented (OR= 0.59, IC 95%: 0.10-3.49, p = 0.56) and placebo (OR=13.74, IC 95%: 1.94-97.24, p=0.01) groups when compared with the lowest tertile; in the third tertile the ORs were bigger for both groups, however, these were not significant.

CONCLUSIONS: Prenatal exposure to NOx can affect the WHtR outcome in children and prenatal supplementation with DHA can decrease this effect. The lack of protection of DHA at higher levels of exposure could suggest a need for higher doses of supplementation.

KEYWORDS: Prenatal, Waist-to-Height Ratio, Nitrogen Oxides, Cardiovascular Risk

P-0514 Nocturnal temperature range and in children asthma exacerbations in Lima, Peru, 2011-2016

Diego Fano-Sizgorich[1,2], Vilma Tapia[1], Gustavo F. Gonzales[1], William Checkley[3], Stella Hartinger[2]
[1]Laboratory of Endocrinology and Reproduction, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Centro Latinoamericano de Excelencia en Cambio Climático y Salud, Universidad Peruana Cayetano Heredia, Peru, [3]Johns Hopkins University, Baltimore, USA

BACKGROUND AND AIM: Asthma is the most common chronic disease in children <5-years-old, especially in LMIC's as Peru. Although the etiology of asthma is not known, environmental factors are considered one of its main triggers. Different studies have determined that temperature is associated with asthma exacerbations, but there is still low evidence about the effect of temperature variability. Thus, the aim of the study was to evaluate the association between nocturnal temperature range (NTR) and asthma in children <5 years-old in Lima, Peru, 2011-2016.

METHODS: Ecological study. Satellite mean (Tprom), minimum (Tmin) and maximum (Tmax) daily temperature and relative humidity (HR) for Lima were obtained from the NASA POWER platform; daily asthma exacerbation counts per district were obtained from Peru´s CDC; and daily district PM2.5 from WRF-Chem model. PM2.5 was grouped in quintiles, and present-day-Tprom in P5 (reference category), P95 and quartiles. NTR was calculated as present-day Tmin minus the previous day Tmax. The association was evaluated with negative binomial regression models clustered by districts, and adjusted for PM2.5, HR, and interaction terms between NTR and present-day-Tprom categories.

RESULTS: Nocturnal Temperature Range acted as a risk factor in the crude model (RR: 1.06, 95%CI 1.05-1.08, p<0.001). While in the adjusted model, there was a strong interaction effect of Tprom over NTR, in which for hotter days, NTR acted as an asthma risk factor in a semi-monotonic manner: RR 1.06 (95%CI 1.01-1.13) in present-day-Tprom Q1, 1.10 (95%CI 1.04-1.16) in Q2, 1.14 (95%CI 1.09-1.19) in Q3, 1.20 (95%CI 1.15-1.26) in Q4, and 1.09 (95%CI 1.01-1.18) in P95.

CONCLUSIONS: NTR acted as a risk factor for asthma exacerbation in children <5 year-old, with increasing risks for hotter days, since it could be related to airway inflammation thus leading to asthma.

P-0517 Combined exposures to air toxics in early-life and academic achievement in childhood

Jeanette Stingone[1]
[1]*Columbia University, Mailman School of Public Health, New York, USA*

BACKGROUND: Previous research has found associations between exposure to single air pollutants and children's cognitive health but has often lacked the ability to investigate combined impacts of pollutants. Characterizing the effects of combined exposures can provide a more realistic assessment of health effects for burdened communities, as well as identify interactions between pollutants. Identifying interpretable associations and interactions within the context of high-dimensional exposure data presents a computational challenge. Methods from domains such as data science can be incorporated into our analytic toolbox to address this challenge. Results from these data-driven approaches need to produce interpretable results that can be followed by targeted techniques. The objective of this research is to utilize tree-based methods, such as random forest, to develop an analytic pipeline to discover interpretable combinations of air toxics associated with children's academic outcomes.

METHODS: Residence at birth was used to link EPA data on estimated ambient concentrations of 40 air toxics to an administrative data linkage of public health and education registries for approximately 220,000 children born and raised in New York City. The random forest algorithm was applied to a 1/3 subset of the data to generate a collection of regression trees that identify the combinations of air toxics associated with 3rd grade standardized test scores in math and English language arts. Methods to account for confounding and validation of identified combinations were assessed and compared in a second 1/3 subset, with the remaining data held out for final analyses.

RESULTS: Our results suggest that early-life exposure to air toxics is associated with lower test scores but high correlation between pollutants and with social factors remains a challenge for interpretation.

CONCLUSIONS: Enhancements to the analytic pipeline, including incorporation of toxicological knowledge of pollutants, will be discussed.

KEYWORDS: mixtures, interactions, urban health

P-0518 Thyroid Nodules and Cancers in Fukushima: Analysis with Updated UNSCEAR Thyroid Dose Estimates

Yutaka Hamaoka[1]
[1]*Keio University, Minato-ku, Tokyo, Japan*

BACKGROUND AND AIM: After the Fukushima–Daiichi nuclear power plant (NPP) disaster, thyroid ultrasound examination (TUE) has been performed on subjects who were aged ≤18 years. In the 1st round of TUE (October 2011 to March 2014) and the 2nd round of TUE, 115 and 71 malignancies were detected, respectively. Following to previous study (Hamaoka 2021), I analyzed the same data with updated thyroid absorbed dose estimates (UNSCEAR 2022) that are about 1/8 lower than the previous estimates (UNSCEAR 2013).
DATA AND

METHODS: The relationship between radiation dose and the number of participants with thyroid nodule or malignancy was analyzed using publicly available municipality-level data without regional grouping (N=59). To analyze two-wave screening data, the multi-level random-effect Poisson regression model was applied. Interaction between dose and screening round dummy (0 for first and 1 for second screening) was also introduced to take into account latency.

RESULTS: UNSCEAR(2022) re-estimated thyroid dose to incorporate the latest information on ingestion of contaminated food, the flow of radiation plumes, and other factors. Although magnitudes were reduced, previous and re-estimated thyroid dose have a positive and significant correlation of 0.314. The number of participants with small nodules (≦5.0mm) was regressed on screening round dummy, estimated thyroid dose, and their interaction term. Although thyroid dose was insignificant (β=-0.017, z=-1.463), the interaction term was positive and significant (β= 0.033, z=4.42). Similar results were obtained for larger nodules (≧5.1mm) and malignancy.

CONCLUSIONS: These robust results are consistent with the conjecture: due to latency, the relationship between radiation exposure and impact on the thyroid will be observed in the later screening. Although this was an ecological study, health follow-up for children in Fukushima is urgent. Since the third screening, municipality-level data has been undisclosed because of privacy concerns. Data disclosure is necessary to understand the effect of the Fukushima disaster.

P-0521 Effect modification of greenspace on the associations between environmental exposures and childhood asthma: an intra-city study

Yabin Hu, Shenghui Li, Jianguo Tan, Yon Ying, Fan Jiang, Guangjun V, Chonghuai Yan, Shilu Tong
[1]*Shanghai Children's Medical Center, Shanghai, China*

BACKGROUND AND AIM: Greenspace may have a protective effect against the adverse health effects of non-optimal environmental exposures (EEs) such as temperature extremes and air pollution. However, inter-relations between these EEs and asthma haven't been quantified. This study aimed to examine if greenspace modifies the effects of EEs on childhood asthma.

METHODS: We conducted a population-based cross-sectional study among preschool and primary school children from 13 districts of Shanghai in 2019. The International Study of Asthma and Allergies in Childhood questionnaire was adopted to assess the childhood asthma. We collected the data on annually average climate conditions, air pollutants, and greenspace rate at different districts. Bayesian spatial models were used to evaluate the associations between environmental exposures and childhood asthma and the effect modification of greenspace.

RESULTS: There were 16,606 children aged 3-11 years in this study, including 8,709 (52.4%) boys. The prevalence of ever diagnosed asthma was 14.2%. An interquartile range (IQR) increase in mean temperature was associated with increased odds ratio (OR) of asthma (1.14, 95% confidence interval (CI): 1.04, 1.25). Greenspace rate was negatively associated with the OR of childhood asthma (0.244, 95% CI: 0.067, 0.887), and appeared to modify the associations between EEs and childhood asthma to various extents.

CONCLUSIONS: Non-optimal environmental exposures (e.g., temperature and NO2) could be the triggers of childhood asthma, and greenspace seemed to modify the adverse effects of EEs on childhood asthma.

P-0524 Prevalence of asthma and asthma symptoms among rural and urban pre-school children in Mpumalanga Province, South Africa

Joyce Shirinde[1], Rodney Mudau[1], Kuku Voyi[1]
[1]*University of Pretoria, Pretoria, South Africa*

BACKGROUND AND AIM: Asthma is the most common chronic illness in South African children and its prevalence is increasing in both urban and rural areas. Little is known about the prevalence of asthma amongst pre-school children living in Mpumalanga province, South Africa, which forms part of the Highveld region, a priority area in terms of air pollution. The area is known for poor air quality and elevated concentrations of criteria pollutants. The aim of the study was to investigate the prevalence of asthma and asthma symptoms among rural and urban pre-school children and the association with environmental risk factors.

METHODS: This analytical cross-sectional study that included 3145 pre-school children from Mpumalanga Province, South Africa. Parents of the children were requested to complete a modified ISAAC questionnaire. We analyzed the influence of potential risk factors on dependent variables using bivariate analysis. Significant risk factors identified in the bivariate analysis were included in a multiple logistic regression to develop a final model.

RESULTS: Self-reported prevalence of asthma was 2.3% (66/2810), with pre-school children in rural areas reporting a higher rate than pre-school children in urban areas (1.3% vs 1%), $\chi 2=10.86$, $P <0.001$). The prevalence of asthma symptoms was 15.1% (467/3084), with rural pre-school children reporting a higher prevalence of symptoms than urban pre-school children (10% vs 5%), $\chi 2 = 24.45$, $P < 0.001$). Risk factors for asthma and asthma symptoms were vigorous physical activity (odds ratio (OR) 2.31, 95% CI 1.14-4.66), home smoking exposure (OR 2.94, 95% CI 1.40-6.19) and male parent smoking (OR 1.46, 95% CI 1.01-2.12).

CONCLUSIONS: Pre-school children in rural areas reported a higher prevalence of asthma compared to pre-school children in urban areas. Risk factors for asthma included physical activity and smoking exposure in the home.

KEYWORDS: asthma, pre-school children, risk factors

P-0533 Early-life exposure to cadmium and onset of puberty in girls: a longitudinal mother-child cohort study in Bangladesh

Annachiara Malin Igra[1], Anisur Rahman[2], Anna L.V. Johansson[1], Jesmin Pervin[2], Pernilla Svefors[3], Shams El Arifeen[2], Marie Vahter[1], Lars-Åke Persson[3,4], Maria Kippler[1]
[1]Karolinska Institutet, Solna, Sweden, [2]icddr,b, Dhaka, Bangladesh, [3]Uppsala University, Uppsala, Sweden, [4]London School of Hygiene and Tropical Medicine, London, UK

BACKGROUND AND AIM: Cadmium is a toxic metal with endocrine disrupting properties, but there are few studies about its impact on puberty onset. We aimed to evaluate if early-life exposure to dietary cadmium is associated with the timing of female puberty.

METHODS: In a mother-child cohort in rural Bangladesh (n=935), we assessed the exposure to cadmium during pregnancy through concentrations in erythrocytes (half-life 3-4 months) and in the daughters at 5y and 10y through concentrations in urine, a marker of long-term exposure. Cadmium was measured with inductively coupled plasma mass spectrometry. Between the ages of 12 and 15 years, the girls were interviewed twice with a 6-month interval about their date of menarche, and they self-assessed their pubertal development according to Tanner stages. Associations with age at menarche were evaluated with Kaplan-Meier analysis and multivariable-adjusted Cox regression, and associations with pubertal stages with ordered logistic regression.

RESULTS: Median age at menarche was 13.0 years. We found no association between maternal exposure to cadmium during pregnancy and the daughters' age at menarche. Median urinary cadmium concentrations at 10y were 0.25 µg/L. Girls belonging to the highest quartile of urinary cadmium at 10y attained menarche 3.8 months later than girls in the lowest quartile. In multivariable-adjusted analysis, the corresponding hazard ratio of reaching menarche comparing girls in the highest and the lowest quartile of urinary cadmium was 0.77 (95% CI 0.60, 0.98). Similar associations were found for urinary cadmium at 5y. Urinary cadmium at 10y was also associated with delayed breast development; the odds ratio of reaching more advanced breast development stages comparing girls in the highest and the lowest quartile of urinary cadmium was 0.63 (0.40; 0.99).

CONCLUSIONS: Elevated childhood exposure to cadmium was associated with a pubertal delay in girls.

KEYWORDS: Cadmium, early-life, female puberty, menarche, longitudinal

P-0534 Nearby wildfire impacts, social vulnerability, and birthweight in a rural population

Cindy S. Leary[1], Jonathan M. Graham[1], Patrick Freeborn[2], Erin O. Semmens[1]
[1]Center for Population Health Research, University of Montana, Missoula, USA, [2]Rocky Mountain Research Station, Missoula Fire Sciences Laboratory, Missoula, USA

BACKGROUND AND AIM
Wildfires are increasing across the world and are associated with adverse impacts on vulnerable populations including pregnant people and young children. Wildfires may exert their harmful effects by elevating air pollutant exposure and may also fuel stress by disrupting daily activities and, if extreme, threatening or forcing evacuation. We aimed to estimate exposure disparities by social vulnerability and quantify the impact of nearby wildfires during pregnancy on birthweight.

METHODS: Our study population included 139,671 maternal-infant dyads from birth certificate records between 2008 and 2019 in Montana, USA. We classified pregnant people as "exposed" if they had an active, large (≥ 1000 acres) fire within 5 kilometers of their home detected by Moderate Resolution Imaging Spectroradiometer (MODIS) sensors. We characterized the population by neighborhood social vulnerability index (SVI), rurality, and race and estimated associations between nearby fires and birthweight in linear regression analyses adjusted for gestational and maternal age, education, race, parity, prenatal visits, and SVI.

RESULTS: Exposure to at least one large wildfire within 5 km of home occurred for 0.5% (n=712) of births in Montana between 2008 and 2019. Mean neighborhood SVI as well as rates of both rural residence and American Indian/Alaska Native maternal race were all significantly greater in "exposed" pregnancies. . Having at least one large nearby fire during pregnancy was associated non-significantly with a 21 gram (95% CI: -52.2, 10.2) lower birthweight in adjusted analyses.

CONCLUSIONS: Social vulnerability appears greater in those experiencing nearby wildfires during pregnancy. Although wildfire exposure within 5 km of home does not appear to influence birthweight, future work should evaluate whether the effects of nearby fires are felt more strongly in socially vulnerable populations.

KEYWORDS: wildfire, birthweight, social vulnerability, rurality

P-0536 Allergic rhinitis, rhinoconjunctivitis and hayfever symptoms among pre-school children are associated with school transport mode: an analytical cross sectional study

Joyce Shirinde[1], Rodney Mudau[1], Kuku Voyi[1]
[1]*University of Pretoria, Pretoria, South Africa*

BACKGROUND: Allergic rhinitis (AR) is a common condition affecting many people in the globally. In addition, the condition is mostly prevalent amongst children. The aim of the study was to investigate the association between the school transport mode and allergic rhinitis symptoms, rhinoconjunctivitis and hayfever among pre-school children living an in Mpumalanga Province, which in an area known for high levels of air pollution in South Africa.

METHODS: An analytical cross-sectional study consisting of 3145 participants was conducted in Mpumalanga South Africa. A modified ISAAC questionnaire was used to collect data. Bivariate analysis was performed between potential risk factors and dependent variables. Risk factors that showed association in the bivariate analysis were included in the multiple logistic regression to develop a final model.

RESULTS: The prevalence of self-reported rhinitis ever, current rhinitis rhinoconjunctivitis and hayfever was 21, 7, 8 and 4 % respectively. Rhinitis ever, current rhinitis, current rhinoconjunctivitis and hayfever were significantly associated with the frequent use of motorcar to school, (OR 1.45 95 % CI: 1.15 − 1.83), (OR 1.62 95 % CI: 1.27–2.08), (OR 1.64 95 % CI: 1.17–2.29) and (OR 3.36 95 % CI: 2.16–5.21) respectively. No associations were observed between trucks/buses/taxis traffic in resident area and allergic rhinitis symptoms in the multiple analyses.

CONCLUSIONS: The study shows a high prevalence of allergic rhinitis symptoms amongst Pre-schoolers. The results have shown that frequent use of motorcar pays a role in the prevalence of allergic rhinitis symptoms in preschool children.

Chan School of Public Health, Boston, USA, [9]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [10]Department of Psychiatry and Behavioral Sciences, Boston Children's Hospital, Boston, USA, [11]Department of Psychiatry, Harvard Medical School, Boston, USA

BACKGROUND AND AIM: Emerging studies investigated the adverse health effects of fine particulate matter (PM2.5) using data from multiple cohorts. However, associations often are not generalizable across cohorts. Our objective was to assess associations between prenatal PM2.5 and childhood cognition in two U.S. cohorts while accounting for between-site heterogeneity.

METHODS: We included 349 mother-child dyads enrolled from the dual-site (New York City and Boston) PRogramming of Intergenerational Stress Mechanisms (PRISM) study and the First Thousand Days of Life (FTDL) study participating in the Environmental influences on Child Health Outcomes (ECHO) consortium. Daily PM2.5 was estimated using satellite-based models linked to each woman's residential address during pregnancy. Children's cognition was assessed using the NIH Toolbox Cognition Battery between ages 3 and 8 years. We used a log-linear model applied to contingency tables formed by cross-classifying covariates by site to examine between-site heterogeneity. Multivariable linear regression was used to estimate the coefficients and 95% confidence intervals for the trimester-specific PM2.5 exposure and age-corrected standardized cognition scores (mean=100, SD=15), stratified by study site, child sex, and urbanicity.

RESULTS: The log-linear model indicated that inter-study associations were similar between PRISM-NYC and FTDL, which were different from those in PRISM-Boston. Accordingly, we combined the PRISM-NYC and FTDL cohorts. Findings showed that 1 μg/m³ increase of 3rd trimester PM2.5 was associated with -4.75 (95% CI= -11.86, -0.50) mean early childhood cognition scores in females in PRISM-Boston. We additionally observed a significant association between PM2.5 and picture vocabulary scores [-3.82, (-13.75, -0.01)] in males in NYC+FTDL non-urban areas.

CONCLUSIONS: We found associations between prenatal PM2.5 and impaired childhood cognition in this pooled analysis. Given that multi-site analyses are increasingly conducted, our findings suggest expanding the awareness of between-site heterogeneity, including site-specific confounders and effect modifiers.

P-0542 Air Pollution Mixture and Birth Outcomes: Modification of Placenta Leukocyte Telomere Length and Infant Sex

Xueying Zhang[1], Elena Colicino[1], Whitney Cowell[1], Allan Just[1,2], Itai Kloog[1,2,3], Brent Coull[4,5], Robert Wright[1,2], Rosalind Wright[1,2,6]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Institute of Exposomic Research, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Department of Geography and Environmental Development, Ben-Gurion University of the Negev, Beersheba, Israel, [4]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, USA, [5]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [6]Department of Pediatrics, Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: Multiple air pollutants such as fine particles matter (PM2.5), nitrogen dioxide (NO2), and ozone (O3) were associated with adverse birth outcomes, and their associations were potentially modified by the cellular aging of placenta and infant sex. But the joint association of those factors was less examined.
METHOD: This analysis included 310 mother-infant dyads (142 girls and 168 boys) enrolled in the PRogramming of Intergenerational Stress Mechanisms (PRISM) study. We applied Bayesian Kernel Machine Regression (BKMR) to examine the independent and mixed effects of prenatal PM2.5, NO2, O3, and placenta relative leukocyte telomere length (rLTL) on two birth outcomes (i.e., birth weight for gestational age z-score and preterm birth defined as less than 37 gestational weeks). The mixed effect was examined using an exposure index calculated as the summed multiplicities of the quintiles of pollutant and pollutant-specific weights estimated using Bayesian Weighted Quantile Sum (BWQS). The associations between exposure, outcome, and rLTL were examined for boys and girls separately.

RESULTS: NO2 drove the exposure effect on birth weight z-score in girls and on preterm birth in boys. Sex differences were observed. The estimated exposure index was negatively and positively associated with birth weight z-score and preterm birth in girls. These associations were inversed for boys. The observed modification effects of rLTL were varied by pollutant, outcome, and infant sex. for example, the results of the exposure index suggested stronger modification effects in boys, in which mothers with lower rLTL and higher exposure index jointly contribute to the higher birth weight z-scores and preterm birth.

CONCLUSIONS: Co-exposure to elevated air pollution and lower LTL during prenatal may contribute to adverse birth outcomes, especially among boys.

P-0548 Prenatal Ambient Air Pollutant Mixture Exposure and Neurodevelopment in Urban Children in the Northeastern USA

Yueh-Hsiu Mathilda Chiu[1], Brent A. Coull[2], Hsiao-Hsien Leon Hsu[1], Ander Wilson[3], Joel Schwartz[2], Robert O. Wright[1], Rosalind J. Wright[1]

[1]Icahn School of Medicine at Mount Sinai, New York, USA, [2]Harvard University, TH Chan School of Public Health, Boston, USA, [3]Colorado State University, Fort Collins, USA

BACKGROUND AND AIM: Prior studies of prenatal air pollution (AP) exposure on child neurodevelopment largely focus on a single pollutant. We leveraged daily exposure data and implemented novel data-driven statistical approaches to assess effects of prenatal exposure to a mixture of seven air pollutants on cognitive outcomes in children from an urban pregnancy cohort in the Northeastern USA.

METHODS: Analyses included 236 children born at ≥37 weeks gestation. Maternal prenatal daily exposure levels for nitrogen dioxide (NO_2), ozone (O_3), and constituents of fine particles [elemental carbon (EC), organic carbon (OC), nitrate (NO_3-), sulfate (SO_4^{2-}), ammonium (NH_4+)] were estimated based on residential addresses using validated satellite-based hybrid models or global 3-D chemical-transport models. Children completed the Wechsler Intelligence Scale for Children (WISC-IV), Wide Range Assessment of Memory & Learning (WRAML-2), and Conner's Continuous Performance Test (CPT-II) at 6.5±0.9 years of age. Time-weighted pollutant exposure levels were estimated using Bayesian Kernel Machine Regression Distributed Lag Models. Resulting weighted exposures were used in Weighted Quantile Sum regressions to examine AP mixture effects on cognitive outcomes, adjusted for sex, maternal age, education, and temperature. Sex-stratified models were explored.

RESULTS: Mothers were primarily ethnic minorities (81% Hispanic and/or black) reporting ≤12 years education (68%). Prenatal exposure to AP mixture (per decile increase) was associated with decreased WISC-IV IQ (β=-0.94, 95%CI=-1.69 to -0.19), decreased memory-related attention/concentration (β=-1.03, 95%CI=-1.78 to -0.27) and general memory (β=-0.64, 95%CI=-1.40 to 0.00) indices from WRAML-2, and increased CPT-II omission errors (β=1.55, 95%CI=0.34–2.77). When stratified by sex, associations with IQ and omission errors were significant in boys only, while associations with memory-related indices were significant in girls only. Sulfate, NO_2, and EC were major contributors.

CONCLUSIONS: Prenatal exposure to an AP mixture was associated with child cognitive outcomes in a sex- and domain-specific manner.

KEYWORDS: air pollution, mixture, prenatal, neurodevelopment

P-0549 Associations between Exposure to Prenatal Air Pollution Mixtures and Behavioral Problems in Urban Children

Hsiao-Hsien Hsu[1], Brent Coull[2], Ander Wilson[3], Yueh-Hsiu Mathilda Chiu[1], Joel Schwartz[2], Robert Wright[1], Rosalind Wright[1]

[1]Icahn School of Medicine at Mount Sinai, New York, USA, [2]Harvard School of Public Health, Boston, USA, [3]Colorado State University, Fort Collins, USA

BACKGROUND AND AIM: Previous studies investigating associations between prenatal air pollution and childhood behavior mainly focused on PM2.5, while little is known about the effect of air pollution mixtures and exposure timing throughout pregnancy. We used individual-level daily exposure data and implemented novel weighting approaches to assess effects of prenatal exposure to a mixture of seven air pollutants on behavioral outcomes in children from a Northeastern USA urban pregnancy cohort.

METHODS: Participants included 234 full-term
singleton children (≥37 weeks gestation). Children completed the Behavior Assessment System for Children 2nd Edition (BASC-2) at age 6.5±0.9 years. Daily exposure levels for nitrogen dioxide (NO_2), ozone (O_3), and constituents of fine particles [elemental carbon (EC), organic carbon (OC), nitrate (NO_3-), sulfate (SO_4^{2-}), ammonium (NH_4+)] were estimated based on residential addresses using satellite-hybrid models and 3D chemical-transport models. Time-weighted exposure levels of the seven air pollutants in the mixture were estimated using Bayesian Kernel Machine Regression Distributed Lag Models. We subsequently used in multivariable linear regressions including time-weighted exposures for all pollutants in the mixture., adjusted for sex, maternal age, education, and temperature. Effect modification by sex was also examined.

RESULTS: Participants were primarily Hispanic (59%) and Black (25%), with ≤12 years of education (68%). Time-weighted O_3 level (per one standard deviation increase) was associated with 4.77% increase in External Problems (95%CI= 0.7%–9%), 4.41% increase in Aggression (95%CI=0.9%–8.1%), 4.36% increase in Internal Problems (95%CI=0.5%–8.3%), and 4.18% increase in Anxiety (95%CI=0.1%–8.4%). When stratified by sex, these associations were only significant in boys. Time-weighted OC level was significantly associated with Internal Problems in girls only (4.6% increase, 95%CI=1.7%–7.7%).

CONCLUSIONS: In a prenatal air pollution mixture, ozone is associated with child behavioral problems, and the association is specific to sex and measured outcome scale.

KEYWORDS: mixture, air pollution, prenatal, children behavior

P-0550 Proximity to coal flyash disposal site and infant neurodevelopment in Sri Lanka

Meghan Tipre[1], Amandhi Caldera[2], Ruwanthi Perera[2], Pavithra Godamune[2], Nalini Sathiakumar[1], Rajitha Wickremesinghe[2]

[1]University of Alabama at Birmingham, Birmingham, USA, [2]Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka

BACKGROUND: Fly ash from coal-fired power plants (CPP) often consist of trace heavy metals such as arsenic and lead which have been linked with deleterious health effects in exposed communities.
Objective. A cross-sectional study examined relationship between proximity to CPP, an indirect measure for environmental exposure to flyash, and neurodevelopment in infants 1- 3 years of age, measured using 'Bayley Scales of Infant and Toddler Development, third edition (BSID-III)'

METHODS: Set in Puttalam District in Sri Lanka, the study enrolled 208 children: 108 from the buffer zones around the CPP with radii of '<5kms' and 100 from '≥10kms', respectively. In a multivariable general linear regression, we analyzed the relationship between proximity to CPP and BSID-III cognitive, motor and language scores, adjusting for maternal age, ethnicity, wealth index, and child's age, sex and birthweight.

RESULTS: On average, children were 23.4 months (±6.4) old and 60.2% were female. Compared to children residing away from the CPP (≥10 kms), children residing in close proximity (<5 kms) had lower composite scores for BSID-III language (adj. means: 93.7 vs. 88.8, p= 0.0057), motor (88.0 vs. 86.0, p=0.2126) and cognitive (84.4 vs. 83.1, p= 0.4395) but only language was significant, after adjusting for covariates.
DISCUSSION. Our findings suggest lower developmental scores among children residing closer to CPP compared to those further away. Results of the study have scientific and policy implications for low- and middle-income countries as well as developed countries like US, where low-income, minority, rural and inner-city urban communities continue to disproportionately be exposed to higher levels of trace heavy metals released from industrial effluents, mining, fertilizers, and pharmaceuticals.

P-0551 The mortality burden of nervous system diseases attributed to ambient temperature: a multi-city study in China

Yonghong Li[1], Yibin Cheng, Xiaoyuan Yao
[1]*National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUNDS: Studies on the association between ambient temperature and human mortality have been widely reported, focusing on common diseases such as cardiopulmonary diseases. However, multi-city studies on the association between both high and low temperatures and mortality of nervous disorders were scarce, especially on the evidence of vulnerable populations.

METHODS: Weekly meteorological data, air pollution data and mortality data of nervous system were collected in 5 cities in China. A quasi-Poisson regression with distributed lag non-linear model was applied to quantify the association between extreme temperatures and mortality of nervous system diseases. Multivariate meta-analysis was applied to estimate the pooled effects at overall level. The attributable fractions (AFs) were calculated to assess the mortality burden attributable to both high and low temperatures. Stratified analyses were also performed by gender and age-groups through the above steps.

RESULTS: A total of 12,132 deaths of nervous system diseases were collected. The overall minimum mortality temperature was 23.9 ℃ (61.9th), the cumulative relative risks of extreme heat and cold for nervous system diseases were 1.33(95%CI: 1.10, 1.61) and 1.47(95%CI: 1.27, 1.71). The mortality burden attributed to non-optimal temperatures accounted for 29.54% (95%eCI: 13.45 %, 40.52%), of which the mortality burden caused by low temperature and high temperature accounted for 25.89% (95%eCI: 13.03%, 34.36%) and 3.65% (95%eCI: 0.42%, 6.17%), respectively. The mortality burden attributable to ambient temperature was higher in both males and the elderly (> 74 years old), with the AF of 31.85% (95%eCI: 20.68%, 39.88%) and 31.14% (95%eCI: -6.83%, 49.51%), respectively.

CONCLUSIONS: The non-optimal temperature can increase the mortality of nervous system diseases and the males and the elderly over 74 years have the highest attributable burden. The findings add the evidence of vulnerable populations of nervous system diseases against ambient temperatures.

P-0557 Association of heat wave exposure with increased risk of hospitalization for dehydration or heat-related illness in young children in South Korea: A Time-series study

Jongmin Oh[1], Eunji Kim[1,2], Ji Hyen Lee[1], Youngrin Kwag[1], Hyungmi An[4], Eunhwa Kang[5], Hae Soon Kim[3], Yongho Jee[6], Eunhee Ha[1,2]

[1]Department of Environmental Medicine, School of Medicine, Ewha Womans University, Seoul, Republic of Korea, [2]Graduate Program in System Health Science and Engineering, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [3]Department of Pediatrics, Ewha Womans University College of Medicine, Seoul, Republic of Korea, [4] Institute of Convergence Medicine Ewha Womans University Mokdong Hospital, Seoul, Republic of Korea, [5]Ewha Womans University Seoul Hospital, Seoul, Republic of Korea, [6]Advanced Biomedical Research Institute Ewha Womans University Seoul Hospital, Seoul, Republic of Korea

BACKGROUNDS
Numerous studies have investigated the association between summer temperatures and increased heat related hospitalizations in the general population. However, little is known about the heat-related morbidity of heat waves in children. We aimed to evaluate the association between hospitalization for dehydration or heat-related illness in children and heat wave exposure in South Korea.

METHODS: We used the National Health Insurance Service (NHIS) database, which provides medical records from 2015 to 2019 in South Korea. We defined daily hospitalizations for dehydration or heat-related illness of children younger than five years of age during the summer period (June to August). A heat wave was defined using a total of six criteria from a maximum temperature 28°C or higher to 33°C or higher per day. A time-series analysis was used to investigate the association between the maximum temperature and a heat wave and hospitalization for dehydration or heat-related illness of children younger than five years of age. We used a two stage design involving a meta-analysis after modeling by each city.

RESULTS: We included 16,879 daily hospitalizations for dehydration or heat-related illness among children younger than five years of age during 2015 to 2019. The relative risk (RR) of hospitalization for dehydration or heat related illness was 1.023 [95% confidence interval (CI): 1.013, 1.034] per 1°C increase in the 3-day moving average maximum temperature during summer. The RR due to heat wave exposure (6 definitions: 28°C to 33°C) was ranged from 1.10 (95% CI: 1.06, 1.15) to 1.05 (95% CI: 0.98, 1.12). In the subgroup, we did not observe statistically significant gender differences.

CONCLUSIONS: Exposure to a heat wave during summer is associated with an increased risk of hospitalization for dehydration or heat-related illness among children younger than five years of age.

P-0559 Seasonal Temperature Variability and Mortality across the USA

James Patrick Healy[1], Mahdieh Danesh Yazdi[1], Yaguang Wei[1], Francesca Dominici[1], Liuhua Shi[2], Joel Schwartz[1]
[1]Harvard T. H. Chan School of Public Health, Boston, USA, [2]Emory Rollins School of Public Health, Atlanta, USA

BACKGROUND: Seasonal temperature variability remains understudied and is set to be modified by climate change. Most temperature studies consist of short-term exposures using time series data. These studies are limited by an inability to observe longer-term trends in temperature and mortality along with regional adaptation and short-term mortality displacement. Cohort studies can address these limitations, but no countrywide cohort study has been conducted to study these long-term temperature trends, especially in a cohort with differing climatic zones.
AIM:
We aimed to examine the association between seasonal temperature variability and mortality across the contiguous US with its five defined regional climate zones. Further, we aimed to investigate effect modification by race, poverty, population density, and green space.

METHODS: We carried out this analysis in the US Medicare cohort (age 65+) from 2000-2016 with 622,427,230 years of person time. Our exposure was seasonal temperature variability or the standard deviation of warm (April to September) and cold (October to March) season temperature.
We used adapted difference-in-difference, quasi-experimental methods to reduce unobserved confounding at the ZIP-code level. We employed a clustering approach based on climate zone and socioeconomic factors, combined with a meta-analysis.

RESULTS: We showed that for every 1 °C increase in warm and cold season temperature variability, the mortality rate increased by 1.54% and 0.69% in over 65s, respectively. Over 270 million Americans are exposed to at least one form of seasonal temperature variability. These effects were most pronounced in low-income individuals, low green space residents, and those in lower population density areas such as rural locations. Further, these effects were not modified by one's climate zone of residency.
CONCLUSION: Seasonal temperature variability was associated with an increased risk of mortality in over 65s across the US.

P-0564 Is short-term exposure to heat associated with mental health compared to other conditions?

Anne Weaver[1], Christine L. Gray[2], Erik Slawsky[3], Joshua Moyer[1], Cavin Ward-Caviness[1]
[1]US Environmental Protection Agency, Chapel Hill, USA, [2]Duke University Global Health Institute, Durham, USA, [3]Oak Ridge Associated Universities at US Environmental Protection Agency, Chapel Hill, USA

BACKGROUND AND AIM: Health impacts of heat exposure are increasingly important due to climate change. Anxiety and depression are common and understudied mental health conditions, possibly associated with heat exposure. We examined associations between short-term (5-day) apparent temperature and health visits for anxiety and/or depression in North Carolina.

METHODS: We linked electronic health records from a random sample of adults seen at University of North Carolina Healthcare System hospitals 2004-2018 in the EPA CARES resource with climate data from PRISM Climate Group. We examined 5-day mean apparent temperature (incorporating temperature and humidity) at the ZIP code level for patients diagnosed with anxiety and/or depression compared to first recorded visit for those with any other diagnosis. We used log binomial regression models adjusted for personal (age, sex, race, health insurance status), environmental (season, annual PM2.5 concentration, climate division) and neighborhood (median household income, percent Bachelor's degree or more, percent urban) covariates.

RESULTS: We included 17,145 patients, 2219 of whom were diagnosed with anxiety and/or depression. Those with anxiety and/or depression were, on average, younger (46.4 vs 48.0 years), more likely to be female (69.7% vs 59.7%), and White (74.7% vs 62.4%), compared to those with other diagnoses. Mean five-day apparent temperature was 17.6 degrees C (SD 10.4). The prevalence of having a diagnosis of anxiety and/or depression was 1% higher per degree increase in five-day mean apparent temperature (PR 1.01, 95% CI 1.00, 1.02) compared to other diagnoses. Results were similar when limiting to anxiety, depression, and geographic region.

CONCLUSIONS: We did not observe substantial associations between apparent temperature and anxiety or depression relative to other outcomes. Future studies should expand this work to larger areas with more temperature variability and consider mental health trends independent of other outcomes. This abstract does not reflect EPA policy.

KEYWORDS: climate, heat, mental health

P-0569 Temporal Variation in the Association between Temperature and Cardiovascular and Respiratory Mortality in 15 German cities

Masna Rai[1], Susanne Breitner, Siqi Zhang, Francesca de'Donato, Annette Peters, Alexandra Schneider
[1]*Helmholtz Center Munich, Neuherberg, Munich, Germany*

BACKGROUND AND AIM: There is limited evidence of temporal changes in the association between air temperature and the risk of cause-specific cardiovascular [CVD] and respiratory [RD] mortality. We explored temporal variations in the association between short-term exposures to air temperature and cause-specific CVD and RD mortality in the 15 largest German cities from 1993 to 2016.
METHOD: We applied time-stratified time-series analysis using city-specific confounder-adjusted Poisson models and estimated the temperature–mortality associations with distributed lag non-linear models with 14 lag days and then pooled by a multivariate meta-analytical model. We performed age- and sex-stratified analysis. A meta-regression with socioeconomic and demographic effect modifiers is currently being performed. Cold and heat effects are reported as relative risks [RR] at the 1st and the 99th temperature percentile, relative to the 25th and the 75th percentile, respectively.
RESULT: We analyzed a total of 1,003,305 CVD and 173,154 RD deaths. Cold-related RR for CVD mortality was seen to rise consistently over time from 0.98 (95% confidence interval [95% CI] 0.96, 1.01) in the period 1993-2004 to 1.10 (95% CI 1.08, 1.10) in the period 2005-2016. A similar increase in cold-related RR was also observed for RD mortality. The heat-related RR for RD mortality increased from 1.44 (95% CI 1.22, 1.70) to 1.83 (95% CI 1.66, 2.00). Males were particularly susceptible to cold for all causes of death and heat for total and RD mortality. The age group >64 years was susceptible to cold mainly for CVD mortality, whereas the younger age group (0-64 years) showed stronger effects of heat for RD mortality.

CONCLUSIONS: We found evidence of rising population susceptibility to both heat- and cold-related CVD and RD mortality. These findings may be useful to design targeted heat- and cold- adaptation plans in Germany.

KEYWORDS: Cardiovascular mortality, respiratory mortality, temperature, temporal variation

P-0570 Projecting future risk of dengue related to hydrometeorological conditions in mainland China under climate change scenarios

Chuanxi Li[1], Zhao Liu[3], Wen Li[1,2], Jianbin Huang[4], Yidan Chen[5], Xuejie Gao[6], Ying Xu[7], Can Wang[5], Qi Zhao[1,2,8], Qiyong Liu[2,9,10], Wei Ma[1,2], Wenjia Cai[4], Peng Gong[11], Yong Luo[4]

BACKGROUND AND AIM: Limited knowledge is known about the impact of hydrometeorological conditions on dengue incidence in China, and the associated disease burden in the climate-changing future. This study projects the attributable excess risk of dengue in 365 cities across mainland China under climate change scenarios.

METHODS: The association between Palmer drought severity index (PDSI) and dengue in the historical period (2013-2019) was estimated with a spatiotemporal Bayesian model. We developed a dengue transmission biological model to project the potential risk area of dengue by 2100 under three representative concentration pathways (RCP 2.6, 4.5, and 8.5). The association combined with biological model was then used to project the annual excess risks of dengue related to PDSI by 2100. We further calculated attributable excess risk for dry and wet conditions.

RESULTS: A total of 93,101 dengue cases were reported between 2013-2019 in mainland China. Dry and wet conditions within three months lag were associated with increased risk of dengue. Locations with potential dengue risk in China will expand in the future. The hydrometeorological changes are projected to substantially affect the risk of dengue in regions with mid-low latitude, especially the coastal areas under high emission scenarios. By 2100, the annual average increased excess risk is expected to range from 7.49% (95% empirical CI: 4.55-16.64) in northwest to 71.89% (55.66-123.62) in south under RCP 8.5. Moderate dry is predicted to have the greatest impact on dengue risk across all regions.

CONCLUSIONS: Hydrometeorological conditions are predicted to increase the dengue risk in the future in the south, east, and central areas of mainland China in disproportional patterns. Our findings have implications for the preparation of public health interventions to minimize the health hazards of non-optimal hydrometeorological conditions under climate change context.

P-0571 The association between ambient temperature and cause-specific cardiovascular disease admissions in Japan: a nationwide study

Pan Rui[1], Okada Akira[2], Yamana Hayato[3], Yasunaga Hideo[4], Kumazawa Ryosuke[4], Matsui Hiroki[4], Fushimi Kiyohide[5], Kim Yoonhee[1]

[1]Department of Global Environmental Health, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, Tokyo, Japan, [2]Department of Prevention of Diabetes and Lifestyle-Related Diseases, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, Tokyo, Japan, [3]Department of Health Services Research, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, Tokyo, Japan, [4]Department of Clinical Epidemiology and Health Economics, The University of Tokyo, Tokyo, Japan, Tokyo, Japan, [5]Department of Health Policy and Informatics, Tokyo Medical and Dental University, Tokyo, Tokyo, Japan

BACKGROUND AND AIM: Substantial evidence suggests that non-optimal temperatures increase the risk of cardiovascular disease (CVD) mortality and morbidity. However, limited studies have reported inconsistent results for hospital admissions depending on study locations that also lack investigations on cause-specific CVDs at a national level. We aim to examine the short-term associations between temperature and acute CVD hospital admissions by specific categories [ischemic heart disease (IHD), heart failure (HF) and stroke] in 47 prefectures of Japan from 2011 to 2018.

METHODS: We performed a two-stage meta-regression analysis. First, we estimated prefecture-specific associations between temperature and CVD admissions using the time-stratified case-crossover design with a distributed lag nonlinear model over the lag of 21 days. Then we used a multivariate meta-regression model to obtain national average associations.

RESULTS: During the study period, a total of 2,416,707 CVD admissions were reported. We found significant cold risks on all CVD admissions and cause-specific categories. Compared with minimum hospitalization temperature (MHT) at 95th percentile of temperature, the cumulative relative risks (RRs) of cold (5th) and heat (99th) on all CVD were 1.222 [95% confidence interval (CI): 1.190, 1.255] and 1.003 (95% CI: 0.996, 1.011), respectively. The cold risk for HF [RR=1.566 (95% CI: 1.477, 1.660)] was higher than IHD [RR=1.136 (95% CI: 1.048, 1.231)] and stroke [RR=1.107 (95% CI: 1.057, 1.160)]. The MHTs varied by the specific causes. We also observed significant heat risk of temperature on HF with RR of 1.069 (95% CI: 1.030, 1.110). The subgroup analysis showed the ≥ 85-year age group was more vulnerable to the risk of temperature.

CONCLUSIONS: This study indicated that exposure to cold and heat could increase the risk of CVD hospital admissions, varying depending on the cause-specific, which may provide new evidence to reduce the burden of CVD.

KEYWORDS: Temperature; Morbidity.

P-0574 Childhood cognitive and behavioral effects of high summer temperatures

Scott Delaney[1], Keith Spangler[2], Michael Leung[1], Rachel Nethery[1], Henning Tiemeier[1], Marc Weisskopf[1]
[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: As climate change accelerates, the frequency of high summer temperatures will increase, affecting nearly every domain of health, including behavioral health. Research suggests high temperatures increase aggressive behaviors and decrease cognitive performance in adults, but these effects in children remain poorly understood. Our work addresses this knowledge gap.

METHODS: We derived daily maximum heat indexes using meteorologic data from the PRISM Climate Group and linked them to cognitive and behavioral data from 4,387 children aged 9-10 who completed assessments from June-August in the Adolescent Brain Cognitive Development Study baseline wave, 2016-2018.
At 21 sites in the USA representing 5 climate types identified by the U.S. Department of Energy (Cold, Marine, Mixed-Humid, Hot-Dry, Hot-Humid), children completed NIH Toolbox neurocognitive assessments (age-normed total cognition score; mean=100.5; sd=17.9), and their caregivers completed the Achenbach Child Behavior Checklist (aggressive behavior subscale t-score; mean=52.2; sd=4.0).
We modeled site-specific 6-day lagged relationships using distributed lag nonlinear models adjusted for known confounders, then used meta-regression to estimate climate-specific associations.

RESULTS: for participants living in the Cold climate (n = 1886), the overall cumulative association for heat indexes in the 99th percentile (vs. the 90th percentile) of the site-specific summertime heat index distribution was a -11.5 (95% CI: -21.7, -1.2) unit lower cognition score and a 2.6 (95% CI: -1.0, 6.2) unit higher aggressive behavior score. Both point estimates are more than half a standard deviation from Cold climate means.
In other climate types, which included fewer participants (n = 288 to 1017), we found no consistent evidence of any association.
CONCLUSION: Hot summer temperatures were associated with decreased cognitive performance and increased aggressive behavior in children living in a Cold climate. These results suggest a novel mechanism by which climate change may impact childhood neurodevelopment.

P-0579 Impact of Wildfire Exposure on Preterm Births Identified in MarketScan Claims-Based Cohort, 2010-2015

Brooke Staley[1], Corinna Keeler[1], Cavin Ward-Caviness[2], Meghan E. Rebuli[3,4], Kristen Rappazzo[3,4], Ilona Jaspers[3,4], Linda Wei[2], Ana Rappold[2], Radhika Dhingra[5]

[1]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, USA, [2]USA Environmental Protection Agency, Center for Public Health and Environmental Assessment, Research Triangle Park, USA, [3]Department of Pediatrics, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, USA, [4]Center for Environmental Medicine, Asthma and Lung Biology, University of North Carolina at Chapel Hill, Chapel Hill, USA, [5]Department of Environmental Sciences and Engineering, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, USA

BACKGROUND AND AIM: Wildfire smoke is a growing contributor to ambient particulate matter and may lead to elevated risk of preterm birth. Studies that have investigated the effects of gestational wildfire smoke exposure (WSE) on preterm birth are inconsistent and inconclusive. This study aimed to estimate the effect of near-birth and trimester-based WSE on preterm births using a large-scale claims database.

METHODS: We linked IBM's MarketScan Commercial Claims and Encounters database with smoke plume data from NASA MODIS satellites using metropolitan statistical area (MSA) of residence at birth. Children born in an MSA in six Western states between 2010-2015, whose gestational age (GA) and birthdate were estimable from claims data were included (N=115,469); 759 births with <32 weeks gestation were excluded. MSA, GA, and birthdate were used to estimate average weekly days of WSE for each trimester and two near-birth periods (2 and 4 weeks pre-birth). Preterm birth was defined as live birth at GA between 32 and 37 weeks. Odds ratios were estimated using logistic regression models accounting for clustering by MSA and adjusted for maternal age (restricted cubic spline), birth season, and average temperature within each exposure period.

RESULTS: WSE in the first or second trimesters was associated with reduced likelihood of preterm birth (0.96 [95% CI: 0.91, 1.02] and 0.92 [95% CI: 0.87, 0.98], respectively), while WSE in the third trimester was associated with increased risk of preterm birth (1.05 [95% CI: 0.98, 1.12]). There was no evidence of association for the 2- and 4-week periods before birth. Sex-stratified analyses of near-birth and trimester exposures were not different from overall effect estimates.

CONCLUSIONS: We observed evidence of an association between WSE and pre-term birth that varied based on trimester of exposure, with increased risk seen for exposures during the third trimester.

P-0583 Comparison of heat-related mortality estimated using ambient temperature and wet-bulb globe temperature in Japan: Supporting evidence for heat health warning system

Hironobu Watanabe[1], Yasushi Honda[2,3,4], Kazutaka Oka[3], Masahiro Hashizume[4,5], Aurelio Tobias[4,6], Yoonhee Kim[1]
[1]Department of Global Environmental Health, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Faculty of Health and Sport Sciences, University of Tsukuba, Tsukuba, Japan, [3]Center for Climate Change Adaptation, National Institute for Environmental Studies, Tsukuba, Japan, [4]School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan, [5]Department of Global Health Policy, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [6]Institute of Environmental Assessment and Water Research (IDAEA), Spanish Council for Scientific Research (CSIC), Barcelona, Spain

BACKGROUND AND AIM: Wet-bulb globe temperature (WBGT) receives attention as a criterion in heatstroke alert system in Japan. However, epidemiological evidence related to its suitability as a heat indicator for all-cause mortality is insufficient. This study compares temperature and WBGT based on (1) their association with all-cause mortality (relative risk; RR) and (2) heat-related mortality burden (attributable fraction; AF) at high percentiles, such that a heat alert is issued. In addition, it evaluates if there are any regional tendency in the suitability of WBGT.

METHODS: A three-stage time-series analysis using data from 47 prefectures in Japan during the warm months (May-October) of 2010-2019 was conducted. First, we performed a time-series regression analysis for each prefecture to obtain prefecture-specific temperature- and WBGT-mortality associations. Second, we quantified prefecture-level RRs and AFs for the 90th percentiles of temperature and WBGT, respectively. Third, the prefecture-level RRs and AFs were pooled into region-level results, and a meta-regression analysis was conducted to compare the differences in prefecture-level RRs and AFs derived from temperature and WBGT.

RESULTS: The RRs for the 90th percentile of WBGT were 0.02% (95% confidence interval [CI]: -0.29%, 0.32%) higher than those for the 90th percentile of temperature. In addition, the AFs above the 90th percentile of WBGT were 0.16% (95% CI: -0.32%, 0.63%) lower than those above the 90th percentile of temperature. In Western Japan, temperature-related risk measures were higher than WBGT-related risk measures.

CONCLUSIONS: We found no evidence that which heat indicator shows higher risk measures for all-cause mortality. As a policy implication, it is advisable to consider practical aspects other than the magnitude of temperature- and WBGT-mortality association for the development of the heat health warning system that targets all-cause mortality.

KEYWORDS: Wet-bulb globe temperature, Heat Health Warning System

P-0585 Meteorological Factors Associated with Visceral Leishmaniasis in São Paulo State, Brazil

Quinn Adams[1], Ian Sue Wing[2], Guilherme Werneck[3], Clarissa Valim[4], Gregory A. Wellenius[1]
[1]Boston University School of Public Health, Department of Environmental Health, Boston, USA, [2]Boston University, Earth and Environment, Boston, USA, [3]Instituto de Estudos em Saúde Coletiva, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [4]Boston University School of Public Health, Department of Global Health, Boston, USA

BACKGROUND AND AIM: Human visceral leishmaniasis (VL) is a vector-borne disease of significant public health concern in Brazil. Areas of high prevalence have shifted in recent decades due to rapid development, changing socioeconomic conditions, and climate change. Emerging evidence suggests that incidence is affected by regional weather patterns such as the El Niño-Southern Oscillation, which has profound impacts on local meteorological conditions in Brazil. However, understanding of the effects of short-term weather variability remains inadequate, particularly in the context of VL. Accordingly, we explored the relationship between local weather conditions and VL in São Paulo State, Brazil.

METHODS: We obtained monthly cases of VL in São Paulo State from the Ministry of Health Information System for Notifiable Diseases for each municipality from 2010-2020. We extracted monthly average temperature, precipitation, and specific humidity from ERA5. We used conditional quasi-Poisson regression models to assess the relationship between meteorological variables and VL, conditioning on municipality and adjusting for temporal trends. We assessed lagged effects of meteorological variables from 0 to 6 months, corresponding with the long incubation period for VL in humans.

RESULTS: There were 1,958 documented cases of VL from 2010-2020. We observed higher rates of VL associated with increased precipitation and humidity and decreased temperatures. Specifically, a 1˚C decrease in average monthly temperature was associated with a 4.6% (95% CI: 2.5%, 6.7%) increase in VL cases two months later. A 1 mm increase in precipitation and 1 g/kg increase in humidity led to a respective 2.5% (1.2%, 3.8%) and 3.3% (1.3%, 5.2%) increase in VL cases one month later.

CONCLUSIONS: Local weather patterns are associated with the incidence of human VL in São Paulo State. These results highlight the potential importance of continued climate change on the fluctuating distribution of VL.

P-0586 Climate change and migrant workers: Projections of temperatures and mortality in Kuwait

Barrak Alahmad[1], Ana Maria Vicedo-Cabrera[2], Kai Chen[3], Eric Garshick[4], Aaron Bernstein[5], Joel Schwartz[1], Petros Koutrakis[1]

[1]Harvard T H Chan School of Public Health, Boston, USA, [2]Oeschger Center for Climate Change Research, University of Bern, Bern, Switzerland, [3]Yale Center on Climate Change and Health, Yale School of Public Health, New Haven, USA, [4]Harvard Medical School, Boston, USA, [5]Center for Climate, Health and the Global Environment, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND–It is uncertain what climate change could bring to populations and countries in the hot desert environment of the Arabian Peninsula. Not only because they are already hot, countries in this region also have unique demographic profiles, with migrant populations potentially more vulnerable and constituting a large share of the population. In Kuwait, two-thirds of the population are migrant workers and record-high temperatures are already common.

AIM–We quantified the temperature-related mortality burdens in Kuwait in the mid- (2050-2059) and end-century (2090-2099) decades under moderate (SSP2-4.5) and extreme (SSP5-8.5) climate change scenarios.

METHODS–We fitted time series distributed lag non-linear models to estimate the baseline temperature-mortality relationship which was then applied to future daily mean temperatures from the latest available climate models to estimate decadal temperature-mortality burdens under the two scenarios.

RESULTS–By mid-century, the average temperature in Kuwait is predicted to increase by 1.80°C (SSP2-4.5) to 2.57°C (SSP5-8.5), compared to a 2000-2009 baseline. By the end of the century, we could see an increase of up to 5.54°C. In a moderate scenario, climate change would increase heat mortality by 5.1% (95% empirical confidence intervals [eCI]: 0.8, 9.3) by end-century, whereas an extreme scenario increases heat mortality by 11.7% (2.7, 19.0). Heat mortality for non-Kuwaiti migrant workers could increase by 15.1% (4.6, 22.8). for every 100 deaths in Kuwait, 13.6 (-3.6, 25.8) could be attributed to heat driven by climate change by the end of the century.

CONCLUSION–Climate change induced warming, even under more optimistic mitigation scenarios, may markedly increase heat related mortality in Kuwait. Migrant worker, who are already vulnerable, could borne a larger impact from climate change.

P-0592 Nonlinear Association between summer high Temperature and Mortality in people aged 65 or more: Past and Recent periods

Jonghyuk Choi[1], M.D. Hyungryul Lim[1], Ph.D. Sanghyuk Bae[2], Ph.D. Kyung-Hwa Choi[1], Ph.D. Xue Han[1], Ph.D. Mina Ha[1], Ph.D. Ho-Jang Kwon[1]

[1]Department of Preventive Medicine, College of Medicine, Dankook University, Cheonan, Republic of Korea, [2]Department of Preventive Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

BACKGROUND AND AIM: Climate change induces extreme weather including frequent heat waves in summer. We aimed to examine how the impact of high air temperature exposure to mortality of older people, a vulnerable group, has been changed from the past to recent periods.

METHODS: Temperature data from the Korea Meteorological Administration and mortality data from Statistics Korea were used. The time-series analysis was performed for the periods 1991–1995 and 2015–2019, in which included the recorded heat wave. We used the distributed lag non-linear models (DLNM) to estimate cumulative relative risks (CRRs) to see an association between daily temperature for July to August and mortality of people aged 65 or more. The CRR was estimated at each province and pooled the CRRs of all provinces using a random effect meta-analysis.

RESULTS: The CRRs on mortality of the daily mean temperature in summer for the population aged 65 or more for the whole 10-year period (1991-1995 and 2015-2019) were 1.098 (1.012, 1.192), 1.124 (1.027, 1.231), and 1.172 (0.986, 1.392) at 90%tile, 95%tile, and 99%tile, compared to 50%tile of the temperature. When the nonlinear associations between temperature and mortality were plotted in the past and recent periods separately, the CRR in the past increased substantially with temperature increases, while the increase of CRR in the recent appeared to be relatively small.

CONCLUSIONS: The effects of high temperatures in summer on mortality of people aged 65 or more have changed from the past to recent periods, and further studies are needed to explore factors potentially related with resilience of the society against climate change.

P-0607 Projections of temperature-attributable suicide under climate change scenarios in Japan

Ramita Thawonmas[1], Masahiro Hashizume[1], Yoonhee Kim[2]
[1]Department of Global Health Policy, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Japan, [2]Department of Global Environmental Health, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Japan

BACKGROUND AND AIM: Recent studies have projected all-cause mortality attributable to non-optimal temperature under climate change scenarios. However, the impact of climate change on mental health remains to be assessed. The short-term association between suicide and temperature has been reported, but there is a lack of future projections of temperature-attributable suicide. We projected the excess temperature-related suicide mortality in Japan under three climate change scenarios until the 2090s.

METHODS: Daily time series of mean temperature and the number of suicide deaths in 1973-2015 were collected for 47 prefectures in Japan. A two-stage time-stratified case-crossover analysis was used to estimate the temperature-suicide association. We obtained the modeled daily temperature series using five general circulation models (GCMs) under three climate change scenarios from the latest Coupled Model Intercomparison Project Phase 6 (CMIP6) Shared Socioeconomic Pathways scenarios (SSPs): SSP1-2.6, SSP2-4.5, and SSP5-8.5. We projected the excess temperature-related suicide mortality until 2099 for each scenario and evaluated the net relative changes compared with the 2010s.

RESULTS: During 1973-2015, there was a total of 1,049,592 suicides in Japan. Net increases in temperature-related excess suicide mortality were estimated under all scenarios, with the highest increase under the high-emission scenario (SSP5-8.5). The net change in 2090-99 compared with 2010-19 was 0.6% (95% empirical confidence interval [eCI]: 0.1, 1.6) for a low emission scenario (SSP1-2.6), 1.3% (95% eCI: 0.6, 2.4) for an intermediate scenario (SSP2-4.5), and 2.4% (95% eCI: 0.7, 3.9) for a high emission scenario (SSP5-8.5). The increases were greater the higher the emission scenarios were. The increase in excess temperature-related suicide mortality was minimized under the SSP1-2.6 scenario assuming mitigation strategies.

CONCLUSIONS: The comparison of projection results under different scenarios underscores the importance of mitigation, with the higher the emissions, the greater impact on the temperature-related suicide mortality.

P-0608 Prediction of the impact of climate change on the number of heatstroke patients in Tokyo, Japan with heat-adaptation effects

Kazutaka Oka[1], Yasushi Honda[1], Vera Ling Hui Phung[1], Yasuaki Hijioka[1]
[1]*National Institute for Environmental Studies, Tsukuba, Japan*

BACKGROUND AND AIM: Heatstroke has become a serious issue in Japan. To plan future adaptation measures, it is essential to understand to what extent the number of heatstroke patients will increase. Previous studies have predicted the number of heatstroke patients; however, they did not consider the effect of heat-adaptation. In this study, we conducted a future prediction study taking the effect of heat-adaptation into consideration.

METHODS: Japan, with its long north-south range, has a variety of climates, and it is necessary to explore its heat-adaptation effects. Our previous study showed that there was a positive correlation between the wet bulb globe temperature (WBGT) value at which heatstroke patients start to increase (WBGT threshold) and regional climate (average daily maximum WBGT between May and September: RCWBGT). Using the relationship, we translated this geographical effect of heat-adaptation to temporal adaptation by shifting the WBGT threshold to a higher side when the RCWBGT increases in the future owing to climate change. We focused on the age groups of 65+ yr, constituting the most vulnerable age group. Five future climate change scenarios and RCP8.5 scenario were adopted. All the data utilized in this study were public domain data and are available from the corresponding website.

RESULTS: In Tokyo, the number of heatstroke patients by mid-21st century will be 2.2 times as high as that of heatstroke patients at present and 6.9 times by the end of the century without heat-adaptation; however, the corresponding numbers will be 1.4 times and 2.5 times, respectively, with heat-adaptation.

CONCLUSIONS: The increase in the number of heatstroke patients was projected to substantially reduce owing to the effect of heat-adaptation.
Acknowledgement: This work was supported by the Climate Change Adaptation Research Program of the National Institute for Environmental Studies.

P-0609 Long-Term Exposure to Temperature, Residential Heating and Diabetes Incidence among the elderly population in China

Bo Yin[1], Keyi Lyu[1], Qian Di[1]
[1]*Tsinghua University, Beijing, China*

BACKGROUND: Mounting evidence has shown that short-term exposure to ambient temperature can increase mortality. However, the health effects associated with long-term temperature are less clear. Furthermore, more research has been focused on the mortality instead of prevalence of chronic diseases.

METHODS: We constructed two cohorts using China Family Panel Study (CFPS) and assigned annual means of wet bulb temperature and PM2.5 to study participants based on their ID code of residential. Cox proportional hazards models were used to examine the association between long-term exposure to ambient temperature, residential heating and diabetes incidence, adjusting for potential confounders.

RESULTS: We found a non-linear relationship between the long-term temperature and diabetes in multipollutant model, which is a U-shaped curve ($p<0.001$). The optimal temperature to lower diabetes risk was around 12°C. In addition, spring temperatures were negatively associated with diabetes risk, with warm temperature being protective of diabetes; while autumn temperatures were positively associated with diabetes incidences, with warm temperature being harmful. Apart from the long-term temperature, residential heating was also great threat to the diabetes incidence, with a HR = 1.18 (95% CI: 1.03, 1.36). Finally, we evaluated the extra diabetes cases in China if (1) central heating is installed in Southern China and (2) under different climate change scenarios.

CONCLUSIONS: Using two representative cohorts, we found that either higher or lower annual temperature deviating 12°C is harmful to the diabetes incidence. Therefore, the climate change will contribute different influence in Southern China and Northern China. To our surprise, residential heating is also bad for the diabetes incidence, which alert us that if it is necessary about the installing of residential heating in those areas without residential heating.

P-0616 Seasonal variation in the association between temperature variability and emergency department visits: a multi-site study in China

Yu Wang[1], Pro. Yibin Cheng[1], Pro. Dianxiu Ye[2], Pro. Xiaoyuan Yao[1], Pro. Yonghong Li[1]
[1]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]National Climate Center, China Meteorological Administration, Beijing, China

BACKGROUND AND AIM: Seasonal variation of temperature variability (TV) on emergency department visits (EDVs) remains unclear. We aimed to quantify the association between TV and cause-specific EDVs in China during 2014-2018, and explore seasonal variation, vulnerable populations, and sensitive diseases.

METHODS: We collected data on EDVs, weather, and air pollution from 20 sites in China. TV was calculated from the standard deviation of the minimum and maximum temperatures during exposure days. We applied a quasi–Poisson regression with a distributed lag nonlinear model to evaluate the TV-EDVs association. We used meta-analysis to pool site-specific estimates. We also conducted seasonal analysis and assessed the effects of modifiers.

RESULTS: A 1 ℃ increase in TV0-1 was associated with 0.36% [95% confidence intervals (CI): 0.24%, 0.48%)] increase in total EDVs. The effects became larger as exposure days increased and reached 0.59% (CI: 0.20%, 0.99%) for TV0-7. Male and people aged 0–17 were sensitive to TV with 0.40% (CI: 0.29%, 0.51%) and 0.58% (CI: 0.27%, 0.89%) increase per 1 ℃ increase in TV0-1. In seasonal analysis, effects of TV on total EDVs were lower in summer. People aged 60+ were vulnerable in winter. A 1 ℃ increase in TV0-1 corresponded to 1.84% (CI: 0.54%, 3.21%) increase of mental disease in spring, 0.43% (0.08%, 0.79%) increase of injury in autumn, and 0.63% (0.04% and 1.24%) increase of circulatory diseases in winter.

CONCLUSIONS: Exposure to TV was associated with increased risk of EDVs in China but varied in different seasons. Our results provided seasonal periods and vulnerable populations to conduct adaptive strategies and preventive measures.

P-0617 Effect modification of diabetes as a comorbidity on temperature variability and hospitalization for cardiovascular disease

Akira Okada[1], Hayato Yamana[2], Rui Pan[3], Ryosuke Kumazawa[4], Hiroki Matsui[4], Kiyohide Fushimi[5], Toshimasa Yamauchi[6], Masaomi Nangaku[7], Hideo Yasunaga[4], Takashi Kadowaki[8], Yoonhee Kim[3]

[1]Department of Prevention of Diabetes and Lifestyle-Related Diseases, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Department of Health Services Research, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [3] Department of Global Environmental Health, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [4]Department of Clinical Epidemiology and Health Economics, Tokyo, Japan, [5]Department of Health Policy and Informatics, Tokyo Medical and Dental University, Tokyo, Japan, [6]Department of Diabetes and Metabolism, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [7]Division of Nephrology and Endocrinology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [8]Toranomon Hospital, Tokyo, Japan

BACKGROUND AND AIM: Evidence has accumulated that large temperature variability (TV) is associated with an increased risk for hospitalization or death. However, no previous studies examined whether the association for TV is modified by diabetes comorbidity, which is particularly vulnerable to cardiovascular disease (CVD). We aimed to explore the short-term association between TV and CVD hospitalization, stratified by presence of diabetes as a comorbidity in 47 prefectures of Japan from 2011 to 2018.

METHODS: A two-stage meta-analysis was used. First, we used a time-stratified case-crossover design to estimate the association between TV and CVD admissions with and without diabetes comorbidity for each prefecture. We then pooled the estimates using a multivariate meta-regression model across the prefectures. The associations were also stratified by sex, age, smoking status, and season.

RESULTS: A total of 4,482,583 hospitalizations for CVD were included in this study. Each 1°C increase in 0–7 days TV exposure was associated with a 0.58% (95% confidence interval, CI= 0.20% to 0.96%) increase in risk for total CVD admission and a 2.07% (95% CI= 1.16% to 2.99%) increase in risk for heart failure admission in subjects with diabetes, while the respective increases in subjects without diabetes were 0.37% (95% CI= 0.12% to 0.63%) and 0.61% (95% CI= -0.02% to 1.23%). These patterns were broadly similar to those stratified by age, sex, and smoking status, while the association for TV was greater in spring in the season-stratified analysis.

CONCLUSIONS: Susceptibility to TV in relation to CVD onset may be stronger in subjects with diabetes than those without. Our findings may suggest that subjects with diabetes should be more cautious to sudden temperature changes.

P-0623 The association between ambient temperature and snakebites in Georgia, USA: a case-crossover study

Mariah Landry[1], Rohan D'Souza[1], Shannon Moss[1], Howard Chang[1], Stefanie Ebelt[1], Lawrence Wilson[2], Noah Scovronick[1]

[1]Rollins School of Public Health, Emory University, Atlanta, USA, [2]Emory University, Atlanta, USA

BACKGROUND AND AIM: The World Health Organization has identified snakebite as a highest priority neglected tropical disease, yet there is a dearth of epidemiologic research on environmental risk factors, including outdoor temperature. Temperature may affect snakebites through human behavior or snake behavior; snakes are ectotherms, meaning outdoor temperatures influence their internal body temperature and thus their behavior. Here we investigate the relationship between short-term temperature and snakebites in Georgia, one of the most biodiverse US states in terms of herpetofauna.

METHODS: We acquired emergency department visit data for Georgia between January 1, 2014 and December 31, 2018. Visits for venomous and non-venomous snakebites were identified using diagnosis codes. for comparison, we also considered visits for non-snake (e.g. insects, spiders, scorpions) envenomation. Daily meteorology from the Daymet 1km product was linked to patient residential ZIP codes. We applied a case-crossover design to estimate associations with maximum temperature.

RESULTS: During the five-year study period, there were 2,785 visits for venomous snakebites, 825 visits for non-venomous bites and 48,248 visits for non-snake envenomation. Across the entire period, a one-degree Celsius increase in same-day maximum temperature was associated with a 6.2% (95%CI: 4.0-8.5) increase in the odds of venomous snakebite and a 7.4% (95%CI: 3.5-11.4) increase in non-venomous snakebite. Associations were most robust in the spring and fall, particularly for venomous snakebites. We also observed a positive and significant association for non-snake envenomation, albeit slightly weaker and more consistent across seasons compared to those for snakebites.

CONCLUSIONS: Our study indicates an association between outdoor temperature and snakebites in Georgia. The results suggest that climate change could alter snakebite patterns in the future; however, impacts are likely to be dependent on the local climate and snake ecology (amongst other factors).

P-0624 Decrease and seasonal changes of suicides and suicide attempts in France over the last 10 years

Marine Ambar Akkaoui[1,2], Christine CHAN CHEE[3], Karine LAAIDI[3], Gregory FIFRE[4], Pierre Alexis GEOFFROY[1]
[1]Ghu Paris Psychiatrie & Neurosciences, Paris, France, [2]EPS Ville Evrard, psychiatric Emergency, Saint Denis, France, [3]Santé Publique France, France, [4]Météo France, France

INTRODUCTION: The objective of this study was to examine the evolution of suicides and suicide attempts over the last 10 years in France, according to the season.

METHODS: We analyzed the number of deaths by suicide and suicide attempts in metropolitan France (2009-2018) from French national databases, on a daily, weekly or monthly basis. Seasonal variation in suicide rates was modeled using a cosinor function. Based on this model, we determined the association of suicides and suicide attempts with geographic characteristics of the departments, age, gender, and psychiatric disorders. We also collected data on the means of suicide and suicide attempt.

RESULTS: The number of suicides and suicide attempts decreased over the last ten years in France (mean decrease of 14.49% and 11.69% per year). We observed a significant and recurrent seasonal pattern of suicides and suicide attempts in France, with a peak in spring. The suicide and suicide attempt rates were higher in the northern departments of France. Suicides are more common among men (75%) and middle-age individuals (45-54 years old), while suicide attempts affected more frequently women (62%) and young adults (15-19 and 40-49 years old). Nearly two-thirds of the patients who attempted suicide suffered from comorbid psychiatric disorder, with mood disorders being the most frequent psychiatric disorder. Voluntary drug intoxication was the most common means of suicide attempt (80%), while hanging was the most common means of suicide (54%).

CONCLUSIONS: The number of suicides and suicide attempts decreased in France over the last 10 years, with large seasonal variations. Further studies are warranted to better understand the underpinning physiological and meteorological factors that may influence these seasonal variations.

P-0625 Impact of meteorological factors and psychiatric disorders : a French exploratory study.

Marine Ambar Akkaoui[1], Damien Pires[1], Karine Laaidi[3], Christine Chan Chee[3], Gregory Fifre[4], Pierre Alexis Geoffroy[1]
[1]Ghu Paris Psychiatrie & Neurosciences, Paris, France, [2]EPS Ville Evrard, psychiatric Emergency, Saint Denis, France, [3]Santé Publique France, Paris, France, [4]Météo France, Paris, France

INTRODUCTION: The objective of our work was to study the link between meteorological factors (temperature, sunshine duration, rain, wind, humidity) and psychiatric disorders. for this purpose, we conducted two exploratory studies in France : the first one, studying the link between the weather and suicidal behaviors (suicides and suicide attempts); the other one between alcohol use disorders (AUD) and the weather.

METHODS: We analyzed the number of deaths by suicide and suicide attempts in metropolitan France (2009-2018) from French national hospitalization databases; patients who were admitted to an emergency department for an alcohol related condition were included using the Oscour database, and we used meteorological database from national weather services. Based on this model, we determined the association of suicides and suicide attempts with weather factors, and then between AUD and meteorological factors.

RESULTS: The number of suicides and suicide attempts decreased over the last ten years in France (mean decrease of 14.49% and 11.69% per year). We observed a significant and recurrent seasonal pattern of suicides and suicide attempts in France, with a peak in spring. The suicide and suicide attempt rates were higher in the northern departments of France. We found significant positive correlations between the number of alcohol-related ED visits and the mean temperature ($r = 0.55$; $p = 1.87e$) and the duration of sunlight ($r = 0.42$; $p = .0015$). Negative correlations were also found significant with rain ($r = −0.40$; $p = .0014$), humidity ($r = –0.41$; $p = .0023$) and wind speed ($r = −0.40$; $p = .0031$).

CONCLUSIONS: The number of suicides and suicide attempts decreased in France over the last 10 years, with large and recurrent seasonal variations. Emergency visits for AUD seem to increase with the temperature and duration of sunlight, and decrease with rain, humidity and wind speed.

P-0626 Long term associations of climatic factors on cognition in olderadults: Results from the Reasons for Geographic and Racial Differences in Stroke (REGARDS) Cohort

Peter Larson[1], Anam Khan[1], Robert Melendez[1], Philipa Clarke[1], Carina Gronlund[1]
[1]*University of Michigan, Ann Arbor, USA*

BACKGROUND: Evidence suggests that short term exposures to extreme heat and/or cold are associated with declines in cognition among older adults. However, the effect of long term exposures are not well understood.

METHODS: The Reasons for Geographic and Racial Differences in Stroke (REGARDS) study is a nationwide cohort study exploring regional and racial differences in stroke and cognitive function over time. ~30,000 people from all areas of the US were enrolled at age 45. Word List Learning (WLL) and Word List Delayed Recall (WLD) tests were administered on a yearly basis. Continuous cognition scores were produced using factor analysis based methods and applied to each measured time point for each individual. Associations of cognition with the number of extreme hot and cold days relative to region were tested using regression models of the continuous measure of cognition within a directed non linear Distributed Lag Non-linear Modelling framework.

RESULTS: Cognition data was available for 20,091 people with a mean age of 64.6 years over miltiple time points. of these, 39.2 percent were Black. On average, respondents experienced 25.4 and 14 extremely hot and cold days the year previous to the last date of survey. Cognition was significantly and negatively impacted by same year exposure to increased numbers of extreme heat days. No association of long term heat and/or cold exposure was found for exposure days greater than one year, or for exposure to cold or precipitation for all time periods tested.

CONCLUSIONS: Evidence suggests that the greatest impacts of temperature on cognition occurs within one year of exposure. Future work should explore the potential role of climate change in increasing incidence of cognitive decline in older adults.

P-0630 Heat Exposure and Emergency Department Visits for Sepsis in Phoenix, Arizona

Bailey Englund[1], Rohan D'Souza[1], Noah Scovronick[1], Jordan Kempker[1], Howard Chang[1], Stefanie Ebelt[1]
[1]*Emory University, Atlanta, USA*

BACKGROUND AND AIM: Climate change is increasing exposures to high temperatures, which can lead to death and illnesses requiring emergency care. Sepsis, the body's response to severe infection, is usually diagnosed in emergency departments (EDs). Little is known about outdoor temperatures as a risk factor for sepsis. Here, we assessed the association between temperature and sepsis-related ED visits in Phoenix, Arizona during 2016-2019.

METHODS: We acquired ED visit data for Arizona and selected visits among patients residing within the two-county Phoenix area with a diagnosis of sepsis present on arrival at the ED. We characterized the focus of infection (FOI, respiratory, urogenital, abdominal, bone and soft tissue, blood) for each sepsis visit through diagnosis codes. Using daily population-weighted average maximum temperature data from Daymet, we estimated associations with sepsis and FOI-specific sepsis ED visits via Poisson time-series regression.

RESULTS: During 2016-2019, there were 97 sepsis-related ED visits per day in Phoenix; the average daily maximum temperature was 30.5 degrees Celsius. Overall, we observed a positive association between same-day maximum temperature and sepsis-related ED visits (rate ratio: 1.014, 95% confidence interval: 1.000-1.028 for a 5 degree increase from 24 to 29 degrees Celsius). Associations were strongest in the warmer seasons of Spring, Summer, and Autumn. When stratifying by FOI, associations of same-day maximum temperature and ED visits for sepsis with infection of the urogenital area were positive; other FOIs showed null or negative (for blood) associations with temperature.

CONCLUSIONS: Results suggest that outdoor heat exposure may be an important risk factor for sepsis, in particular during the warm season and for urogenital-based infections. During times of high heat, exposure mitigation measures may reduce emergency care needs, and emergency department preparedness may be needed to ensure positive outcomes for patients.

KEYWORDS: Climate, Heat, Temperature, Sepsis, Morbidity

P-0632 Central heating in China and protection against cold temperature mortality: a longitudinal cohort study of older adults

Haofan Zhang[1], John Ji[2], Miaomiao Liu[1], Jun Bi[1], Yi Zeng[3]
[1]Nanjing University, Nanjing, China, [2]Tsinghua University, Beijing, China, [3]Duke University, Durham, USA

Central heating in northern China during the months is reliant on biomass combustion and causes air pollution. Prior studies using natural experiment design (north and south of Huai river) attribute higher pre-mature mortality due to central heating-related air pollution. However, the original intention of central heating is to protect against the cold. We used the 2000-2018 Chinese Longitudinal Healthy Longevity Survey (CLHLS), a nationwide cohort of older adults aged 65. We focused on five provinces that are between heating and non-heating areas. The heating status was measured according to the resided city. We obtained daily meteorological data from the closest national station and measured residential air pollution. Cox proportional hazards models were used to assess the effects of central heating and air pollution. We further compared the mortality risk of long-term and short-term cold temperatures for participants with and without central heating. Winter average temperature and temperature variability were used to measure the long-term cold temperature. for the acute exposure, we used a distributed lag non-linear model. We included 5,334 participants, totaling 34,608 person-years of follow-up. We recorded 6,667 deaths, and 2,051 occurred in winter. In the adjusted model, the mortality hazard ratio (HR) for central heating was 0.80 (95% CI 0.76, 0.85). In our subgroup analyses, the HR for each 1℃ increase in winter temperature variability was higher for participants without central heating than for participants with central heating (1.21 vs.1.08), but the HR for each 10 μg/m³ increase in PM2.5 was similar(1.13 vs. 1.14). Participants without central heating also had for higher mortality risk of extremely cold at the 5th percentile compared to the 60th percentile than participants with central heating (1.48 vs.1.14). Our results suggested that central heating significantly decreased winter mortality, which may partly be achieved by attenuating the mortality caused by cold temperatures.

P-0634 Allostatic load and climate change: analyzing epidemiological confounding variables, health effects and adaptative response in osteoporosis and kidney disease associated with NDVI greenness index

Fernando Gonzalez Botija[1], Pedro Diaz Peralta[2]
[1]Universidad Complutense de Madrid, Madrid, Spain, [2]Yale School of The Environment- Michelle L. Bell´s Research Group, New Haven, USA

BACKGROUND AND AIM: To explain individual response to stressors, research has brought attention to the common underlaying mechanisms for catecholamine- dependent adaptive response. Under this perspective, a trigger factors is the adaptation to extreme weather events linked to climate change (droughts, long warm summers, heat waves, etc) closely connected with the related concept of "allostasis" defined as “the physiological or behavioural changes required to stabilize the biological systems". As long as allostasis implies resilience (Karatsoreos, McEwen, 2011) it can be connected, conversely, with the negative effect of “allostatic load”. Nevertheless, its concurrence with confounding variables should be also evaluated: Allostasis can influence occurrence of osteoporosis-related fracture and changes on Bone mineral density (BMD) where researchers have found the apparently beneficial effect of greenness in relation to the positive impact of outdoor exercise as a stress reduction mechanism, also identified as a factor influencing BMD (Follis, Bea, Klimentidis et al. 2019)
Other example is the beneficial effect in kidney disease incidence and air pollution, where results shown that stricter air quality standards benefit kidney patients. (Lee, W, 2022)

METHODS: Systematic review on cases involving BMD and kidney disease and subsequent the catecholamine-dependent response following a two stage analysis. Residential proximity is defined as average of satellite-based Normalized Difference Vegetation Index (NDVI) in buffers of 50 m, 100 m and 250 m, 500 m

RESULTS: Evidence of beneficial effect of the greenness estimated from analysis of Normalized difference Vegetation Index- NDVI has

CONCLUSIONS: The influence of allostasis should be supported by clinical research evidence(Ramsay et al 2014). A number of studies estimating beneficial effects or greenness suggest that allostasis, as a measure of catecholamine-dependent response could be a valid approach for understanding the underlying mechanisms in environmental stressors

KEYWORDS: Allostasis, allostatic load, NDVI, greenness, behavioural changes

P-0638 Knowledge, Attitude and Practice of Health Workers and Shopping mall operators towards Decontamination during COVID -19 Pandemic in Ibadan

Taiwo Alawode[1]
[1]*University of Ibadan, Ibadan, Nigeria*

BACKGROUND AND AIM: Public facilities such as hospitals and shopping malls are a potential hotspot for transmission of infectious disease like COVID-19. Decontamination practice is therefore an essential infection prevention and control strategy used in preventing disease outbreaks. Information on knowledge, attitude, and practice of facilities workers towards decontamination are poorly investigated and documented in developing countries. This study, therefore, assessed the knowledge, determined the attitude and practice of hospital and shopping mall workers towards decontamination during the Covid-19 pandemic.

METHODS: The cross-sectional study utilized a comparative approach involving the use of Adeoyo hospital and a shopping mall in Ibadan, Nigeria. An interviewer-administered questionnaire was used to assess the knowledge, attitude, and practices of decontamination among 250 respondents. Data collected were analyzed using SPSS version 25, for mean, standard deviation, and T-test at 5% significance level.

RESULTS: Most (64%) of Adeoyo respondents and majority (89%) of Shopping mall respondents had a poor practice level towards decontamination at their workplaces, however, the majority (89.8%) and (81.1%) of the respondents in Adeoyo and shopping mall respectively had a good attitude towards decontamination. Although there was a significant association between knowledge ($p = 0.001$), practice ($p < 0.001$), and study location. A little more than half (56.1%) and some (21.2%) of respondents in Adeoyo and Shopping mall respectively had poor knowledge about decontamination. Among respondents from Adeoyo, level of education ($p = 0.006$) was significantly associated with level of practice on decontamination.

CONCLUSIONS: The study revealed that both study locations had poor decontamination practice and a large percentage had poor knowledge about decontamination, therefore Hospital and mall workers should be educated on the importance of decontamination. Necessary infrastructure should be put in place to ensure decontamination practice and ensure infection control.

KEYWORDS: Decontamination, Knowledge, attitude, practice, hospital, shopping mall

P-0645 Impact of air pollution on cardiovascular mortality during the COVID-19 pandemic in South Korea

Whanhee Lee[1,2], Lina Madaniyazi[3], Wook Bum Pyun[4], Chris Fook Sheng Ng, Jieun Min[6], Jongmin Oh[1], Ho Kim[6], Masahiro Hashizume[5], Eunhee Ha[1,2,7]

[1]Department of Environmental Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [2]Institute of Ewha-SCL for Environmental Health (IESEH), College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [3]School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan, [4]Division of Cardiology, Department of Internal Medicine, Ewha Womans University Medical Center, Seoul, Republic of Korea, [5]Department of Global Health Policy, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [6]School of Public Health Science, Seoul National University, Seoul, Republic of Korea, [7]Department of Environmental Medicine, College of Medicine, Graduate Program in System Health Science and Engineering, Ewha Womans University, Seoul, Republic of Korea

BACKGROUND AND AIM Multiple studies have reported the impacts of the coronavirus-2019 pandemic on cardiovascular disease (CVD) and the concentration of air pollution, respectively. Although the association between air pollution and CVD outcomes has been widely identified, the changes in the association during the pandemic period have not been fully investigated. This study aimed to examine the nationwide changes in the short-term effect of fine particulate matter (PM2.5) on CVD deaths in South Korea.

METHODS: We performed an interrupted time-series analysis to estimate temporal changes in the association between PM2.5 and CVD-related deaths (total, ischemic health disease [IHD], cerebrovascular disease [CD], and hypertension) before (Jan 01, 2016 to Feb 17, 2020) and during the pandemic (Feb 18, 2020 to Dec 31, 2020), using daily data. Relative humidity, day-of-week, seasonality, and temporal trend were controlled. We conducted a two-stage analysis to estimate the risk of air pollution on CVD deaths for each of 16 regions and then generated an overall estimate.

RESULTS: The total number of CVD mortality was 53,552. The average annual concentration of PM2.5 changed before (23.8 μg/m3) and during the pandemic (17.1 μg/m3) in South Korea. for total CVD deaths, the changes in relative risks (RRs; for 10 μg/m3 increase in PM2.5) were not pronounced during the pandemic. Whereas, for ISH and CD, the RRs increased during the pandemic: (pre-pandemic to pandemic period) 1.00 (0.99, 1.01) to 1.02 (1.00, 1.04) for IHD and 1.00 (1.00, 1.01) to 1.02 (1.00, 1.04) for CD, although the changes were not statistically significant (p-values 0.08 and 0.24).

CONCLUSIONS:We found that the risks of short-term exposure to PM2.5 on mortality for IHD and CD increased in the first pandemic year in South Korea, compared to the pre-pandemic years.

KEYWORDS: COVID-19, Pandemic, PM2.5, Cardiovascular mortality.

P-0648 Higher incidence of novel coronavirus (COVID-19) cases in areas with combined sewer systems, heavy precipitation, and high percentages of impervious surfaces

Alisha Chan, Honghyok Kim, Michelle Bell
[1]*Yale University, Olney, USA*

Combined sewer systems (CSS) are water management systems that collect and transport stormwater and sewer water in the same pipes. During large storm events, stormwater runoff may exceed the capacity of the system and lead to combined sewer overflows (CSOs), where untreated sewer and stormwater are released into the environment. Previous studies identified SARS-CoV-2 in sewage, urine, feces, and municipal wastewater. As such, areas contaminated by CSOs may be a reservoir of SARS-CoV-2 and may result in illness after the ingestion and/or inhalation of contaminated splashes, droplets, or aerosols. We investigated the association between COVID-19 incidence and CSSs and whether this association differed by precipitation and percent impervious surfaces as a proxy for possible CSOs. We fitted a quasi-Poisson regression model to estimate the change in percentage of incidence rate of COVID-19 cases in counties with a CSS compared to those without, adjusting for potential confounders (i.e., state, population density, date of first documented COVID-19 case, social vulnerability, and percent vaccinated) and including interaction variables between CSS, precipitation, and impervious surfaces. Our findings suggest that heavy precipitation in combination with high percentages of imperviousness is associated with a higher incidence rate of COVID-19 cases in counties with a CSS compared to in counties without a CSS. We theorize that more COVID-19 cases may be seen in counties with a CSS, heavy precipitation, and high percentages of impervious surfaces because of the possible increase in frequency and severity of CSOs. The results suggest links between climate change, urbanization, and COVID-19.

P-0650 Using Google data and weather factors to predict COVID-19 transmission in Melbourne, Australia: A time-series predictive model

Hannah McClymont[1], Xiaohan Si[1], Wenbiao Hu[1]
[1]*Queensland University of Technology, Brisbane, Australia*

BACKGROUND AND AIM: We aimed to assess the effect of weather variability and Google data on COVID-19 transmission and develop multivariable time series AutoRegressive Integrated Moving Average (ARIMA) models for predicting COVID-19 transmission and outbreaks in Australia.

METHODS: Data including COVID-19 case notifications, meteorological factors and Google data were collected for the period of the Delta outbreak in Melbourne, Australia from the 1st of August to 15th November 2021. Time-series cross-correlation (TSCC) was used to evaluate the temporal correlation between weather factors, Google search trends, Google Mobility data and COVID-19 transmission. Time series ARIMA models with potential predictors were used to forecast COVID-19 incidence and Effective Reproductive Number (Reff) in the Greater Melbourne region. Five models were fitted to compare and validate predictive models using three-day ahead increments to test the predictive accuracy for both COVID-19 incidence and Reff. ARIMA models were fitted and validated using 70% training (75 days) and 30% validating (32 days) from 1st August 2021 to 15th November 2021 (107 days).

RESULTS: Maximum temperature (Tmax), absolute humidity, solar exposure, and transit station mobility (TSM) were significantly positively associated with COVID-19 incidence over time. Tmax and TSM were selected at a lag of 8 and 7 days respectively to develop multivariable ARIMA models. Multivariable ARIMA models including Tmax or TSM improved the predictive accuracy of COVID-19 cases slightly.

CONCLUSIONS: ARIMA modelling was useful for predicting epidemic growth, there is also a potential application for inclusion of weather and Google data in creating effective early warning systems for future outbreaks. Our results suggest that TSM and Tmax would be useful for further exploration and developing weather-informed early warning models for future potential COVID-19 outbreaks.

KEYWORDS: COVID-19, ARIMA, forecasting, weather, internet search queries, mobility

P-0652 Health impacts of a reduced aircraft noise exposure during the Covid-19-pandemic - A natural experiment in Stockholm, Sweden

Charlotta Eriksson[1,2], Andrei Pyko[1,2], Staffan Betnér[1,2], Caisa Laurell[1,2], André Lauber[1,2], Antonios Georgelis[1,2]
[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Center for Occupational and Environmental Medicine, Region Stockholm, Stockholm, Sweden

BACKGROUND AND AIM: The lock-downs during the Covid-19-pandemic induced significant changes in travel patterns. In Stockholm, Sweden, the aircraft traffic around Bromma airport reduced by 77 percent during the first wave of the pandemic, March 1 to June 15, 2020, resulting in a sharp decline in residential exposure to noise. Based on this "natural experiment", we aimed to assess the impact of the reduced aircraft noise exposure on population well-being and health.

METHODS: In September 2020, we invited 10 000 individuals residing in the vicinity of Stockholm Bromma airport (n=7 500) and in Nacka municipality (n=2 500), serving as a reference, to a web-based questionnaire survey. The questions related to a pre- and during the pandemic situation, respectively, and concerned individual and housing factors and various disturbances, e.g., noise annoyance, sleep impairment, and stress related symptoms. Residential exposure to aircraft noise was assessed for a pre-pandemic situation in 5 dB categories ranging from ≤45 to ≥55 dB Lden. Logistic general estimating equation models were used to assess Relative Risks (RR) and 95% Confidence Intervals (95% CI).

RESULTS: In total, 3 582 individuals responded to the survey (35,8%). In the pre-pandemic situation, statistically significant associations were found between aircraft noise and all investigated disturbances. During the pandemic, the associations reduced and approached unity. The RR for high noise annoyance dropped from 7.51 (95% CI 5.18-10.90) among those exposed ≥46 dB Lden compared to the reference before the pandemic, to 2.18 (95% CI 1.24-5.9) during the pandemic. Corresponding figures for high sleep disturbance were 7.64 (95% CI 3.90-15.0) and 1.57 (95% CI 1.62-1.02), respectively. Improvements were also seen for stress symptoms.

CONCLUSIONS: The reductions in aircraft noise exposure around Stockholm Bromma airport during the Covid-19-pandemic resulted in an overall improved health in the local population.

KEYWORDS: Aircraft noise, Covid-19-pandemic, annoyance, sleep, stress

P-0653 Environmental surveillance and clinical assessment of SARS-CoV-2 epidemiology and variant prevalence in an urban area in Spain

Veronica Chico[1], Judith Sanchez[2], Antonio Galiana[2], Antonio Martinez-Murcia[3], Maria del Mar Ortega-Villaizan[1], Belen Almendro[4], Jose Navarro-Pedreño[4], Luis Perez[1]

[1]Instituto de Investigación Desarrollo e Innovación en Biotecnología Sanitaria de Elche (IDiBE), Universidad Miguel Hernández (UMH), Elche, Spain, [2]Area de Microbiología, Hospital General Universitario de Elche, Elche, Spain, [3]Departamento de Producción Vegetal y Microbiología (UMH), Elche, Spain, [4]Departamento de Agroquímica y Medio Ambiente, (UMH), Elche, Spain

BACKGROUND AND AIM: Wastewater-based epidemiology (WBE) provides the means to monitor pathogens prevalence in the sewage system of a community. SARS-CoV-2, the virus responsible for the COVID-19 global pandemic, can be detected in the feces of infected individuals. Therefore, viral concentrations in wastewater can be taken as an indication of SARS-CoV-2 prevalence in the entire population. This work was aimed at the detection and sequence analysis of SARS-CoV-2 RNA in wastewater and its correlation with clinical data.

METHODS: Samples collected over a nine-month period (2020-21) at a wastewater treatment plant in Elche (Spain) were concentrated by ultrafiltration and analyzed for the presence of SARS-CoV-2 RNA by reverse transcriptase quantitative polymerase chain reaction (RT-qPCR). Sequences generated from cDNA samples with a MinION Nanopore device were compared to SARS-CoV-2 sequence databases.

RESULTS: The appearance of the first qPCR positive signals correlated with the increasing number of covid-19 cases in Elche at the onset of the second wave of COVID-19 (july 2020). Measurements of viral genomes in water samples in October-November 2020 reflected the higher number of clinical cases within that period. Nanopore sequencing assay allowed the detection of spike (S) protein mutations associated with circulating SARS-CoV-2 variants both in environmental as well as in clinical samples, reflecting the emergence of the B.1.1.7 variant in Elche in late 2020.

CONCLUSIONS: This study highligted the potential of wastewater-based epidemiology (WBE) in revealing the presence of pathogenic viruses in urban populations. By the use of the nanopore sequencing technology we were able to assess the changes in circulating SARS-CoV-2 variants in a whole population.

KEYWORDS: environmental epidemiology, SARS-CoV-2 variants, wastewater, nanopore sequencing

P-0670 COVID-19 in the Eastern Caribbean: Engaging the Root of Ill-Health and Unhappiness

Steve Whittaker[1], Samantha Bedford[1,2], Phibi Joseph[2], Alaynah Mitchell[2], Mx. Cyndi Joseph[1,2]
[1]Clarence Fitzroy Bryant College, Basseterre, Saint Kitts and Nevis, [2]Science, Technology, Research and Work Study (STRaWS),

BACKGROUND: The peripheral impacts of the global COVID-19 pandemic have had enduring effects on our everyday lives. Citizens of small island Caribbean states in particular faced increased frequencies and odds of morbidity beyond SARS-COV-19 infections.
AIM: Our pilot project sought to probe health-relevant outcomes among Eastern Caribbean residents.

METHODS: We surveyed residents of St. Kitts-Nevis, ages 17 to 55 and facilitated student focus groups (SFG) in 2021 and 2022. Analyses produced descriptive methods and odds ratios.

RESULTS: Among 81 respondents, 72.8% identified as female and 82.7% had been involved in academic training within a year of completing the questionnaire. Physical activity (50.6%) and mental health (69%) were at least moderately impacted due to the atmosphere of risk and restrictions. Male participants were less likely (OR: 0.32) to have friendships greatly impacted (95CI%: 0.11 - 0.86) while female participants were more likely (OR: 1.15) to report at least moderate declines in mental health (95CI%: 3.21 - 9.16). Students and teachers had a 3.92 higher odds (95CI%: 3.92 - 13.52) of experiencing mental health challenges relative to other occupations. Persons with moderate-to-severe feelings of negative mental health had increased odds (OR: 5.70; 95%CI: 2.05 - 17.83) of a moderate-to-severe comprise of diet relative to individuals feeling little to no changes in mental well-being. Informational sources such as TV as a source of COV-19 information was linked to greater mental health deficits (OR: 3.44; 95%CI; 1.31 - 9.45). SFG participants (n=8) qualified mental health challenges during the pandemic, highlighting lack of communication and clear instructions from their institutions, insufficient feedback and guidance from teachers, absenteeism due to parent(s) serving as essential worker(s) and isolation due to quarantine and/or lockdown.

CONCLUSIONS: Results reflect both unique and relatable ways in which Caribbean folks experience and reflect on health status throughout the unprecedented COV-19 pandemic.

P-0671 Long-term exposure to ambient air pollution and COVID-19 incidence in Italy

Andrea Ranzi[1], Massimo Stafoggia[2], Simone Giannini[1], Carla Ancona[2], Lisa Bauleo[2], Antonino Bella[3], Giorgio Cattani[4], Federica Nobile[2], Patrizio Pezzotti[3], Ivano Iavarone[3]

[1]Environmental Health Reference Centre, Regional Agency for Environmental Prevention of Emilia-Romagna, Modena, Italy, [2]Department of Epidemiology, Lazio Region Health Service / ASL Roma 1, Rome, italy, [3]Italian National Institute of Health (ISS), Rome, Italy, [4]Italian Institute for Environmental Protection and Research, ISPRA, Rome, Italy

BACKGROUND AND AIM: The SARS-CoV-2 pandemic gave rise to a large number of epidemiological studies linking ambient air pollution (AP) to COVID-19 incidence. However, to date, the role of chronic exposure to AP in explaining COVID-19 occurrence is still not clarified.

METHODS: Within a national study (EpiCovAir) promoted by National Institute of Health (ISS) and Italian Network of Environmental Protection (SNPA), we identified all COVID-19 cases in Italy from February 2020 to June 2021. Chronic exposure to particulate matter < 10 micron (PM10), < 2.5 micron (PM2.5) and nitrogen dioxide (NO2) were assigned at municipality level (n=7800) using a national satellite-based AP exposure model (1-km2 spatial resolution) for the period 2016-2019. We applied principal component analysis (PCA) and generalized propensity score (GPS) approaches to summarize information of about 50 area-level covariates to account for major determinants of the spatial distribution of COVID-19 cases (municipality characteristics, population density, mobility, population health, socio-economic status). Finally, we applied generalized negative-binomial regression models matched on GPS, age, sex, province and month to study the association between AP and COVID-19 incidence.

RESULTS: 3,995,202 COVID-19 cases occurred in Italy in the entire period (incidence rate=67x1000). Overall, incidence rates increase by 0.6% (95% CI: 0.5%, 0.7%), 0.5% (95% CI: 0.4%, 0.6%) and 0.9% (95% CI: 0.9%, 1.0%) per 1 □g/m3 increment in PM2.5, PM10 and NO2, respectively. Associations were consistent to different sensitivity analyses, particularly for NO2. Increments were higher among elderly subjects, and during the second pandemic waves (Sept. 2020-Dec. 2020). In two-pollutant models, NO2 estimates were robust to PM adjustment, while PM showed no associations after adjustment for NO2.

CONCLUSIONS: We found evidence of association between long-term exposure to ambient AP (particularly NO2) and the occurrence of 4 million COVID-19 cases in Italy, suggesting a role of AP in increasing the incidence of COVID-19 disease.

P-0674 Long-term Air Pollution Exposure on COVID-19 Risk and Severity

Saira Tasmin[1], Brisa Aschebrook-Kilfoy[1], Habibul Ahsan[1]
[1]*The University of Chicago, Chicago, USA*

Since the emergence of the COVID-19 pandemic, long-term exposure to air pollution has emerged as a possible risk factor for increased COVID-19 disease risk, severity, and mortality.
The objective of this study was to examine the association between COVID-19 and long-term exposure to air pollution.
This retrospective cohort study included patients who had a COVID-19 test at the University of Chicago Medicine Center from March 18, 2020, to March 30, 2021. Air pollution exposure was assessed using models developed for Chicago by the MESA Air Study and data from the Environmental Protection Agency's EJSCREEN. Air pollution exposure estimates were linked to the University of Chicago Medicine patients using residential addresses. Air pollution measurements included PM2.5 (MESA Air and EPA), NO2, diesel PM, the respiratory hazard index, traffic proximity, and ozone. The outcome was COVID-19 risk and severity (ICU admission). Mixed effect analyses were performed to test whether poor air quality status was associated with COVID-19 risk and severity, controlling for demographic, smoking, and comorbidity indicators collected from the medical records.
A total of 74,004 patients (mean [SD] age 44.0 [22.51] years; 42,979 [58.09%] women; and 32,870 [49.09%] African Americans) were linked to air quality exposure based on residence and other covariates using electronic medical record data in addition to COVID-19 test results. Overall, 8,463 participants (11.4%) tested positive for COVID-19. In the mixed effect analysis, long-term PM2.5 exposure was associated with increased risk of testing positive for COVID-19 (odds ratio [OR], 1.30; 95% CI, 1.23-1.38; P <0.01) and increased severity from COVID-19 (OR= 2.28; 95% CI, 2.00-2.60; P = <0.01).
The results of this retrospective cohort study provide some evidence of the effect of long-term air pollution exposure on COVID-19 risk and severity.

P-0678 Field measurements of indoor and community air quality in rural Beijing before, during, and after the COVID-19 lockdown

Xiaoying Li[1], Xiang Zhang[1], Talia Sternbach[1], Collin Brehmer[2], Jill Baumgartner[1], Christopher Barrington-Leigh[1], Sam Harper[1], Brian Robinson[1], Guofeng Shen[3], Shu Tao[3], Yuanxun Zhang[4], Ellison Carter[2]
[1]Mcgill University, Montreal, Canada, [2]Colorado State University, Fort Collins, USA, [3]Peking University, Beijing, China, [4]University of Chinese Academy of Sciences, Beijing, China

BACKGROUND AND AIM: The outbreak of the coronavirus (COVID-19) initiated a global prevention response to curb the spread of the virus, including a series of actions to reduce human mobility. Previous studies report reductions in outdoor $PM_{2.5}$ associated with COVID-19 lockdown in many countries and regions. Few studies assessed the impacts of COVID-19 on local air quality in environments with diverse socioeconomic and household energy use patterns. We evaluated whether indoor and community $PM_{2.5}$ in homes with different energy use patterns in rural Beijing, China differed before, during, and after the lockdown.

METHODS: We deployed low-cost $PM_{2.5}$ sensors (Plantower), calibrated with co-located filter-based $PM_{2.5}$, to measure indoor and community air quality in 147 homes from 30 villages in Beijing in January-April, 2022. We apply mixed-effects models to assess the impact of the COVID-19 lockdown on indoor $PM_{2.5}$ and used the random component superposition model (RCSM) to estimate the contributions of indoor and outdoor sources to indoor $PM_{2.5}$.

RESULTS: Community pollution was higher during the lockdown period (61 ± 47 μg/m³) compared with before (45 ± 35 μg/m³) and after (47 ± 37 μg/m³) the lockdown. However, we did not observe higher indoor $PM_{2.5}$ during the lockdown (during vs. before: 98 ± 86 vs. 96 ± 83 μg/m³). Indoor-generated $PM_{2.5}$ was lowest in homes using clean energy exclusively for heating and without smokers, and did not change significantly during the lockdown compared with homes using solid fuels.

CONCLUSIONS: Indoor air quality did not worsen during the COVID-19 lockdown in our rural Beijing sites, though community $PM_{2.5}$ was higher during the lockdown. Indoor-generated $PM_{2.5}$ in homes using clean energy exclusively for heating was low and stable, while decreased during the lockdown in homes using solid fuel, which may be due to less solid fuel burning for heating because outdoor temperatures warmed.

P-0680 How the COVID-19 infection and deaths are shaped by socioeconomic inequities and air pollution exposure in Mumbai, India?

Avik Kumar Sam[1], Siuli Mukhopadhyay[1], Harish C. Phuleria[1]
[1]*Indian Institute of Technology Bombay, Mumbai, India*

BACKGROUND: The COVID-19 pandemic caused a global health crisis and exposed the low socioeconomic groups to higher exposure and death due to the existing social inequalities. India witnessed three unprecedented waves of COVID infection and deaths. However, a systematic analysis of the impact of socioeconomic inequities and other environmental factors on COVID-19 infection and mortality are not well examined in India.
AIM:
The present study aims to understand the impact of socioeconomic inequities and air pollution on COVID-19 infection and deaths in Mumbai, India.

METHODS: Ward-level data on COVID-19 cases and deaths from 24 wards is obtained from the Municipal Corporation of Greater Mumbai. Socioeconomic data is acquired from the official Govt. of India 2011 census. Bivariate and multivariate regression is applied to examine the impact of various socioeconomic factors on COVID fatalities and infections.

RESULTS: Mumbai reported 1,032,563 positive cases with an overall mortality rate of 18.9. The maximum mortality (41.9) and recovery rate (991.4) were observed in wards B and A in south Mumbai. A significant negative correlation (r=-0.55) was observed between deaths and the total population, irrespective of gender. Education (defined by literacy rate) showed a positive association with the COVID cases for both genders, suggesting no significant disparity based on gender and education ($p<0.05$). The homeless population depicted a positive correlation with mortality rates and positive cases, indicating the role of economic inequities. The higher population density in the wards may have caused higher mortalities, as suggested by a significant positive association (r= 0.46).
CONCLUSION: Our initial analysis suggests the influence of healthcare and housing affordability on the mortality rates, whereas the total positive cases seem to be driven by the non-slum population. The effect of other socioeconomic variables and air pollution, and multivariate analysis is currently underway.

KEYWORDS: COVID-19, Socioeconomic inequity, Air Pollution, Healthcare, Mortality

P-0683 Environmental, health and economic benefits of Covid-19 lockdown in Morocco

Imane Sekmoudi[1], Kenza KHOMSI[2,3], Laila IDRISSI[1], Yassmine BELAMRI[4]

[1]Process and Environment Engineering Laboratory, Faculty of Sciences and Technologies, Mohammedia. Hassan II University, Casablanca, Morocco, Mohammedia, Morocco, [2]General Directorate of Meteorology, Casablanca, Morocco, [3]Laboratory of Chemistry-Biochemistry, Environment, Nutrition and Health, Faculty of Medicine and Pharmacy, Hassan II University, Ain Chock, Casablanca, P.O. Box 5696, Morocco, [4]Faculty of Sciences and Technologies, Mohammedia. Hassan II University, Casablanca, Morocco,

Several measures have been taken to mitigate the effects of the Covid-19 pandemic. In this context, almost all non-essential activities in Morocco have been halted since March 20, 2020. The main objectives of this work are firstly to study the effects of lockdown measures on air quality, by analyzing dust PM2.5, NO2 and O3. Secondly, to estimate the health and the total economic benefits caused by PM2.5 during the Covid19 scenario based on Environmental Benefits Mapping and Analysis Program (BenMAP). A review of the various health and economic studies of the impact of lockdown on air quality was conducted and taken into account. The dust PM2.5 analysis was carried out from 2016 to 2020. NO2 and O3 analysis was carried out in 2019 and 2020. This study, which is based on satellite data from TROPOMI Sentinel 5P and MERRA, has shown that Morocco has experienced an improvement in air quality during the lockdown. A significant reduction in surface dust PM2.5 and tropospheric NO2 was observed (-10%, -4%, respectively on average). The total column of ozone recorded a slight increase on average of around 1%. According to the results obtained, it is inferred that the reduction of PM2.5 concentration saved lives mainly from cardiovascular and respiratory diseases, with 291 and 137 avoided deaths respectively. According to the VSL method, the economic benefits of avoiding deaths from all causes due to a decrease in PM2.5 concentration of the order of 67 % in Morocco have been estimated at about 451 million USD. This hypothetical clean air scenario has shown us the significant health and economic benefits that could be achieved through transport, climate and environmental strategies and policies that at the same time support a robust economic recovery and reduced emissions.

KEYWORDS: Air quality, Covid-19, Morocco, health impacts, economic benefits.

P-0685 Race-ethnicity disparities in COVID-19 outcomes may be worsened by shorter- and long-term aerosol pollutants exposure

Arshad Arjunan Nair[1], Ian Ryan[1], Gan Luo[1], Xinlei Deng[1], Wangjian Zhang[1], Fangqun Yu[1], Shao Lin[1]
[1]*State University of New York at Albany, Albany, USA*

BACKGROUND AND AIM: The importance of ultrafine particles (UFP or $PM_{0.1}$) exposure to respiratory disease has been identified. However, its effect (and that of $PM_{2.5}$) on COVID-19 outcomes remain unknown. This study aims to identify and quantify shorter- and long-term aerosol impacts on COVID-19 in context of disparate outcomes observed for minority race-ethnicity groups in New York State (NYS).

METHODS: COVID-19 outcomes included infections, hospitalizations, ICU admissions, and deaths reported by the CDC COVID-19 Case Surveillance Restricted Access Detailed Data, 2020–2022. UFP and $PM_{2.5}$ data were simulated by a global three-dimensional model of chemical transport with state-of-the-science aerosol microphysical processes extensively validated with observations. for shorter-term (0–30 lag days) UFP and $PM_{2.5}$ exposure, Distributed Lag Non-linear Model (DLNM) were used to examine the association at county-level, adjusting for meteorological factors. Long-term (average level of 2013–2020) associations with COVID-19 were assessed by Negative Binomial Mixed Models adjusting for county-level confounders. County-level confounders from the Census Bureau, Behavioral Survey, and Homeland Infrastructure Data were used.

RESULTS: Compared to White, Hispanic/Black subgroups had greater excess risk of COVID-19 infection (+25%), hospitalization (+31%), ICU admission (+60%), and death (+5.5%). Excess risk per IQR increase for long-term UFP ($PM_{2.5}$) exposure was significant for COVID-19 hospitalization: +40%; 95%-CI=20.5–63.6% (+22%;18.8–25.5%), ICU admission: +44%;39.1–49.2% (+24%;18.6–30.5%), and death: +40%;38.0–42.4% (+19%;8.2–30.7%). for short-term exposures, risks for all COVID-19 outcomes were elevated (RRs range from 1.0–4.6, all $p < 0.05$) when UFP > 2000 #·cm−3 and $PM_{2.5}$ > 6.3 μg·m−3.

CONCLUSIONS: Both shorter- and long-term exposure to aerosols increased the risk of COVID-19 infection and subsequent outcomes, with ultrafine particles (UFP) exerting larger effects than $PM_{2.5}$, and with greater likelihood. The UFP and $PM_{2.5}$-associated risks were disproportionately higher for race-ethnicity minorities (particularly Hispanic and Black) and for their economically vulnerable subgroups.

KEYWORDS: COVID-19, ultrafine aerosol, particulate matter, environmental justice, socioeconomic status

P-0688 Maximum apparent temperature lowers birth weight and increase hazards of preterm birth in a constant high ambient temperature exposed population in Piura, Peru

Diego Fano-Sizgorich[1,2], Cinthya Vasquez-Velasquez[1,4], Vanessa Vasquez[1], Vilma Tapia[1], Jose Chauca[1], Victor Sernaque[3], Gustavo F. Gonzales[1,4]

[1]Laboratory of Endocrinology and Reproduction, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Centro Latinoamericano de Excelencia en Cambio Climático y Salud, Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Hospital Nacional Cayetano Heredia, Lima, Peru, [4]High Altitude Research Institute, Universidad Peruana Cayetano Heredia, Lima, Peru

BACKGROUND AND AIM: Exposure to high environmental temperature during pregnancy has been associated with lower birth weight and an increased risk of preterm birth (PTB). The province of Piura is a region with a higher environmental temperature than the rest of the country; however, it is unknown how temperature would be impacting reproductive health in populations exposed to high basal temperatures. The aim of the study is to determine the association between maximum apparent temperature (HImax) during pregnancy with birth weight and preterm birth in newborns in the province of Piura, 2011-2016.

METHOD: Semi-ecological study, where maternal-perinatal data from Santa Rosa Hospital (N=17,788); and maximum apparent temperature data were evaluated. Four exposure windows were analyzed: the entire pregnancy, and each gestational trimester, which were assigned according to date of birth and gestational age, categorized into quartiles. The association with birth weight was assessed by linear regression; and Cox regression for PTB.

RESULTS: A negative association was found between birth weight and HImax in all exposure windows, except for the first trimester, the effect being greater during the third trimester. As for preterm birth, higher HImax increased the hazard of PTB, with the highest effect seen in the P95 exposed group in every exposure window; nonetheless, the first and second trimester being the most temperature-sensitive exposure windows.

CONCLUSIONS: HImax during pregnancy is related to lower birth weight and higher PTB hazards, but with different susceptibility according to the stage of pregnancy.

KEYWORDS: Apparent Temperature, Heat Index, Birth Outcomes, Peru, Latin America

P-0689 Residential exposure to Pesticides and Cleaning Detergents with increased risk of respiratory and allergic symptoms among farmworkers in Northern Tanzania

Joseph Bukalasa[1], Rose Owisso[2], Raphael Mwezi[1]
[1]Tropical Pesticides Research Institute, Arusha, Tanzania, United Republic of, [2]Arusha District Council, Department of Health and Sokoine University of Agriculture, College of Veterinary Medicine and Biomedical Sciences, Arusha, Tanzania, United Republic of, [3]Tropical Pesticides Research Institute, Arusha, Tanzania

BACKGROUND AND AIM: It has been suggested that environmental exposures to pesticides and cleaning detergents have an increased risk of respiratory and allergic symptoms in adults. However, the evidence of residential exposure to pesticides and cleaning detergents with increased risk of respiratory and allergic symptoms among farmworkers is limited. The aim was to investigate the association of environmental exposure to pesticides and cleaning detergents with increased risk of respiratory and allergic symptoms in farmworkers.

METHODS: In this cross-sectional analysis, we included farmworkers at the ages of 18 and 48 years from Kilimanjaro and Arusha region with information on residential exposure to pesticides, cleaning detergents, cough, rhinitis, wheeze, shortness of breath, cough with phlegm and itching skin collected in 2021 (N = 389) through administered questionnaires. Logistic regression analysis was used to estimate associations between exposure and outcomes, adjusting for potential confounders.

RESULTS: Cleaning detergents was associated with an increased risk of cough among farmworkers [adjusted odds ratios (95% CI) 3.90 (1.33, 11.38)]. However, there was a reduction of risk for itching when the farmworkers use cleaning agents [adjusted odds ratios (95% CI) 0.32 (0.16, 0.67)]. We found that there were risk reduction for cough, rhinitis, wheeze, shortness of breath, cough with up phlegm, difficulty in breathing and itching skin for farmworkers who had vegetable garden at their homes [adjusted odds ratios (95% CI) 0.31 (0.18, 0.54),0.48 (0.29, 0.78), 0.14 (0.05, 0.37), 0.35 (0.13, 0.96), 0.18 (0.07, 0.44), 0.20 (0.09, 0.47), 0.49 (0.25, 0.96)].

CONCLUSIONS: The findings of this study suggest that vegetable gardens at their homes had public health concerns as it reduced the risk of respiratory and allergic symptoms among our study participants. This is an important issue for future research.

P-0696 Ambient air pollution and Carotid Intima-Media Thickness: a cross-sectional analysis from the Mexican Teachers' Cohort (MTC)

Karla Cervantes-Martínez[1], Dalia Stern[1], MSc. Rocío Torrico-Lavayen[1], Jorge Octavio Acosta-Montes[1]
[1]*World Health Organization, Cuernavaca, Mexico*

BACKGROUND AND AIM. Is well known that ambient air pollution increases the risk of cardiovascular health outcomes. Carotid Intima-Media Thickness (CIMT) is a marker of subclinical atherosclerosis and a strong predictor of both prevalent and incident cardiovascular morbidity and mortality, including coronary heart disease, myocardial infarction, and stroke. CIMT has been positively associated with air pollutants such as PM2.5 and NO2, nevertheless evidence from low- and middle-income countries is scarce. We evaluated the cross-sectional association between long-term exposure to air pollutants and mean (left and right) CIMT in a population of middle-aged women from the MTC.

METHODS: We analyzed a randomized selected clinical subsample of the MTC participants living in the Mexico City Metropolitan Area, who were measured the mean CIMT once in 2017, using a standardized protocol (n=265). Self-administered questionnaires collected information on health and sociodemographic characteristics. Ambient PM2.5 and NO2 annual averages were predicted at home and work addresses using high resolution Generalized Additive Models, which were validated using ground measurements. We fitted multiple linear regression models adjusting for potential confounders: age, diabetes, body mass index, cholesterol, triglycerides, smoking and socioeconomic status.

RESULTS: Mean CIMT among participants was 618.5 µm (±86.5 SD), while mean PM2.5 and NO2 exposure was 22.5 µg/m3 (±3.5 SD) and 22.5 ppb (±6.6 SD) respectively. After confounder adjustment, each 10-unit increment of PM2.5 and NO2 exposure was positively non-significant associated with a 12.97 µm (95% CI: -16.91, 42.86) and 12.26 µm (95% CI: -1.46, 29.97) higher CIMT, respectively. Sensitivity analyses evaluating CIMT sides shown larger effects on the left CIMT.

CONCLUSIONS: Although with limited precision, these results suggest that long-term PM2.5 and NO2 exposure is associated with subclinical atherosclerosis in an upper-middle income country women population. Small sample size may have limited the statistical power to detect the effect.

KEYWORDS: Air pollution, atherosclerosis, Carotid Intima-Media Thickness

P-0712 The association between urinary concentrations of organophosphate metabolites and asthma-related outcomes at 12-month follow-up among children from informal settlements in Western Cape, South Africa

Mohamed Aqiel Dalvie[1], Mashudu Mthethwa[1], Mohamed Jeebhay[1], Toyib Olaniyan[1]
[1]*University of Cape Town, Cape Town, South Africa*

BACKGROUND AND AIM: There is limited evidence on the relationship between pesticide exposure and child respiratory outcomes in non-agricultural settings. This study investigated the association between organophosphate pesticide (OP) exposure and child asthma-related outcomes among children from four informal settlements.

METHODS: This study was a longitudinal study of 590 schoolchildren, with a 12-month follow-up period. A standardised questionnaire adopted from the International Study of Asthma and Allergies in Childhood (ISAAC) was administered to caregivers on child's respiratory symptoms and household characteristics. Spirometry and fractional-exhaled nitric oxide (FeNO), including a phadiatop test (atopy status) and urinary concentrations of dialkyl phosphate (DAP) metabolites diethylphosphate (DEP), dimethylthiophosphate (DMTP)] were measured at baseline and follow-up. Dimethylphosphate (DMP) was measured only at baseline.

RESULTS: The mean age of schoolchildren were 9.9 ± 0.91 years and median sum DAP was 32.9 ng/ml (18.4 – 52.9 ng/ml) at baseline. Incidence proportions of new asthma outcome cases at 12-months were 2.2 % doctor diagnosed asthma, 17.8 % asthma-symptom score ≥ 2, 14.5 % forced expiratory volume 1< lower limit of normal, and 5.9 % airway inflammation across all areas. In the linear mixed and fixed effect model, no consistent patterns of increased risk of new asthma-associated outcomes at the 12-month was found. However, there was a significant increase in airway inflammation (β:2.99 (95% CI: 0.48 - 5.50) in the 3rd DEP quintile (1.9 – 3.0 ng/mL) compared to the reference quintile (1.10 ng/ml).

CONCLUSIONS: DAP concentrations were higher than those of children in other settings. However, the study did not find consistent associations between urinary concentrations of DAP metabolites and asthma related outcomes over a 12-month follow-up period among schoolchildren. Future studies with a longer follow-up period and repeated OP pesticide biomonitoring are recommended.

P-0716 Epidemiological characteristics and spatio-temporal distribution patterns of human norovirus outbreaks in China, 2012-2018

Mengying Zhai[1], Jiao Wang[1]
[1]*China CDC, Beijing, China*

BACKGROUND AND AIM: Human norovirus are the leading cause of acute viral gastroenteritis worldwide. In China, the occurrence of norovirus outbreaks in different regions shows significant heterogeneity, while few study has focused on the spatial epidemiological characteristics of norovirus outbreaks. Thus, the aim of this study is to clarify the epidemiological characteristics and spatial distribution patterns of norovirus outbreaks.

METHODS: In China, according to the National Notifiable Disease Reporting System (NNDRS), 964 human norovirus outbreaks involving 50,548 cases in 26 provinces reported from 2012 to 2018 were analyzed in this study.

RESULTS: The outbreaks showed typical seasonality, with more outbreaks in winter and fewer in summer, and the total number of infected cases increased over time. The most common setting of norovirus outbreaks was school especially middle schools and primary schools with major transmission route of life-contact. More outbreaks occurred in southeast coastal areas of China and showed significant spatial aggregation. The highly clustered areas of norovirus outbreaks have expanded towards northeast over time.

CONCLUSIONS: By identifying the epidemiological characteristics and high-risk areas of norovirus outbreaks, this study provides important scientific support for the development of preventive and control measures of norovirus outbreaks, which is conducive to the administrative management of high risk settings and reduction of disease burden in susceptible areas.

KEYWORDS: norovirus outbreak; epidemiological characteristics; spatio-temporal heterogeneity; spatio-temporal aggregation

P-0718 The Risk of CVDs from Desalinated Seawater: A Nested Case-Control Study

Shaoxia Dong[1], Juexin Shi[1]
[1]*National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND AND AIM: Desalinated water has already been incorporated into municipal water supplies as the major source of water. The aim of this paper is to assess the association between desalinated seawater and cardiovascular diseases (CVDs).

METHODS: We conducted a nested case-control prospective study on a cohort of 7,806 subjects who live on an island of China that lacks fresh water. From this cohort, we identified 140 paired CVD cases and matched controls by sex and age during the same period. Questionnaires were used in order to investigate basic sociodemographic information and risk factors for CVDs, and urine samples were collected to measure calcium and magnesium levels. Using these data we developed and tested both univariate and multivariate logistic regression models.

RESULTS: We observed no significant differences in urinary calcium and magnesium levels between groups with and without directly desalinated seawater intake. From multivariate logistic regression, we found that obesity (OR= 5.38, 95% CI: 1.05 - 27.45), physical activity (OR= 0.35, 95% CI: 0.16 - 0.75), hypertension (OR= 3.61, 95% CI: 1.58 - 8.25), alcohol consumption (OR= 2.57, 95% CI: 1.02 - 6.47), and irritability (OR= 4.30, 95% CI: 1.93 - 9.60) were associated with an increased risk of CVD.

CONCLUSIONS: In this population, we found no association between desalinated seawater intake and CVDs; the incidence of CVDs was primarily related to lifestyle.

KEYWORDS: desalination, cardiovascular disease, incidence

P-0719 Socio-demographic heterogeneities govern the spatial dynamics of water and food-borne infections in the urban city of Ahmedabad, India

Ayushi Sharma[1], Bhavin Solanki[2], Veena Iyer[3], Ayushi Sharma[1]
[1]Chung Yuan Christian University, 200 Chung-Pei Road, 320, Zhongli, Taiwan, [2]Ahmedabad Municipal Corporation, Ahmedabad, India, [3]Indian Institute of Public Health Gandhinagar (IIPHG), Public Health Foundation of India (PHFI), Near Lekwada Bus Stop, Opp. Air force station, Gandhinagar, India

BACKGROUND AND AIM: Urban areas of low and middle-income countries (LMICs) are conducive to inequality, environmental hazards, and infectious diseases due to a confluence of unique and complex risk factors such as in-migration and informal settlements. Therefore, this study aims to evaluate socio-demographic heterogeneities as determinants of water and food-borne infections in an urban city of Ahmedabad, India.
METHOD: Spatial disease dynamics of viral hepatitis, typhoid, and diarrhea in Ahmedabad from 2010 to 2017 were analyzed with socio-demographic risk factors of age/gender, slum population density, and illiteracy rates. Additionally, the administrative units' geographical distance was also considered, i.e., wards vicinity from the river. The association was delineated by spatial regression models of Ordinary Least Square (OLS) and Spatial Lag Regression (SLR).

RESULTS: A total of 97,171 cases from 2010 to 2017 were reported of viral hepatitis, typhoid, and diarrhea. Temporal trend analysis identified a rising trend of cases over the study period. Further, spatial autocorrelation analysis revealed a significant positive correlation with Moran's I statistics ranging from 0.09 for typhoid to 0.21 for diarrhea, i.e., a similar prevalence in nearby wards. The multivariate regression model revealed slum population density as a significant risk factor for all three diseases. Illiteracy rate and vicinity to the river also significantly contribute to the prevalence of viral hepatitis. Finally, excess risk mapping of diseases identified central and southern zones of the city, to the east of river Sabarmati as hotspots wards.

CONCLUSIONS: This study identified spatial disease dynamics of water and food-borne infections in Ahmedabad with hotspot wards that can be relevant from a public health perspective. The study recommends advocating rehabilitation, capacity building, and health system strengthening at sub-ward/ward levels through micro-planning to reduce the risk of diseases arising from spatial heterogeneities.

P-0720 Factors underlying urinary arsenic levels in a population residing close to a coastal heavy-industrial area in southern Taiwan

Acharee Kaewlaoyoong[1], Shih-Ting Huang[1,2], Chao-Hung Kuo[3,4], Chih-Hsing Hung[1,5,6], Szu-Chia Chen[1,3,7], Assist. Chia-Fang Wu[1,8], Wen-Yi Lin[1,9], Ming-tsang Wu[1,2,10,11]

[1]Research Center for Environmental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, [2]Graduate Institute of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, [3]Department of Internal Medicine, Kaohsiung Municipal Siaogang Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [4]Faculty of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, [5]Department of Pediatrics, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [6]Department of Pediatrics, Kaohsiung Municipal Siaogang Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [7]Department of Internal Medicine, Division of Nephrology, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [8]International Master Program of Translational Medicine, National United University, Miaoli, Taiwan, [9]Health Management and Occupational Safety Health Center, Kaohsiung Municipal Siaogang Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [10]Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [11]Department of Public Health, College of Health Sciences, Kaohsiung Medical University, Kaohsiung, Taiwan

The public in the southwestern Taiwan's Kaohsiung City expressed concern over risk of arsenic (As) to people living in six of that city's townships nearby a coastal area with heavy industry. To investigate, we first analyzed urinary total As levels in 539 subjects administered Taiwan's Nutrition and Health Survey, a nationwide survey of nutritional status 2005-2008 (NAHSIT 2005-8). We found the top three highest median urinary total As levels in residents from Penghu island (136.93 μg/L, n = 24), the upper northern region of Taiwan (78.54 μg/L, n = 69), and the southwestern region of Taiwan (71.87 μg/L, n = 36). We then measured total urinary As levels in 1,801 and 1,927 voluntary residents of the above-mentioned six townships in 2016 and 2018, respectively, and compared with those with people residing in the top three highest total As levels of NAHSIT 2005-8. Median urinary As levels were 84.6 μg/L in 2016 and 72.5 μg/L in 2018, similar to those in southwestern region of Taiwan, but far below those in Penghu island ($p < 0.05$). Finally, in 2020, we interviewed 116 healthy and voluntary residents from the same six townships and collected one-spot urine samples to analyze total inorganic-related As (TiAs), a summation of As3+, As5+, monomethylarsonic acid (MMA), and dimethylarsinic acid (DMA). Median urinary TiAs in participants consuming seafood two days before urine sampling (n=15) was 24.0 μg/L, significantly higher than those not consuming seafood then (median: 20.5 μg/L, n=101, $p=0.029$). The results remained significant after adjusting for other covariates ($p = 0.028$). These findings suggest that seafood consumption is probably the main source of urinary total As and TiAs in people residing close to that coastal heavy industrial area of southern Taiwan. A future intervention study (dietary control) could be conducted to re-confirm our findings.

P-0726 Determinants of carbon load in airway macrophages in pregnant women

Mohammad Miri[1], Lucia Alonso[2,3,4], Cathryn Tonne[2,3,4], Xavier Basagaña[2,3,4], Mark J. Nieuwenhuijsen[2,3,4], Jordi Sunyer[2,3,4], Tim S Nawrot[5,6], Payam Dadvand[2,3,4]

[1]Sabzevar University of Medical Sciences, Sabzevar, Islamic Republic of Iran, [2]ISGlobal, Barcelona, Spain, [3]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [4]CIBER Epidemiología y Salud Pública (CIBERESP), Spain, [5]Centre for Environmental Sciences, Hasselt University, Belgium, [6]Centre for Environmental Sciences, Hasselt University, Hasselt, Belgium

BACKGROUND AND AIM: The airway macrophages carbon loading (AMCL) has been suggested to be a biomarker of the long-term exposure to air pollution; however, to date no study has characterized AMCL for the pregnancy period. Therefore, this study aimed to assess the determinants of AMCL during pregnancy in Iran, a middle-income country.

METHODS: This study was based on a sample of 234 pregnant women with term and normal vaginal delivery who were residing in Sabzevar, Iran (2019). Image analysis was applied to calculate the carbon area (µm2) in airway macrophages as an indicator of AMCL. Measuring the AMCL was performed by two independent investigators and checked by third investigator to reduce the AMCL measurement bias. We characterized 35 potential determinants of personal exposure to air pollution for each participant, including six personal, nine indoor, and 20 home-outdoor factors. We applied Deletion/Substitution/Addition algorithm to identify the most relevant determinants that could predict AMCL levels.

RESULTS: The median (IQR) of AMCL level was 0.12 (0.30) µm2 with a successful sputum induction in 82.9% (194) of participants. Ambient residential PM2.5 levels were positively associated with higher AMCL levels. On the other hand, increased residential distance to the traffic lights, squares and ring-roads, the duration of opening window per day, and opening window during cooking were inversely associated with AMCL levels.

CONCLUSIONS: This study is the first to characterize AMCL during pregnancy. Moreover, this is one of the largest reported studies on characterization of AMCL levels. Furthermore, this is the first study to explore the personal, indoor and outdoor determinates of personal exposure to air pollution in pregnant women in an LMIC. Our findings provide novel insights on the different personal, indoor, and outdoor determinants of personal exposure to air pollution during pregnancy in a middle-income country.

KEYWORDS: Air pollution, Pregnancy, Biomarker, Lung

P-0727 Association of Traffic-Related Air Pollution with Newborn's Anthropometric Indexes at Birth

Mohammad Miri[1], Vahideh MoghaddamHosseini[1]
[1]*Sabzevar University of Medical Sciences, Sabzevar, Islamic Republic of Iran*

BACKGROUND AND AIM: The evidence suggested many adverse health effects due to exposure to traffic-related air pollution (TRAP). However, the evidence on neonatal anthropometric measurements (NAPM) in low and middle-income countries is very scarce yet. Therefore, we investigate the association of prenatal exposure to indicators of traffic and ambient particulate matter (PM) with NAPM.

METHODS: This cross-sectional study was based on hospital medical records of 4053 mother-neonate pairs (2016-2018). Pwere estimated at residential addresses based on validated spatiotemporal models. Moreover, total street length in 100, 300 and 500m buffers around the home, residential distance to the ring road, major roads, heavy-traffic lights, gas station, motorway junction, bank, square, bus terminal, public parking and industrial land-use were calculated as indicators of traffic. The head circumference (HC), birth weight (BW) and birth length (BL) of neonates were collected as NAPM. Multivariate regression models were applied to evaluate the relationship between PMs and indicators of traffic with NAPM, controlled for relevant covariates.

RESULTS: The adjusted models revealed that higher exposure to PM2.5 and PM10 was significantly related with lower BW and BL. Similarity results were observed for total street length in a 100 m buffer around maternal home with BW and BL. Moreover, higher distance to heavy traffic lights was significantly associated with higher BW and BL. An IQR increase in PM10 was significantly related to lower HC (95% CI: -0.11, -0.01, P-value = 0.03). An increase in distance from residential address to heavy traffic lights, ring roads, bus terminal, and transportation land-use was associated with higher HC.

CONCLUSIONS: This is the first study on the association of prenatal exposure to ambient PMs and different indicators of traffic with NAPM. Overall, our findings suggested that higher prenatal exposure to TRAP was related with lower BW, BL and HC.

BACKGROUND: Health is inextricably linked to, among various lifestyle factors, physical activity. However, countries in the Caribbean are understudied relative to other nations in North America, Europe and Asia regarding probes of potential associations between well-being and physical activity.
AIM: Our pilot study aimed to investigate physical activity in the Caribbean.

METHODS: We survey Caribbean ages 18 to 75 from 2016 to 2022. Analyses included descriptive statistics and logistic regression.

RESULTS: Among 272 survey respondents including a 10-member fitness tracker focus (FTF) group, approximately 53.0% reported not having diagnoses or symptoms of any illnesses. The most popular activities that persons engaged in were dancing (34.9%), football (27.6%), track and field (26.1%) and walking (38.2%). at least one hour was spent per week exercising (70.2%) and socializing (83%). The most popular recreational event types were related to carnival festivities (46.2%) and concerts (26.7%). Persons who participated in carnival were less likely to report recent maladies relative to non-participants (OR: 0.57; 95%CI: 0.35, 0.92). FTF group members report greater activity when supported by peers. FTF "revelers" (carnival participants) logged up to ten times more steps on carnival event days than non-event days. The top three barriers to being consistent in physical activity were lack of time (72.1%), lack of motivation (58.1%) and access to workout facilities (27.2%). While persons 30 and over were less likely than persons under 30 to be perceive facility access as an obstacle (OR: 0.45, 95%CI: 0.26, 0.78), persons under 30 were more likely to report insufficient time as a challenge to being more active relative to their older counterparts (OR: 1.84; 95%CI: 1.08, 3.17).

RESULTS: Findings proffer insight into the unique ways in which Caribbean peoples pursue and participate in various forms of physical activity with potential health benefits, partially mediated by peer support and fitness technology.

P-0732 NutriBodEC: A Cross-sectional Survey on Nutrition and Body Image in the Eastern Caribbean

Steve Whittaker[1,2], Mx. Cyndi Joseph[1,2], Phibi Joseph[2], LaBiska Prince[3]
[1]Clarence Fitzroy Bryant College, Basseterre, Saint Kitts and Nevis, [2]Science, Technology, Research and Work Study (STRaWs), [3]Holistic Education, Research and Conservation (HERC), Saint Kitts and Nevis

BACKGROUND: Body image dissatisfaction often driven by experiences as well as exposure to “unrealistic” body images through various visual media, has been linked to individual health.
AIM: Our pilot study intended to assess perceptions of body image and links to various lifestyle factors including diet.

METHODS: We surveyed 115 persons, ages 17 to 65, between 2018 and 2022 in the Eastern Caribbean country of St. Kitts and Nevis. Logistic analyses were applied.

RESULTS: Less than 20% of participants regarded their diet as "healthy". Neither food type nor portion sizes were significantly associated with weight, body types or perceptions of self. However, respondents with higher BMI (>25 kg/m2) were more likely (OR: 3.64; 95%CI: 1.63, 8.60) to eat larger portions of fish than those with lower BMI. The most desirable body types were (i) for women: hourglass (wide bust, narrow waist, with wide hips) and triangle (wide hips) and (ii) for men: inverted triangle (broad shoulders with small waist) and trapezium (broad shoulders with medium waist). Median complexions were higher ranked than extremes. While most respondents did not rate body types similar to their own as highly desirable, persons tended to rank complexion at least somewhat similar to their own more favorably. Male respondents were less likely to have negative thoughts about their appearance (OR: 0.41; 95%CI: 0.17, 0.94). Persons with BMI>25 kg/m2 were marginally more likely to be dissatisfied with taking selfies (OR: 2.84; 95%CI: 0.90, 10.91) than participants with lower BMI. Students, many of whom had to wear tailored uniforms to school, had a higher likelihood of anxiety (OR: 3.19; 95%CI: 1.10, 11.62) around their appearance relative to their non-academic counterparts.

CONCLUSIONS: Findings contribute to existing literature on perceptions of body image, while providing profiles of diet, body image satisfaction and health in an overlooked population

P-0744 Household fuel choices and the risks of cooking-related burns in Ghana

Courage` Gidglo, Ann Brettah Cudjoe, Reginald Quansah[1]
[1]*School of Public Health, University of Ghana, Accra, Ghana*

BACKGROUND AND AIM: Cooking-related burns are a major public health concern in developing countries. Women and children are extremely vulnerable to burns at home. This study aimed to assess the determinants of household fuel choices and the risk of cooking-related burns among two riparian peri-urban communities along the Lower River Volta of Ghana.

METHODS: This cross-sectional study was conducted as part of a baseline assessment of an ongoing Invasive Aquatic Weeds Biomass Briquette Production for use as a Cooking Fuel project (AQUAWEB). The AQUAWEB is a cluster randomized control trial involving 400 households in intervention and control riparian communities (1:1) along the Lower Volta Lake in Ghana. In-person interviews guided by structured questionnaires hosted on the REDCap application served as the primary data source for the study. Chi-square tests and Logistic Regression tests were employed to analyze the data.

RESULTS: The majority of the households depended largely on charcoal (64.99%) and less on wood fuel (15.12%) and LPG (19.89%) as their primary cooking fuel. of the LPG users, 53.7% used LPG exclusively, whereas 3.3% and 43.3% used wood fuel and charcoal as secondary fuels respectively. Among charcoal users, 57% used it exclusively but 11% and 31.8% used wood fuel and LPG as their secondary fuel respectively. Among the primary users of wood fuel, 75% used it exclusively. But 23.6% and 1.3% used charcoal and LPG as their secondary fuel respectively. 68.5% of the adult population in households suffered any household air pollution cooking-related burns. Charcoal (OR=2.15, p-value = 0.004) and wood fuel (OR=1.98, p-value = 0.038) were associated with cooking-related burns.

CONCLUSIONS: Charcoal is predominantly used in riparian communities as a primary fuel. Wood fuel and LPG were also used to support the primary fuel. Charcoal and wood fuel is associated with cooking-related burns.

P-0745 Urinary pesticide residual levels and acute respiratory infections in children under five years of age: Findings from the Offinso North Farm Health Study

Reginald Quansah[1]
[1]*School of Public Health, University of Ghana, Accra, Ghana*

BACKGROUND: Several environmental factors are associated with the risk of acute lower respiratory infections (ALRIs) and upper respiratory infections (URIs) in children under five years of age (YOA). Evidence implicating chemical pesticides remains equivocal. There are also no data on this subject in these children in Ghana. This study investigated the association between urinary pesticide residual levels and the risk of ALRIs/URIs in children under five YOA .

METHODS: The participants for this study were from the Offinso North Farm Health Study, a population-based cross-sectional study. 254 parents/guardians who had answered affirmatively to the question "Has your child ever accompanied you to the farm?" were interviewed on household socio-demographic and environmental factors, being breastfed, child education, age, gender, and respiratory infection. 150 children were randomly selected to provide the first void urine.

RESULTS: The proportion of children with ALRI was 22.1% and those with Upper Respiratory Infection (URI) were 35.8%. We observed a statistically significant exposure-response relation of p,p'-DDE (tertile) with ALRI [1.7-3.2 µg/L urine: prevalence ratio (PR)=1.22 (1.05-1.70), ≥ 3.2 µg/L urine: 1.50 (1.07-3.53) (p-for trend=0.0297)]. This observation was observed in children older than 2 YOA (p-for trend=0.0404). Delta-HCH and beta-HCH (2-levels) were significantly associated with ALRI but not URI. The risk of ALRI increased with deltamethrin levels in an exposure-response manner [2.5-9.5 µg/L urine: 2.10 (1.37-3.24), ≥ 9.5 µg/L urine: 4.38 (1.87-10.32) (p-for trend=0.0011) and this was also observed in older than 2 YOA. Similar observation was noted for URI. Bifenthrin (>0.5µg/L urine) was associated with ALRI and URI. But permethrin (≥1.2 µg/L urine) was associated with URI.

CONCLUSIONS: The present study reinforces the hypothesis that exposure to chemical pesticides is associated with respiratory infections in children under five YOA.

P-0746 Differential impact of environment on malaria due to control interventions in Uganda, 2010-2018

Margaux Sadoine[1,2], Dre Audrey Smargiassi[1,2], Dre Ying Liu[1,2], Philippe Gachon[3], Guillaume Dueymes[3], Jane Frances Namuganga[4], Grant Dorsey[5], Michel Fournier[6], Dre Bouchra Nasri[1,2], Dre Kate Zinszer[1,2]

[1]School of Public Health of Montreal University, Montréal, Canada, [2]Centre de recherche en santé publique (CReSP), Montréal, Canada, [3]Étude et Simulation du Climat à l'Échelle Régionale, Montréal, Canada, [4]Infectious Diseases Research Collaboration, Kampala, Uganda, [5]University of California San Francisco, San Fransisco, USA, [6]Montreal Regional Department of Public Health, Montréal, Canada

BACKGROUND AND AIM: Studies have estimated the impact of environment on malaria incidence although few have explored the differential impact due to vector control interventions. We aimed to evaluate the influence of temperature, rainfall, humidity, and vegetation, in presence or absence of long-lasting insecticide treated bednets (LLIN) and indoor residual spraying (IRS).

METHODS: This study used weekly malaria cases from 2010 to 2018 from six health facility-based malaria surveillance in Uganda. Environmental variables were extracted from remote sensing sources and include enhanced vegetation index (MODIS), cumulative rainfall (ARC2), minimum and maximum temperature (ERA5), specific humidity (ERA5), averaged over different time periods (one to four months). Non-linearity of environmental variables was investigated, and general linear models based on a negative binomial distribution was used to explore the influence of ITN and LLIN on the malaria-environment relationship.

RESULTS: A total of 204,252 malaria cases were laboratory confirmed and the median (range) weekly cases was 58.0 (0-597), rainfall 18.6 mm (0-129), minimum temperature 17.6˚C (12.3-24.2), maximum temperature 26.7˚C (20.1-34.8), and humidity 0.014 kg.kg (0.006-0.018). The best fit model was with the meteorological measures averaged over 3 months. All environmental variables showed a relatively linear pattern. Both IRS and LLIN were significantly associated with risk reduction (IRR: 0.39, 95% CI: 0.36–0.42 ; IRR: 0.71, 95% CI: 0.67–0.75, respectively). Marginal effects of environmental variables showed that joint effect of IRS and LLIN reduced the weekly predicted counts of malaria by 72.5% compared to no intervention.
CONCLUSION: LLIN and IRS both reduced the influence of environmental drivers of malaria and therefore morbidity in various transmission setting in Uganda. The benefits appeared to be greatest when the two interventions are used in combination.

P-0751 Personal exposure to heat amongst older adult women in Tamil Nadu, India

Aniruddha Deshpande[1], Noah Scovronick[2], Ajay Pillarisetti[3], Kalpana Balakrishnan[4], Vigneswari Aravinth[4], Thomas Clasen[2], Jennifer Peel[5]

[1]Department of Epidemiology, Emory University, Atlanta, USA, [2]Gangarosa Department of Environmental Health, Emory University, Atlanta, USA, [3]Department of Environmental Health Sciences, University of California, Berkeley, Berkeley, USA, [4]Department of Environmental Health Engineering, ICMR Center for Advanced Research on Air Quality, Climate and Health, Sri Ramachandra Institute for Higher Education and Research (Deemed University), Chennai, India, [5]Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, USA

BACKGROUND AND AIM: In 2019, 127,000 deaths were attributed to heat exposure globally, with over 40% in India, where a substantial portion of the population has limited access to cooling technologies. This substantial burden is expected to worsen with climate change, but little is known about personal exposure to outdoor temperatures in India We leverage data collected as part of the Household Air Pollution Intervention Network (HAPIN) randomized controlled trial to describe personal temperature exposure of older adult women in Tamil Nadu. We compare personal exposure to ambient monitoring stations and modelled temperature products.

METHODS: As part of HAPIN, older adult women in Tamil Nadu periodically wore instrumentation for a 24-hr period to measure air pollution; these instruments also measure temperature. We analyzed temperature measurements taken between 2018 and 2021 and compared them to the nearest identified ambient monitoring stations, and to the ERA5 and GLDAS meteorological products.

RESULTS: Personal measurements were recorded from 105 different participants for a total of 1.7 million datapoints. The mean temperature recorded was 28.6 °C with a standard deviation of 3.5 °C. Differences of ≥5 °C across individuals on the same day were not uncommon, nor were intra-individual exposures that varied by several degrees within an hour -- potentially a result of elevated heat while cooking. ERA5 estimates were more positively correlated with personal exposure than with GLDAS or ambient monitors. Correlations varied by season, with best performance across all products during the monsoon season.

CONCLUSIONS: Accurate exposure assessment is important for assessing health effects of heat – a growing problem. There is substantial variability in how well public datasets correlate with personal experience, not only by product type but also location and season. It is important to quantify these differences to appropriately estimate health effects.

P-0762 Health outcomes in redlined versus non-redlined neighborhoods: A systematic review and meta-analysis

Eun Kyung Lee[1], Gwendonlyn Donley[2], Timothy Ciesielski[2], India Gill[2], Owusua Yamoah[2], Abigail Roche[2], Roberto Martinez[2], Darcy Freedman[2]
[1]Boston University School of Public Health, Boston, USA, [2]Case Western Reserve University, Cleveland, USA

BACKGROUND AND AIM: Redlining was a racialized zoning practice in the U.S. that blocked fair access to home loans during the 1930s, and recent research is illuminating health problems in the current residents of these historically redlined areas. However, this work has not yet been holistically summarized. Here, we present the first systematic review and meta-analysis comparing health outcomes in redlined versus non-redlined neighborhoods in U.S. cities.

METHODS: We extracted relevant articles in PubMed, Web of Science, Cochrane and Science Direct databases published from January 2010 to September 2021.

RESULTS: The search revealed 12 studies on preterm births (n=3), gunshot-related injuries (n=2), cancer (n=1), asthma (n=1), self-rated health (n=1), multiple health outcomes (n = 2), heat-related outcomes (n=1) and COVID-19 incidence and mortality (n=1). A meta-analysis of three studies found the odds of having preterm birth was significantly higher (OR=1.41, 95% CI: 1.05-1.88; p=0.02) among women living in redlined areas compared to those in non-redlined areas. Review of other outcomes revealed that gunshot-related injuries, asthma, heat-related outcomes, and multiple chronic conditions were worse in redlined areas, while associations with cancer varied by cancer type. In terms of cause-specific mortality, one study revealed no link between residential redlining and infant mortality rate, while one study on COVID-19 outcomes was inconclusive.

CONCLUSIONS: Overall, this review presents evidence that living in historically redlined areas is associated with increased risk of multiple serious adverse health outcomes. Further research on mechanisms, remediation, and neighborhood-level interventions is needed to strengthen the understanding of the impacts of redlining on health.

P-0764 Identifying susceptibility factors for methylmercury-induced developmental neurotoxicity

Bita Khoshhal[1,2], Leonid Kopylev[2], Alexandra Larsen[2], Rebecca Nachman[2], Onyemaechi Nweke[2], Elizabeth G. Radke[2], Deborah Segal[2]

[1]George Mason University, Fairfax, USA, [2]USA Environmental Protection Agency, Washington, USA

BACKGROUND AND AIM: Methylmercury (MeHg) exposures during pregnancy or childhood can cause developmental neurotoxicity (DNT), including cognitive, behavioral, and other effects. While many studies have reported on these effects, fewer have examined other factors that contribute to susceptibility to MeHg-induced DNT. The first objective of this project is to determine whether there are demographic, biological, psychosocial, societal, environmental, or other factors that may make developmentally exposed individuals more susceptible to these effects. A second objective is to develop a replicable approach for identifying susceptibility data in assessments of the health effects of chemicals.

METHODS: A systematic literature search for 2019-2021 aimed to identify all epidemiology studies that examined methylmercury exposure and DNT. Identified studies were then screened for susceptibility information at the title/abstract and full text levels by two reviewers. A search string was also developed and applied to title/abstracts to determine whether these studies could be identified without extensive screening. Susceptibility information was then summarized.

RESULTS: Data examining several potential susceptibility factors for MeHg were identified, including genetic polymorphisms, sex, maternal factors, nutritional status, and multi-chemical exposures.

CONCLUSIONS: This project identifies potential susceptibility factors associated with MeHg and DNT. The methods applied to MeHg may be adapted and utilized for identifying and interpreting the literature on susceptibility factors for adverse health effects from other chemical exposures.

KEYWORDS: methylmercury, developmental neurotoxicity, susceptibility, systematic review, environmental justice

P-0769 Association between historical redlining and preterm birth in North Carolina, 2003-2015

Adrien Wilkie[1], Monica Jimenez[1], Christine Grey[2], Wei-Lun Tsai[3], Alison Krajewski[3], Kristen Rappazzo[3], Thomas Luben[3]

[1]Oak Ridge Institute for Science and Education (ORISE) Postdoctoral Fellow at US EPA, Research Triangle Park, USA, [2]Duke Global Health Institute, Duke University, Durham, USA, [3]US Environmental Protection Agency, Center for Public Health and Environmental Assessment, Research Triangle Park, USA

BACKGROUND AND AIM: Starting mid-1930s, the Home Owners' Loan Corporation (HOLC) ranked urban neighborhoods as least to most desirable in terms of perceived mortgage stability. This racist practice, redlining, likely led to disparities in proximity to environmental pollutants in these areas. Recent research suggests associations between historical redlining and adverse birth outcomes today. We investigated the association between historical redlining and preterm birth (PTB, <37 weeks gestation) in North Carolina (NC) and evaluated modification of that association by gestational parent (GP) race/ethnicity.

METHODS: We assembled a retrospective, administrative cohort of singleton births in NC from 2003-2015, linking geocoded residences at time of delivery to Mapping Inequality's HOLC polygons. Eligible births were assigned HOLC grade A (Best), B (Still desirable), C (Declining), or D (Hazardous). We estimated odds ratios (OR (95%CI)) using logistic regression adjusting for GP age at delivery and smoking during gestation, and applying generalized estimating equations to account for clustering by city.

RESULTS: Our analysis included 36,571 births within historically redlined cities in NC (Asheville, Charlotte, Durham, Greensboro, Winston-Salem). for births within the historically defined HOLC grades B, C, and D, respectively, the odds of PTB were 1.43 (95%CI: 1.10, 1.86), 1.77 (1.50, 2.09), and 2.10 (1.79, 2.48) compared to HOLC grade A. In stratified analyses, ORs were null and imprecise for all HOLC grades compared to HOLC grade A among non-Hispanic Black individuals (e.g. D vs A: 1.01 (0.60, 1.72)). ORs were positive but similarly imprecise among Hispanic and non-Hispanic white individuals with ORs that ranged from 1.61 (0.57, 4.54) to 1.70 (0.74, 3.93) and 1.20 (0.96, 1.50) to 1.27 (0.97, 1.67), respectively.

CONCLUSIONS: These preliminary results suggest that historical redlining is associated with poorer PTB outcomes decades later, providing additional evidence that historically racist practices continue to have lasting negative environmental burdens and health impacts on communities today.

P-0772 Quantifying sociodemographic inequities in exposure to point source carcinogenic industrial pollution emissions across the USA

Jessica Madrigal[1], Abigail Flory[2], Jared Fisher[1], Danielle Duarte[1], Mary Ward[1], Rena Jones[1]
[1]Occupational and Environmental Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, USA, [2]Westat, Inc., Rockville, USA

BACKGROUND AND AIM: Few studies have investigated how carcinogenic environmental exposures are distributed among the general population. We described recent cross-sectional relationships between carcinogenic industrial emissions and sociodemographic characteristics across the USA (US).

METHODS: We linked US Environmental Protection Agency's 2018 Toxics Release Inventory to sociodemographic characteristics in 2010 Census tracts. Using chemical abstract service registry numbers, we identified onsite emissions (e.g., air, landfill, surface) of known and probable carcinogens as classified by the International Agency for Research on Cancer. Tract characteristics included total population, median household income, Yost neighborhood deprivation index, poverty, and percentages of Black, Hispanic, and white populations. We used linear regression to investigate the relation between quintiles of emissions in each census tract and distributions of these characteristics.

RESULTS: 5,209 (7%) tracts with an estimated 23.2 million population contained 7,028 facilities emitting known (n=22) or probable (n=33) carcinogens, including 1 billion pounds of these emissions in total (median: 226; IQR 7-5970 pounds/tract). Compared to tracts without emissions (all p-values <0.01), those with the highest quintile of emissions had higher proportions of rural (44% vs. 19%) and white (71% vs. 62%) populations, lower median household income ($45,000 vs. $55,000), and a higher deprivation score (62 vs. 49). Tracts with the highest emissions had a higher proportion of population with a high school education or less (53% vs. 44%). Overall, the proportions of families below the poverty level did not differ; however, greater numbers of black and white families below poverty lived in the tracts with the highest emissions. We observed similar demographic patterns in analyses restricted to air emissions.

CONCLUSIONS: Our novel assessment demonstrates that carcinogenic emissions are not homogeneously distributed among the US population. It may be important to consider joint distributions of sociodemographic characteristics when describing environmental exposures and associated health disparities.

KEYWORDS: carcinogens, health disparities

P-0786 Quantification of green and walkable neighbourhoods across the distribution of social and material deprivation in Metro Vancouver, Canada

Katherine White[1], Kate Weinberger[1], Connor Wolff[2], Trevor Dummer[1], Lawrence Frank[3]
[1]School of Population and Public Health, University of British Columbia, Vancouver, Canada, [2]School of Community and Regional Planning, University of British Columbia, Vancouver, Canada, [3]Urban Studies and Planning, University of California San Diego, San Diego, USA

BACKGROUND AND AIM: Along with other environmental exposures, both neighbourhood walkability, and greenspace exposure and access have been linked to many diverse health benefits. Previous work has examined the spatial relationship of built and natural environments according to levels of neighbourhood deprivation; however, less is known about how these relationships may vary when different greenspace metrics are used. This work examines how normalized differences vegetation index (NDVI), tree canopy cover, green land cover, and park count metrics relate to walkability, and how these neighbourhood characteristics associate with both social and material deprivation.

METHODS: Greenspace exposure was measured using NDVI, tree canopy cover, and green land cover, while park access was quantified by the number of designated public parks within 1000m and 400m network buffers for each six-digit postal-code centroid in Metro Vancouver, Canada. Local area deprivation was measured using the 2016 Material and Social Deprivation Index (MSDI). Pearson's correlation coefficients were calculated to compare these neighbourhood characteristics.

RESULTS: Walkability was positively associated with social deprivation (1000m $r = 0.48$; 400m $r = 0.48$, $p < .01$), while walkability has a weak inverse relationship with material deprivation (1000m $r = -0.21$, $p < .01$). Tree canopy was negatively related to both social (1000m $r = -0.23$, 400m $r = -0.23$, $p < .01$) and material deprivation (1000m $r = -0.24$, 400m $r = -0.23$, $p < .01$). In contrast, the relationship between park count and both deprivation measures was weak.

CONCLUSIONS: In this study, areas with greater social and material deprivation tend to have less greenspace, but not necessarily less park access. The identification of neighbourhoods with higher material deprivation, low walkability, and low greenspace, may be prioritized by urban planners and decision makers as possible locations for additional greenspace allocation.

KEYWORDS: greenspace, walkability, social deprivation, material deprivation

P-0794 Disparities in adverse birth outcomes attributable to elevated ambient air pollution in the U.S.

Laura Gladson[1,2], Julia Gohlke[3], Kevin Cromar[1,2]
[1]Marron Institute of Urban Management, New York University, Brooklyn, USA, [2]New York University Grossman School of Medicine, New York, USA, [3]Environmental Defense Fund, Washingon, USA

BACKGROUND AND AIM: Preterm birth and low birth weight are global health challenges that increase a child's lifelong risk for chronic disease. These adverse birth outcomes (ABO) are associated with ambient air pollution with differential risks across socioeconomic groups, yet are not presently accounted for in environmental policy assessments. This study estimates annual counts of ABO associated with $PM_{2.5}$ exceeding American Thoracic Society (ATS) recommended standards and investigates relevant disparities by race and income.

METHODS: Pollution increments of annual $PM_{2.5}$ were calculated for all monitored U.S. counties by comparing 2018-2020 EPA design values to counterfactuals meeting ATS recommended levels (8 μg/m³ for annual and 25 μg/m³ for 24-hour $PM_{2.5}$). Increments were coupled with current concentration-response functions and CDC baseline incidence data to determine county-level annual numbers of ABO associated with $PM_{2.5}$ above counterfactual levels. Sub-group analyses by mother's race and source of delivery payment were conducted to determine exposure differentials.

RESULTS: Across monitored U.S. counties, approximately 7,300 (95% CI: 3,700–11,500) preterm and 5,200 (95% CI: 3,300–7,500) low weight births are associated with $PM_{2.5}$ levels above ATS recommendations. $PM_{2.5}$-related ABO rates were higher among Black vs. White mothers, driven by higher baseline incidence rates experienced by Black mothers. $PM_{2.5}$-related ABO rates were higher among Medicaid vs. non-Medicaid payees, a result of both higher $PM_{2.5}$ increments and higher baseline incidence among Medicaid payees.

CONCLUSIONS: Approximately 12,500 annual U.S. ABO can be linked to $PM_{2.5}$ above ATS recommended levels, with trends towards greater air pollution-related ABO for both Black mothers and Medicaid recipients. The magnitude of this effect, combined with lifelong health impacts attributable to these birth outcomes, provides a compelling argument that ABO should be factored into future environmental policy assessments.

P-0806 Use of gradient boosting machine for exposome-wide analyses: application for pharmaceutical risk factors for amyotrophic lateral sclerosis

Ran Rotem[1,2], Andrea Bellavia[1], Gabriel Chodick[2], Marc Weisskopf[1]
[1]Harvard TH Chan School of Public Health, Boston, USA, [2]Maccabi Healthcare Services, Tel Aviv, USA

BACKGROUND
Accumulating evidence suggests that human health is affected by a complex set of exposures, including to environmental toxicants, dietary constituents, psychosocial stressors, and physical factors. Capturing the complexity of the whole exposome is pivotal for advancing etiological knowledge, yet standard statistical methods, as well as recent developments for mixtures analysis, are limited to considering only a modest number of exposures and interactions while often also making the implicit assumption that the exposures are continuous. Machine learning approaches could offer benefits in these very high-dimensional settings.
METHOD
Using gradient boosted decision trees coupled with Bayesian model optimization and a nested cross-validation design, we describe an approach for outcome prediction based on a mixture of exposures, and for identification of specific culprit factors within the mixture that consistently drive the association while allowing for synergistic or antagonistic interactions between the predictors. While this flexible approach is applicable to many settings, we used it to evaluate the association between patients' history of medication use and risk of amyotrophic lateral sclerosis (ALS), as a steppingstone for integrating additional exposures and in a setting that largely avoids exposure measurement errors that further complicate many toxicant mixtures.

RESULTS: of nearly 800 binary predictors, we identified 7 medication classes that were consistently associated with ALS risk across independently trained models. Interactions between medication groups did not substantially affect the risk. Prediction accuracy was consistent, but low due to the lack of information on other etiological risk factors for ALS.
SUMMARY
The described methodology allows to predict the overall effect of a mixture and to identify specific culprit factors in very high dimensional settings and when both continuous and categorical exposures are of interest. While causal interpretation of purely predictive models should generally be avoided, the repeated sampling of the dataset has interesting causal inference implications.

P-0808 World Trade Center Exposome: A novel, data-driven approach to modeling risk and protective factors for adverse mental and physical health outcomes among WTC Responders

Elza Rechtman[1], Elena Colicino[1], Christopher R. Dasaro[2], Christopher J. Hahn[2], Azzurra Invernizzi[1], Susan L. Teitelbaum[1], Andrew C. Todd[1], Megan K. Horton[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]World Trade Center Health Program General Responder Data Center, Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: Responders involved in rescue and recovery efforts following the 9/11 World Trade Center (WTC) attacks were exposed to hazardous working conditions and toxic agents. Previous studies associating WTC exposure with adverse health outcomes focus on a small number of risk factors selected a priori. We proposed a data-driven, exposomic approach to investigate the mixture of risk and protective factors experienced by WTC responders (i.e., a 'WTC exposome') and its relation to responder health.

METHODS: We included 34,096 responders from the WTC Health Program (WTC-HP) with a physical and mental health evaluation and exposure assessment at first (post 9/11/01) visit. We used generalized weighted quantile sum (gWQS) regression to examine positive (i.e., risk) and negative (i.e., protective) associations between the "WTC Exposome" index containing 84 factors (i.e., dust and traumatic exposures, baseline health information, social support) and five WTC-related health outcomes as dichotomous (ever/never): post-traumatic stress disorder (PTSD), gastroesophageal reflux disease (GERD), respiratory problems, diabetes, and headaches. All models were adjusted for age, race, ethnicity, and gender.

RESULTS: The WTC exposome was associated with all five health outcomes (PTSD β_{risk} = 6.4, $\beta_{protective}$ = 0.1; GERD β_{risk} = 4.4, $\beta_{protective}$= 0.5; respiratory problems β_{risk} = 3.9, $\beta_{protective}$ = 0.6; diabetes β_{risk} = 1.6, $\beta_{protective}$ = 0.7; headaches β_{risk} = 5.6, $\beta_{protective}$ = 0.3; $p<0.0001$ for all models). The WTC exposomic profile (i.e., the mix of risk and protective factors) differed by health outcome. for example, working in an enclosed area contaminated with dust contributed most to PTSD risk while full-time employment post 9/11 appeared protective against PTSD.

CONCLUSIONS: Understanding WTC-related risk and protective factors enable us to better identify responders vulnerable to adverse outcomes and identify factors that may protect against the development or progression of disease. This approach has potential for future disaster response studies.

P-0815 Sex-specific associations between prenatal exposure to phthalates and neurocognitive development in Taiwanese children: Application of environmental mixture methods to small study sample

Juwel Rana[1,2,3], Stefano Renzetti[4], Shu-Li (Julie) Wang[5], Alexander Keil[6], Youssef Oulhote[7]
[1]North South University, Dhaka, Bangladesh, [2]McGill University, Montreal, Canada, [3]South Asian Institute for Social Transformation (SAIST), Dhaka, Bangladesh, [4]Università degli Studi di Brescia, Brescia, Italy, [5]National Institute of Environmental Health Sciences, Taipei, Taiwan, [6]National Cancer Institute, Bethesda, USA, [7]University of Massachusetts Amherst, Amherst, USA

BACKGROUND AND AIM: Few studies have examined the sex-specific effect of phthalates as a mixture by applying multiple mixture methods to a small study sample. This study, therefore, examined sex-specific associations of prenatal exposure to urinary phthalates with neurocognitive development in Taiwanese children aged two to three years old.

METHODS: The study included 127 children who were followed up at the ages two-three years in the Taiwanese Maternal and Infant Cohort Study. The Mental Development Index (MDI) and Psychomotor Development Index (MDI) were measured in children using the Bayley Scales of Infant Development-II (BSID-II). The monomethyl phthalate, monoethyl phthalate, mono-butyl phthalate (MBP), mono-benzyl phthalate, mono-2-ethylhexyl phthalate (MEHP), mono(2-ethyl-5-hydroxyhexyl) phthalate, mono (2-ethyl-5-oxohexyl) phthalate (MEOHP) were measured in urine samples collected from mothers during pregnancy. Multivariable linear regression (MLR), Weighted Quantile Sum (WQS) regression, quantile g-computation (qgcom), Bayesian Kernel Machine Regression (BKMR), the Super Learner with g-computation were applied and compared to examine the sex-specific effects of the phthalate mixture on MDI and PDI.

RESULTS: The mediation MDI and PDI were 94.0 and 99.0, respectively. The spearman correlation ranged between -0.01 and 0.74. None of these methods could detect any sex-specific associations between phthalates and MDI. Results suggest that WQS and qgcomp were able to detect inverse associations between phthalates and PDI with a stronger effect in boys. BKMR and Super Learner with g-computation were unable to detect any precise associations of phthalates with PDI. However, mixture methods detected mixtures' negative directionality and linear dose-response effects on neurocognitive development. MBP, MEHP, and MEOHP dominated these associations with PDI.

CONCLUSIONS: Mixture methods outperformed MLR. However, flexible approaches like BKMR and Super Learner with g-computation may perform better with larger samples. Therefore, the study recommends using multiple mixtures methods for getting comprehensive results from mixture studies.

P-0820 Residential greenness, air pollution, and incident ischemic heart disease: A prospective cohort study in China

Tiezheng Li[1], Zhebin Yu[1], Lisha Xu[1], Yonghao Wu[1], Luhua Yu[1], Zongming Yang[1], Menglin Tang[1], Minjuan Jin[1], Kun Chen[1], Jianbin Wang[1]
[1]*Zhejiang University, Hangzhou, China*

BACKGROUND AND AIM: Green living environments are associated with beneficial health outcomes, whereas higher air pollution exposure might increase the risk of chronic diseases. Moreover, few studies have explored the interaction between residential greenness and air pollution on the risk of ischemic heart disease (IHD). Therefore we aimed to estimate the associations of residential greenness and air pollution with IHD and their interaction.

METHODS: We performed a prospective cohort study that included 29,141 adult participants recruited from Yinzhou District, Ningbo, China. Normalized Difference Vegetation Index (NDVI) around each participant's residence was calculated to measure residential greenness exposure. Land-use regression models were conducted to estimate long-term individual exposure to air pollutants, including nitrogen dioxide (NO2) and particulate matter with aerodynamic diameters ≤ 2.5 μm (PM2.5) and ≤10 μm (PM10). Cox proportional hazard models were used to calculate the hazard ratios (HRs) and 95% confidence intervals (95% CIs) for the association of residential greenness and air pollutants with the risk of incident IHD.

RESULTS: During 101,172.5 person-years of follow-up, 1,392 incident IHD cases were reported in the study population. Residential greenness, expressed as an interquartile range (IQR) increase in NDVI within 300m, was inversely associated with incident IHD. However, long-term air pollution exposures were associated with higher IHD incidence. Mediation analyses suggested that the beneficial effect of residential greenness on incident IHD could be partly mediated by reducing the exposure to PM2.5.

CONCLUSIONS: Higher greenness was associated with decreased risk of IHD, while air pollutants were positively associated with incident IHD. Meanwhile, residential greenness may decrease the risk of IHD by reducing PM2.5 exposure.

KEYWORDS: Residential greenness; Air pollution; Ischemic heart disease; Cohort study; Effect mediation

P-0827 Solar and Geomagnetic Activity Reduces Pulmonary Function and Enhances Particulate Pollution Effects

Kritika Anand[1], Carolina L.Z. Vieira[1], Eric Garshick[2,3], Veronica Wang[1], Annelise Bloomberg[1,5], Diane R Gold[1,3], Joel Schwartz[1,3], Pantel Vokonas[4], Petros Koutrakis[1]

[1]Department of Environmental Health, Harvard T.h. Chan School of Public Health, Boston, USA, [2]Pulmonary, Allergy, Sleep, and Critical Care Medicine Section, VA Boston Healthcare System, Boston, USA, [3]Channing Division of Network Medicine, Brigham and Women's Hospital, and Harvard Medical School, Boston, USA, [4]VA Normative Aging Study, Veterans Affairs Boston Healthcare System and the Department of Medicine, Boston University School of Medicine, Boston, USA, [5]Division of Occupational and Environmental Medicine, Lund University, Lund, Sweden

BACKGROUND: Increased solar and geomagnetic activity (SGA) may alter sympathetic nervous system activity, reduce antioxidant activity, and modulate physiochemical processes that contribute to atmospheric aerosols, all which may reduce pulmonary function.
Aim: Investigate associations between forced expiratory volume at 1 second (FEV1) and forced vital capacity (FVC) with SGA, and assess whether SGA enhances adverse effects of black carbon (BC) and particulate matter ≤2.5 μm in diameter (PM2.5).

METHODS: We conducted a repeated measures analysis in 726 Normative Aging Study participants (Boston, USA) between 2000 and 2017, using interplanetary magnetic field (IMF), planetary K index (Kp), and sunspot number (SSN) as SGA measures. Linear mixed effects models were used to assess exposure moving averages up to 28 days for both SGA and pollution.

RESULTS: Increases in IMF, Kp Index and SSN from the day of the pulmonary function test averaged through day 28 of were associated with a significant decrement in FEV1 and FVC, after adjusting for potential confounders. There were greater effects for longer moving averages and enhanced effects of PM2·5 and BC on FEV1 and FVC with increased SGA. for example, for each inter-quartile increase (4.55 μg/m3) in average PM2·5 28 days before testing, low IMF (10th percentile: 3.2 nT) was associated with a -21.4 ml (95% CI:-60.8, 18.1) and -7.1 ml (95% CI:-37.7, 23·4) decrease in FVC and FEV1, respectively; high IMF (90th percentile: 9.0 nT) was associated with a -120.7 ml (95% CI:-166.5, -74.9) and -78.6 ml (95% CI: -114.3, -42·8) decrease in FVC and FEV1, respectively.

CONCLUSIONS: Increased periods of SGA may directly contribute to impaired lung function and enhance effects of PM2.5 and BC. Since exposure to solar activity is ubiquitous, stricter measures in reducing air pollution exposures are warranted, particularly in elderly populations.

KEYWORDS: Pulmonary Function, Air pollution, Solar and Geomagnetic Activity

P-0841 The urban vegetation and allergic rhinitis in Montreal, Canada

Alexandre Barris[1], Sophie Goudreau[2], Ying Liu[1,3], Naizhuo Zhao[4,5], M.D. David Kaiser[2,6,7], Audrey Smargiassi[1,3]
[1]Department of Environmental and Occupational Health, School of Public Health, University of Montreal, Montreal, Canada, [2]Montreal Department of Public Health, Montreal, Canada, [3]Centre of Public Health Research, University of Montreal and CIUSSS du Centre-Sud-de-l'Île-de-Montréal, Montreal, Canada, [4]Centre d'étude de la forêt, Département des Sciences Biologiques, Université du Québec à Montréal, Montreal, Canada, [5]Division of Clinical Epidemiology, McGill University Health Centre, Montreal, Canada, [6]Department of Epidemiology, Biostatistics and Occupational Health, Faculty of Medicine and Health Sciences, McGill University, Montreal, Canada, [7]Department of Social and Preventive Medicine, School of Public Health, University of Montreal, Montreal, Canada

BACKGROUND: Urban vegetation offers many benefits to population health and wellbeing. In addition to these benefits, trees also emit pollen that can cause allergies.
Objective: This study aimed to assess the association between urban vegetation and allergic rhinitis in the Montreal area.

METHODS: Data on spring symptoms (April, May, June) of allergic rhinitis were retrieved from the 2008 and 2014-2015 Quebec Population Health Surveys (EQSP) and population-weighted. 2015 Landsat-8 satellite images and LiDAR (Light Detection and ranging) point cloud were used to calculate, respectively, the Normalized Difference Vegetation Index (NDVI) and the average crown volume of trees. The values of these indices were classified into population quintiles. Associations between vegetation parameters and the prevalence of symptoms of allergic rhinitis were assessed with logistic regression models within buffer zones of 100, 250, 500, and 1000 meters around the respondent's six-digit residential postal codes, adjusting for sex, age and categories of income.

RESULTS: The combined sample of the two surveys totaled 6,901 respondents. The estimated prevalence of spring symptoms of allergic rhinitis in the population was 11.3% (CI95%: 10.4 – 12.2). The NDVI and average crown volume were not associated with symptoms of allergic rhinitis for any of the buffer zones. for a buffer zone of 250 meters, the adjusted odds ratio for an increase from the lowest to the highest NDVI value (Q1 and Q5) was 1.029 (CI95%: 0.764 – 1.385). The adjusted odds ratio for an increase from the lowest to the highest average crown volume value was 1.167 (CI95%: 0.878 - 1.552).

CONCLUSIONS: The results suggest that vegetation density does not have an impact on the prevalence of spring symptoms of allergic rhinitis in residents of the Montreal urban area. More detailed assessments on the associations with vegetation types are needed.

KEYWORDS: Urban vegetation, allergic rhinitis, Remote Sensing, NDVI

P-0843 Spatiotemporal exposure modeling of environmental circadian misalignment

Mimi Ton[1,2], Matthew D. Weaver[3,4], Trang VoPham[1,5]
[1]Department of Epidemiology, University of Washington, Seattle, USA, [2]Cancer Prevention Program, Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, USA, [3]Division of Sleep and Circadian Disorders, Departments of Medicine and Neurology, Brigham and Women's Hospital, Boston, USA, [4]Division of Sleep Medicine, Harvard Medical School, Boston, USA, [5]Epidemiology Program, Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, USA

BACKGROUND AND AIM: Light exposure is the most powerful resetting signal for circadian rhythms. Environmental circadian misalignment (ECM) occurs from geographic variation in light exposure due to location within a time zone (delayed circadian phase from less morning and greater evening light exposure moving west in a time zone). The aim of this study was to develop and validate the first-ever nationwide spatiotemporal exposure model of ECM in the US.

METHODS: for all US census tracts, the ECM exposure model incorporated elevation (in meters) and the average difference (in minutes) in sunrise time and sunset time between the census tract center of population and the eastern-most time zone boundary. Higher ECM exposure values indicate higher circadian misalignment due to higher elevation (fewer obstructions/extended field of view) and larger differences in sunrise and sunset times. Spearman correlation coefficients and multivariable linear regression adjusting for age, sex, race, ethnicity, median household income, and population density were used to validate the ECM exposure model with census tract-level prevalence of obesity (2016-2019) (known outcome associated with circadian misalignment).

RESULTS: Among the 60,943 census tracts included in this study, obesity prevalence was 32.62%. ECM exposure was positively correlated with obesity prevalence, with the strongest correlation in the Eastern time zone (r_s=0.44, $p<0.01$). The highest vs. lowest ECM quintile was associated with higher obesity prevalence in the Eastern (adjusted β=6.00, 95% CI 6.68, 7.11) and Central time zones (adjusted β=2.85, 95% CI 2.62, 3.09), which are the US time zones characterized by the largest east-to-west distance (i.e., opportunity for ECM).

CONCLUSIONS: We developed and validated a US nationwide spatiotemporal ECM exposure model, which can be used for exposure assessment in epidemiologic studies to enable comprehensive characterization of geographic variation in light exposure potentially impacting circadian phase.

P-0846 Phenols, parabens and triclosan in maternal urine, Medellín-Colombia

Carlos Alberto Gómez-Mercado[1], Gregory Mejía- Sandoval[2], Albino Barraza-Villareal[3], Catalina Arango-Álzate[1], Angela Maria Segura-Cardona[1], Liliana Acevedo-Saenz[4], Damaskini Valvi[5], Amrit Kaur Sakhi[6], Cathrine Thomsen[6]
[1]CES University, Medellín, Colombia, [2]CES University, Medellín, Colombia, [3]National Institute of Health of Mexico, Cuernavaca, México, [4]CES University, Medellín, Colombia, [5]Icahn School of Medicine at Mount Sinai, New York, EEUU, [6]Norwegian Institute of Public Health, Oslo, Norway

INTRODUCTION: Phenols, phthalates, parabens and triclosan are endocrine disruptors and are suspected of generating epigenetic damage during prenatal life (1). The biological matrix most used to measure them is urine (2). Objective: to quantify the concentrations of phenols, parabens and triclosan) in pregnant women in two health institutions in Medellín.

METHODS: 400 pregnant women were recruited and of these it was possible to analyze 38 pools of urine (20 punctual samples) to quantify the metabolites of phenols, parabens and triclosan, the analysis was carried out at the Norwegian Institute of Public Health (NIPH), by ultra-high resolution liquid chromatography coupled to tandem mass spectrometry (UPLC-MS-MS) (2), the analyzes were corrected by specific gravity.

RESULTS: the geometric means according to the metabolites were Bisphenol A (BPA: 1.78 ng/mL), Methyl paraben (MEPA: 88.91 ng/mL), Ethyl paraben (ETPA: 2.95 ng/mL), Propyl paraben (PRPA: 10.32 ng/mL), Oxybenzone (OXBE: 27.94 ng/mL) and Triclosan (TRCS: 36.74 ng/mL).

CONCLUSIONS: This is the first study in Colombia that quantifies concentrations of phenols, phthalates, parabens and triclosan in pregnant women from Medellin. The geometric means of the metabolites BPA and parabens are in the middle when comparing with studies, but TRCS is above other studies in the world.

KEYWORDS: phenols, parabens, triclosan, endocrine disruptors; urine

P-0849 Personal exposure to radiofrequency electromagnetic fields in various occupations in Spain

Maxime Turuban[1,2], Hans Kromhout[4], Javier Vila[5], Ghislaine Bouvier[6], Michelle Turner[1,3]
[1]Isglobal, Barcelona Institute for Global Health, Barcelona, Spain, [2]Universitat Pompeu Fabra, Barcelona, Spain, [3]CIBER Epidemiología y Salud Pública, Madrid, Spain, [4]Institute for Risk Assessment Sciences (IRAS), Division of Environmental Epidemiology, Utrecht University, Utrecht, Netherlands, [5]Environmental Protection Agency (EPA), Office of Radiation Protection and Environmental Monitoring, Wexford, Ireland, [6]Inserm UMR 1219 EPICENE Team, Bordeaux Population Health Research Center, Bordeaux, France

BACKGROUND: A Job-Exposure Matrix (JEM) for radiofrequency electromagnetic fields (RF-EMF) was previously created based on measurements collected from the literature and individualized EMF source-based information. In the context of an international study aimed at enhancing this preliminary JEM, personal measurements of occupational exposure to RF-EMF were conducted among various occupations in Spain.

METHODS: Identification and prioritization of occupations to be measured were based on the levels and prevalence of exposure to RF fields in the preliminary RF-JEM and expert judgements. A screening questionnaire developed within our project was used to identify potential participants, based on job titles, tasks, and reported sources of RF exposure. Personal full-shift measurements were conducted using 10 Narda RadMan 2XT personal measurement devices.

RESULTS: Personal full-shift measurements were collected for 285 workers of various occupations in Spain. Exposures to electric (E) and magnetic (H) fields were low (99.74% of (E-fields) measurements <1% ICNIRP standards). Results exceeded the ICNIRP limits for only 3% of the workers, though these exceedances lasted a few seconds. Overall, almost 50% of workers had values above 1% of the ICNIRP standards (exposure duration between 1 second and 27.13 minutes). Electric and magnetic fields peaks exceeding 100% of the standards were observed among 8% of the physiotherapists (N=59) and 7% of the nursing auxiliaries (N=28), with exposure durations ranging from 1 to 13 seconds (E-fields) and 2 to 36 seconds (H-fields) of exposure above the limits, respectively.

CONCLUSIONS: We performed the first phase of data collection of personal RF-EMF measurements among various occupations in Spain in the framework of an international study. The initial results in Spain showed low prevalence and low overall levels of exposure to RF fields, despite some short-term peaks. Additional measurements will be conducted in France and the Netherlands.

P-0857 Assessing environmental exposure and socioeconomic history prior to cancer diagnosis

Bian Liu[1,2], Furrina Lee[3], Li Niu[2], Francis Boscoe[3,4]

[1]Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Bureau of Cancer Epidemiology, Division of Chronic Disease Prevention, New York State Department of Health, Menands, USA, [4]Pumphandle, LLC, Portland, USA

BACKGROUND AND AIM Exposure assessment solely based on the address at cancer diagnosis assumes fixed exposure over time, while ignoring exposures from other addresses prior to cancer diagnosis. We aim to examine excess exposure risks of non-asbestos air toxics and socioeconomic status (SES) estimated over available residential history for mesothelioma patients.

METHODS: Patients' residential histories were obtained by linking mesothelioma cases (n=1,015) diagnosed during 2011-2015 from the New York State Cancer Registry to LexisNexis administrative data and inpatient claims data. Percentile ranking of lifetime cancer risk from inhalation of non-asbestos air toxics was based on the National Air Toxic Assessment. SES was measured by Yost index, which is a percentile ranking derived from U.S. Census data. Excess exposure risk was calculated by dividing exposures at individual census tracts by the state-level average and subtracting one. We used a generalized linear regression model with the generalized estimating equation to compare the excess exposure risk in years prior to and at cancer diagnosis.

RESULTS: Approximately 43% of the study sample had a residential history prior to the cancer diagnosis for up to 30 years, and 94% up to 5 years. The excess exposure risks at the cancer-diagnosis tracts were below the state average, with means ranging from -0.22 to -0.11 for air toxics, and from -0.23 to -0.18 for SES. Excess exposure risks for both air toxics and SES tended to be higher in earlier addresses than addresses at cancer diagnosis, though the effect size was relatively small (1%-6.2%).

CONCLUSIONS:We demonstrated the feasibility of including residential history in cancer research and revealed differences between multiple approaches of estimating residence-related exposure risks over time. As the findings may be unique to the mesothelioma patients studied, future examinations using different exposure indicators and among different patient populations and other cancer types are needed.

P-0864 Influence of Environmental and Dietary Exposures on Trace Metals and Organochlorine Pollutants Accumulation Among the Residents of a Major Industrial Harbour (Fos-sur-Mer, France)

Maxime Jeanjean[1], Sylvaine Goix[1], Marine Periot[1], Julien Dron[1], Marie−Pierre Etienne[2], Renaud Persoons[3], Philippe Marchand[4], Annabelle Austruy[1], Gautier Revenko[1], Philippe Chamarret[1]

[1]Institut Écocitoyen Pour la Connaissance Des Pollutions, Fos-sur-mer, France, [2]University of Rennes, Agrocampus Ouest, CNRS, UMR 6625 IRMAR, Rennes, France, [3]University of Grenoble Alpes, CNRS, Grenoble INP, CHU Grenoble Alpes, TIMC, Grenoble, France, [4]LABERCA, Oniris, INRAE, Nantes, France

BACKGROUND AND AIM. – We investigated whether residents who lived closer to the core of one of the largest industrial zone in Europe (Fos-sur-Mer, France) had higher serum or urine levels of trace metals (Antimony, Arsenic, Cadmium, Chromium, Cobalt, Mercury, Nickel, Lead and Vanadium) and organochlorine indicators (NDL-PCBs, DL-PCBs and PCDD/Fs) than people who lived out of the industrial core zone (Saint-Martin-de-Crau, France).

METHODS: –The INDEX cross-sectional study was conducted from September to November 2016. We collected blood samples from 138 people (80 in the exposed area and 58 in the control area), which were included using a stratified random sampling method and selected with strict criteria (e.g., 30–65 years old, living in the area for at least 3 years, not working in the industrial sector, non-smoker). Biomonitoring indicators were calculated using single-pollutant multivariate linear regression models (using substitution when censored data were under 15% and Tobit models alternatively), adjusting for personal physiological, social, dietary, housing characteristics and leisure activities. We also measured these pollutants in samples of lichens (Xanthoria parietina) and atmospheric particles (PM2.5).

RESULTS: – Living close to the core industrial zone was significantly associated with an increase in blood levels of lead (adjusted geometric mean = 17.2 [15.8-18.7] vs 15.1 [13.7–16.7] µg.g-1 creatinine, $p<0.05$). We reported that behaviours that involved environmental exposures (i.e., gardening, dietary history of consumption of vegetables, eggs, poultry, and local seafood) were significantly associated with an increase in some organochlorine and trace metals urine/serum levels amongst residents of the industrial port zone compared to the residents of the control area.

CONCLUSIONS: - These results brought interesting clues, in complement to national programs, regarding the exposure to trace metals of residents living in a major industrial european harbor.

KEYWORDS: - Industrial pollution - Biomonitoring - Heavy metals - PCBs – Dioxines - Dietary habits

P-0867 Urinary Creatinine Concentrations and Its Explanatory Variables in General Chinese Population: Implications for Creatinine Limits and Creatinine Adjustment

Miss. Saisai Ji[1], Yuebin Lv[1], Yingli Qu[1], Xiaojian Hu[1], Yifu Lu[1], Junfang Cai[1], Shixun Song[1], Xu Zhang[1], Yingchun Liu[1], Yanwei Yang[1], Wenli Zhang[1], Yawei Li[1], Miss. Mingyuan Zhang[2], Chen Chen[1], Chengcheng Li[1], Zheng Li[1], Heng Gu[1], Ling Liu[1], Jiayi Cai[1], Miss. Tian Qiu[1], Hui Fu[1], John Ji[3], Feng Zhao[1], Ying Zhu[1], Zhaojin Cao[1], Saisai Ji[1]

[1]National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]School of Public Health, Jilin University, Jilin, China, [3]Vanke School of Public Health, Tsinghua University, Beijing, China

BACKGROUND AND AIM Urinary creatinine (Ucr) is commonly used to determine the acceptability of spot urines and to adjust for dilution variation of spot urine specimens. However, some controversy exists over the creatinine limits (0.3–3.0 g/L) recommend by WHO. Ucr concentrations variy across individuals and are affected by numerous factors, which may complicate epidemiologic associations related to chemical-to-creatinine ratios. An improved understanding of the variation and predictors of Ucr concentrations is necessary. The study aimed to analyze the applicability of the WHO's exclusionary guidelines in the general Chinese population, and to identify Ucr related factors.

METHODS: The cross-sectional study included 21,167 participants aged 3 to 79 years from the initial cycle of the China National Human Biomonitoring Program. We used mixed linear models and restricted cubic splines (RCS) to analyze associations between explanatory variables with Ucr.

RESULTS: In general Chinese population, the geometric mean and median concentrations of Ucr were 0.90 g/L and 1.01 g/L, respectively. 9.36% samples were outside 0.3-3.0 g/L, including 7.83% below the lower limit and 1.53% above the upper limit. Middle age, male, obesity, smoking, higher frequency of red meat consumption and chronic kidney disease were significantly associated with higher concentrations of Ucr. Results of RCS showed Ucr was inversely and linearly associated with BMI, systolic blood pressure, diastolic blood pressure, triglycerides and glomerular filtration rate, and were non-linearly associated with triiodothyronine.

CONCLUSIONS:The age- and sex-specific cut off values of Ucr determining the validity of urine samples in general Chinese population were recommended. To avoid introducing bias into epidemiologic associations, potential predictors of Ucr observed in the present study should be considered when choosing correction methods.

P-0872 Metal contaminants in river water and human urine after an episode of major pollution by mining wastes in the Kasai province of DR Congo

Rémy MPULUMBA BADIAMBILE[1], Paul Musa Obadia[2,4], Malick Useni Mutayo[2], Jeef Numbi Mukanya[2], Patient Nkulu Banza[2], Tony Kayembe Kitenge[3], Erik Smolders[5], Jean-François Picron[5], Vincent Haufroid[5], Célestin Banza Lubaba Nkulu[2], Benoit Nemery[4]

[1]Health public and Medecine,Official University of Mbujimayi and Regional Research and Medical Benefit, Mbujimayi, Congo-Kinshasa (The Democratic Republic of the Congo), [2]Toxicology and Environment Unit, Department of Public Health, Faculty of Medicine, University of Lubumbashi, Lubumbashi, DR Congo, Lubumbashi, Congo-Kinshasa (The Democratic Republic of the Congo), [3]Higher Institute of Medical Techniques Lubumbashi (ISTM), Lubumbashi, Congo-Kinshasa (The Democratic Republic of the Congo), [4]Department of Public Health and Primary Care, Leuven, KU Leuven, Leuven, Belgium, [5]Catholic University of Leuven, Brussels Leuven, Leuven, Belgium

BACKGROUND: In July2021, the Tshikapa river became heavily polluted by mining wastes from a diamond mine in neighboring Angola, leading to massive killing of fish, disease and even deaths among residents living along the Tshikapa and Kasai rivers. The exact nature of the pollutants was unknown.

METHODS: In a cross-sectional study, conducted in the city of Tshikapa in August 2021, we enrolled by opportunistic sampling 65 residents (11 children <16y) living alongside the polluted rivers, and 65 control residents (5 children) living alongside the Kasai river upstream from the Tshikapa-Kasai confluence. We administered a questionnaire and obtained river water and spot urine samples for measuring thiocyanate (a metabolite of cyanide) and 26 trace metals (by ICP-MS).

RESULTS: Participants from both groups consumed river water. In the area affected by the pollution, most participants had eaten dead fish. Prevalences of reported health symptoms were higher in the exposed group than among controls: skin rashes (52% vs 0%), diarrhea (40% vs 8%), abdominal pain (8% vs 3%), nausea (3% vs 0%). In polluted water, concentrations [median (range)] were only higher for nickel [(2.2(1.4–3.5)µg/L] and uranium [78(71–91)ng/L] than in non-polluted water [0.8(0.6–1.9)µg/L; 9(7–19)ng/L]. In urine, concentrations [µg/g creatinine, median(IQR)] were significantly higher in the exposed group than in controls for lithium [19.5(12.4–27.3) vs 6.9(5.9–12.1)], thallium [0.41(0.31–0.57) vs 0.19(0.16–0.39)], and uranium [0.026(0.013–0.037)] vs 0.012(0.006–0.024)]. Urinary thiocyanate concentrations did not differ.

CONCLUSION. This study after an ecological disaster in DR Congo has documented contamination of river water by nickel and uranium, and high urinary levels of some trace metals among affected riverine populations. However, the exact cause of the massive fish kill and disease among residents remains elusive. The capacity to rapidly investigate toxic pollution events must be increased in the area.

KEYWORDS: Trace Metals,mining,Water pollution,Kasai province.

P-0874 An ecological analysis of the association between industrial air pollution and asthma onset in children of Quebec, Canada

Ying Liu[1], Marianne Hatzopoulou[2], Jad Zalzal[2], Sham Gamage[2], Shoma Yamanouchi[2], Sara Torbatian[2], Ling Liu[3], Michel Fournier[4], Elhadji Anassour Laouan Sidi[5], Stéphane Buteau[6], Audrey Smargiassi[1]

[1]Department of Environmental and Occupational Health, School of Public Health, University of Montreal, Montreal, Canada, [2]Department of Civil & Mineral Engineering, University of Toronto, Toronto, Canada, [3]Environmental Health Science and Research Bureau, Health Canada, Ottawa, Canada, [4]Montreal Department of Public Health, Montreal, Canada, [5]Institut National de Santé Uublique du Québec, Quebec City, Canada, [6]Institut National de Sante Publique du Quebec, Montreal, Canada

BACKGROUND AND AIM: Asthma is the most prevalent respiratory disease in children worldwide. During the past decades, industrial emissions decreased dramatically in Canada. However, whether these decreases contributed to the decrease in asthma cases is still unclear. The aim of this study was to assess the associations between the changes in concentrations of industrial PM2.5, NO2, and SO2 emissions and the changes in asthma onset in children (<12 years) in Quebec, Canada with an ecological longitudinal design.

METHODS: Within 1310 small geographic sectors of Québec, yearly new cases of asthma in children were compiled from linked medico-administrative databases. The annual ambient concentrations of PM2.5, NO2, and SO2 related to industrial emissions from overall sectors for 2002 to 2015 were estimated by the POLAIR3D chemical transport model. Fixed-effects regression models were used to assess the associations between the time trend of industrial air pollution levels and the time trend of rates of asthma onset within the small areas, adjusting for median annual household income. Environmental tobacco smoke was additionally adjusted in sensitivity analyses.

RESULTS: The pollutant levels from industrial emissions per small area ranged from 0 to 12.91 µg/m3 for PM2.5, 0 to 28.63 ppb for NO2, and 0 to 494.34 ppb for SO2, respectively. The adjusted incidence rate ratios per 1 µg/m3 increase in PM2.5 and per 1 ppb increase in NO2 and SO2, were 1.045 (95% CI: 1.016 - 1.075), 1.045 (1.032 - 1.060), and 1.006 (1.004 - 1.07), respectively.

CONCLUSIONS: Industrial emission-related air pollutions were significantly associated with childhood asthma onset in Quebec. Since significant reductions in industrial emissions of air pollutants and asthma incidence have been observed in Quebec over the past two decades, our results suggest that the reduced industrial emissions may have contributed to the decreased asthma onset rate.

P-0877 Predicting Monthly Community-level Radon Concentrations with Spatiotemporal Random Forest METHOD: a Study in Northeastern and Midwestern USA

Longxiang Li[1], Petros Koutrakis[1]
[1]*Department of Environmental Health, Harvard T.H Chan School of Public Health, Boston, USA*

BACKGROUND AND AIM: Exposure to radon gas is the lead cause of lung cancers in never-smokers in the USA. Studies associating radon to other health outcomes have reported conflicted results, likely due to the inaccurate exposure assessments. Most previous radon-related epidemiological studies relied on an out-of-date county-level exposure model without temporal variation, which introduced misclassifications. Tens of millions of radon measurements have been conducted in the U.S, therefore enabling us to estimate radon concentrations at higher resolutions with better accuracy.

METHODS: We obtained over four million radon measurements from Spruce Environmental Technologies, Inc, a leading radon detector manufacturer. Community-level monthly radon concentrations were predicted based on geological, architectural, meteorological, and socioeconomic factors. Our innovative spatiotemporal random forest method extended the original one by allowing the relation between radon and its predictors to vary across space and time. Specifically, we fitted an independent model for each ZCTA and month based on the nearby radon measurements that are defined by the spatiotemporal proximity. The abundance of measurements enabled us to predict concentrations in the basement and upstairs respectively.

RESULTS: In Northeastern and Midwestern U.S, the average radon concentrations are 81.8 Bq/m3 in the basement and 50.7 Bq/m3 in the upstairs. The correlation (R2) between the predicted and observed geometric mean of radon concentrations is 0.77 in the basement and 0.57 in the upstairs if there are over 10 radon measurements in the same ZCTA and month. The mean absolute error (MAE) and mean relative error (MRE) are 19.7 Bq/m3 and 14.3% without obvious spatial trends.

CONCLUSIONS: Our predicted radon concentrations are highly correlated with the observed levels, therefore can be used in epidemiological studies to reduce misclassifications. The temporal variation characterized in our model will facilitate studies regarding the acute effects of radon.

P-0879 A National Comparison Between Short- and Long-term Radon Measurements in the USA

Longxiang Li[1], Brent Coull[1,2], Petros Koutrakis[1]
[1]Department of Environmental Health, Harvard T H Chan School of Public Health, Boston, USA, [2]Biostatistics Department, Harvard T H Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Understanding the spatiotemporal distribution of radon is essential to assess residential radon exposure. Long-term radon measurements that last over 90 days are considered gold standard to assess residential exposure but were conducted in a limited quantity due to the long duration. Tens of millions of short-term radon measurements, which normally last 2 to 4 days, have been conducted in the past decades because radon disclosures are required during property transaction in 35 out of 48 contiguous states. However, the application of these massive short-term measurements is limited likely because of the unknown real-life uncertainty.

METHODS: We therefore collected 2,450 pairs of collocated short- and long-term measurements, evaluated the pairwise correlation between them, and investigated the factors that determine the correlation between them via stratified linear regression and bootstrapping resampling.

RESULTS: We found that the pairwise correlation between the short- and long-term radon measurements is a joint function of two factors: the temporal difference between two measurements and the measuring length of the following long-term measurements. The correlation was as high as 0.76 (0.95 Confidence Interval [CI]: 0.70 to 0.84) when the temporal difference was shorter than two weeks and the length of long-term measurement was shorter than 100 days. Meanwhile, the correlation can be as low as 0.13 (0.95 CI: 0.09 to 0.32) when the temporal difference was over two months, and the length was close to a calendar year.

CONCLUSIONS: The high correlations indicates that short-term measurements can be used as a reliable proxy to a long-term measurement under specific conditions after adjusting for inherent differences. Our conclusion will facilitate the usage of this abundant data source, which has been obtained but was underutilized, thus likely enhancing our knowledge regarding other health effects associated with radon.

P-0883 Case-crossover study between PM2.5 and hospital admissions for respiratory diseases in Pretoria

Chantelle Howlett-Downing[1], Joyce Shirinde[1], Janine Wichmannn[1]
[1]*University of Pretoria, Pretoria, South Africa*

BACKGROUND: Particulate matter air pollution has been associated with adverse health effects. Air pollution epidemiology traditionally focuses on the relationship between individual air pollutants and health outcomes (e.g., mortality). To account for potential co-pollutant confounding, individual pollutant associations are often estimated by adjusting or controlling for other pollutants in the mixture. The objective of the study is control for components within the mixture which are highly correlated.
METHOD: An overall study is performed where PM2.5, BC, UV-PM and trace elements were controlled for Tapp and public holidays, stratified for age and sex. A second model, where PM2.5 is also controlled, was performed.

RESULTS: In total, there were 15 155 reported hospitalisations for respiratory diseases (J00-J99) over the 34-month period. The increase in respiratory hospital admissions was significantly increased by an increase in total PM2.5 of 2.7% (95% CI: 0.6, 4.9) per 10 µg/m3 increase. respiratory hospital admissions significantly increased for Ca by 4.0 % (95% CI: 1.4% - 6.8%), Cl by 0.7 % (95% CI: 0.0% - 1.4%), Fe by 3.3 % (95% CI: 0.5% - 6.1%), K by 1.8% (95% CI: 0.2 – 3.5) and Si by 1.3 % (95% CI: 0.1% - 2.5%). When controlling for PM2.5, respiratory hospital admissions increased significantly for total Ca by 3.2 % (95% CI: 0.3, 6.1) and for the 0 – 14 age group by 5.2 % (95% CI: 1.5, 9.1). Hospital admissions was positive and significantly increased with an increase in resuspended dust matrix by 2.9 % (95% CI: 0.1% - 5.7%) and for biofuel burning by 1.6 % (95% CI: 0.1% - 3.2%) sources.

CONCLUSIONS: Controlling for a co-pollutant which is highly correlated with PM2.5 does reduce overestimation, but further studies should include deposition rates and parallel sampling analysis.

P-0896 Intrauterine exposure to phthalates in pregnant women, Colombia

Carlos Alberto Gómez-Mercado[1], AK Sakhi[2], Thomsen Cathrine[2], Valvi Damaskini[3], CM Arango-Álzate[1], AM Segura-Cardona[1], A Barraza-Villareal[4], L Acevedo-Saenz[5], G Mejía- Sandoval[6]
[1]CES University, Graduate School, Medellín, Colombia, [2]Norwegian Institute of Public Health, Oslo, Norway, [3]Icahn School of Medicine at Mount Sinai, New York, EEUU, [4]National Institute of Health of Mexico, Cuernavaca, Mexico, [5]CES University, Faculty of Nursing, Medellin, Colombia, [6]CES University, MVZ Faculty, Medellin, Colombia

INTRODUCTION: Phthalates are endocrine disruptors used in the manufacture of multiple industrial products, mainly plastics. Intrauterine life represents the main window of vulnerability and exposure to phthalates in this stage of life generates adverse fetal and postnatal effects (1). The most reliable biomarker for phthalate measurement is urine.
OBJECTIVE: To characterize the different sources of exposure to endocrine disruptors and to quantify the urinary concentration of phthalates in pregnant women.

METHODS: 400 women ≤12 weeks pregnant were included at baseline, and of these 38 pools of urine (20 spot samples) were analyzed for phthalate metabolites, analysis was performed at the Norwegian Institute of Public Health (NIPH) (2), analyzes were corrected for specific gravity and descriptive statistics are presented.

RESULTS: The geometric means of phthalate Di(2-ethylhexyl)phthalate(DEHP), Mono-n-butyl phthalate(MnBP), Mono-2-ethyl-5-hydroxyhexyl phthalate(MEHHP), and Mono-2-ethyl-5- oxohexyl phthalate(MEOHP) were 162.72 µg/L, 58.50 µg/L, 33.93 µg/L and 31.63 µg/L, respectively.

CONCLUSIONS: it is the first study that quantifies phthalate metabolites in Colombia. Concentrations of MnBP, MEHHP, and MEOHP in urine are higher than those found in pregnant women around the world.

P-0898 Occupational Exposure to Diesel Exhaust in Bus Drivers in the New York Metropolitan Area

Hsiao-Hsien Hsu[1], MPH Demetrios Papazaharias[1], JD, MA, SM Lynn Onyebeke[1], MSPH CIH Alice Freund[1], MS Norman Zuckerman[1], BA Mathew Pendo[2], Luz Claudio[1], Roberto Lucchini[2], Yueh-Hsiu Mathilda Chiu[1]
[1]Icahn School of Medicine at Mount Sinai, New York, USA, [2]Florida International University, Miami, USA

BACKGROUND AND AIM: Exposure to diesel exhaust (DE) has been associated with adverse respiratory health outcomes and bus drivers could be at significant risk. We leveraged exposure data collected from real-time personal monitoring and geospatial location information to identify the factors influencing DE exposure in New York bus drivers.

METHODS: DE exposure was estimated via black carbon (BC; a component of DE) measurements recorded using a micro-Aethalometer (microAeth®Model-AE51) every minute over six 24-hour periods in four bus drivers during September-October 2014. Driving routes originated from two Westchester bus depots and traversed lower Westchester. Each driver's location was continuously recorded every minute using a global positioning system (GPS) device. Information on fuel type, smoking status, worker activities, and meteorological variables were collected. Road density indices were calculated based on an 100-meter buffer. We performed multivariable-adjusted regression models to assess the factors associated with BC levels.

RESULTS: BC data were collected for a total of 2682 working minutes and 4328 non-working minutes. Overall median BC level was 578 ng/m3 (IQR: 189-1487 ng/m3) [working hours: 1166 (612-2168) ng/m3; non-working hours: 351 (132-860) ng/m3]. Multivariable-adjusted models predicted that compared to times working in office, workers were on average exposed to an additional 1403.5 ng/m3 and 2150.4 ng/m3 of BC when they were in the depot yard and driving the bus, respectively. Driving a diesel-powered vehicle was associated with 2.7-fold increase in BC levels compared to gasoline-powered. for every 10% increase in the sum of road length index, BC level increased by 19% (95%CI=15-24%). Further, for every 10% increase in average speed, BC level increased by 20% (95%CI=17-23%).

CONCLUSIONS: Driving a diesel-powered vehicle presented significantly more BC exposure comparing to gasoline-powered vehicle. Roadway density and driving speed contributed to elevated BC levels.

KEYWORDS: diesel, transportation, bus driver, occupational exposure

P-0912 Health Benefit of PM2.5 Control Legislations in Korea

Eunjin Oh[1], Soontae Kim[2], Ho-Jang Kwon[3], Sanghyuk Bae[4]
[1]The Catholic University, Seoul, Republic of Korea, [2]The Ajou University, Suwon, Republic of Korea, [3]The Dankook University, Cheonan, Republic of Korea, [4]The Catholic University, Seoul, Republic of Korea

BACKGROUND AND AIM: Exposure to PM2.5 has been associated with increased mortality. The aim of the present study was to evaluate the health benefit of policies to reduce air pollution.

METHODS: We selected three air pollution control policies that were implemented between 2006 and 2018 in Seoul and Incheon, Korea. We estimated three types of impacts to evaluate the benefit of each policy. These impacts are benefit from reduced PM2.5 concentration (Impact 1), benefit from reduced magnitude of association (Impact 2) and reduced both concentration and magnitude of association (Impact 3). We conducted interrupted time series analyses to examine changes in PM2.5 concentration and magnitude of association with mortality after the implementation of the policies. We calculated the health benefit accounting for reduced daily PM2.5 concentration and its association with mortality.

RESULTS: We observed a decrease of PM2.5 concentrations after interventions in Seoul and Incheon. The effect of policy on associations between PM2.5 and mortality were different from intervention to intervention, but the magnitude of association in Seoul continued to decline. The numbers of prevented deaths in Seoul in one year after the implementation of each policy were 252 (95% CI: 221, 293), 365 (95% CI: 24, 432) and 120 (95% CI: 0, 262), respectively. In Incheon, the numbers of prevented deaths were 68 (95% CI: 0, 197), 167 (95% CI: 0, 184) and 149 (95% CI: 0, 298), respectively.

CONCLUSIONS: The present results suggests that air pollution control policies in Seoul and Incheon were effective in terms of preventing mortality.

KEYWORDS: mortality, health impact assessment, policy, particulate matter, attributable deaths

P-0913 Association of sound pressure levels and frequency components of road traffic noise with prevalent depression in Taichung, Taiwan

Jia Yi Lin[1], Wan Ju Cheng[2], Chang Fu Wu[3], Jia-Yi Lin[4]

[1]China Medical University, Taichung City, Taiwan, [2]China Medical University Hospital, Taichung City, Taiwan, [3]National Taiwan University, Taipei City, Taiwan, [4]China Medical University, Taichung City, Taiwan

The World Health Organization has reported that the prevalence of mental illness is 4% in the global population. Epidemiological studies have reported a relationship between road traffic noise exposure and depression, but the association between noise frequency components and depression remains unclear. This cross-sectional study investigated the associations between road traffic noise exposure and its frequency components with prevalent depression. A total of 3,200 residents living in Taichung who participated in the Taiwan Biobank between 2010 and 2017, were included as study participants. We used land-use regression models to evaluate individual annual average values of A-weighted equivalent sound level over 24 h (Leq,24h) and particulate matter with an aerodynamic diameter less than 2.5 μm (PM2.5) using the geographic information system. Multiple logistic regression was applied to estimate the odds ratios (ORs) for depression after adjusting for potential risk factors and PM2.5. An interquartile range increase in Leq,24h at full frequency (4.7 dBA), 1000 Hz (5.2 dB), and 2000 Hz (4.8 dB) was significantly associated with an elevated risk for depression with ORs of 1.62 (95% confidence interval [CI]: 1.03, 2.55), 1.58 (95% CI: 1.05, 2.37), and 1.58 (95% CI:1.03, 2.43), respectively, by controlling for PM2.5. The high-exposure group (≥ the median of noise levels) at full frequency, 500 Hz, and 2000 Hz had an increased risk for depression with ORs of 1.87 (95% CI: 1.03, 3.39), 1.94 (95% CI: 1.03, 3.65), and 1.86 (95% CI: 1.03, 3.37), respectively, compared with the low-exposure group (< the median of noise levels) after adjustment for PM2.5. Road traffic noise exposure may be associated with an increased prevalence of depression, particularly at 500 to 2000 Hz.

P-0917 Multiple xenoestrogen air pollutants and breast cancer risk: statistical approaches to investigate the combined exposures effect

Amina Amadou[1,2], Fabiola Ngaleu[1,2], Delphine Praud[1,2], Thomas Coudon[1,2], Camille Giampiccolo[1,6,7,8], Lény Grassot[1,2], Elodie Faure[3], Florian Couvidat[4], Julien Caudeville[4], Gianluca Severi[3,5], Francesca Romana Mancini[3], Pr Pascal Roy[6,7,8], Pr Béatrice Fervers[1,2]

[1]Department of Prevention Cancer Environment, Centre Léon Bérard, Lyon, France, [2]Inserm U1296 Unit, «Radiation: Defense, Health and Environment», Lyon, France, [3]Université Paris-Saclay, UVSQ, Inserm U1018, CESP, "Exposome Heredity, Cancer and Health", Gustave Roussy, Villejuif, France, [4]National Institute for industrial Environment and Risks (INERIS), Verneuil-en-Halatte, France, [5]Department of Statistics, Computer Science and Applications (DISIA), University of Florence, Florence, Italy, [6]Service de Biostatistique–Bioinformatique, Pole Sante Publique, Hospices Civils de Lyon, Lyon, France, [7]Laboratoire de Biometrie Et Biologie Evolutive, CNRS UMR 5558, Villeurbanne, France, [8]Université Claude Bernard Lyon 1, Lyon, France

BACKGROUND AND AIM: Despite that the population is exposed to a mixture of multiple air pollutants, the joint effect of these pollutants on breast cancer (BC) has never been investigated. We applied two new statistical approaches to assess the complex effect of exposure to a mixture of four xenoestrogen air pollutants (Benzo-[a]-pyrene (BaP), cadmium, dioxins, Polychlorinated Biphenyl 153(PCB153)) on the risk of BC.

METHODS: The study was conducted on 5,222 cases and 5,222 matched controls nested within the French national E3N cohort. Annual estimates of exposures to pollutants at participants' addresses for each year from recruitment 1990 through 2011, were assessed using a chemistry transport model. Mean annual concentrations for each pollutant was then estimated from inclusion in the study to the index date. We fitted the bayesian kernel machine regression (BKMR) and the weighted quantile sum (WQS) regression models to estimate the risk of BC associated with the joint effect of co-exposure of four xenoestrogens air pollutants.

RESULTS: In BKMR, despite the no statistically significant association, there was an increasing trend between the joint effect and the risk of BC, when fixing other chemicals at their median concentrations. BaP, cadmium and PCB153 showed positive trends in the multi-pollutant mixture, while dioxin showed a modest inverse trend. In WQS, there was a borderline positive association between the WQS index of the joint effect and the risk of BC (odds ratio (OR)=1.06, 95% confidence intervals (CI):0.99-1.10). By menopausal status, there was a differential joint effect, with a significant positive association observed only in women who underwent menopausal transition (OR=1.09, 95% CI:1.02-1.14)

CONCLUSIONS: Overall, although no clear association was observed with BKMR model, there was a tendency of an increased risk of BC associated with co-exposure to long-term xenoestrogens air pollutants using both approaches. Further studies are needed to confirm these findings.

P-0921 Estimating attributable deaths from short-term pollution effects: Differential air pollution impact on cause-specific mortality

Ariel Spira-Cohen[1], Rebecca Goldberg[1], Sarah Johnson[1], Masha Pitiranggon[1], Kazuhiki Ito[1]
[1]*New York City Dept. of Health and Mental Hygiene, New York, USA*

BACKGROUND AND AIM: Health impact assessment (HIA) is a common policy tool that quantifies health burden from air pollution under different policy scenarios. Most HIAs consider all-natural-cause deaths from single-pollutant models, leaving uncertainty about varying impacts on cause-specific mortality from multiple air pollutants.

METHODS: Daily city-wide average air pollution concentrations were collected from the Environmental Protection Agency's Air Quality System and mortality records (2005-2019) from New York City (NYC) Vital Statistics. Total cumulative pollution attributable fractions (AFs) and annual average attributable counts (ACs) of mortality were estimated from single- and co-pollutant quasi-Poisson distributed lag time-series models at one lag day. Three mortality outcomes were evaluated: all-natural-cause, cardiovascular (CVD), and respiratory. Full year and seasonal models, adjusting for temperature and seasonal trends, were fit for sulfur dioxide (SO_2), nitrogen dioxide (NO_2), ozone, fine particulate matter ($PM_{2.5}$), and carbon monoxide (CO).

RESULTS: Across all pollutants, outcomes, and seasons, single-pollutant models showed positive associations, although cold-season models generally had lower AFs and larger confidence bands. for all-natural-cause mortality, NO_2 AF from the full-year, single-pollutant model was 1.4% (95% CI: 0.6%, 2.3%) representing the largest pollution AC, about 660 deaths annually, which did not change when additional pollutants were added to the model. CVD full-year model of $PM_{2.5}$ was robust to addition of NO_2, contributing about 250 deaths annually: 1.2% AF (0.5%, 1.9%). for respiratory mortality, warm-season NO_2 AF was 4% (-0.4%, 7.9%) and robust in co-pollutant models with $PM_{2.5}$ and NO_2, but not ozone. Warm-season ozone AF was 8.1% (2.9%, 13%), representing about 125 respiratory deaths annually.

CONCLUSIONS: Concentration-response functions used to quantify health burden based on air pollution attributable all-natural-cause deaths must consider short-term NO_2 associations in NYC. Cause-specific associations differ from those for all-natural-cause deaths, with $PM_{2.5}$ more important for CVD deaths and ozone for respiratory deaths.

KEYWORDS: Air pollution, Mortality

P-0922 Chronic exposure to ambient air pollution and the risk of non-alcoholic fatty liver disease: A cross-sectional study in Asia

Yacong Bo[1], Changqing Lin[2], Cui Guo[3], Bo Huang[4], Martin Wong[3], Alexis Lau[2], Yu Huang[5], Xiang Qian Lao[3]
[1]School of Public Health, Zhengzhou University, Zhengzhou, China, [2]The Hong Kong University of Science and Technology, Hong Kong, Hong Kong, [3]School of Public Health, The Chinese University of Hong Kong, Hong Kong, China, [4]Department of Geography and Resource Management, The Chinese University of Hong Kong, Hong Kong, China, [5]City University of Hong Kong, Hong Kong, China

BACKGROUND AND AIM: Information on the relation between air pollution and non-alcoholic fatty liver disease (NAFLD) is scarce. We conducted a population-based cross-sectional study to evaluate the relationship between air pollution and NAFLD.

METHODS: We recruited 329,048 adults (mean age: 41.0 years) without other liver disease (hepatitis and cirrhosis) or excessive alcohol consumption in Taiwan and Hong Kong from 2001 to 2018. The levels of PM2.5 were estimated using a satellite-based spatio-temporal model, and the concentrations of NO2 and O3 were measured using a space–time regression model. NAFLD was determined using the hepatic steatosis index (HSI) or the fatty liver index (FLI). NAFLD-related advanced fibrosis was determined using fibrosis-4 (FIB-4) or the BARD score. A logistic regression model was used for data analysis.

RESULTS: We found positive relationships between PM2.5 and the odds of NAFLD and NAFLD-related advanced fibrosis, with a 10% (95% confidence interval [CI]: 9%–11%) increase in the prevalence of NAFLD and an 8% (95% CI: 7%–9%) increase in the prevalence of advanced fibrosis for every standard deviation (SD, 7.5 μg/m3) increase in PM2.5 exposure. Similarly, every SD (18.9 μg/m3) increase in NO2 concentration was associated with 8% (95% CI: 7%–9%) and 7% (95% CI: 6%–8%) increases in the prevalence of NAFLD and NAFLD-related advanced fibrosis, respectively. In addition, every SD (9.9 μg/m3) increase in O3 concentration was associated with 12% (95% CI: 11%–13%) and 11% (95% CI: 9%–12%) decreases in the prevalence of NAFLD and advanced fibrosis, respectively.

CONCLUSIONS: Long-term exposure to PM2.5 and NO2 is associated with higher odds of NAFLD and NAFLD-related fibrosis. Our findings indicate that reducing PM2.5 and NO2 concentrations may be an important strategy for preventing NAFLD. Further investigations on O3 are warranted.

KEYWORDS: PM2.5; NO2; ozone; non-alcoholic fatty liver disease; advanced fibrosis

P-0933 Interdisciplinary Community-based Participatory Health Research across a Major Industrial Harbour (Fos-sur-Mer, France)

Maxime Jeanjean[1], Johanna Lees[2], Barbara L. Allen[3], Alison K. Cohen[4]
[1]Institut Écocitoyen Pour la Connaissance Des Pollutions, Fos-sur-mer, France, [2]Centre Norbert Elias (UMR 8562), Laboratoire de sciences sociales appliquees, Marseille, France, [3]Department of Science, Technology and Society, Virginia Tech University, Falls church, USA, [4]University of California San Francisco, Department of Epidemiology & Biostatistics, San Francisco, USA

BACKGROUND AND AIM. – We conducted a community-based participatory environmental health study in three towns: two in the heart of Marseille's (France) industrial zone (Fos-sur-Mer and Port-Saint-Louis-du-Rhône) and one on the periphery located about 30 km away (Saint-Martin-de-Crau).

METHODS: – We first conducted a cross-sectional survey of a random sample of residents in each of the three towns. We asked study participants to self-report a wide variety of health issues (Port-Saint-Louis: n = 272, Fos-sur-Mer: n = 543, Saint-Martin-de-Crau: n = 439). We then conducted focus groups with residents and other stakeholders to share preliminary data in order to propose areas of reflection and collaboratively produce contextually-situated knowledge of their health and environment. We directly standardized the prevalences (by age and gender) to the French metropolitan population to make our results more comparable.

RESULTS: – Study participants who lived closer to the core industrial zone (residents of Fos-sur-Mer and Port-Saint-Louis-du-Rhone) had significant higher prevalences of eye irritation, nose and throat problems, chronic skin problems and headaches than people who lived further away (residents of Saint-Martin-de-Crau). Residents also offered diverse qualitative insights about their environment and health experiences, strengthening an understanding of their own empirical observations which helps to produce knowledge about health in an industrial context. The results of the workshops show an important benefit from the co-production of local knowledge.

CONCLUSIONS: – We encourage future researchers to do in-depth, community-based research to comprehensively describe the health of residents in other heavily polluted zones, product local knowledge and to help identify policy solutions, engender trust among the local people, and identify opportunities for intervention.

P-0934 Association between polycyclic aromatic hydrocarbon exposure and esophageal cancer risk in typical areas of China

Yifu Lu[1], Xiaoyan Dong[1], Jiayi Cai[1], Wenli Zhang[1]
[1]*China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND: Studies of people show that individuals exposed by breathing, skin contact, or diet for long periods to polycyclic aromatic hydrocarbon (PAHs) can develop cancer, such as lung, skin, and bladder cancer. However, their effects on esophageal cancer have not been well examined.
AIM: This study is to compare the concentration of PAHs metabolite(OH-PAHs) in the urine of patients in the early stages of esophageal cancer and healthy people, and to evaluate the association between PAHs exposure and esophageal cancer risk.

METHODS: The 211 urine samples were collected from 105 esophageal cancer patients in the early stages and 106 healthy people in three high Incidence districts of esophageal cancer from November 2019 to June 2020. The 10 OH-PAHs (including 1-NAP, 2-NAP, 2-FLU,3-FLU,9-FLU,1-PHE,2-PHE, 3-PHE, 4-PHE,1-PYR) were analyzed with isotope dilution gas chromatography/tandem mass spectrometry (GC-MS/MS) based on CDC method.

RESULTS: The 10 OH-PAHs detection rate were relatively high more than 90%. 1-NAP and 2-NAP were the most abundant contributor to the total concentration of OH-PAHs.The mass concentration of OH-PAHs in the urine of healthy people was in the range of 1.5-44.6 μg/g, the median concentration of ∑OH-PAHs was 6.1 μg/g and the geometric mean concentration was 6.8 μg/g. ∑OH-PAHs concentration in the urine of esophageal cancer patients in the early stages was in the range of 3.6-104.2 μg/g, the median concentration of ∑OH-PAHs was 9.8 μg/g and the geometric mean concentration was 10.2 μg/g.

CONCLUSIONS: The results showed ∑OH-PAHs concentrations in urine from esophageal cancer patients in the early stages were higher than healthy people. The different habits and way of life, such as smoking and fried food, were increasing the PAHs exposure causing esophageal cancer risk.

KEYWORDS: polycyclic aromatic hydrocarbon, urine, esophageal cancer risk, typical areas

P-0938 Cluster analysis of premature deaths attributable to PM2.5 in aging population, South Korea

Cham Nguyen Thi[1]

[1]*National Cancer Center, Graduate School of Cancer Science & Policy, Korea, Goyang, Republic of Korea*

BACKGROUND AND AIM: Health impact analysis for PM2.5 can display spatial heterogeneity of premature deaths attributable to PM2.5 and stands out as one of the best effective tools to present scientific evidence to guide policy actions. Subsequent spatial cluster analysis allows us to detect the areas with large burden and guide intervention programs to target such areas. We aimed to estimate the number of attributable deaths associated with PM2.5 exposure and identify the clustered areas with large attributable deaths compared to other areas in Korean aging population.

METHODS: We computed district-specific attributable deaths for lung cancer, chronic obstructive pneumonia disease, ischemic heart disease, and stroke each year for 2016 – 2019 using district averages of PM2.5 obtained from a previously-validated prediction model, district-level population aged 65 years and over, provincial-level mortality rate, and relative risks of cause-specific deaths for PM2.5. Then, we aggregated to total attributable deaths including all four causes in each of the 250 districts over four years. Finally, we applied spatial scan statistic with optimal size of elliptic shape window and identified the most significant cluster of high premature deaths.

RESULTS: Over four years, the total number of deaths attributable to PM2.5 was 49,449 out of 35,368,100 old adults in South Korea. The premature deaths attributable to PM2.5 were higher in the Northwest and Southeastern districts where population is relatively old. The cluster analysis showed the Southeastern districts as the significantly high mortality burden cluster attributed to PM2.5.

CONCLUSIONS: This study suggests that the cluster analysis can increase the benefit of the health impact analysis.

P-0939 NATURGREEN: Health impact assessment of greening Denver through native plants

Michael Garber[1], Michael Guidi[1], Jennifer Bousselot[1], Tarik Benmarhnia[2], David Rojas-Rueda[1]
[1]Colorado State University, Fort Collins, USA, [2]University of California San Diego, San Diego, USA

BACKGROUND: Cities often use exotic plants (e.g., turf grass and non-native trees) to expand green space to reduce micro-heat islands or promote physical activity. Native plants, however, may require less water, be more drought-tolerant, and have co-benefits for local biodiversity (e.g., pollinators). Epidemiologic studies suggest urban green space can improve human health and prevent premature mortality, but the benefits associated with this specific type of vegetation has received little attention.
AIM: We aim to estimate premature deaths that would be prevented by the implementation of native-plants policy scenarios in the City of Denver, Colorado, USA.

METHODS: To develop realistic native-plants policy scenarios, we conducted interviews with local stakeholders engaged in green-space advocacy, research, and policy in Denver. We build four scenarios: 1) greening a 20% of all city census-block groups to the greenness level of native plants, 2) adding 200-foot native-plants buffers around riparian areas, 3) constructing additional large water retention ponds landscaped with native plants, and 4) greening parking lots. We measured existing green space with satellite imagery and linked with census and land-use data. Using a health-impact assessment approach, we estimated premature mortality averted under each scenario.

RESULTS: In the most ambitious scenario, we estimated that 45 (95% confidence interval (CI): 42, 49) annual premature deaths would be prevented by greening 20% of all city census block groups with native plants. We estimated that greening 20% of parking-lot surface with native plants would prevent 8 annual deaths (95% CI: 7, 9), adding the native buffers around riparian areas would prevent 8 annual deaths (95% CI: 6, 9), and adding the planned native-landscaped stormwater retention ponds would prevent 1 annual death (95% CI: 1, 1).

CONCLUSIONS: Using native plants to increase green spaces has the potential to prevent substantial premature deaths in the City of Denver.

P-0941 Health risk assessment of PM2.5 and PM2.5-bound trace elements in Pretoria, South Africa

Chantelle Howlett-Downing[1], Joyce Shirinde[1], Janine Wichmannn[1]
[1]*University of Pretoria, Pretoria, South Africa*

BACKGROUND: The objective of the present study was to assess the human health risks associated with fine particulate matter (<PM2.5) and trace elemental constituents in Pretoria, South Africa.
METHOD: Outdoor ambient PM2.5 was sampled at the School of Health Systems and Public Health from 18 April 2017 to 28 February 2020. The health risk assessment method followed the USA Environmental Protection Agency's (US EPA) health risk assessment method. Reference doses for PM2.5 were taken from the World Health Organization (WHO) guidelines and the South African National Ambient Air Quality Standards (NAAQS).

RESULTS: The average yearly concentration for PM2.5 was 23.2 µg/m3 (N = 350) for the 34-month sampling campaign. This is above the yearly WHO guidelines (5 µg/m3) and the South African NAAQS (20 µg/m3). The monthly PM2.5 concentration is seasonal as is the concomitant Health Quotient (HQ). The calculated HQ for Adults, Children and Infants was above 1 when utilising both the WHO guidelines and the SA standard for ambient PM2.5. Children and Infants were three times higher at risk than adults throughout the year for summer and in winter for K and Si. Particle-bound Ni presented a cancer risk (CR) throughout the year.

CONCLUSIONS: It can be concluded that PM2.5 poses health risks in central Pretoria.

KEYWORDS: Air pollution, PM2.5, Seasons, Health Risk Assessment, South Africa, Trace elements

P-0943 Effects of hourly levels of ambient air pollution and the emergency department visits for asthma in Taiwan

Mu-Jean Chen[1], Pau Chung Chen[1], Yu Cheng Chen[1]
[1]*National Health Research Institutes, Miaoli County, Taiwan*

BACKGROUND AND AIM: Daily exposure to O_3, NO_2, and $PM_{2.5}$ is associated with asthma attacks. However, peak exposure (hourly) of such air pollution exacerbating asthma symptoms remains unknown.

METHODS: Daily emergency department visits (EDVs) of asthma from the National Health Insurance Research Database and hourly concentrations of O_3, $PM_{2.5}$, and NO_2 recorded at fixed-site monitoring stations in Taiwan from 2006 to 2016 were used. Excess risks (ERs) of asthma EDVs (ICD-10-CM: J45) at 0–2 lag days associated with daily maximum rolling 1-, 3-, 8-, and 24-hour concentrations of air pollutants were evaluated using the quasi-Poisson generalized additive models (GAMs). Models were stratified by warm and cold season and adjusted for townships, days of the week, and the smoothing splines as the year, temperature, and relative humidity at the same hours.

RESULTS: A total of 369,256 asthma EDVs in 50 townships of Taiwan from 2006 to 2016 were observed. The cold period (110 ± 125) had a higher average count of daily asthma EDV than the warm period (70 ± 90). Among air pollutants, there were positive associations between concentrations of all hourly pollutants and asthma EDVs, even in 1-hour exposure. Every a 10-unit increase in 1-hour exposure to $PM_{2.5}$ in warm (lag2) and O_3 in cold (lag2) increases the risks of daily asthma EDVs by 1.74% (95% CI, 1.43–2.04%) and 1.13% (95% CI, 0.83–1.44%), respectively. Exposure to 1-hour NO_2- in warm had the most significant effect (ER = 2.91%, 95% CI: 2.36–3.46%) on daily asthma EDVs. Then, all pollutants indicated that the 24-hour exposure was much more severe than 1-hour.

CONCLUSIONS: Short-term (1-hour) exposure to air pollutants is significantly associated with daily asthma EDVs. Hourly standard of air quality is suggested.

P-0946 The effectiveness of a text messaging intervention trial to reduce mercury contaminants and conserve healthy fish consumption in reproductive age Chicago Asian women

Mariam Oladosu[1], Susan Buchanan[2], Jing Zhang[2], Noel Chavez[3], Sally Freels[1], Kyeezu Kim[1], Mary Turyk[1]

[1]University of Illinois at Chicago, Division of Epidemiology and Biostatistics, Chicago, USA, [2]University of Illinois at Chicago, Division of Environmental and Occupational Health Sciences, Chicago, USA, [3]University of Illinois at Chicago, Division of Community Health Sciences, Chicago, USA

BACKGROUND AND AIM: Hg exposure during pregnancy can impact cognition, memory, attention, language, fine motor skills, and visual spatial skills in offspring. There is a high prevalence of elevated mercury (Hg) levels among Asian communities, attributable to frequent fish consumption. A controlled, cluster-randomized, 6-month intervention trial was conducted to decrease consumption of fish with moderate to high mercury levels and/or very frequent fish consumption and to reduce hair Hg levels.

METHODS: Reproductive age Asian women were recruited with the help of community organizations serving the Chinese, Vietnamese, and Korean communities in Chicago. The control group (n = 131) received general nutrition text messages, while the intervention group (n = 154) received text messages on risks and benefits of fish consumption, with advice tailored to the Chicago Asian communities based on a prior community assessment. Outcomes were hair Hg measurements and rates of fish consumption. Non-parametric tests compared treatment groups at baseline and six months and the effect of the intervention on outcomes was tested using longitudinal linear models with random effects for cluster.

RESULTS: Geometric mean hair mercury decreased 16% in the intervention group and increased 2% in the control group (p=0.04, Figure). In Chinese women, hair Hg decreased 9% in intervention and control groups, while in Korean women hair Hg decreased 27% in the intervention and increased 10% in the control group (p=0.04). The rate of ingestion of moderate and high mercury fish (g/day) decreased 50% in the intervention and 35% in the control group (p = 0.15).

CONCLUSIONS: Our findings suggest that in reproductive age Asian American women, a text messaging intervention providing information on healthy fish consumption and health risks of contaminated fish consumption decreased hair mercury levels, but efficacy differed by Asian ethnicity.

P-0952 The Association of Air Pollution and Serum Biomarker Abnormalities in Individuals with Hemodialysis-Dependent Kidney Failure

Yuzhi Xi[1,2,3], David Richardson[3], Abhijit Kshirsagar[4,5], Jennifer Flythe[4,5], Eric Whitsel[3,5], Timothy Wade[6], Ana Rappold[6]
[1]Emory University, Atlanta, USA, [2]Oak Ridge Institute for Science and Education at the USA Environmental Protection Agency, National Health and Environmental Effects Research Laboratory, Environmental Public Health Division, Research Triangle Park, USA, [3]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, USA, [4]University of North Carolina Kidney Center, Division of Nephrology and Hypertension, Department of Medicine, UNC School of Medicine, Chapel Hill, USA, [5]Department of Medicine, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, USA, [6]USA Environmental Protection Agency, Center for Public Health and Environmental Assessment, Public Health and Integrated Toxicology Division, Research Triangle Park, USA

BACKGROUND AND AIM: Ambient PM2.5 is a ubiquitous air pollutant with established adverse health consequences. While postulated to promote a systemic inflammatory response, few studies have demonstrated changes in serum biomarkers related to PM2.5 exposure. To examine associations between short-term PM2.5 exposure and commonly measured biomarkers known to be affected by inflammation among patients receiving maintenance in-center hemodialysis.

METHODS: We conducted a retrospective open cohort study from 1/1/2008 to 12/31/2014 among 173,697 cohort patients identified from the USA Renal Data System and linked at the patient level to laboratory data from a large dialysis organization. Daily ambient PM2.5 was estimated on a 1 km grid for the entire contiguous US and assigned to cohort patients based on the ZIP code of their dialysis clinics. Serum albumin, serum ferritin, transferrin saturation (TSAT), and serum hemoglobin were ascertained from the dialysis provider organization database. Mixed-effect models were used to assess the changes in biomarker concentrations associated with PM2.5 exposure.

RESULTS: Among study cohort, 50.3% patients were older than 65 years at the initiation of hemodialysis, 44% were female, and 62.8% were of white race. Overall, the daily ZIP-level ambient PM2.5 averages were 8.4 to 8.5 µg/m3, and the inter-quartile ranges (IQRs) were 5.9 to 6.0 µg/m3 for dates when biomarkers were measured. A 10 µg/m3 increase in same-day ambient PM2.5 exposure was associated with higher relative risks of low albumin (RR: 1.01, 95% CI: 1.01, 1.02) and low hemoglobin (RR: 1.02, 95%CI: 1.01, 1.03). Associations of same-day ambient PM2.5 exposure and high ferritin and low TSAT did not reach statistical significance.

CONCLUSIONS: Short-term PM2.5 exposure was associated with low serum hemoglobin and albumin. The findings among patients receiving in-center hemodialysis lend support for the potential of inflammation-driven changes after PM2.5 exposure.

P-0953 Diesel exhaust particles affected heart rate variability but not endothelial function – results from a controlled chamber study

Leo Stockfelt[1], Yiyi Xu[1], Anders Gudmundsson[2], Jenny Rissler[2,3], Christina Isaxon[2], Jonas Brunskog[4], Joakim Pagels[2], Patrik Nilsson[2], Margareta Berglund[5], Lars Barregard[1], Mats Bohgard[2], Maria Albin[6,7], Inger Hagerman[5], Aneta Wierzbicka[2]

[1]Gothenburg University/Sahlgrenska University Hospital, Gothenburg, Sweden, [2]Ergonomics and Aerosol Technology, Department of Design Sciences, Lund University, Sweden, Lund, Sweden, [3]Bioeconomy and Health, RISE Research Institutes of Sweden, Lund, Sweden, Lund, Sweden, [4]Department of Electrical Engineering, Technical University of Denmark, Denmark, [5]Department of Cardiology, Karolinska Institute, Karolinska University Hospital, Huddinge, Sweden, Stockholm, Sweden, [6]Division of Occupational and Environmental Medicine, Lund University, Sweden, Umeå, Sweden, [7]Unit of Occupational Medicine, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden

BACKGROUND: Adverse cardiovascular effects have been associated with exposure to both diesel exhaust and road traffic noise. Effects of these highly correlated exposures are hard to disentangle in epidemiological studies, but effects on intermediary outcomes and mechanisms can be studied experimentally. Heart rate variability (HRV) and peripheral arterial tonometry (PAT), a measure of endothelial function, are noninvasive methods to study mechanisms related to the autonomic nervous system associated with cardiovascular risk. The aim of this study was to evaluate the impact of diesel exhaust particles and traffic noise on HRV and PAT, and possible synergistic effect of combined exposure.

METHODS: Eighteen healthy adults were in a controlled chamber exposed to four exposure scenarios in a randomized cross-over fashion. Each scenario consisted of either filtered (clean) air or diesel engine exhaust (PM concentrations around 300 µg/m3), and low (46 dB(A)) or high (75 dB(A)) traffic noise for three hours at rest. ECG was recorded for 10-minute periods before and during each scenario, and frequency-domain heart rate variability (HRV) computed. Endothelial function and arterial stiffness were assessed after each exposure using EndoPAT 2000.

RESULTS: Compared to the control scenario, HRV in the high frequency band decreased during exposure to diesel exhaust, both alone and combined with noise, but not during exposure to noise only. The differences were stronger in women. There were no synergistic effects of combined exposure, no significant differences between exposure scenarios for other HRV indices, and no effect on endothelial function or arterial stiffness after exposure.

CONCLUSION: Three-hour exposure to diesel exhaust, but not noise, was associated with decreased HRV in the high frequency band. This indicates activation of irritant receptor-mediated autonomic reflexes, and increased cardiovascular risk during chronic diesel exposure.

P-0954 Placental Cellular Composition and Umbilical Cord Metal Concentrations: A Descriptive Molecular Epidemiology Study Leveraging DNA Methylation

Catherine Bulka[1], Lauren A. Eaves[1], Amaree J. Gardner[1], Patrick J. Parsons[2,3], Aubrey L. Galusha[2,3], T. Michael O'Shea[4], Rebecca C. Fry[1,5,6]

[1]Department of Environmental Sciences & Engineering, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA, [2]Division of Environmental Health Sciences, Wadsworth Center, New York State Department of Health, Albany, USA, [3]Department of Environmental Health Sciences, School of Public Health, University at Albany, Rensselaer, USA, [4]Department of Pediatrics, School of Medicine, University of North Carolina, Chapel Hill, USA, [5]Institute for Environmental Health Solutions, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA, [6]Curriculum in Toxicology, University of North Carolina, Chapel Hill, USA

BACKGROUND AND AIM: During pregnancy, potentially toxic metals and metalloids can cross the placenta with varying degrees of efficiency. We hypothesized metal toxicokinetics may be regulated by placental cellular composition. Until recently, disentangling complex placental tissue at the population level has been challenging. Here, we leveraged DNA methylation profiles to characterize major placental cell types and described relationships with umbilical cord metal concentrations in an extremely preterm birth cohort.

METHODS: Among 145 infants born before 28 weeks' gestation enrolled in the US-based ELGAN cohort (2002-2004), we quantified concentrations of 7 non-essential metals/metalloids in cord tissue, representing passage through the placental barrier. Placental DNA methylation profiles were measured by the Illumina EPIC BeadChip and deconvoluted using a novel reference-based approach (planet) to estimate proportions of six constituent cell types. To satisfy the sum-to-one constraint of proportions, we transformed the data into pivot coordinates (a special case of isometric log-ratios) before fitting linear regression models with cord tissue metal concentrations.

RESULTS: Arsenic, lead, strontium, and barium were detected in all umbilical cord tissue samples; cadmium and mercury were detected in 97.9% and antimony in 93.7%. The most relatively abundant cell type in placental tissue was syncytiotrophoblast (31.7%), followed by nucleated red blood (27.3%), endothelial (19.4%), Hofbauer (9.6%), stromal (8.8%), and trophoblast cells (3.2%). As syncytiotrophoblasts increase, arsenic levels in cord tissue decrease (Coefficient = -0.6 ng per 1-percentage point, p-value = 0.03) whereas as Hofbauer cells increase, cadmium levels increase (Coefficient = 0.3 ng per 1-percentage point, p-value = 0.03). Null associations were observed for the other metals/metalloids.

CONCLUSIONS: The findings suggest the cellular composition of the placenta may influence the transport of environmental metals to the fetus. Future studies examining prenatal environmental exposures should consider methylation-based deconvolution as a powerful tool for investigating placental biology.

P-0965 Impact of urban exposures during pregnancy on placental small non-coding RNAs

Marta Cosin-Tomas[1,2,3], Sofia Aguilar-Lacasaña[1,2,3], Ramil Nurtdinov[7], Ioar Rivas[1,2,3], Maria Foraster[1,2,3,8], MDolores Gomez-Roig[4], Elisa Llurba-Olivé[5,6], Payam Dadvand[1,2,3], Mariona Bustamante[1,2,3], Jordi Sunyer[1,2,3]

[1]ISGlobal, Barcelona, Spain, [2]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [3]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [4]BCNatal – Barcelona Center for Maternal Fetal and Neonatal Medicine (Hospital Sant Joan de Déu and Hospital Clínic), University of Barcelona, Barcelona, Spain, [5]Maternal and Fetal Medicine Unit, Obstetrics and Gynecology Department, Sant Pau University Hospital, Barcelona, Spain, [6]Development Network (SAMID), RD16/0022/0015, Instituto de Salud Carlos III, Madrid, Spain, [7]Centre for Genomic Regulation (CRG), The Barcelona Institute of Science and Technology, Barcelona, Spain, [8]PHAGEX Research Group, Blanquerna School of Health Science, Universitat Ramon Llull (URL), Barcelona, Spain

BACKGROUND AND AIM: Epidemiological studies show that urban exposures (e.g., air pollution, built and natural environment, and noise) during pregnancy could adversely influence the developing foetus. Although the underlying mechanisms are unclear, recent findings suggest that placental transcriptome can be a proxy of placental function during pregnancy and a plausible mediator of the association between intrauterine environmental exposures and foetal growth and development, and childhood and adult health trajectories. In particular, there is an increasing interest in small non-coding(nc)RNAs, including microRNAs (miRNAs), which are regulatory RNAs critical for placenta function and foetal development. Our main aim is to assess the association of several urban exposures during pregnancy with placental small ncRNA profiles in the Barcelona Life Study cohort (BiSC).

METHODS: BiSC is a population-based birth cohort of 1,086 mother-child pairs from the Barcelona metropolitan area (2018 onwards). We will characterize exposure to air pollution, noise, green space, and built environment as indicators of the urban exposome. Placental RNA was obtained from 450 placental foetal villi biopsies. Small ncRNA profiles were measured by RNA-sequencing (library insert of 17-52 nucleotides length, 50 nucleotides sequencing length, and 5M reads/sample). Quality control, processing of RNA-sequencing data, and small ncRNAs annotation and quantification will be done with the SeqCluster/SeqBuster bioinformatic tool.

RESULTS: A pilot study of 8 samples identified a total of 550 small ncRNAs, 44% being miRNAs. MiRNAs of the placental specific C19MC cluster were found among the most abundant. In the ISEE Conference we will present the placental small ncRNA profiles and their association with urban-related exposures.

CONCLUSIONS: Studying the impact of pregnancy exposures on the foetus and its biological intermediates is crucial to prevent their harmful effects and to develop biomarkers that allow early monitoring and treatment.

P-0968 Epigenome-Wide Association of Neonatal Methylation and Prenatal PM2.5 Exposure Suggests Timing-Specific Effects

Milan Parikh[1], Cole Brokamp[1,2], Erika Rasnick[1], Lili Ding[1,2], Tesfaye Mersha[2,3], Katherine Bowers[1,2], Alonzo Folger[1,2]
[1]Division of Biostatistics and Epidemiology, Cincinnati Children's Hospital Medical Center, Cincinnati, USA, [2]Department of Pediatrics, University of Cincinnati College of Medicine, Cincinnati, USA, [3]Division of Asthma Research, Cincinnati Children's Hospital Medical Center, Cincinnati, USA

BACKGROUND AND AIM: Exposure to particulate matter with an aerodynamic diameter smaller than 2.5 microns (PM2.5) can affect birth outcomes through physiological pathways such as inflammation. One potential way PM2.5 affects physiology could be through altering DNA methylation (DNAm). Considering that exposures during specific windows of gestation may have unique effects on DNAm, we hypothesized a timing-specific association between PM2.5 exposure during pregnancy and DNAm in the neonatal epithelial-cell epigenome.

METHODS: After collecting salivary samples from a cohort of 91 neonates, DNAm was assessed using the MethylationEPIC array (EPIC) which covers over 850,000 CpG methylation sites (850K) on the epigenome. Daily ambient PM2.5 concentrations were estimated based on the mother's address of primary residence during pregnancy. PM2.5 was then averaged over the first two trimesters, separately and combined, and tested for association with DNAm through an epigenome-wide association (EWA) analysis. for each EWA, FDR-corrected $p < 0.05$ constituted a significant finding, and every CpG site with uncorrected $p < 0.0001$ was selected to undergo pathway and network analysis to identify molecular functions enriched by them.

RESULTS: Our analysis showed that cg18705808 was associated with the combined average of PM2.5. Pathway and network analysis revealed little similarity between the first two trimesters. Previous studies reported that TMEM184A, the gene regulated by cg18705808, has a putative role in inflammatory pathways.

CONCLUSIONS: The differences in pathway and network analyses could potentially indicate trimester-specific effects of PM2.5 on DNAm. Further analysis with greater temporal resolution would be valuable to fully characterize the effect of PM2.5 on DNAm and child development.

P-0972 Exposure to Metals and the microRNA Profile of Participants in the Normative Aging Study

Mahdieh Danesh Yazdi[1], Cuicui Wang[1], Anna Kosheleva[1], Nicole Comfort[2], Haotian Wu[2], Andrea Baccarelli[2]
[1]Harvard TH Chan School of Public Health, Boston, USA, [2]Columbia Mailman School of Public Health, New York City, USA

BACKGROUND AND AIM: Metals have previously been associated with adverse effects in multiple organ systems. However, the molecular mechanisms by which they cause these effects are not fully elucidated. MicroRNAs are short non-coding RNA sequences that play an important role in the regulation of gene expression and may be a mechanism by which metals influence health.

METHODS: The study population consisted of496 persons (with 694 samples) enrolled in the Normative Aging Study (NAS). This cohort began recruiting male veteran who lived in the New England area in 1963 and has followed up with them every three to five years ever since. Our study period includes visits from 1999 to 2014. Extracellular microRNAs were sequenced from participants' plasma, and toenail samples were used to measure levels of metals, namely: arsenic (As), cadmium (Cd), lead (Pb), manganese (Mn), and mercury (Hg). We used canonical correlation analysis (CCA) to find whether metal levels correspond with microRNA levels. We further assessed the relationship between metals and microRNA using Bayesian kernel machine regression (BKMR).

RESULTS: Our preliminary CCA results showed very strong correlations between the first five canonical variables of the metals and those of the microRNA, with correlation values of 0.937, 0.923, 0.903, 0.894, 0.886, respectively. However, only the correlation between the first canonical variables was statistically significant. Pb and Cd showed the strongest association with the first canonical variable of the metals dataset. The strongest associations between the first canonical variable in the microRNA set were with the following microRNAs: miR-182-5p, miR-183-5p, miR-516b-5p, and miR-26a-5p.

CONCLUSIONS: There was a strong correlation between the first canonical variables of the metals and the microRNA, indicating a potential association between them. Future analyses will use BKMR to assess the joint effect of metals on the microRNA profile.

KEYWORDS: Metals, microRNA, Epigenetics, Mixtures Analysis

P-0975 Exposure to persistent organic pollutants and biomarkers of oxidative stress - A scoping review

Jiawen Chen[1], Brittney Baumert[1], Shante Robinson[2], Yiping Li[1], Yijie Li[1], Elizabeth Costello[1], Sarah Rock[1], Jesse Goodrich[1], Yinqi Zhao[1], Sandrah Eckel[1], Max Aung[1], Rob McConnell[1], David Conti[1], Lida Chatzi[1]
[1]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, USA, [2]University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Oxidative stress is a known mediator in pathways related to environmental exposures and numerous diseases. However, epidemiological studies investigating the association of persistent organic pollutants (POPs) and oxidative stress are limited and revealed inconsistent results. This scoping review evaluates the effect of POPs, including per- and polyfluoroalkyl substances (PFAS), polychlorinated biphenyls (PCBs), organochlorine pesticides, and polybrominated diphenyl ethers (PBDEs), on oxidative stress biomarkers in epidemiological studies.

METHODS: A search was conducted in PubMed and Embase through September 7, 2021, to identify all published studies related to POPs and oxidative stress. Search results were uploaded into Covidence systematic review management tool for de-duplication and for double independent abstract and full-text screening. We included human observational studies reporting at least one exposure and oxidative stress biomarker of interest for data extraction. The Office of Health Assessment and Translation risk of bias assessment tool was implemented for quality assessment.

RESULTS: Thirteen epidemiological studies met inclusion criteria – 7 for organochlorine pesticides, 5 for PFAS, 3 for PCBs, and 1 for PBDEs. Ten studies have overall low risk of bias. We found consistent positive associations of organochlorine pesticides and PFAS with several oxidative stress biomarkers, eg, of organochlorine pesticides with protein carbonyls, nitric oxide, and malondialdehyde, and of PFAS with 8-hydroxyguanosine and malondialdehyde. Additionally, we found consistent negative associations of organochlorine pesticides with several antioxidants, such as with acetylcholine esterase and paraoxonase-1, but associations of organochlorine pesticides, PCBs, and superoxide dismutase were inconsistent.

CONCLUSIONS: This is the first review of association of POPs and oxidative stress biomarkers in humans. Lack of prospective studies and some inconsistent results pose challenges to draw causal inference. Further evidence is needed to better elucidate the relationship of POPs and oxidative stress.

P-0979 Use of high-resolution metabolomics to assess the biological perturbations associated with maternal exposure to Bisphenol A and Bisphenol F among pregnant African American women

Youran Tan[1], Rachel Tchen[1], Dana Barr[1], P. Barry Ryan[1], Tran ViLinh[2], Zhenjiang Li[1], Yi-Juan Hu[3], Alicia K. Smith[5], Dean P. Jones[4], Anne L. Dunlop[5], Donghai Liang[1]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Clinical Biomarkers Laboratory, Division of Pulmonary, Allergy and Critical Care Medicine, School of Medicine, Emory University, Atlanta, USA, [3]Department of Biostatistics and Bioinformatics, Emory University, Atlanta, USA, [4]Department of Medicine, School of Medicine, Emory University, Atlanta, USA, [5]Department of Gynecology and Obstetrics, School of Medicine, Emory University, Atlanta, USA

BACKGROUND: Human and animal exposure to bisphenol A (BPA) is strongly associated with adverse developmental and reproductive effects. The molecular mechanisms by which BPA exposure exerts its effects are not well-understood, even less known about its analogues bisphenol F (BPF). To address these knowledge gaps, we conducted an untargeted metabolome-wide association study (MWAS) to identify metabolic perturbations associated with BPA/BPF exposures in a pregnant African American cohort.

METHODS: From a subset (N=230) of study participants enrolled in the Atlanta African American Maternal-Child cohort, we collected both urine samples, for targeted exposure assessment of BPA and BPF, and serum samples, for high-resolution metabolomics (HRM) profiling, during early pregnancy (8-14 weeks' gestation). Using an established untargeted HRM workflow consisting of MWAS modeling, pathway enrichment analysis, and chemical annotation and confirmation, we investigated the potential metabolic pathways and features associated with BPA/BPF exposures.

RESULTS: The geometric mean creatinine-adjusted concentrations of urinary BPA and BPF were 0.85±2.58 and 0.70±4.71 μg/g creatinine, respectively. After false positive discovery rate correction at 20 % level, 264 and 733 unique metabolic features were significantly associated with urinary BPA and BPF concentrations, representing 10 and 12 metabolic pathways, respectively. Three metabolic pathways, including steroid hormones biosynthesis, lysine and lipoate metabolism, were significantly associated with both BPA and BPF exposure. We confirmed the chemical identity of 16 of the metabolites significantly associated with BPA or BPF exposure with Level One evidence using reference standard.

CONCLUSIONS: Our findings support that exposure to BPA and BPF in pregnant women is associated with the perturbation of aromatic amino acid metabolism, xenobiotics metabolism, steroid biosynthesis, and other amino acid metabolism closely linked to stress responses, inflammation, neural development, reproduction, and weight regulation.

P-0982 Short-term PM2.5 exposure and executive function: association and neurophysiological mechanisms

Limei Ke[1], Yao Zhang[1], Qian Di[1]
[1]*Tsinghua University, Beijing, China*

INTRODUCTION: Although converging evidence has shown that exposure to PM2.5 caused adverse effects on brain structure and cognitive function, the association between the short-term exposure to PM2.5 and cognition dysfunction remain underexplored, especially possible neurophysiological mechanisms.

METHODS: We conducted a longitudinal observational study with four repeated measurement sessions among 90 young adults from September 2020 to June 2021. During each measurement session, we measured participants' personal level air pollution exposure for one week with portable monitors, followed by executive function assessment and electrophysiological signals recordings at the assessment center. Standard Stroop color-word test was used accompanied with electrophysiological recordings to assess performance on executive function.

RESULTS: Adjusted mixed-effect models demonstrated that elevated PM2.5 exposure three days prior to cognitive assessment (lag 3) was associated with (1) declined performance in both congruent and incongruent tasks in Stroop tests, (2) reduced lower alpha event-related desynchronization (ERD) during 500-1000 ms after stimuli, both indicating impaired executive control. No associations were found between short-term PM2.5 exposure and aperiodic exponents both in tonic and phasic state, residual periodic alpha oscillation in tonic state.

CONCLUSIONS: Our results provided evidence that short-term PM2.5 exposure was associated with brain executive dysfunction. Reduced alpha ERD was likely to be the underlying pathway through which PM2.5 induced adverse effects on neuron activities during cognitive tasks. This study implies that transcranial electric stimulation and transcranial magnetic stimulation could be applied to access cortical neuron excitability to compensate for the cognitive impairment caused by PM2.5 exposure.

P-0983 Persistent organic pollutant exposure contributes to Black/White differences in leukocyte telomere length: Evidence from NHANES 1999-2002

Emily Roberts[1], Jonathan Boss[1], Stephen Salerno[1], Bhramar Mukherjee[1], Ami Zota[2], Belinda Needham[1]
[1]University of Michigan, Ann Arbor, USA, [2]Columbia University, New York, USA

BACKGROUND AND AIM: Despite racial disparities in diseases of aging and premature mortality, non-Hispanic Black Americans tend to have longer leukocyte telomere length (LTL), a biomarker of cellular aging, than non-Hispanic White Americans. Previous findings suggest that exposures to certain persistent organic pollutants (POPs) are both racially-patterned and associated with longer LTL. We examine whether Black/White differences in LTL are explained by differences in exposure to 15 POPs by estimating the indirect effect (IE) of race on LTL that is mediated through polychlorinated biphenyls (PCBs), furans, and dioxins, as well as their mixtures.

METHODS: Our study includes 1,251 adults from the 1999-2000 and 2001–2002 cycles of the National Health and Nutrition Examination Survey (NHANES). We characterized single-pollutant mediation effects by constructing survey-weighted linear regression models and implemented various approaches to quantify a global mediation effect of POPs, including unpenalized linear regression, ridge regression, and three summary exposure scores (derived from principal components analysis [PCA], principal direction of mediation, and the Toxic Equivalency Quotient [TEQ] score) using survey weights when possible.

RESULTS: We found support for the hypothesis that exposure to PCBs partially mediates Black/While differences in LTL. In single-pollutant models, there were significant IEs of race on LTL through PCBs 118, 138, 153, 170, 180, and 187 (percent mediated ranging 18.4-43.4%) after correction for multiple testing. Ridge regression and models examining summative exposure scores with linear combinations derived from PCA and TEQ scores showed significant IE when incorporating survey weights (percent mediated 26.0-34.8%), which also supports our hypothesis based on the IE attributable to exposure mixtures.

CONCLUSIONS: Exposures to individual POPs and their mixtures, which may arise from residential and occupational segregation, may help explain why Black Americans have longer LTL than their White counterparts, challenging genetic explanations for counterintuitive race differences in cellular aging.

P-0984 Effects of prenatal exposure to air pollution on placental molecular hallmarks and black carbon load

Laura-Concepció Gómez Herrera[1,2,5], Dries S Martens[2], Marta Cosin-Tomas[1], Eva Bongaerts[2], Sofia Aguilar-Lacasaña[1,5], Yumjirmaa Mandakh[7], Ioar Rivas[1], Maria Foraster[1,3,4], Maria Dolores Gomez-Roig[6], Payam Dadvand[1,3,4], Tim S Nawrot[2], Mariona Bustamante[1,3,4], Jordi Sunyer[1,3,4]

[1]ISGlobal, Barcelona, Spain, [2]Centre for Environmental Sciences, Hasselt University, Hasselt, Belgium, [3]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [4]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [5]Universitat de Barcelona (UB), Barcelona, Spain, [6]BCNatal | Barcelona Center for Maternal Fetal and Neonatal Medicine, Hospital Sant Joan de Déu, Barcelona, Spain, [7]Environment, Society and Health, Division of Occupational and Environmental Medicine, Department of Laboratory Medicine, Lund University, Lund, Sweden

BACKGROUND AND AIM: There is a rising social concern regarding the effects of air pollution on fetal development, as increasing epidemiological evidence shows an association with several adverse birth outcomes. However, the specific mechanisms that drive these outcomes are still not comprehensively elucidated. To better understand the pathophysiology of prenatal exposure to air pollution through the placenta is precisely one of the aims of the Barcelona Life Study Cohort (BiSC).

METHODS: BiSC is a birth cohort of 1086 mother-child pairs residing in the Barcelona metropolitan area (Spain) that includes a comprehensive follow-up, both environmental (personal exposure to noise and air pollution) and clinical (3rd trimester comprehensive sonography and reproductive outcomes). Further post-natal follow-up is focused on neurocognitive development and includes a Bayley's test (BSID-III) at 6 months.
A specific work package in BiSC is focused on how the placenta responds to prenatal exposure to air pollution, as an intermediate organ between the environment and its effects on early-life development. Specific sections include:
1. To precisely evaluate the personal exposure to air pollution during pregnancy and quantify the translocation of air pollution particles (black carbon) to placental tissue through advanced microscopy.
2. To evaluate placental function measuring maternal-fetal circulation through Doppler sonography, as well as molecular biomarkers (telomere length and mitochondrial DNA content through qPCR) to define both the degree of tissue aging and metabolic capacity.

RESULTS: Black carbon particle detection, telomere length and mitochondrial DNA content measures are currently being performed in placental samples from the BiSC cohort. Dose response associations between air pollution exposure, placental carbon load and markers of placental function (maternal-fetal circulation, placental telomere length and mitochondrial DNA content) will be investigated.

CONCLUSIONS: This study will help to understand underlying mechanisms of air pollution effects on early life.

KEYWORDS: Air pollution, DOHaD, placental function, fetal development

P-0990 Phthalates and Adipokines in Midlife Women: A Cross-sectional Study in the Study of Women's Health Across the Nation (SWAN)

Mia Peng[1], Carrie Karvonen-Gutierrez[1], William Herman[1,2], Bhramar Mukherjee[1,3], Sung Kyun Park[1,4]
[1]Department of Epidemiology, University of Michigan School of Public Health, Ann Arbor, USA, [2]Department of Internal Medicine, School of Medicine, University of Michigan, Ann Arbor, USA, [3]Department of Biostatistics, University of Michigan School of Public Health, Ann Arbor, USA, [4]Department of Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, USA

BACKGROUND AND AIM: Phthalates are associated with obesity and its metabolic complications, but the mechanisms are not well-understood. We examined if phthalate exposure was associated with adverse adipokine profiles, a potential mechanism of metabolic disturbance.

METHODS: In 1250 midlife women in the Study of Women's Health Across the Nation (SWAN), we measured 11 phthalate metabolites in spot urine samples and leptin and high-molecular-weight (HMW) adiponectin in fasting blood samples from 2002/2003. We used linear regression to examine the association between each hydration-adjusted metabolite and log-transformed leptin, HMW adiponectin, and the leptin:HMW adiponectin ratio, adjusting for demographic, lifestyle, and menopause-related factors. Additionally, we used Bayesian kernel machine regression (BKMR) to examine the joint associations between the phthalate metabolite mixture and adipokines.

RESULTS: In single-pollutant models adjusted for all covariates except body mass index (BMI), most phthalate metabolites were positively associated with leptin. Mono(2-ethylhexyl) phthalate (MEHP) was positively associated with HMW adiponectin and inversely associated with the leptin:HMW adiponectin ratio. Adjustment for BMI attenuated all associations with leptin, but MEHP remained robustly associated with higher HMW adiponectin and a lower leptin:HMW adiponectin ratio. Compared to the 1st quartile, the 2nd to 4th quartiles of MEHP were associated with -16.9% (95% confidence interval (CI): -29.1, -2.6), -24.0% (-35.2, -10.8), and -17.7% (-30.2, -3.1) lower leptin:HMW adiponectin ratio. BKMR revealed a statistically significant, positive association between the phthalate metabolite mixture and HMW adiponectin and identified MEHP as the most important metabolite.

CONCLUSIONS: Phthalates were not associated with leptin concentrations independent of BMI. MEHP was associated with higher HMW adiponectin and a lower leptin:HMW adiponectin ratio, suggesting a more beneficial adipokine profile. The apparent difference between these findings and phthalates' associations with metabolic diseases calls for further investigations on phthalates' potential metabolism-disrupting mechanisms.

P-0992 Periconceptional and Prenatal Metals Exposure and Extracellular Vesicle miRNA in Breast Milk: A Pilot Study

Caitlin Howe[1], David Armstrong[2], Meghan Muse[1], Diane Gilbert-Diamond[1], Jiang Gui[1], Anne Hoen[1], Thomas Palys[1], Brock Christensen[1], Margaret Karagas[1]
[1]Dartmouth College, Lebanon, USA, [2]White River Junction VA Medical Center, White River Junction, USA

BACKGROUND AND AIM: Breast milk is a rich source of extracellular vesicle (EV) miRNA, which are hypothesized to contribute to maternal-offspring communication during the postnatal period and child development. Impacts of environmental contaminants on EV miRNA in breast milk are largely unknown. Our pilot study examined the relationships of metal exposures during the periconceptional and prenatal periods with breast milk-derived EV miRNA.

METHODS: EV miRNA were extracted from breast milk samples collected approximately 6 weeks postpartum from participants (N=54) in the New Hampshire Birth Cohort Study. 799 miRNA were profiled using the NanoString nCounter platform; 200 miRNA were widely detectable and retained for downstream analyses. Exposure to five metals (arsenic, manganese, mercury, lead, and selenium) during the periconceptional and prenatal periods was measured in maternal toenail clippings collected at two time points. Metal-miRNA associations were evaluated using covariate-adjusted robust linear regression models.

RESULTS: In this preliminary analysis, we found 12 miRNA to be inversely associated with As exposure in the periconceptional period and 42 miRNA to be inversely associated with As exposure in the prenatal period. Four miRNA were inversely associated with As exposure at both time points (miR-106b-5p, miR-152-3p, miR-429, miR-1234-3p). Associations for other metals showed potential trends which motivate further investigation in a larger study.

CONCLUSIONS: In a pilot study of participants in northern New England, we identified four miRNA that were inversely associated with both periconceptional and prenatal As exposure and an additional set of miRNA that were inversely associated with As exposure in a time-dependent manner. In future studies, we plan to expand the number of participants with these measures to investigate multiple metal exposures simultaneously using environmental mixture modeling approaches, examine possible downstream consequences for children's health, and conduct validation studies in other cohorts.

P-1004 Hair cortisol as a biomarker of chronic stress: influence of school context and bullying

Izaro Babarro[1,2], Ainara Andiarena[1,2], Elvar Theodorsson[3], Eduardo Fano[1,2], Andrea Lebeña[3], Monica Guxens[4,5,6,7], Jordi Sunyer[4,5,8], Jesus Ibarluzea[1,2,4,9]

[1]University of the Basque Country (UPV/EHU), Donostia/San Sebastian, Spain, [2]Biodonostia Health Research Institute, Donostia/San Sebastian, Spain, [3]University of Linköping, Linköping, Sweden, [4]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Madrid, Spain, [5]Institute for Global Health (ISGlobal), Barcelona, Spain, [6]University of Pompeu Fabra (UPF), Barcelona, Spain, [7]Erasmus University Medical Centre-Sophia Children´s Hospital, Roterdam, The Netherlands, [8]Municipal Institute of Medical Research (IMIM-Hospital del Mar), Barcelona, Spain, [9]Health Department of Basque Government, Donostia/San Sebastian, Spain

BACKGROUND: Bullying has been identified as the most common form of aggression and the main source of stress during childhood and adolescence. The study aimed to analyze the effects of school context and bullying (victim, bully and bully/victim roles) as chronic stressors, using hair cortisol as a biomarker. Moreover, executive function was examined for its relationship with cortisol as well as its influence on bullying and academic skills.
METHOD: The study included 659 eleven-year-old preadolescents from the INMA cohorts of Gipuzkoa and Sabadell. Bullying (Olweus Bully Victim Questionnaire) and variables related to the school context were used as stressors: perception of the school environment (Kidscreen-27 questionnaire), problems with peers (SDQ: strength and difficulties questionnaire) and academic skills (ad hoc questionnaire). Hair samples were used to measure cortisol levels. Additionally, executive function was evaluated using the Cups Task neuropsychological test. To test our hypothesis, structural equation modeling was conducted.

RESULTS: In this study, it was found that being a bully/victim in bullying situations is associated with higher hair cortisol concentrations (b=0.075; p=0.056). Additionally, higher hair cortisol concentrations were associated with worse executive functions across all models (victims: b=0.113; p=0.004; bullies: b=0.112; p=0.004; bullies/victims: b=0.112; p=0.004). Finally, having a poorer relationship with peers, a poorer perception of a school environment or lower academic skills did not affect hair cortisol levels (p>0.05).

CONCLUSIONS: The present study examines the relationship between school context in general and bullying in particular with hair cortisol concentrations as an indicator of chronic stress for the first time. Despite concluding that the role of bully/victim appears to be related to hair cortisol concentrations, more research is needed to study this relationship.

P-1006 The Association between Exposure to Metals and Phthalates during Pregnancy and Children's DSM-oriented Problems at Age Four Years

Tsung-Lin Tsai[1], Chia-Jung Hsieh[2], Ming-Tsang Wu[3], Mei-Lien Chen[4], Po-Hsiu Kuo[5], Chien-Wen Sun[1], Shih-Fen Tsai[1], Huei-Ju Liu[1], Shu-Li Wang[1]

[1]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli, Taiwan, [2]Department of Public Health, Tzu Chi University, Hualien, Taiwan, [3]Research Center for Environmental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, [4]Institute of Environmental and Occupational Health Sciences, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan, [5]Department of Public Health, Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan

BACKGROUND AND AIM: About 10%–20% of children and adolescents suffer from mental problems worldwide, and it may increase the global burden of disease. Neurotoxic metals are associated with inflammation or cytotoxicity in the brain. Prenatal phthalates (PAEs) exposure is associated with cognitive function deficits. However, the effect of co-exposure to metals, PAEs, and the association with child behaviors are less well studied. We aimed to investigate prenatal co-exposure to metals and PAEs and the consequent behavioral outcomes in early childhood.

METHODS: Participants from the central, southern, and eastern areas of the Taiwan Maternal and Infant Cohort Study were followed up during 2015–2017. We quantified the maternal urinary concentration of metals and metabolites of PAEs as prenatal exposure. Child mental disorders at age four years were according to caregiver-reported scales of the Child Behavior Checklist to define DSM (The Diagnostic and Statistical Manual of Mental Disorders)-oriented problems. Finally, there were 408 children included in further statistical analysis.

RESULTS: Maternal urinary copper was significantly associated with depressive (OR=2.30), attention-deficit/hyperactive (OR=2.31), and oppositional defiant (OR=1.98) in children. Increased concentration of cadmium and lead was significantly associated with attention-deficit/hyperactive (OR=2.55), and oppositional defiant (OR=1.70) problems, respectively. Maternal urinary concentration of mono-isobutyl phthalate was also significantly associated with depressive problems (OR=1.72) in children. In the further analysis that considering prenatal co-exposure to metals and PAEs, co-exposure to these materials was significantly associated with autism spectrum problems in children (OR=5.15).

CONCLUSIONS: We observed that prenatal exposure to copper, cadmium, lead, and dibutyl phthalate was associated with some DSM-oriented problems in children at age four. Also, prenatal co-exposure to metals and PAEs may play a certain role in children's mental health. Reduction of exposure to metals and PAEs in pregnancy is suggested to prevent increased mental problems in childhood.

P-1007 Pesticide exposure and development in children living in low- and middle-income countries: a systematic review

Lilia Bliznashka[1], Aditi Roy[2], Lindsay Jaacks[1]
[1]Global Academy of Agriculture and Food Systems, University of Edinburgh, Midlothian, UK, [2]Public Health Foundation of India, New Delhi, India

BACKGROUND AND AIM
Pesticides are widely used in residential and agricultural settings in low- and middle-income countries (LMICs). Evidence from high-income settings shows that pesticide exposure in pregnancy and childhood is associated with poor child development. Our aim was to systematically review evidence on the associations between pesticides and development in children <18 years in LMICs.

METHODS: We searched 10 electronic databases through November 2021 with no language restriction. We included prospective cohort and cross-sectional studies investigating associations between self-reported or measured pesticide exposure in children and development. Two independent researchers screened studies and extracted data. Results were summarised narratively.

RESULTS: of 3372 records retrieved, 31 articles from 12 countries met the inclusion criteria. All articles assessed associations cross-sectionally; sample sizes ranged from 35 to 1762 (n=9083 total participants). Twenty-one articles assessed urine or blood biomarkers, five assessed self-reported exposure, and five used community of residence as a proxy for exposure. Two articles assessed organochlorines, 26 organophosphates, 11 carbamates, and eight pyrethroids.
In the three articles assessing children <2 years, pesticides were negatively associated with motor and social development (n=2), but not with language or adaptive development (n=2). In the 12 articles assessing pre-schoolers (2-5 years), pesticides were negatively associated with motor (n=4), language (n=3), and social (n=3) development, and with attention, memory, and processing speed (n=2). Two studies found no associations between organophosphates and these outcomes. In the 21 articles assessing school-aged children (6-18 years), pesticides were negatively associated with motor development (n=4), memory (n=6), attention (n=4), processing speed (n=4), and IQ (n=2). Five studies found no associations between pesticides and these outcomes.

CONCLUSIONS: Pesticides may be associated with deficits in multiple child development domains. However, evidence in LMICs remains inconclusive due to the small number of studies and variable methodologies used.

KEYWORDS: pesticides, child development, developing countries

P-1009 Associations of gestational phenol exposure with cognition in 7.5-month-old infants

Jenna Sprowles[1], Megan Woodbury[2], Elizabeth Enright[3], Andrea Aguiar[1], Antonia Calafat[4], Susan Schantz[1]
[1]Beckman Institute for Advanced Science and Technology, University of Illinois, Urbana-Champaign, Urbana, USA, [2]College of Engineering, Northeastern University, Boston, USA, [3]Department of Psychology, St. Mary's College of Maryland, St. Mary's City, USA, [4]Division of Laboratory Sciences, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA

BACKGROUND AND AIM: Triclosan and benzophenone-3 are ubiquitous phenolic endocrine disrupting chemicals. Similar chemicals are associated with adverse neurodevelopmental outcomes, but little is known about the effects of triclosan and benzophenone-3 on neurodevelopment. We investigated associations of gestational triclosan or benzophenone-3 exposure with infant cognitive outcomes.

METHODS: A visual recognition memory task assessed 312 7.5-month-old infants (151 males; 161 females) from a prospective birth cohort study. Triclosan and benzophenone-3 concentrations were quantified in maternal urines pooled from five timepoints across pregnancy. Infrared eye-tracking recorded infants' looking as they observed identical black-and-white photographs of human faces side-by-side (familiarization) and then the familiar next to a novel face (test trials). All infants saw the same face pairs. However, half the infants saw one set of faces as familiar (stimulus set 1), and half saw the other set as familiar (stimulus set 2). Multivariable generalized linear models (adjusted for income, parity, gestational age, testing age, child sex, stimulus set) assessed associations of triclosan or benzophenone-3 with time to familiarization (time to accrue 20s of looking during familiarization; attention measure), average run duration (time looking at stimuli before looking away; information-processing speed measure), and novelty preference (proportion of time looking at novel faces; recognition-memory measure).

RESULTS: Mothers were mostly white and college-educated with household income >$50,000/yr. Urinary concentrations (mean ± SD μg/L) of triclosan (68.8 ± 43.5) and benzophenone-3 (339.2 ± 638.5) were higher than those in reproductive-age females in the general U.S. population. Sex- and set-specific estimates demonstrated associations only in males who saw set 2: triclosan with longer time to familiarization (β=0.076; 95%CI: 0.04,0.112; p<0.0001) and benzophenone-3 with longer run duration (β=0.001; 95%CI: -0.0001,0.002; p=0.067).

CONCLUSIONS: In male infants, gestational exposure to triclosan and benzophenone-3 may be associated with poorer attention and slower information processing, respectively. (ES007326;ES022848;RD83543401;OD023272)

KEYWORDS: phenols, infant cognition, neurodevelopment

P-1011 The effect of Bisphenol A exposure on Attention Deficit Hyperactivity Disorder

I-Jen Wang[1]

[1]*Department of Pediatrics, Taipei Hospital, Ministry of Health and Welfare; School of Medicine, National Yang-Ming University; China Medical University, Taiwan,*

BACKGROUND The effect of Bisphenol A (BPA) on attention deficit/hyperactivity disorder (ADHD) is not fully understood. This study investigated the associations (i) between postnatal BPA exposure and ADHD in children; and (ii) between BPA and IgE levels for the possible disease pathogenesis.

METHOD A total of 453 children from Childhood Environment and Allergic Diseases Study cohort with urine samples were recruited in Taiwan. Urinary BPA glucoronide (BPAG) levels were measured by UPLC-MS/MS. The associations between BPAG levels and IgE levels and the risk of ADHD were evaluated by multivariate linear regression and logistic regression.

RESULT The geometric mean (SD) of BPAG concentrations was 8.84(±2.57) ng/ml at age 6. Urinary BPAG levels were positively associated with the risk of ADHD at age 6 (β=3.21 KU/l per ln-unit increase BPAG level; 95% CI, 0.99- 10.51 KU/l), after adjusting for potential confounders . There was no significant gender difference. The BPAG levels were positively associated with IgE levels at age 6 (β=64.85 KU/l per ln-unit increase BPAG level; 95% CI, 14.59- 115.11 KU/l).

CONCLUSION BPA exposures were positively associated with the risk of ADHD in children. The BPAG levels were positively associated with IgE levels.

P-1019 Early-life critical windows of metal exposure associated with internalizing symptoms in young adolescents

Elza Rechtman[1], Christine Austin[1], Paul Curtin[1], Esmeralda Navarro[1], Demetrios M. Papazaharias[1], Libni A. Torres-Olascoaga[2], Luis Bautista[2], Sandra Martínez-Medina[3], Rafael Lara-Estrada[4], Erika Proal[2], Viviana Villicana[2], Cheuk Y. Tang[5], Martha M Téllez-Rojo[3], Robert O. Wright[1], Megan K. Horton[1], Manish Arora[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Center for Nutrition and Health Research, National Institute of Public Health, Mexico, [3]National Institute of Perinatology, Mexico, [4]National Research Laboratory in Imaging and Medical Instrumentation, Universidad Autónoma Metropolitana, México, [5]Department of Diagnostic, Molecular, and Interventional Radiology, Icahn School of Medicine at Mount Sinai, New York, USA

Introduction and Aim: Internalizing disorders, such as anxiety and depression, affect 10 – 20% of children and increase the risk for later-life psychopathology. The neural circuitry subserving internalizing phenotypes begins developing in utero and is vulnerable to early-life environmental exposures. Although early-life exposure to metals can adversely impact children's neurodevelopment and have lifelong impacts on mental health, little is known about critical windows to metal exposures and adolescent internalizing disorders. In this study, we hypothesized that early-life exposure to a mixture of metals is associated with increased internalizing problems in early adolescence.

METHODS: Among 431 (8-12 years; 216 females) pre-adolescents enrolled in the Programming Research in Obesity, Growth, Environment and Social Stressors (PROGRESS) longitudinal birth cohort study in Mexico City, we estimated weekly concentrations of 15 metals in naturally shed deciduous teeth using laser ablation-inductively coupled plasma-mass spectrometry (i.e., Ba, Bi, Cd, Co, Cr, Cu, Li, Mg, Mn, Mo, Ni, Pb, Sn, Sr, and Zn) from the 14th gestation week through one year of age). Internalizing problems were assessed using the Behavior Assessment System for Children, 2nd edition (BASC-2). We used lagged weighted quantile sum (lWQS) regression to estimate a time-varying mixture effect of multiple metals on internalizing problems. Models were adjusted for age and sex.

RESULTS: A higher metal mixture index in the 22nd-43rd postnatal weeks was associated with increased internalizing problems (maximum $\beta = 0.37$ [95% CI 0.06, 0.69]), driven mainly by Mg, As, Sn, and Bi.

CONCLUSIONS: This study supports the hypothesis that mixed metal exposure during specific critical windows in early life may associate with mental health disorders in childhood and adolescence. Our lWQS modeling approach and results may inform the role of exposure timing in driving neurodevelopmental outcomes, thereby pointing to future optimal, efficient, and properly timed public health interventions.

P-1022 Associations of Prenatal Metal Exposure and Non-nutritive Suck Among Infants from the Puerto Rico Testsite for Exploring Contamination Threats (PROTECT) Birth Cohort Study

Christine Kim[1], Deborah Watkins[1], Emily Zimmerman[2], Bhramar Mukherjee[1], Zaira Rosario-Pabon[3], Carmen Velez-Vega[3], Akram Alshawabkeh[2], Jose Cordero[4], John Meeker[1]

[1]University of Michigan, Ann Arbor, USA, [2]Northeastern University, Boston, USA, [3]University of Puerto Rico, San Juan, Puerto Rico, [4]University of Georgia, Athens, USA

BACKGROUND AND AIM: Infant non-nutritive sucking (NNS) has been used as an early marker of neonatal brain function. Although there is an established relationship between metal exposure and brain development, the association between prenatal metal exposure and NNS has yet to be explored. To have a better understanding of the relationship, in this study, we explored associations between maternal urinary metal concentrations and NNS measurements among 116 infants from the Puerto Rico PROTECT birth cohort.

METHODS: We measured urinary concentrations for seven metals collected between 16-20 weeks and 24-28 weeks gestation. Linear mixed effects models (LMEs) were used to regress NNS on metals, adjusting for specific gravity, maternal age, birth weight, and fetal sex. Fetal sex effects were estimated using interaction terms between metal exposure variables and fetal sex indicators.

RESULTS: We observed significant positive associations between mercury and manganese with NNS duration (mercury: Δ= 1.08, 95% CI: 0.42, 1.74; manganese: Δ= 0.67, 95% CI: 0.15, 1.20) and NNS cycles/min (mercury: Δ= 1.85, 95% CI: 0.58, 3.11; manganese: (Δ= 1.37, 95% CI: 0.40, 2.34). Furthermore, the association between NNS cycles/burst and manganese (Δ= 4.44, 95% CI: 1.40, 7.47) were in the opposite direction from its association with zinc (Δ= -9.30, 95% CI: -14.71, -3.89), as well as with copper (Δ= -6.58, 95% CI: -12.06, -1.10). We also observed differences in metal-NNS associations by fetal sex.

CONCLUSIONS: We observed significant associations between prenatal metal exposure and child neurodevelopment, using NNS measurements, among infants from the ongoing Puerto Rico PROTECT cohort. We believe this study will inform future efforts aimed at reducing health risks related to early life metal exposures, such as developing early identification of metal-induced adverse outcomes in child neurodevelopment.

KEYWORDS: Exposure, Child Neurodevelopment, Pregnancy, Metals, Puerto Rico

P-1029 Early-life exposure to a mixture of phthalates and phenols and child social behavior in a new type of mother-child cohort relying on within-subject pools of repeated urine biospecimens

Vicente Mustieles[1], Matthieu Rolland[1], Isabelle Pin[1], Cathrine Thomsen[2], Amrit Sakhi[2], Azemira Sabaredzovic[2], Karine Guichardet[1], Rémy Slama[1], Claire Philippat[1], SEPAGES Study Group[1]

[1]University Grenoble Alpes, INSERM, CNRS, Team of Environmental Epidemiology applied to Reproduction and Respiratory Health, Institute for Advanced Biosciences (IAB), Grenoble, France, Grenoble, France, [2]Norwegian Institute of Public Health (NIPH), Oslo, Norway

BACKGROUND AND AIM: Previous cohorts characterized exposure to phenols and phthalates using few spot urine samples, incurring in exposure misclassification. Early infancy exposure remains understudied. We relied on a cohort with improved exposure assessment to examine associations of phthalates and phenols with child autistic traits.

METHODS: This analysis included 406 mother-child pairs from the French SEPAGES cohort. 25 phenols/phthalate metabolites were measured in within-subject pools of repeated urine samples collected at second and third pregnancy trimesters (median= 21 samples/trimester), and at 2 and 12 months of age (median= 7 samples/period). Autistic traits were parent-reported at 3 years using the Social Responsiveness Scale (SRS). Adjusted differences in SRS raw scores were estimated per doubling in each biomarker concentration using linear regression. A literature review was performed to prioritize the measured phthalates/phenols based on their likelihood to affect social behavior. The mixture effect was estimated for the prioritized compounds (bisphenol A, triclosan, DEHP, MEP, MnBP and MBzP) using Bayesian Weighted Quantile Sum (BWQS) regression.

RESULTS: Most associations were observed in the 12-months exposure window. Among the prioritized compounds, triclosan (β= 0.79; 95%CI: 0.01, 1.56) and MEP (β= 0.92; 95%CI: -0.11, 1.95) were associated with worse total SRS scores, while MnBP and ∑DEHP were associated with worse social awareness (β= 0.25; 95%CI: 0.01, 0.50), and social communication (β= 0.43; 95%CI: -0.02, 0.88) scores, respectively. The mixture of prioritized compounds was associated with worse total SRS scores (Beta1= 1.40; 95%CrI: -0.22, 2.99), driven by the social awareness (Beta1= 0.36; 95%CrI: 0.03, 0.70) and social communication (Beta1= 0.87; 95%CrI: 0.31, 1.51) subscales.

CONCLUSIONS: The literature search allowed to prioritize the compounds with a higher weight of evidence. Our results suggest that early infancy is a critical window for the effects of phenols and phthalates on child social development.

KEYWORDS: phthalates, bisphenol, neurodevelopment, social behavior, autism

P-1034 Associations between phthalates and sleep quality in pregnant women with repeated assessment of exposure

Archana Lamichhane[1], Myung-Sook Park[2], Hwan-Cheol Kim[1]
[1]Department of Occupational and Environmental Medicine, Inha University School of Medicine, Incheon, Republic of Korea, Incheon, Republic of Korea, [2]Institute of Environmental Medicine, Seoul National University Medical Research Center, Seoul, Republic of Korea, Seoul, Republic of Korea

BACKGROUND AND AIM: Phthalates are associated with sleep disorders in midlife women. However, this relationship among pregnant women remains unknown. This study investigated associations of repeated measures of urinary phthalates in early and late pregnancy with sleep quality in pregnant women.

METHODS: This study analyzed eight urinary phthalates in pregnant women from the Korean Children's Environmental Health Study (n = 2,324). Multiple informant models were fit using generalized estimating equations to examine the association between phthalate metabolites measured in early and late pregnancy and sleep quality. Summary measures of phthalate mixtures, including the phthalates from plastic sources (∑Plastic), anti-androgenic phthalates (∑AA), di-(2-ethyhexyl) phthalate (∑DEHP), and all phthalate metabolites measured (∑All), were calculated from urinary phthalate metabolites. The sleep quality was assessed by the Pittsburgh Sleep Quality Index (PSQI) global and subscale scores.

RESULTS: Compared to the lowest quartile, ∑Plastic (adjusted odds ratio [OR] = 1.36; 95% confidence interval [CI]: 1.02, 1.81), ∑AA (OR = 1.60; 95% CI: 1.20, 2.12), ∑DEHP (OR = 1.37; 95% CI: 1.03, 1.82), and ∑All (OR = 1.66; 95% CI: 1.25, 2.20) in the highest quartile were significantly associated with increased odds of low sleep efficiency (85% or less). The highest quartile of ∑All had 1.40 times (95% CI: 1.02, 1.94) the odds of short sleep duration (7 hour or less). In linear models, there was a trend with any of the summary phthalate measures and sleep efficiency: each log-unit increase in concentration was associated with 1.20 to 1.24 times the odds of low sleep efficiency. Summary phthalate measures showed a nonlinear association with sleep efficiency and sleep duration (p for nonlinearity < 0.05) in the restricted cubic spline regression.

CONCLUSIONS: Our findings suggest that phthalate exposure is associated with poor sleep quality in pregnant women.

KEYWORDS: Phthalates, Pittsburgh Sleep Quality Index, sleep efficiency, pregnant women

P-1038 Wildfire Smoke and Symptoms Affecting Mental Health among Adults in Oregon

Maria Mirabelli[1], Ambarish Vaidyanathan[2], Audrey Pennington[1], Dongni Ye[1,3], Carol Trenga[4]
[1]Asthma and Community Health Branch, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA, [2]Climate and Health Program, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA, [3]Oak Ridge Institute for Science and Education, Oak Ridge, USA, [4]Public Health Division, Oregon Health Authority, Portland, USA

BACKGROUND AND AIM: The impact on mental health status of experiencing a wildfire is believed to be substantial; however, few data are available to describe symptoms affecting mental health among people affected by wildfires. We assessed associations between exposure to wildfire smoke and self-reported symptoms affecting mental health among adults living in Oregon, a geographic area of the USA regularly affected by wildfires.

METHODS: We analyzed data from 5,807 adults in Oregon who responded to the 2018 Behavioral Risk Factor Surveillance System's depression and anxiety module. We linked by interview date and county of residence each adult's responses about the symptoms affecting their mental health status with smoke plume density, a proxy for wildfires and wildfire smoke exposure. Associations between days in the past year with light, medium, and heavy smoke plume densities and symptoms affecting mental health during the two weeks before the interview date were estimated using predicted marginal probabilities from logistic regression models.

RESULTS: In the year before completing the interview, 100% of respondents experienced ≥14 days of medium or heavy smoke plumes, with an average exposure duration of 32 days. Nearly 10% reported being unable to stop or control their worrying more than half the time over the past two weeks. Medium or heavy smoke for 42–74 days in the past year, compared to ≤27 days in the past year, was associated with a 30% higher prevalence of being unable to stop or control worrying more than half the time during the past two weeks (prevalence ratio: 1.30, 95% confidence interval: 1.03, 1.65).

CONCLUSIONS: Among adults in Oregon, selected symptoms affecting mental health were associated with extended durations of medium and heavy smoke. These findings highlight the burden of symptoms affecting mental health among adults living in communities affected by wildfires and wildfire smoke.

P-1050 Effect of Cadmium on the Association between Blood Pressures and Telomere Length: A Population-based Cross-sectional Study in Japan

Kyi Mar Wai[1], Masahiro Umezaki, Yuki Mizuno, Kaori Sawada, Okuyama Shinya, Shigeyuki Nakaji, Kazushige Ihara
[1]*Department of Social Medicine, Hirosaki University, Hirosaki, Japan*

BACKGROUND AND AIM: Telomeres (TL) are repeated oligomers in the end of chromosome. TL shortening is associated with many pathophysiological outcomes, later in life such as cardiometabolic diseases and malignancy. However, not much is known regarding the role of heavy metals in TL shortening in association with increased blood pressure (BP). The objective of this study is to determine whether the association between high BP and TL shortening could be modified by the environmental cadmium (Cd) exposure.

METHODS: This study was a community-based cross-sectional study with 1047 individuals of age more than 19 years of 2019 Iwaki Health Promotion Project, Japan. A questionnaire survey, blood pressure measurement and blood sampling were performed by the trained research teams. Spot urine sample was also collected, and urinary Cd concentrations was measured, while Leucocyte TL was assessed by G-tail telomere hybridization protection assay. Regarding the statistical analysis, first, descriptive analysis was done using means, frequency, and percentage. Later, multivariate linear regression analysis was performed to evaluate the associations between urinary Cd concentration, BP/hypertension, and TL in relevance.

RESULTS: In high Cd concentration group, systolic blood pressure (SBP), diastolic blood pressure (DBP) and pulse pressure were significantly higher while TL was significantly shorter. By stratified multivariate regression models, telomere G-tail shortening was significantly associated with higher SBP (beta= -27.31; 95% CI: -50.71, -3.91, p=0.022) and DBP (beta= -49.33; 95% CI: -87.25, -11.42, p=0.011), only in high Cd concentration group. Similarly, TL was shorter among the hypertensive individuals (beta= -978.79; 95% CI: -1920.09, -37.51, p=0.042).

CONCLUSIONS: This study firstly identified that the negative associations of BP and TL were observed only in high Cd concentration group. These findings indicate that the associations of BP and TL could be mediated by environment Cd exposure.

P-1054 The Effects of Minimally Processed and Ultra-Processed Food Intake on Cardiovascular Health based on the Korea National Health and Nutrition Examination Survey (KNHANES), 2013-2015

Lita Kim[1,2], Yun-Hee Choi[1,2], Da-An Huh[3], Kyong Whan Moon[1,2,4]

[1]Department of Health and Safety Convergence Science, Korea University, Seoul, Republic of Korea, [2]BK21 FOUR R&E Center for Learning Health System, Korea University, Seoul, Republic of Korea, [3]Institute of Health Sciences, Korea University, Seoul, Republic of Korea, [4]Department of Health and Environmental Science, Korea University, Seoul, Republic of Korea

Cardiovascular disease (CVD) is the leading cause of death worldwide. CVD risk factors are usually chronic, and a diet and lifestyle can be important determinants of cardiovascular health (CVH). Recently, the importance of dietary patterns rather than single nutrients has been emphasized for CVH. Consumption of processed food is increasing due to socio-economic changes in Korea. Although harmful substances may be added or created during the processing and packaging of foods, few studies evaluated the CVH effects of processed foods in Koreans. This study investigated the effect of minimally processed food (MPF) and ultra-processed food (UPF) intake on CVH. We used the data of 6,945 adults from the Korea National Health and Nutrition Examination Survey 2013–2015. Based on the CVH metrics (Life's simple 7), the CVH indicator was estimated as the sum (0–12) of the six (blood pressure, fasting plasma glucose, total cholesterol, body mass index, smoking status, physical activity) scores, and categorized as Inadequate (0–4), Average (5–8), and Optimum (9–12). MPF and UPF intake were estimated as the distribution of total energy intake using NOVA food classification. The mean (standard deviation) of MPF and UPF intake was 61.28(0.28) and 20.27(0.24) %kcal/day, respectively. After adjusting for all covariates, we found significant positive associations between MPF intake and CVH ($p<0.001$), while associations between UPF intake and CVH were significantly negative ($p<0.001$). Comparing the highest quartiles with the lowest of MPF intake, the adjusted odds ratio (OR) (95% Confidence interval) for Inadequate (compared with Optimum) was 0.36 (0.22–0.58), while UPF intake, adjusted OR was 2.63 (1.52–4.55). This study suggests that processed food intake was significantly associated with CVH in Korean adults. Public health policies are needed to promote choosing less processed foods to prevent CVD.

KEYWORDS: Cardiovascular Health, Minimally Processed Food, Ultra-Processed Food, Dietary, NOVA food classification

P-1055 Association of perfluoroalkyl substances (PFAS) with lipid trajectories in midlife women: the Study of Women's Health Across the Nation

Habyeong Kang[1], Ning Ding[1], Carrie Karvonen-Gutierrez[1], Bhramar Mukherjee[2], Sung Kyun Park[1,3]
[1]Department of Epidemiology, University of Michigan School of Public Health, Ann Arbor, USA, [2]Department of Biostatistics, University of Michigan School of Public Health, Ann Arbor, USA, [3]3Department of Environmental Health Sciences, University of Michigan School of Public, Ann Arbor, USA

BACKGROUND AND AIM: Despite lipid-lowering effects of perfluoroalkyl substances (PFAS) observed in rodent models, PFAS have been associated with unfavorable blood lipid profiles in human populations. However, evidence from longitudinal studies in the general population is limited. We examined the association of serum concentrations of PFAS with longitudinal trajectories of blood lipids in the Study of Women's Health Across the Nation.

METHODS: We included 1143 women aged 45-56 years in 1999-2000. Concentrations of PFAS including linear and branched perfluorooctane sulfonic acid (n-PFOS and Sm-PFOS), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), and perfluorohexane sulfonic acid (PFHxS) were measured in serum collected at baseline. Total, low-density lipoprotein (LDL), and high-density lipoprotein (HDL) cholesterol, and triglycerides were measured in blood annually or biannually during follow-up through 2016. Using latent class growth models (LCGMs), trajectories of each lipid were estimated based on the population data. The associations between PFAS and lipid trajectory classes were evaluated by multinomial log-linear models with latent class membership as outcomes and log-transformed PFAS as exposure.

RESULTS: Three distinct lipid trajectories (low, medium, and high trajectories) were identified. After adjustment for covariates, n-PFOS and Sm-PFOS were positively associated with higher LDL cholesterol [ORs (95% CI) for high vs. low trajectory per doubling of each PFAS: 1.28 (1.04, 1.56) and 1.24 (1.04, 1.48), respectively]. N-PFOS, n-PFOA, PFNA, and PFHxS were inversely associated with higher triglycerides [ORs (95% CIs) for high vs. low trajectory per doubling of each PFAS: 0.72 (0.55, 0.94), 0.65 (0.50, 0.84), 0.78 (0.62, 1.00), and 0.76 (0.62, 0.93), respectively]. The associations of PFAS with total or HDL cholesterol were insignificant.

CONCLUSIONS: Higher serum concentrations of selected PFAS were associated with a higher trajectory of LDL cholesterol and a lower trajectory of triglycerides. Further studies on the underlying mechanisms of the findings are warranted.

KEYWORDS: PFAS, dyslipidemia, midlife women

P-1056 Frequent Cannabis Smoking and Association with Prediabetes and Diabetes in Early Adulthood

Janet Gukasyan[1], Jesse Goodrich[1], Sarah Rock[1], Liz Costello, Arlette Lopez[1], Katerina Margetaki[1], Tanya Alderete[2], Zhanghua Chen[1], Frank Gilliland[1], David Conti[1], Lida Chatzi[1]

[1]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, USA, [2]Department of Integrative Physiology, University of Colorado Boulder, Boulder, USA

BACKGROUND: Cannabis use in young adulthood has been linked with increased risk of prediabetes later in life. However, many previous studies have only used fasting blood samples to determine risk for type 2 diabetes (T2D), which may not detect early changes in glucose homeostasis. The objective of this study was to determine the association between cannabis use and risk for prediabetes and T2D in young adults using several measures of glucose homeostasis, including an oral glucose tolerance test (OGTT).

METHODS: The Meta-CHEM study is a subset (N=84) of overweight and obese young adults aged 22–25 years from the Children's Health Study (CHS). Participants underwent a single clinical visit which included a 2-hour OGTT and questionnaire about cannabis smoking habits in the past year. Participants were classified as non-smokers, light cannabis smokers (smoke <once a week), and heavy cannabis smokers (smoke >once a week). Those smoking more than one cigarette in the past week were excluded from the study. Participants were classified as having prediabetes or T2D if they had a HbA1c >5.6%, fasting glucose >99 mg/dL, and/or 2-hour OGTT glucose >139 mg/dL. Logistic regression was used to assess the associations between cannabis smoking habits and metabolic outcomes after adjusting for age, sex, education, body mass index, Hispanic ethnicity, physical activity, and alcohol consumption.

RESULTS: 52 (62%) participants were non-diabetic, 28 (33%) had pre-diabetes, and 4 (0.05%) had T2D. 25 (30%) participants were nonsmokers, 47 (56%) were light cannabis smokers, and 12 (14%) were heavy cannabis smokers. The odds of having prediabetes or T2D was 7.3 times higher among heavy smokers (95% CI: 0.94, 7.7), and 1.5 times higher among light smokers (CI: 0.43, 6.0) than nonsmokers (P-value for trend = 0.03).

CONCLUSIONS: Cannabis use in overweight and obese young adults was significantly associated with risk of having prediabetes or T2D.

P-1062 Seasonal variations of hospitalizations for chronic rhinosinusitis by different endotypes

Lan Jin[1], Satish Govindaraj[2], Zongzhi Liu[1], Lei Ai[1], Mitchell Higashi[1], Tomi Jun[1], Kyeryoung Lee[1], Kalpana Raja[1], Xingmin Zhang[1], Minghao Li[1], Ediz Calay[1], Radoslav Savic[1], Krish Ghosh[1], Andrew Kasarskis[1], Qi Pan[1], William Oh[1,2], Gustavo Stolovitzky[1], Eric Schadt[1,2], Xiaoyan Wang[1]

[1]Sema4, Stamford, USA, [2]Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: chronic rhinosinusitis (CRS) affects ~12% of the population and costs ~$30 billion each year in the US. A recent study reported winter and spring exacerbations of sinonasal symptoms among CRS patients; however, little is known about seasonal exacerbations by endotypes. This study aims to investigate seasonal variations of CRS hospitalizations among different inflammatory endotypes.

METHODS: CRS patients with different endotypes were identified in Mount Sinai electronic health records using a multi-layer CRS phenotyping algorithm integrating features such as encounter frequencies, surgeries, provider specialties and biomarkers, which was previously evaluated with high prediction performance (PPV=0.91). The patients with hospitalizations from 2003-2019 were included while patients with comorbidities of asthma or allergic rhinitis were excluded. Quasi-Poisson regression models were used to evaluate the associations between seasons and daily counts of CRS hospitalizations, adjusting for long-term temporal trend, day-of-the-week, daily temperature and PM2.5.

RESULTS: The counts of CRS hospitalizations were 32,194 in spring, 31,993 in summer, 32,077 in fall, and 30,584 in winter. for all CRS patients, no significant differences by season were detected. Among patients with nasal polyps (1615/7604), the highest risk of hospitalization was seen in spring (RR: 1.11; 95% CI: 1.06-1.17), followed by fall (RR: 1.06; 95% CI: 1.01-1.12), compared to winter. Similar patterns were observed in patients with blood eosinophil count > 300 cells/mcL (596/7604): increased risks of hospitalization were observed in spring (RR: 1.10; 95% CI: 1.04-1.16) and fall (RR: 1.08; 95% CI: 1.01, 1.14). In contrast, no differences by season were found for CRS patients without nasal polyps or with low eosinophil count.

CONCLUSIONS: Elevated risks of hospitalizations in spring and fall were only observed in CRS patients with endotypes related to eosinophilic type 2 inflammation. The high recurrence and refractory nature of these endotypes might be attributable to seasonal environmental factors.

KEYWORDS: rhinosinusitis, seasonal exacerbations

P-1066 Long-term air pollution, cardiometabolic multimorbidity, and genetic susceptibility: a prospective study in UK biobank cohort

Meijie Jiang[1], Xu Gao[1]
[1]*Peking University, Beijing, China*

BACKGROUND AND AIM: Air pollution has been associated with individual cardiometabolic diseases (CMDs) including type II diabetes (T2D), ischemic heart disease (IHD), and stroke. However, little is known about their relationship with the risk of cardiometabolic multimorbidity (CMM) with at least two of the CMDs. Therefore, we aimed to explore whether the long-term exposure to PM2.5, PM10, PM2.5–10, NO2, and NOx were associated with the progression of CMM.

METHODS: We used data from 415,855 adults of UK Biobank that were free of any of the three CMDs at baseline enrollment with a median follow-up of 8.93 years. The Land Use Regression model was used to estimate the annual average ambient concentrations of PM2.5, PM10, PM2.5–10, NO2, and NOx. We employed a multi-state model to assess associations of five pollutants with different transitions of the CMM trajectory.

RESULTS: A total of 33,375 participants developed one CMD, 3,257 of which subsequently developed another one or two. We found that PM2.5, PM10, NO2, and NOx levels were associated with the transition from healthy to having the first cardiometabolic disease (FCMD), and then to CMM with relatively higher risks. for instance, per 5-μg/m¬3 increasing in PM2.5 levels, the FCMD risk increased 27% (95% CI: 1.20-1.34) and the subsequent CMM risk raised to 41% (95% CI: 1.18-1.68). Robust associations of a weighted air pollution index with the CMM trajectory were also observed. Participants with IHD first were more likely to develop CMM than those with T2D or stroke. Additionally, the observed relationship between air pollution and CMM could be enhanced by the genetic susceptibility of CMDs.

CONCLUSIONS: Air pollution is not only associated with the individual CMDs but also could expedite the progression of CMM, which could be modified by genetic predisposition.

KEYWORDS: air pollution, PM2.5, cardiometabolic multimorbidity, multi-state model, genetic susceptibility

P-1069 Lung Cancer Mortality Risks of Long-term Exposure to Particulate Matter in South Korean Adults Including and Excluding Lung Cancer Patients

Miyoun Shin[1], Sun-Young Kim[1]
[1]*National Cancer Center Graduate School of Cancer Science and Policy, Goyang, Republic of Korea*

BACKGROUND AND AIM: Lung cancer is a major burden of disease worldwide. Many epidemiological studies suggested particulate matter(PM) as a prominent risk factor of lung cancer mortality. The risk also could differ depending on the cancer status related to susceptibility, but few studies focused on this difference. This study aims to compare the associations of PM2.5 and lung cancer mortality by including and excluding lung cancer patients in the Seoul Metropolitan Areas using a population-based nationwide cohort.

METHODS: From the National Health Insurance Services-National Sample cohort for 2002-2015, we selected the study population who carried out national screening during 2005-2007, aged over 30, were non-severely disabled, and had full address information every year. for our comparison, we created two sub-populations excluding and including those who had been diagnosed with lung cancer until the baseline in 2007. Lung cancer deaths were identified for 2007-2015, while individual-level long-term exposures to PM2.5 were assessed as 5-year average concentrations estimated from a previously-validated prediction model. We performed time-dependent Cox proportional hazards model to estimate hazard ratios (HRs) and 95% confidence intervals (95% CIs) per 10ug/m3 increase in PM2.5 adjusting for individual characteristics.

RESULTS: of 87,608 and 86,739 people including and excluding 867 lung cancer patients, 367 (0.42%) and 53 (0.06%) people died with lung cancer, respectively. Although all effect estimates were statistically non-significant, both groups showed positive effect estimates with similar magnitudes. (HR=1.60 [95% CI=0.24-10.76] and 1.55 [0.73-3.26] for the populations excluding and including lung cancer patients, respectively).

CONCLUSIONS: Our finding of positive risk estimates, although non-significant, between two populations including and excluding lung cancer patients suggest a possibility of consistent risks of dying with lung cancer attributed to PM2.5 regardless of susceptibility derived by cancer status. Further studies need to confirm our findings using extended populations.

P-1073 Prenatal Maternal and Paternal Household Pesticide Exposure and Childhood Acute Lymphoblastic Leukemia (ALL): Does Exposure Comparison Modeling Influence Risk Estimates?

Alexandra Ruth[1], Umer Rehman[1], Patricia Stewart[2], Lee Moore[3], Recai Yucel[1], Robin Taylor Wilson[1]
[1]Temple University College of Public Health, Department of Epidemiology and Biostatistics, Philadelphia, USA, [2]Stewart Exposure Assessments, LLC, Arlington, USA, [3]National Cancer Institute, Division of Cancer Epidemiology and Genetics (ret.), Bethesda, USA

BACKGROUND AND AIM: Household pesticide exposure is associated with increased risk of childhood acute lymphoblastic leukemia (ALL). We sought to investigate whether ALL risk estimates for pest-specific use categories (PSUC) change when using an analysis method (AM) versus a design method (DM) of multiple-PSUC confounding adjustment.

METHODS: Cases (N=1810) ages ≤15 were identified through Children's Cancer Group institutions between 1989-1993 and age-/sex-matched to community controls (N=1951). Household pesticide use during pregnancy (including the month prior) was collected via telephone interview. We used unconditional logistic regression to estimate ALL odds ratios (OR) for parental (mother/father/both) exposure to ten household PSUC (ant-cockroach-fly-bees, moths, spiders-mites, rodents, fleas-ticks, termites, slugs-snails, weeds, plants, or commercial exterminator). for AM, we assessed risk by including all PSUC covariates. for DM, each PSUC was assessed as a contrast with a zero-use comparison group (all ten-categories=zero) in adjusted models. All models were adjusted for known ALL risk factors which remained significant in final models (income, maternal age, and prenatal-vitamin use).

RESULTS: Pesticide use during pregnancy was prevalent (54% reported exposure to 2+ PSUC). PSUC bivariate correlations were all less than 0.25. Using AM, elevated ORAM (range: 1.41-1.55) were observed in three maternal and one paternal PSUC ($p<0.05$). All ORs increased when using DM (mother's range: 22.84%-62.50%; father's range: 22.34-60.50%). Risks were highest for termite (ORDM=3.98, 95% CI: 1.24-12.75, mothers) and spider-mite pesticides (ORDM=2.72, 95% CI: 1.29-5.75, fathers).

CONCLUSIONS: ALL risk estimates for exposure to ten pesticide use categories increased among both mothers and fathers when restricting exposure contrasts to a zero-use comparison group. These results are consistent with other studies reporting highest risks for termite pesticide exposure. This may reflect either a true risk difference or other characteristics among zero-use households which reduce risk. Investigation of potential mediation among pesticide classes appears warranted.

KEYWORDS: Acute Lymphoblastic Leukemia; childhood; pesticides; prenatal; case-control

P-1076 Dietary intakes of dioxins and polychlorinated biphenyls (PCBs) and breast cancer risk in 9 European countries

Thibault Fiolet[1], Corinne Casagrande[2], Geneviève Nicolas[2], Zsuzsanna Horvath[3], Pauline Frenoy[1], Manon Cairat[2], Marina Kvaskoff[1], Inge Huybrechts[2], Francesca Romana-Mancini[1], EPIC On Behalf of the EPIC Network[4]
[1]University of Paris-saclay, Cachan, France, [2]International Agency for Research on Cancer, Lyon, France, [3]European Food Safety Authority, Parma, Italy, [4]EPIC Network, Europe, Europe

BACKGROUND AND AIM: Dioxins and polychlorinated biphenyls (PCBs) are known to be mobile and highly persistent in the environment leading to a ubiquitous pollution. These chemicals are carcinogenic. Due to bioaccumulation along the food chain, the main route of exposure in general population is through diet. However, evidence in general population is lacking. The aim of the present study was 1) to estimate dietary intakes for 17 dioxins and 35 PCBs in the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort 2) to investigate the association with breast cancer risk

METHODS: EPIC is a prospective cohort that has enrolled 520,000 adults recruited across 10 European countries. Dietary and lifestyle data have been collected at baseline through validated questionnaires. Dietary intake for 17 dioxins and 35 polychlorobiphenyls were assessed through a combination of EPIC food consumption data and food contaminant levels from the European Food Safety Authority monitoring programs. Association between intakes of dioxins and PCBs and breast cancer risk were estimated using multivariate Cox regression. Analyses included 318,607 women with 13,241 incident breast cancers (median follow-up: 14.9 years).
RESULTS
Exposure to dioxins, Dioxin-Like-PCBs (DL-PCBs), and Non-Dioxin-Like-PCBs (NDL-PCBs) estimated from reported dietary intakes were not associated with breast cancer incidence, with the following hazard ratios (HRs) and 95% confidence intervals for an increment of 1 SD: HRdioxins = 1.00 (0.98 to 1.02), HRDL-PCB = 1.01 (0.98 to 1.03), and HRNDL-PCB = 1.01 (0.99 to 1.03), respectively. Results remained unchanged when analyzing intakes as quintile groups, as well as when analyses were run separately per country, or separating breast cancer cases based on estrogen receptor status

CONCLUSIONS: This large European prospective study does not support the hypothesis of an association between dietary intake of dioxins and PCBs and breast cancer risk.

KEYWORDS: Breast cancer, dioxins, PCBs

P-1077 Dietary intakes of Dioxins and polychlorobiphenyls (PCBs) and mortality: EPIC cohort study in 9 European countries

Thibault Fiolet[1], Geneviève Nicolas[2], Corinne Casagrande[2], Zsuzsanna Horvath[3], Pauline Frenoy[1], Marina Kvaskoff[1], Inge Huybrechts[2], Francesca Romana Mancini[1], EPIC on behalf of the EPIC Network[4]
[1]University of Paris-saclay, Cachan, France, [2]International Agency for Research on Cancer, Lyon, France, [3]European Food Safety Authority, Parma, Italy, [4]EPIC Network, Europe, Europe

BACKGROUND AND AIM: Dioxins and polychlorinated biphenyls (PCBs) are persistent organic pollutants which are carcinogenic. The main route of exposure in general population is through diet. Cohort studies have reported inconsistent associations between these chemicals and mortality. The aim of the present study was 1) to estimate dietary intakes for 17 dioxins and 35 PCBs in the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort 2) to investigate the impact on mortality.

METHODS: EPIC is a prospective cohort that has enrolled 520,000 adults recruited across 10 European countries. Dietary intake of dioxins and PCBs was assessed combining EPIC food consumption data with European food contamination data provided by the European Food Safety Authority. Association between intakes of dioxins and PCBs and breast cancer risk and mortality were estimated using multivariate Cox regression. Analyses included 451,390 adults with 46,627 deaths (median follow-up: 17.4 years).
RESULTS
A U-shaped non-linear association with all-cause mortality for dietary intake of dioxins (Pnon-linearity<0.0001), DL-PCB (Pnon-linearity=0.0001), and NDL-PCBs (Pnon-linearity<0.01) was observed. for example, the hazard ratios (95%Confidance interval) for all-cause mortality obtained with the spline model was equal to 1.03 (1.02-1.05) for low intake of dioxins (7 pg TEQ/day), 0.93 (0.90-0.96) for moderate intake (25pg TEQ/day), while for high intake of dioxins (55pg TEQ /day) it was 1.03 (0.97-1.09). There was no association between intakes of dioxins and cancer mortality, but a U-shaped association was observed for intake of DL-PCBs and intake of NDL-PCBs and cancer mortality. Intakes of dioxins, DL-PCBs and NDL-PCBs was not associated with cardiovascular mortality.

CONCLUSIONS: This large European prospective study does support the hypothesis of a non-linear association between dietary intake of dioxins and PCBs and mortality which might be explained by endocrine disrupting properties

KEYWORDS: mortality, dioxins, PCBs

P-1079 Long-term atmospheric exposure to PM2.5 and PM10 and breast cancer risk in a case-control study nested in the French E3N cohort from 1990 to 2011

Delphine Praud[1], Maryline Bouilly[1], Amina Amadou[1], Thomas Coudon[1], Lény Grassot[1], Margaux Duboeuf[1], Elodie Faure[2], Pr Béatrice Fervers[1]

[1]Department Prevention Cancer Environment, Centre Léon Bérard, Lyon, France, [2]Gustave Roussy Institute, Villejuif, France

BACKGROUND AND AIM: Breast cancer is one of the most prevalent cancers in women and its incidence increased in France during the past thirty years. Known risk factors include ageing, genetic, reproductive, anthropometric, and lifestyle factors. Since they fail to totally explain the observed risk increase, it has been hypothesized that some of this increase could be related to environmental exposure to endocrine disrupting chemicals. Among those, particulate matters (PM) have been pointed out by epidemiological studies due to their potential endocrine disrupting and carcinogen properties We aimed to estimate the association between PM2.5 and PM10 exposure and the risk of breast cancer among women in a case-control study nested in the French E3N cohort.

METHODS: Our study focused on 5222 invasive breast cancer cases diagnosed between 1990 and 2010 and 5222 randomly selected controls matched to cases. Assessment of PM2.5 and PM10 exposures were estimated by land use regression (LUR) models and assigned to the geocoded residential postal codes of participants for each year from recruitment 1990 through 2011. We estimated odds ratios (OR) and 95% confidence intervals (CI) for breast cancer using conditional adjusted logistic regression models.

RESULTS: We found a positive association between breast cancer risk and PM2.5 (OR=1.15, 95%CI: 1.00-1.31, per 10µg/m3) and PM10 (OR=1.07, 95% CI: 0.99-1.15). These results were confirmed estimating PM2.5 and PM10 exposure with a chemistry transport model (CHIMERE).

CONCLUSIONS: We found suggestive evidence of an association between air pollution exposure and incidence of breast cancer risk in French woman

KEYWORDS: Particulate matters, breast cancer, air pollution, risk factor, land use regression models

P-1081 Is Cadmium Exposure associated with Thyroid Cancer? A National Health and Nutrition Examination Survey Analysis

Eric Alerte[1], Mathilda Alsen[1], Eric Genden[1], Maaike Van Gerwen[1]
[1]*Icahn School of Medicine at Mount Sinai, New York, USA*

INTRODUCTION
The increasing thyroid cancer incidence in the past few decades might be partially explained by the changing prevalence of environmental exposures, including to the heavy metal cadmium. Although cadmium is known to accumulate in the thyroid gland and has been labeled a carcinogen, an association between cadmium exposure and thyroid cancer has not been demonstrated to date. To assess this potential effect of cadmium exposure, this study investigated the association between blood cadmium levels and thyroglobulin antibodies (TgAb) as previous studies showed that positive TgAb predicts the presence of thyroid cancer in patients with thyroid nodules.

METHODS: Using the 2007-2012 National Health and Nutrition Examination Survey (NHANES), participants of 20 years and older without thyroid disease/ cancer with reported blood cadmium and thyroid function levels were included (n=7,383). TgAb and cadmium were log-adjusted. Models with cadmium as a log-adjusted continuous variable and divided into quartiles of exposure, adjusted for age groups, sex, race, BMI groups, alcohol, smoking, and iodine status were assessed using complex survey design.

RESULTS: The geometric mean of cadmium across all participants was 0.348 ng/mL (standard error (SE): 0.005). After adjustment, there was no significant association between continuous cadmium levels and TgAb (β=0.057, 95% confidence interval (CI): -0.004; 0.119. Models with cadmium divided into quartiles showed that though quartile 2 and 3 were associated with increased TgAb, this association was only significant for quartile 4 (β=0.193, 95% CI: 0.069; 0.317), versus quartile 1.

DISCUSSION
High levels of cadmium were positively associated with TgAb levels indicating that cadmium exposure needs to be further explored as a potential risk factor for thyroid cancer, especially given the widespread use and exposure of the general population to cadmium. This includes in-depth studies into the potential carcinogenic mechanism of cadmium on the thyroid gland.

P-1085 Household Cooking Fuel and Gallbladder Cancer Risk: A Multi-Centre Case Control Study in India

Krithiga Shridhar[1], Manigreeva Krishnatreya[2], Ranjit Kumar[3], Dimple Kondal[1], Mouchumee Bhattacharyya[2], Banti Kalita[1], Prakriti Snehil[1], Sumita Sarma Barthakur[4], Gayatri Bharali[4], Amulya Kumar Singh[5], Amal Chandra Kataki[2], Ashok Ghosh[3], Dorairaj Prabhakaran[1], Poornima Prabhakaran[1], Preet Kaur Dhillon[1,6]

[1]Public Health Foundation of India, Gurugram, India, [2]Dr.Dr.Bhubaneshwar Borooah Cancer Institute, Guwahati, India, [3]Mahavir Cancer Sansthan and Research Centre, Patna, India, [4]Sri Sankaradeva Netralaya, Guwahati, India, [5]Akshat Seva Sadan, Patna, India, [6]Genentech Roche, USA

BACKGROUND-AIM: Evidence from India, a country with certain unique cancer patterns (e.g., high incidence of gallbladder cancers (GBC)) and distinct risk exposures such as 'biomass burning' for cooking, may offer insights into the role of indoor air pollution in cancer etiology. We evaluated the association between household cooking fuel and GBC risk in a case-control study conducted among long-term residents (i.e., at least 10-years) of North-East and East Indian regions of Assam and Bihar, with high-risk for GBC and intense 'biomass burning'. We explored if these associations were accounted-for by healthy diet, fire-vents and 'daily exposure duration'.

METHODS: We recruited men and women aged 30-69 years from hospitals between 2019 and 2021, with newly diagnosed, biopsy-confirmed GBC (N=214) and unrelated controls frequency-matched by age, sex and region (N=166). Information about cooking fuel, lifestyle, personal and family history, socio-demographics and physical measurements was collected. We tested associations using multivariable logistic regression analyses adjusted-for confounders.

RESULTS: All participants (73.4% women) were categorised based on lifetime use and duration of predominant cooking fuel. Group-1: LPG for ≥20 years (13.5%); Group-2: LPG for 1-19 years with no concurrent biomass (15.6%); Group-3: LPG 1-19 years with concurrent biomass (12.9%); and Group-4: Biomass for ≥20 years (57.9%). Compared to group-1, GBC risk was higher in group-3 [OR=2.69, 95%CI (1.07-6.72)] and group-4 [OR=2.44, 95%CI (1.07-5.56)] but not in group-2 (p-trend=0.020). The associations strengthened in women-only analysis; and attenuated with high daily consumption of fruits-vegetables, but did not alter with fire-vents or 'daily exposure duration'.

CONCLUSIONS: With cautious interpretation for residual confounding, sample-size limitations and possible errors in exposure, the findings identify 'biomass burning' as a modifiable risk factor for GBC in high-risk regions. It further highlights 'clean fuel replacement' can mitigate the risk; and a healthy diet can partially reduce the risk.

KEYWORDS: Gallbladder cancer, biomass, India

P-1086 Lifetime Chronic Arsenic Exposure and Gallbladder Cancer Risk: Evidence from Endemic Regions of India

Krithiga Shridhar[1], Debapriya Mondal[2], Manigreeva Krishnatreya[3], Ranjit Kumar[4], Dimple Kondal[1], Steena Kuriakose[5], Vinutha Ragavaiah Sarma[1], Soumyajit Sarkar[6], Sumita Sarma Barthakur[7], Gayatri Bharali[7], Amulya Kumar Singh[8], Amal Chandra Kataki[3], Ashok Ghosh[4], Abhijit Mukherjee[6], Dorairaj Prabhakaran[1], Poornima Prabhakaran[1], Preet Kaur Dhillon[1,9]

[1]Public Health Foundation of India, Gurugram, India, [2]St. Georges University of London, London, UK, [3]Dr.Bhubaneshwar Borooah Cancer Institute, Guwahati, India, [4]Mahavir Cancer Sansthan and Research Centre, Patna, India, [5]Centre for Chronic Disease Control, New Delhi, India, [6]Indian Institute of Technology, Kharagpur, India, [7]Sri Sankaradeva Netralaya, Guwahati, India, [8]Akshat Seva Sadan, Patna, India, [9]Genentech Roche, USA

BACKGROUND-AIM: Evidence for the associations of varying levels of arsenic in drinking water and digestive tract cancers is limited. Data from endemic regions of India, with high incidence of a rare digestive tract cancer-gallbladder cancer (GBC)- may explain the role of chronic arsenic exposure in cancer etiology. We evaluated the associations between arsenic levels in groundwater and GBC risk in a case-control study conducted among residents of Assam and Bihar (2019-2021), the two most arsenic-impacted states of India next to West Bengal.

METHODS: We recruited men and women aged 30-69 years from hospitals (73.4% women), with newly diagnosed, biopsy-confirmed GBC (N=214) and unrelated controls frequency-matched by age, sex and region (N=166). Information about lifetime residential history, lifestyle, personal and family history, socio-demographics and physical measurements was collected. Average-weighted lifetime arsenic concentration (AwLAC) was estimated extrapolating district-level groundwater monitoring data (2017-2018) and lifetime residential history. Accounting for confounders, tertiles of AwLAC (ug/L) was modelled in multivariable logistic regression analysis (Range: Zero-448.39; median (IQR): T1-0.45(0.0-1.19); T2-3.75(2.83-7.38); T3-17.6(12.34-20.54)).

RESULTS: A higher proportion of participants in the highest tertile of AwLAC compared to the lowest tertile consumed tube-well water for drinking (67.7 vs. 27.9%) with purification (45.2 vs. 25.5%) and reported unsatisfactory water-quality (49.2 vs. 25.0%). These participants in the highest and in middle tertiles of AwLAC were associated with an increased risk of GBC versus the lowest tertile with OR (95%CI) of 2.43(1.30-4.54) and 2.00(1.05-3.79) respectively (p-trend=0.007). The associations remained consistent with 'average-maximum arsenic concentration (any-time)' as exposure variable and in a sub-set with block-level AwLAC estimations.

CONCLUSIONS: Despite limitations of one-time arsenic levels, sample-size and potential residual confounding, the findings indicate chronic arsenic exposure, including low-levels, is a risk factor for GBC. Tackling 'arsenic pollution' may help reduce the burden of GBC and other health outcomes.

P-1092 The relation between air pollution and multiple sclerosis hospital admission in Kerman, Iran using generalized additive models

Mohammad Amin Farahmandfard[1], Hossein Ali Ebrahimi[1], Narges Khanjani[1], Moghaddameh Mirzaee[1], Hoda Kamali[1]

[1]*Kerman University of Medical Sciences, Kerman, Islamic Republic of Iran*

BACKGROUND AND AIM: Air pollution may affect the nervous system and act as an environmental risk factor in increasing multiple sclerosis (MS) incidence and attacks. The aim of this study was to investigate the possible relation between air pollution and MS in Kerman, Iran.

METHODS: This was an ecological study. Data on ambient air pollutants and meteorological variables were inquired from the Kerman Environmental Protection Agency and the Kerman Meteorology Organization, respectively. MS attack incidence data were obtained from Kerman's Shafa hospital MS Registry. Generalized Additive Models with lags were used for estimating Relative Risks.

RESULTS: During 2008 - 2020, 4913 attacks occurred among MS patients in Kerman which 3739 were female. The strongest relation between CO with MS attacks was seen in the under 30 year's group in lag 0 (RR = 1.6544), for O3 in the over 50 year's group in lag 5 (RR =1.0181), for SO2 in lag 5 (RR =1.0237), for NO2 in females in lag 0 (RR =1.0126), for PM10 in the over 50 year's group lag 3 (RR =0.9828) and for PM2.5 in lag 5 (RR = 0.9832).

CONCLUSIONS: Ambient CO,O3, NO2 and SO2 might be important risk factors for MS attacks in Kerman.

P-1093 Association of copper exposure with prevalence of chronic kidney disease among a Chinese elderly population

Fanjia Guo[1], Yaoyao Lin[2], Lin Meng[2], Lihe Peng[3], Yongming Zhang[4], Huafang Zhang[4], Xue Zhang[3], Mingjuan Jin[1], Jianbing Wang[5], Mengling Tang[2], Kun Chen[1]

[1]Department of Public Health, Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [2]Department of Public Health, Fourth Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [3]Physical and Chemical Laboratory, Jiashan Center for Disease Control and Prevention, Jiashan, China, [4]The Fourth Affiliated Hospital, Zhejiang University School of Medicine, Yiwu, China, [5]Department of Public Health, National Clinical Research Center for Child Health of Children's Hospital, Zhejiang University School of Medicine, Hangzhou, China

BACKGROUND AND AIM: Metal exposures are suspected to associate with the risk of chronic kidney disease (CKD). Copper (Cu) is an essential yet toxic trace element in humans. Epidemiological evidence on the association of Cu exposure with CKD remains inconsistent. We aim to investigate the association of blood Cu and its co-exposure to other metals with CKD.

METHODS: A cross-sectional study was conducted among 3,286 Chinese elderly adults in Zhejiang, China. The whole blood levels of Cu as well as other 10 metals were measured by inductively coupled plasma mass spectrometry (ICP-MS). CKD events were defined as the presence of albuminuria or <60 mL/min/1.73m2 estimated glomerular filtration rate (eGFR). Multivariable logistic regression and linear regression models were applied to assess the single-metal association of Cu with kidney function. The Bayesian kernel machine regression (BKMR) was used to estimate associations of the metal mixture with CKD.

RESULTS: In the logistic models, we observed a positive dose-dependent association of blood Cu with CKD prevalence after adjusting for multiple covariates. Positive linear dose-response associations with blood Cu were also found for CKD and negative for eGFR. The positive association between blood Cu and CKD risk also observed in BKMR model and stronger at lower level of manganese (Mn).

CONCLUSIONS: The whole blood level of Cu was remarkably associated with the prevalence of CKD and showed positive dose-response relationships in the elderly Chinese population. The toxicity of Cu on kidney function could be antagonized by the exposure of Mn. These findings have provided new clues of the potential roles of Cu in kidney health, and the needs to develop not only recommended intake but also safe limits for Cu.

KEYWORDS: copper, chronic kidney disease, whole blood, BKMR analysis, manganese.

P-1102 The synergistic effects of Particle Radioactivity (Gross Beta Activity) and PM2.5 on Cardiovascular Diseases Mortality

Shuxin Dong[1], Petros Koutrakis[1], Longxiang Li[1], Brent Coull[2], Joel Schwartz[1,3], Anna Kosheleva[1], Antonella Zanobetti[1]

[1]Department of Environmental Health, Harvard T. H. Chan School of Public Health, Boston, USA, [2]Department of Biostatistics, Harvard T. H. Chan School of Public Health, Boston, USA, [3]Department of Epidemiology, Harvard T. H. Chan School of Public Health, Boston, USA

BACKGROUND: Although the effects of fine particulate matter (particulate matter ≤2.5 μm aerodynamic diameter; $PM_{2.5}$) on cardiovascular diseases (CVD) morbidity and mortality are well established, little is known about CVD health effects of particle radioactivity (PR). In addition, there are still questions about which of the $PM_{2.5}$ physical, chemical, or biological properties are mostly responsible for its toxicity.

METHODS: We investigated the association between PR, measured as gross β-activity from highly resolved spatiotemporal predictions, and mortality for CVD, myocardial infarction, stroke, and all-cause non-accidental mortality in Massachusetts (2001-2015). Within both difference-in-difference (DID) approach and generalized linear mixed-effect model frameworks, we fit gross β-activity-alone, PM2.5 alone, gross β-activity&$PM_{2.5}$ models and examined the interaction between $PM_{2.5}$ and gross β-activity.

RESULTS: We found significant associations between gross β-activity/$PM_{2.5}$ and each mortality cause. Using the DID approach and adjusting for $PM_{2.5}$, we found the highest associations with MI (RR=1.16, 95% CI: 1.08, 1.24) and stroke (RR=1.11, 95% CI: 1.04, 1.18) for an IQR increase (0.055 mBq/m3) in gross β-activity. We found a significant positive interaction between $PM_{2.5}$ and gross β-activity, with higher associations between $PM_{2.5}$ and mortality at a higher level of gross β-activity. We also observed that the associations varied across age groups. The results were comparable between the two statistical methods with and without adjusting for $PM_{2.5}$.

CONCLUSIONS: This is the first study that, using highly spatiotemporal predictions of gross β-activity, provides evidence that PR increases CVD mortality and enhances $PM_{2.5}$ CVD mortality. Therefore, PR can be an important property of $PM_{2.5}$ that must be further investigated. Addressing this important question can lead to cost-effective air quality regulations.

P-1105 Serum levels of per- and polyfluoroalkyl substances (PFAS) and aggressive prostate cancer risk in the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial

Jongeun Rhee[1], Kathryn Barry[2], Wen-Yi Huang[1], Joshua Sampson[3], Jonathan Hofmann[1], Debra Silverman[1], Mark Purdue[1], Sonja Berndt[1]

[1]National Cancer Institute, Rockville, USA, [2]University of Maryland, Baltimore, USA, [3]U.S. Food and Drug Administration, Silver Spring, USA

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) are group of chemicals commonly used in producing non-stick cookware, textiles, and firefighting foams. Exposure to PFAS is widespread in the U.S., with detectable serum levels in 98% of U.S. adults. Epidemiologic studies have suggested positive associations between PFAS and prostate cancer incidence and mortality, but the evidence is limited. We aimed to evaluate the association between pre-diagnostic serum concentrations of PFAS and aggressive prostate cancer risk in a large prospective study.

METHODS: We conducted a nested case-control study within the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial, which enrolled participants from 1993-2001 from 10 U.S. centers. Cases (N=750) included men diagnosed with aggressive prostate cancer (Stage III/IV or Gleason score≥8) at least 1 year after the blood collection. Male controls (N=750) were individually matched to cases based on age, race/ethnicity, study center, year of blood collection, and vial type. Pre-diagnostic serum concentrations of eight PFAS, including perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), and perfluorohexane sulfonic acid (PFHxS), were measured. Conditional logistic regression was used to estimate odds ratios (ORs) and 95% confidence intervals (95% CIs) for the association between PFAS and prostate cancer risk.

RESULTS: Preliminary analyses showed null associations between serum PFAS concentrations and the risk of aggressive prostate cancer (e.g., PFOS: ORcontinuous = 0.93, 95% CI: 0.83-1.05). However, differences were observed by calendar year of blood draw, with later years (1998-2004) suggesting a positive association for some PFAS, such as PFHxS (ORcontinuous = 1.12, 95% CI: 1.01-1.46) and PFOS (ORcontinuous = 1.20, 95%CI: 0.97-1.49).

CONCLUSIONS: This large prospective study did not provide evidence for an association between serum concentrations of individual PFAS and aggressive prostate cancer risk; however, an association among men with blood draws during later years, where measured serum PFAS concentrations were higher, cannot be ruled out.

P-1110 Occupational Hazards among Health Workers in Hospitals of Mukalla City, Yemen

Abdulla Bin-Ghouth[1]
[1]*Hadhramout University, Mukalla,* اليمن

BACKGROUND: Occupational health is a neglected public health issue among healthcare workers in developing countries like Yemen and they may expose them to various forms of hazards, which have had negative consequences on their wellbeing and performance at work.
Objective: The study aims at exploring the forms of occupational health hazards prevalence and methods to mitigate these hazards among Health Care Workers (HCW) in governmental hospitals in Mukalla city.

METHODS: It is a cross-sectional study conducted among health workers in the main hospitals in Mukalla city in Hadhramout province in eastern Yemen. The sample size is calculated statistically as 366 workers from different categories including doctors, nurses and lab technicians. A sample of 391 workers were selected randomly who were distributed to be representative and proportional to the size of each professional category.

RESULTS: The prevalence of biological hazards among the healthcare workers accounted for 298 (76%) whereas the non-biological hazards accounted for 306 (78%). The most prevalent biological hazards are needle prick injury (80%) followed by exposure to contact with contaminated material (75%), while the most frequent non-biological hazards are back pain (79%) followed by extra-time work (72%). In logistic regression age, gender and duration of work and professional category have significant association with exposure of health workers to biological hazards while only gender is the only variable associated with non-biological hazards.

CONCLUSIONS: There is a high prevalence of occupational hazards (biological and non-biological) among health workers in hospitals of Mukalla city. A prevention and infection control and patient safety programs are highly recommended in Mukalla hospitals to save health workers and patients.

P-1122 The impact of farm animal exposures on Campylobacter jejuni antibody levels in rural agricultural communities of Iowa, USA

Ian Buller[1,2], Joseph Shearer[1,2,3], Jared Fisher[1], Laura Beane Freeman[1], Gabriella Andreotti[1], Dale Sandler[4], Christine Parks[4], Karen Krogfelt[5,6], Charlotte Jørgensen[5], Rena Jones[1], Jon Hofmann[1]

[1]Occupational and Environmental Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Rockville, USA, [2]Cancer Prevention Fellowship Program, Division of Cancer Prevention, National Cancer Institute, Rockville, USA, [3]Heart Disease Phenomics Laboratory, Epidemiology and Community Health Branch, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, USA, [4]Chronic Disease Epidemiology Group, Epidemiology Branch, National Institute of Environmental Health Sciences, Research Triangle Park, USA, [5]Department of Virus & Microbiological Special Diagnostics, Statens Serum Institut, Copenhagen, Denmark, [6]Department of Science and Environment, Roskilde University, Roskilde, Denmark

BACKGROUND AND AIM: Campylobacter infections transmitted primarily through improperly cooked meat are the leading bacterial cause of diarrhea worldwide. How exposures to farm animals and animal waste (e.g., through occupational contact or residential proximity to animal feeding operations [AFOs]) contribute to infections has been relatively understudied.

METHODS: We measured antibodies against Campylobacter jejuni using an enzyme-linked immunosorbent assay in participants from Iowa in the Biomarkers of Exposure and Effect in Agriculture study (n=304 farmers; n=146 non-farming controls from similar communities). Participants self-reported occupational animal contact within the past year. We used a statewide database of permitted AFOs that included animal counts standardized by animal size and manure production to characterize the intensity of AFO exposure within 5km of participants' residences. We performed linear regressions of log-transformed optical density units (ODs) for immunoglobulin (Ig) A, G, and M antibody levels in relation to occupational animal and low/high AFO exposures, using non-farming controls with low AFO exposure (n=96) as the referent group. We adjusted for age, season, and other potential confounders. We further examined antibody levels by occupational contact with specific animal types.

RESULTS: Occupational animal contact was associated with elevated IgA and IgG OD levels in those with low AFO exposure (geometric mean ratio [95% confidence interval]; IgA:1.34[1.07-1.67]; IgG:1.34[1.13-1.57]) as well as those with high AFO exposure (IgA:1.48[1.12-1.95]; IgG:1.34[1.09-1.65]). Antibody levels were higher in farmers raising poultry (IgA:2.20[1.03-4.71]; IgG:2.11[1.35-3.32]), swine (IgA:1.52[1.04-2.22]; IgG:1.50[1.17-1.94]), and dairy cattle (IgG:1.65[1.18-2.31]), particularly for IgG levels in those who reported spending time in poultry (2.29[1.25-4.19]) or swine (1.63[1.25-2.12]) confinements within the past month. We found no significant relationships between occupational animal contact and IgM or AFO exposure alone and any antibody levels.

CONCLUSIONS: Occupational animal contact may be a stronger determinant of C. jejuni exposure than residential proximity to AFOs in agricultural communities.

KEYWORDS: Campylobacter, animal exposures

P-1125 Health Risk Assessment for Pest Control Workers Using Biocidal Products after COVID-19 Outbreak: A Comparison of EU and US

Sangji Lee[1], Lita Kim[1,2], Yun-Hee Choi[1,2], Kyoung Whan Moon[1,2,3]

[1]Department of Health and Safety Convergence Science, Korea University, Seoul, Republic of Korea, [2]Bk21 FOUR R&E Center for Learning Health System, Korea University, Seoul, Republic of Korea, [3]Institute of Health Sciences, Korea University, Seoul, Republic of Korea

After the COVID-19 outbreak, the workloads of disinfection have remarkably increased. As disinfectants are harmful to human, health risk assessment of disinfection workers is needed to ensure their safety. However, the acceptable operator exposure level (AOEL) for most disinfectants are not established. Moreover, the method of calculating the AOEL varies across the countries. This study aims to identify the health risks of disinfection workers based on two different risk assessment methods of EU and US after the COVID-19 outbreak.

We surveyed 533 disinfection workers to identify exposure patterns of disinfectants. The inhalation and dermal exposure were calculated based on different work types. The AOEL was calculated and compared using the EU and US methods. The health risks of workers are determined by hazard index based on whether the exposure exceeds AOEL.

Workers used 53 chemicals from 175 biocidal products, and only 34 chemicals (65%) had AOEL. 17 Chemicals with absorption factors for each route or AOEL were selected for risk assessment. When compared the estimated AOEL was calusing EU and US methods, only 2 (4%) were the same. The result of health risk assessment showed 10 (19%) were exceed 1 (acceptable level) using EU method, while 9 (17%) were exceed 1 using US method.

This study performed the health risk assessment of disinfection workers based on EU and US methods after the COVID-19 outbreak. Only 65% had an AOEL, and health risks of workers were differd according to risk calculation methods of EU and US. Given the increasing use of biocides after the COVID-19 outbreak, AOEL need to be established for health risk assessment of workers.

Biocides, Risk assessment, Reference dose, AOEL, COVID-19, pest control worker

P-1126 The Effectiveness of Occupational Health and Safety Management System (OHSMS) Application in the R.O.K. Navy and Improvement Plan

Sangji Lee[1], Yun-Hee Choi[1,2], Da-An Huh[3], Kyoung Whan Moon[1,2,4]

[1]Department of Health and Safety Convergence Science, Korea University, Seoul, Republic of Korea, [2]BK21 FOUR R&E Center for Learning Health System, Korea University, Seoul, Republic of Korea, [3]Institute of Health Sciences, Korea University, Seoul, Republic of Korea, [4]Department of Health and Environmental Science, Korea University, Seoul, Republic of Korea

The Republic of Korea Navy is applying OHSMS (Occupational Health and Safety Management System) to 3 type of units(repair, engineer, ammunition) for workplace safety. Several studies have argued that implementing OHSMS in the workplace is problematic and that measures are needed to improve its effectiveness. Moreover, since OHSMS focuses on corporate safety, it should be adequately reviewed when applied to the military, but studies have not been conducted yet. This study aims to confirm the effectiveness of the Navy's OHSMS and to identify improvement measures.

We surveyed 599 members of the units to determine the impact of OHSMS on unit safety conditions (systems, management, activities). for engineer and ammunition units, the safety conditions were compared according to whether they were OHSMS certified. In the repair units without the OHSMS non-certified comparator, the safety conditions according to the OHSMS application period were compared. To confirm the improvement plan of OHSMS, we surveyed 29 Naval OHSMS experts and analyzed IPA (Importance-performance Analysis) and AHP (Analytic Hierarchy Process).

There was no statistical difference in the level of safety conditions according to whether OHSMS was applied and the operating period, so the effectiveness of OHSMS could not be confirmed. The Navy's OHSMS needed gradual improvement due to its low overall performance. In particular, there was an urgent need for improvement in 1.organizational roles, responsibilities, 2.consultation and participation of members, 3.support, and 4.capabilities. Among them, consultation and participation of members was rated the most as a result of importance weight analysis through AHP.

In this study, the effectiveness of the Navy's OHSMS has not been confirmed, and consultation and participation of members was a vital improvement factor. This can be used as basic data for the practical application of OHSMS in the Navy in the future.

P-1133 Occupational injuries and extreme heat: An analysis from the hot desert climate of Kuwait

Barrak Alahmad[1,2], Ali Al-Hemoud[3], Petros Koutrakis[1]
[1]Harvard T H Chan School of Public Health, Boston, USA, [2]Faculty of Public Health, Kuwait University, Kuwait City, Kuwait, [3]Kuwait Institute for Scientific Research, Kuwait City, Kuwait

BACKGROUND–Temperatures in the harsh summer times of Kuwait commonly exceed 40°C during the day. Since 2015, a ministerial law banned employees from working under the sun (11am to 4pm) from June 1st to August 31st of every year. The vast majority of the affected employees are migrant workers in outdoor jobs such as construction and hospitality.
AIM–We assessed the risk of occupational injuries associated with outdoor extreme hot temperatures during the summertime ban period in Kuwait.
METHODS–We collected daily occupational injuries that are reported to the Ministry of Health's Occupational Health Department for five years from 2015 to 2019. We examined counts of occupational injuries during the same summertime ban period from June 1st to August 31st in each of the five years. We fitted generalized additive models with a quasipoisson distribution in a time series design. A 7-day moving average of daily mean temperature was modelled with penalized splines adjusted for relative humidity, time trend and day of the week.
RESULTS–During the June-August summertime ban, the daily average temperature was 39.4°C(±1.8°C). There were 7.2, 7.6 and 9.4 reported injuries per day in the summer months of June, July and August, respectively. The exposure-response relationship was S-shaped with a decrease in risk at very extreme hot temperatures. Compared to the 10th percentile of summer temperatures in Kuwait (37.4°C), the average day with a temperature of 39.4°C increases the risk of injury by 1.38-fold (95% confidence intervals: 1.30-1.46). Similarly, temperatures of 40°C and 41°C were associated with relative risks of 1.41 (1.33-1.49) and 1.34 (1.21-1.49), respectively. The risks leveled off at 42°C (relative risk 1.21; 0.93-1.57).
CONCLUSIONS–We found substantial increases in occupational injury risk from extremely hot temperatures despite the summertime ban in Kuwait. Calendar-based rather than heat- or risk-based regulation may be inadequate to provide occupational protections for migrant workers.

P-1134 Evaluation of lung inflammation from daily exposures to fine and ultrafine particulate matter in a trade school

Kynda Tinawi[1], Alan da Silveira Fleck[1,2], Maximilien Debia[1,2], Céline Plante[3], Audrey Smargiassi[1,2,4]
[1]Centre De Recherche En Santé Publique (CRESP), Montreal, Quebec, Canada, [2]Department of Environmental and Occupational Health, School of Public Health, University of Montreal, Montreal, Quebec, Canada, [3]Direction de Santé Publique du Centre Intégré Universitaire de Santé et de Services Sociaux du Centre-Sud-de-l Île-de-Montréal, Montreal, Quebec, Canada, [4]Institut National de Sante Publique du Québec (INSPQ), Montreal, Quebec, Canada

BACKGROUND - Daily short-term exposure to ambient fine particles ($PM_{2.5}$; < 2.5 µm) in the general environment has been related to acute respiratory effects such as respiratory symptoms and inflammation, emergency room visits for respiratory conditions and mortality. Although exposure is higher in trade/occupational settings, acute respiratory effects of daily exposures remain unexplored.
OBJECTIVE - To evaluate the association between daily exposures to fine particles ($PM_{2.5}$) and Ultrafine Particles (UFP; < 0.1 µm), and fractional exhaled nitric oxide (FeNO), a relevant indicator of lung inflammation, in two trade settings from a construction school.
METHOD - A repeated-measure panel study was carried out on students performing welding and bricklaying activities (n=30). $PM_{2.5}$ and UFP concentrations were measured daily (area measurements with direct-reading instruments) and fractional exhaled FeNO were measured two times per day, pre-work and post-work, for 5 consecutive days. Mixed GLM models were used to assess associations.

RESULTS: - Daily geometric mean exposure to $PM_{2.5}$ from welding and bricklaying activities were respectively 183 µg/m³ (σg=3.5) and 90.8 µg/m³ (σg=1.6). Daily geometric mean UFP concentrations for these activities were 106,000 (σg=1.6) particles/cm³ and 4,400 (σg=1.7) particles/cm³. Combining bricklaying and welding activities, for a 10,000 particles/cm³ increase in UFP, there was a 0.2 ppb (95%CI: 0.05-0.3) increase in FeNO inter-day. There was also a tendency for a small increase in FeNO (0.2 ppb; 95%CI: -0.06 - 0.5) per 100 µg/m³ of $PM_{2.5}$. Further analyses will be performed with additional participants and stratified by occupational trade.
CONCLUSION - Bricklaying and welding activities expose workers daily to $PM_{2.5}$ and UFP that may contribute to recurrent pulmonary inflammation and impair respiratory health.

KEYWORDS: particulate matter, occupational exposures, short-term exposure, pulmonary inflammation.

P-1136 Association between night shift work and different categories of non-occupational physical activity in the Shahedieh cohort study

AmirHoushang Mehrparvar[1], Mahsa Nazari[2], Seyed Saeed KhayatZadeh[3], Mohammad Javad Zare Sakhvidi[2]
[1]Occupational Health Department, School of Public Health, Shahid Sadoughi University of Medical Sciences, Yazd, Islamic Republic of Iran, [2]. Industrial diseases research center, Shahid Sadoughi University of Medical Sciences, Yazd, Iran, [3]. Department of Nutrition, School of Public Health, Shahid Sadoughi University of Medical Sciences, Yazd, Iran

INTRODUCTION
Shift-work has been associated with physical and mental health problems. This study aimed to explore the association between shift-work and different non-occupational physical activities in Iranian adults enrolled in the Shahedieh cohort study (SCS).

METHODS: The participants were men enrolled in the SCS (2014-2017). Different categories of non-occupational physical activity were quantified by the International Physical Activity Questionnaires and presented (as continuous by the metabolic equivalent of task [MET]), and dichotomous for defining sedentary/non-sedentary behavior based on MET). Shift-work status was asked through a face-to-face interview. The odds of having a sedentary behavior associated with shift-work, and the association between shift-working and daily MET of each category of activity were modeled using adjusted logistic regression and multiple linear regression (presented as odds ratio [OR] and beta respectively, with 95% confidence intervals [CI]). Results are based on the models adjusted for hypothesized confounders.

RESULTS: of 5132 men, 13.3% were shift-worker (more educated, and younger than non-shift-workers). Shift-workers had 20% lower odds of sedentary behavior compared to non-shift-workers (OR = 0.80; 95% CI: 0.60-0.98). Shift-working was associated with higher daily MET related to time spent on driving (ß=0.88; 95%CI: 0.75: 1.02), walking (ß=0.45; 95%CI: 0.33: 0.56), and light manual handling (ß=0.06; 95%CI: 0.01: 0.10), but the negative association with heavy sports activities (ß=-0.01; 95%CI: -0.03:-0.00), time spent on house cleaning (ß=-0.03; 95%CI: -0.06:-0.01), watching television (ß=-0.11; 95%CI: -0.20:-0.02), and working with a computer (ß=-0.13; 95%CI: -0.21:-0.06).
CONCLUSION: Shift-workers spent more energy on non-occupational activities than non-shift-workers, especially on outdoor activities. It implies the importance of considering shift-working as a possible effect modifier in the studies with hypotheses related to exposures linked to residing in outdoor environments such as the use of greenspace and ambient air pollution.

P-1138 Occupational heat exposure and prostate cancer risk: a pooled analysis of case-control studies

Alice Hinchliffe[1], Juan Alguacil Ojeda[2], Wendy Bijoux[3], Manolis Kogevinas[1], Florence Menegaux[3], Marie-Elise Parent[4], Beatriz Pérez Gomez[5], Sanni Uuksulainen[6], Michelle Turner[1]

[1]Isglobal, Barcelona, Spain, [2]Centro de Investigación en Salud y Medio Ambiente (CYSMA), Universidad de Huelva, Huelva, Spain, [3]Center for Research in Epidemiology and Population Health CESP - INSERM, Villejuif, France, [4]Institut national de la recherche scientifique, Quebec City, Canada, [5]Instituto de Salud Carlos III | ISCIII · Department of Epidemiology of Chronic diseases, Madrid, Spain, [6]Finnish Institute of Occupational Health, Helsinki, Finland

BACKGROUND AND AIM: Heat exposures occur frequently in many indoor and outdoor occupations. In our previous work, we observed some evidence for a positive association of occupational heat exposure and breast cancer risk. Here we seek to examine potential associations with prostate cancer risk in a large multi-country study.

METHODS: We performed a pooled analysis of data from 3,175 histologically confirmed prostate cancer cases and 3,529 frequency-matched controls from studies in three different countries, Spain, France, and Canada. The Finnish job exposure matrix, FINJEM, was used to apply estimates of occupational heat exposure to the lifetime occupational history of participants. Three main exposure indices were used: ever vs. never exposed, lifetime cumulative exposure (heat stress years) and duration of exposure (years) with a lag period of 5 years. We estimated odds ratios (ORs) and 95% confidence intervals (CIs), using conditional logistic regression models stratified by 5-year age groups and study and adjusted for potential confounders.

RESULTS: A total of 32% of cases and 33% of controls were classified as being ever occupationally exposed to heat. Highest heat exposed occupations included ore and metal furnace operators, firefighters, and bakers. We found no evidence for an association of ever occupational heat exposure and prostate cancer risk (OR 0.92; 95% CI 0.83, 1.03). There were also no associations observed in the highest categories of lifetime cumulative exposure or duration, and there was no evidence for a trend. Results did not change when stratifying by Gleason scores. When analysing the Spanish case-control study separately using a Spanish job exposure matrix developed for local working conditions, some odds ratios were elevated, though results were imprecise.

CONCLUSIONS: Findings from this pooled study have provided no strong evidence for an association between occupational heat exposure and prostate cancer risk.

KEYWORDS: prostate cancer, occupational exposures, heat, pooled analysis

P-1141 Oxidative stress in workers in indoor and outdoor environments

Marco Panizzolo[1], Federica Ghelli[1], Giulia Squillacioti[1], Enrico Bergamaschi[1], Roberto Bono[1], Valeria Bellisario[1]
[1]*Department of Public Health and Pediatrics, University of Turin, Turin, Italy*

BACKGROUND AND AIM: Occupational exposure to particles can raises important health issues for exposed workers. High concentrations of these particles can be found in a variety of occupational and environmental contexts, depending on the type of scenario, whether indoors or outdoors working environments. The aim of this study was to investigate the role that indoor and outdoor environments play in altering oxidative stress levels in workers in relation to the exposure to particles.

METHODS: 162 subjects were recruited; 62 were subjects working in indoor environments (13 employed in the handling of waste, 49 not exposed to this task), 100 subjects working in outdoor environments (65 employed in sweeping of the streets, 35 not exposed to this task). Oxidative stress was assessed by analysing 15-F2t-isoprostane concentrations in urine samples of all the recruited subjects. In addition, a questionnaire was administered to each to obtain information among which gender, age, BMI, smoking habits. Statistical analyses were done using SPSS and 15-F2t-Isoprostane concentrations were compared each other using the Kruskal-Wallis test.

RESULTS: The analyses showed a higher level of 15-F2t-Isoprostane in workers working in indoor environment when compared to workers working in outdoor environments ($P<0.01$). Furthermore, the employed in the handling of waste in indoors show the highest level of 15-F2t-isoprostane ($P<0.05$) while, subjects not exposed to this task in indoors, place themselves at intermediate 15-F2t-isoprostane levels.

CONCLUSIONS: This study shows that higher levels of oxidative stress were found in both exposed and unexposed workers in indoor environments. Analysing the responses to the questionnaire, we also controlled tobacco smoke exposure because it may have a role in the redox imbalance recorded in workers.
These results hypothesise that particle dilution in outdoor environments may be directly associated with lower levels of oxidative stress in the workers.

KEYWORDS: occupational exposure, environmental exposure, particle emissions.

P-1152 Contribution of Occupational Risk Factors to Lifespan Inequalities across Socio-Occupational Groups in France

Narges Ghoroubi[1,2], Mary Beth Terry[3], Emilie Counil[1,4]

[1]French Institute for Demographic Studies (ined), Aubervilliers, France, [2]Paris Saclay University, Doctoral School of Public Health (EDSP), Villejuif, France, [3]Columbia University Mailman School of Public Health, Department of Epidemiology, New York, USA, [4]Institut de Recherche Interdisciplinaire sur les Enjeux Sociaux - Sciences sociales, politique, santé, IRIS (UMR 8156 CNRS - EHESS - U997 INSERM), Aubervilliers, France

BACKGROUND AND AIM: Occupational risk factors can mediate the effect of socioeconomic status on mortality; however, the reduction in social disparities in mortality that could be achieved by modifying employment and working conditions has been under-studied. Our aim was to quantify the role of occupational risk factors (lack of job control, job insecurity, and unemployment; and in men only: occupational physical activity (OPA)) in producing socio-occupational inequalities in lifespan among the French population.

METHODS: We reviewed the literature on 75 occupational risk factors and selected four of them with a robust all-cause mortality effect size. We used the Health and Career Path survey (SIP-2006) to estimate differential exposures in each French socio-occupational group (SOG) by sex. Then, using the life tables published by The French Institute of Statistics and Economic Studies and developing a method based on population attributable fractions, we estimated loss in life expectancy attributed to workplace exposures by SOG and sex.

RESULTS: Based on life expectancy estimated at age 35 and depending on SOG, from one to three years of life lost for men, and from 0.6 to two years for women are attributed to a combination of high OPA, low job control, job insecurity, and unemployment compared to those who had low OPA, high job control, no concerns about job loss and were employed. The difference in life expectancy at age 35 between senior executives and manual workers would have been reduced from 6.3 to 4.4 years for men and from 3.2 to 2.2 years for women if socio-occupational exposures had been set at the theoretical minimum level for the four risk factors.

CONCLUSIONS: Our results, although based on a limited number of workplace factors due to large data gaps, show that improving employment and working conditions would substantially lessen social inequalities in life expectancies.

P-1153 Agricultural pesticide exposure assessment in Latin America and the Caribbean. A review study

Melisa Romero Asís[1], Mariana Eandi[1], Maria Osley Garzón Duque[2], Nicole Builes[3], Camila Arias Gonzalez[3], Mariana Butinof[1]

[1]Escuela de Nutrición- Facultad de Ciencias Médicas-Universidad Nacional De Córdoba, Córdoba, Argentina, [2]Facultad de Medicina- Escuela de Graduados -Universidad CES., Medellín, Colombia, [3]Facultad de Medicina-Universidad CES, Medellín, Colombia

The region of the Americas shows heterogeneous agricultural labor scenarios. The measurement of pesticide exposure is a challenge and a necessary requirement for prevention. A systematic review of the scientific literature was carried out to identify the methodologies to assess exposure to agricultural pesticides in Latin America and the Caribbean (LAC).

PubMed, Scielo and Lilacs were searched (January 2010 and April 2021). Keywords selected: "pesticides", "occupational exposure", "farmers", "pesticide exposure" and "Latin America". Eighty-two publications from 11 countries were retained for analysis. The exposure assessment methods (EAMs) were analyzed, categorized into direct and indirect, analyzing the productive context of the study, according to whether it belonged to the formal or informal economy.

Most of the articles analyzed came from Brazil (41%) and Colombia (23%); cross-sectional designs predominated (64%). The term "exposure" appears as a scattered concept in the literature; 67% of the studies evaluated exposure to pesticides in informal agricultural contexts where family work was identified, in contrast to formal productive environments where it was not reported. The types of EAMs used were: a) indirect methods (58%): surveys, index construction, and measurement of environmental parameters (water and soil); b) direct methods (15%): biomarkers in blood, urine and other human matrices; c) combination of both methods (27%). Significant differences were identified between the EAMs used (direct/indirect) according to the context (formal/informal) of study (p= 0.016). The use of indirect EAM was more frequent in productive contexts of the informal economy.

Pesticide exposure assessment in LAC is heterogeneous and implemented through methods that are difficult to identify and classify. In the informal economy, family work prevails and there is less knowledge about pesticide exposure. Knowledge about these processes is necessary to reduce risks and vulnerabilities.

Pesticides - exposure - assessment methods - agriculture

P-1161 Physically strenuous work in a hot climate and reduced kidney function in the sugarcane industry

Katie Applebaum[1], Magda Castrillo[2], Morgan Byrne[3], Daniel Brooks[4]
[1]George Washington University, Milken Institute School of Public Health, Department of Environmental and Occupational Health, Washington, USA, [2]Pantaleon Group, Chinandega, Nicaragua, [3]George Washington University, Milken Institute School of Public Health, Department of Epidemiology, Washington, USA, [4]Boston University School of Public Health, Department of Epidemiology, Boston, USA

BACKGROUND AND AIM: Sugarcane workers are reportedly at increased risk of chronic kidney disease of non-traditional causes (CKDnt). Most prior studies have focused on a limited number of jobs, yet suspected risk factors of hot climatic conditions and strenuous work are common across jobs in the industry. We examined whether reduced kidney function was associated with working in hot climatic conditions and strenuous work in an industry-wide program.

METHODS: Data from a surveillance program at a Nicaraguan sugarcane planation 2015-2020 involved random collection of blood, allowing estimation of glomerular filtration rate (eGFR), for all employees. Any eGFR <=60 mL/min/1.73m2 was classified as low. Jobs were classified by whether outside and whether physical labor. Analyses restricted to males <50 years old who were non-supervisors. Multivariable models were used to estimate adjusted odds ratios (aORs) and 95% confidence intervals (CIs) comparing odds of low eGFR for working outside with inside, either adjusted for or stratified by age. Among outside workers, odds of low eGFR for each laborer job was compared with non-laborers. Models also adjusted for repeated measures and harvest period.

RESULTS: Analyses included 2,884 employees with 6,144 eGFR measures. There was no difference in odds of low eGFR between working outside or inside. Among those outdoors, laborers had increased odds of low eGFR compared with non-laborers (OR=3.58, (95% CI 1.85-6.94)). The association was most pronounced among those <=30 years old (OR=11.89 (95% CI 1.68-84.03)). Jobs of seed loader, seeder/reseeder, and weeder had >=6-fold increased odds of low eGFR relative to outdoor non-laborers (p<0.001).

CONCLUSIONS: Physically strenuous jobs in combination with working outside in a hot climate was consistently associated with reduced kidney function, with strongest influence in younger workers. Our results suggest more research should evaluate younger workers in physically demanding jobs to help identify prevention strategies.

KEYWORDS: CKDnt, heat, work

P-1174 Assessment of Portuguese firefighters' lifestyle: results from an online survey

Sónia Namorado[1,2,3], Laura Carmona[4], Raquel Pinheiro[5], Joana Faria-Anjos[6], Maria José Chambel[4]
[1]Department of Epidemiology, National Institute of Health Doutor Ricardo Jorge, Lisbon, Portugal, [2]NOVA National School of Public Health, Public Health Research Centre, Universidade NOVA de Lisboa, Lisbon, Portugal, [3]Comprehensive Health Research Center, Universidade NOVA de Lisboa, Lisbon, Portugal, [4]CicPsi, Faculdade de Psicologia da Universidade de Lisboa, Lisbon, Portugal, [5]National Fire Service School, Sintra, Portugal, [6]Instituto de Emergência Médica, Lisbon, Portugal

Firefighters are an occupational group exposed to multiple agents, such as heat, fatigue, noise and chemical substances. Exposure to these agents can have a severe impact on their health. In addition, lifestyle behaviors may also affect their health and well-being. As such, the aim of this study was to assess health-related lifestyle behaviors in Portuguese firefighters.

Data was obtained via an online survey using an adapted version of the FANTASTIC Lifestyle Assessment Inventory that included questions on relationships with family and friends, physical activity, nutrition, tobacco and alcohol consumption, sleep and stress, career and shifts. The access link to the survey was disseminated through collaboration with the National School of Firefighters. Data was collected between April 24th and May 27th 2021.

From the 861 participating firefighters, the majority were men and had less than 40 years old. Around half were married and were firefighters for more than ten years. The majority referred to have people to talk about important things and to give and receive affection. Regarding physical activity the majority did not practice physical activity in the professional context. Only a quarter reported to have healthy eating habits and the majority reported the consumption of high-calorie foods and to be exceeding their ideal weight. More than a third reported smoking and around 16% reported driving motor vehicles after consuming alcohol. Around 40% reported to consume more than 3 caffeine drinks per day. Around a tenth reported to almost never have good quality sleep and only around 78% reported to have difficulties sleeping. About 43% didn't have capacity to manage stress in their day to day life and about 57% were not able to relax in their free time. Around 40% reported not being happy with their work and a third reported to do periodic medical exams.

P-1177 Impact of the COVID-19 pandemic on a pilot sample of women enrolled in the SEMILLA birth cohort study

Alexis Handal[1], Fadya Orozco[2], Stephanie Montenegro[3], Alexa Kort[1]
[1]University of Michigan, Ann Arbor, USA, [2]Universidad de San Francisco de Quito, Cumbaya, Ecuador, [3]CTT-USFQ/Proyecto Semilla, Cumbaya, Ecuador

BACKGROUND AND AIM
Project SEMILLA, a community-engaged epidemiological cohort study, assesses environmental, occupational, and social factors among pregnant women in a major flower-growing region of Ecuador and the impact of these factors on child growth and development. The COVID-19 pandemic has presented an unprecedented challenge to the implementation of the SEMILLA study. This paper presents the results of a pilot qualitative study with SEMILLA participants examining the impact of the pandemic on their lives.

METHODS: SEMILLA follows pregnant women and their infants up to 18 months of age. Methods include obtaining prenatal urine samples, maternal and neonatal blood samples to assess thyroid hormone levels, and data on working conditions, environmental exposures (home/work), stress, social support, maternal health, socioeconomic factors, and infant neurodevelopment, growth and nutritional status. During the initial months of the pandemic, SEMILLA researchers observed important impacts of the pandemic in the study region and with enrolled participants. In April 2020, we conducted phone interviews with currently enrolled participants (n=11), to assess the experiences of the participants during this time. Semi-structured questions addressed concerns and worries as well as changes in activities (work/home) due to the pandemic.

RESULTS: Emergent themes from qualitative analysis include economic insecurity and job loss, food insecurity and food access issues, strained relationships at home including interpersonal violence, responsibilities at home including additional burdens for participants regarding schooling of other children. Fear and worry about being infected, about having a healthy pregnancy and a healthy delivery and baby, and fear of family members being infected prevailed.
CONCLUSION: Findings from this pilot study helped shape protocol changes and revisions to capture the new reality for women participating in SEMILLA during the pandemic; changes which are critical for understanding the impact of the COVID-19 pandemic on the lives of pregnant women and their families in the region.

P-1178 The environmental risk factors of birth defects in Iraq

Jeffrie Quarsie[1], Kali Rubaii
[1]*Netherlands School of Public and Occupational Health, Netherlands*

BACKGROUND AND AIM: Ever since the war started in 2003, Iraqi doctors have reported an increase in the birth of children with congenital anomalies. According to them, the rise in incidence has been attributed to war-related heavy metal pollution e.g. from depleted uranium and white phosphorus. As the war impeded quality research, the current post-conflict situation has allowed renewed space for quality research. The aim of the study is to assess to what extent exposure to environmental pollution might be associated with the incidence of congenital anomalies in Iraq.

METHODS: We conducted a case-control study in Fallujah, a heavily bombarded city, comparing 50 parents of children with birth defects and 50 parents of children without birth defects. We used a questionnaire to comprehensively document environmental exposure and history of residence of each couple. Further, we complemented the interviews with biomonitoring through hair analysis of parents on heavy metals using ICP-MS. In addition, we took soil samples of the city of Fallujah using grid sampling and compared this to a control city in northern Iraq which has been less bombarded. We used Stata to statistically assess the differences in case and control groups regarding exposure and heavy metal concentrations, correcting for confounders like age and socio-economic status.

RESULTS: Comprehensive data analysis will take place in the summer 2022. Our preliminary results already point to a striking discrepancy between the occupation of the fathers of children children with congenital anomalies and the fathers of the control group. The fathers of the birth defects are more often construction workers, working on houses often damaged or levelled by war.

CONCLUSIONS: Having a child with a congenital anomaly in Iraq might be associated with paternal environmental exposure, possibly through epigenetic pathways.

KEYWORDS: Congenital anomalies, Military pollution, Teratogenicity, Epigenetics, Exposome

P-1179 Associations between traffic-related air pollutants and preterm birth in a North Carolina birth cohort, 2003-2015

Alison K. Krajewski[1], Thomas J. Luben[1], Joshua L. Warren[2], Monica P. Jimenez[3], Kristen M. Rappazzo[1]
[1]USA Environmental Protection Agency, Office of Research and Development, Center for Public Health & Environmental Assessment, Research Triangle Park, USA, [2]Yale School of Public Health, Department of Biostatistics, New Haven, USA, [3]Oak Ridge Institute for Science and Education (ORISE) Postdoctoral Fellow at US EPA, Research Triangle Park, USA

BACKGROUND AND AIM: Preterm birth (PTB; <37 weeks completed gestation) is associated with exposure to fine particles and ozone, but less is known about associations with nitrogen dioxide (NO_2) and other traffic-related air pollutants, such as benzene, toluene, ethylbenzene, and xylene (BTEX). We estimated the associations between PTB and NO_2, with and without adjustment for BTEX.

METHODS: We examined the associations between PTB and gestational exposure to NO_2 in a North Carolina singleton birth cohort (N=1,367,507) from 2003-2015. Daily 8-hour max NO_2 concentrations from a hybrid-model with a spatial resolution of 1km² were aggregated to census tracts and linked to residential address at delivery, then averaged across each week of pregnancy. We obtained annual average ambient concentrations for BTEX for census tracts from the 2011 National Air Toxics Assessment. Modified Poisson regression models with robust errors were used to estimate risk differences (RD(95% CIs)) per 10-ppb increase in NO_2, adjusted for gestational parent marital status, race/ethnicity, age at delivery, Medicaid status, month of conception, and BTEX.

RESULTS: The median (IQR) NO_2 across each day of pregnancy was 15.0(10.2) ppb and 1.6(1.1) ppb for BTEX. The associations between NO_2 and PTB were of similar magnitude across each week of gestation. RDs with and without adjustment for BTEX varied. RDs per 10-ppb increase NO_2 exposure during each week of gestation ranged from -7(95% CI: -14,1) in weeks 17 and 23 to 0(-6,5) in week 36 per 10,000 births, respectively. Adjusting for BTEX, RDs ranged from 19(13,25) in week 36 to 36(27,44) in week 24 per 10,000 births, respectively.

CONCLUSIONS: While the association between NO_2 exposure and PTB were generally null across each week of gestation, when adjusting for BTEX, we observed a consistent pattern of increased risk of PTB with NO_2 exposure.

KEYWORDS: air pollution, preterm birth, nitrogen dioxide, reproductive outcomes

P-1181 Associations between Repeated Measures of Urinary Phthalate Metabolites with Hormones and Timing of Natural Menopause: The Study of Women's Health Across the Nation

Ning Ding[1], Emily Zheutlin[2], Siobán Harlow[1], John Randolph[3], Bhramar Mukherjee[4], Sung Kyun Park[1,2]
[1]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, USA, [2]Department of Environmental Health Sciences, School of Public Health, University of Michigan, Ann Arbor, USA, [3]Department of Obstetrics and Gynecology, School of Medicine, University of Michigan, Ann Arbor, USA, [4]Department of Biostatistics, School of Public Health, University of Michigan, Ann Arbor, USA

BACKGROUND AND AIM: Studies on phthalate metabolites and sex hormones during the menopausal transition are limited and have yielded conflicting results. We aimed to examine the associations of phthalate metabolites with hormones including estradiol, testosterone, follicle-stimulating hormone (FSH), sex hormone-binding globulin (SHBG), anti-Müllerian hormone (AMH), and the timing of natural menopause.

METHODS: We examined 1,189 midlife women from the Study of Women's Health Across the Nation aged 45-56 years in 1999-2000 who had complete information on phthalate metabolites and hormones while not receiving hormone therapy. Urinary concentrations of 12 phthalate metabolites were repeatedly measured in 1999-2000 and 2002-2003. Hormones were measured at the same time points. Linear mixed-effect models were used to calculate percent differences (%D) and 95% confidence intervals (CIs) in serum concentrations of estradiol, testosterone, FSH, SHBG, and AMH per doubling in urinary phthalate metabolites. Cox proportional hazards models were used to calculate hazard ratios (HRs) and 95% CIs of natural menopause per doubling increase in urinary phthalate metabolites.

RESULTS: We observed significant associations of phthalate metabolites with lower testosterone concentrations: mono (7-carboxy-2-methyloctyl) phthalate (MCOP) (%D: -2.08%, 95% CI: -3.66, -0.47), and mono-n-butyl phthalate (MnBP) (%D: -1.99%, 95% CI: -3.82, -0.13), after adjusting for multiple comparisons with false discovery rates < 5%. Lower AMH concentrations were also found with higher MECPP (%D: -14.26%, 95% CI: -24.10, -3.14), MEHHP (%D: -15.58%, 95% CI: -24.59, -5.50), and MEOHP (%D: -13.50%, 95% CI: -22.93, -2.90). No associations were observed for other hormones or timing of natural menopause.

CONCLUSIONS: These results suggest that exposure to phthalates may affect circulating levels of testosterone in midlife women. Exposure to phthalates may also dimmish the ovarian reserve. Given the endocrine-disrupting role of phthalates, future studies are warranted to evaluate their impact on health outcomes among midlife women.

KEYWORDS: Phthalates; endocrine-disrupting chemicals; hormones; midlife women; menopause

P-1185 Urinary concentrations of non-persistent endocrine disrupting chemicals and fecundability in a preconception cohort study

Amelia Wesselink[1], Elizabeth Hatch[1], Ellen Mikkelsen[2], Michael McClean[1], Kathryn Tomsho[3], Birgit Claus Henn[1], Ganesa Wegienka[4], Kenneth Rothman[1], Lauren Wise[1]

[1]Boston University School of Public Health, Boston, USA, [2]Aarhus University Hospital, Aarhus, Denmark, [3]Harvard T. H. Chan School of Public Health, Boston, USA, [4]Henry Ford Health System, Detroit, USA

BACKGROUND AND AIM: Non-persistent endocrine-disrupting chemicals (EDCs) are found in consumer products including personal care products, plastics, and cleaning supplies. EDCs can affect hormonal pathways involved in reproduction. We examined prospectively the association between urinary concentrations of select non-persistent EDCs and fecundability, the per cycle probability of conception.

METHODS: We used data from PRESTO and Snart Foraeldre.dk, web-based preconception cohort studies that recruited female participants who were aged 21-45 years, residents of North America or Denmark, and trying to conceive without fertility treatment (2013-2019). Participants completed a baseline questionnaire and follow-up questionnaires every 8 weeks for up to 12 months. A subset of 207 participants residing in Boston, Massachusetts (n=119), Detroit, Michigan (n=18), or Aalborg, Denmark (n=70) provided urine samples during in-person clinic visits. We measured concentrations of 7 phenols, 4 parabens, triclocarban, 15 phthalate metabolites and 2 phthalate alternative metabolites using on-line solid-phase extraction-high-performance liquid chromatography-isotope dilution-tandem mass spectrometry. We used proportional probabilities models to estimate fecundability ratios (FR) and 95% confidence intervals (CI), adjusting for potential confounders.

RESULTS: Concentrations of some non-persistent EDCs were associated with reduced fecundability. The adjusted FR for the highest vs. lowest quartile of benzophenone-3 was 0.53 (95% CI: 0.28-0.99), with evidence of a monotonic association. Bisphenol S and 2,5'-dichlorophenol, and ethyl paraben concentrations were also associated with reduced fecundability. Among phthalate metabolites, mono-ethyl phthalate (highest vs. lowest quartile: FR=0.71, 95% CI: 0.45-1.12), monocarboxyoctyl phthalate (highest vs. lowest quartile: FR=0.71, 95% CI: 0.44-1.14), and the non-phthalate plasticizer cyclohexane-1,2-dicarboxylic acid monohydroxy isononyl ester (≥0.6 µg/g creatinine vs. <limit of detection: FR=0.59, 95% CI: 0.37-0.95) were associated with reduced fecundability.

CONCLUSIONS: Biomarkers of some non-persistent EDCs were associated with reduced fecundability. Future analysis of additional urine specimens in these cohorts will enable examination of chemical mixtures on fecundability.

KEYWORDS: endocrine-disrupting chemicals, fecundability, fertility, phenols, phthalates

P-1188 Association between maternal $PM_{2.5}$ exposure and gestational diabetes mellitus in Tokyo, Japan

Takehiro Michikawa[1], Seiichi Morokuma[2], Shin Yamazaki[3], Ayako Yoshino[3], Seiji Sugata[4], Akinori Takami[3], Kazushige Nakahara[2], Shinji Saito[4], Junya Hoshi[4], Kiyoko Kato[2], Hiroshi Nitta[3], Yuji Nishiwaki[1]
[1]Toho University, Tokyo, Japan, [2]Kyushu University, Fukuoka, Japan, [3]National Institute for Environmental Studies, Tsukuba, Japan, [4]Tokyo Metropolitan Research Institute for Environmental Protection, Tokyo, Japan

INTRODUCTION
Recent epidemiological findings suggested that $PM_{2.5}$ exposure is a risk factor for diabetes, and the association between $PM_{2.5}$ and glycaemia and insulin resistance provided the biological mechanistic support. Based on these, a hypothesis has been proposed that maternal exposure to $PM_{2.5}$ contributes to the development of gestational diabetes mellitus (GDM). However, the association between $PM_{2.5}$ and GDM was controversial, and there was limited evidence regarding exposure to specific components of $PM_{2.5}$. In this study, we examined the association between the $PM_{2.5}$-GDM association in the Asian population.

METHODS: From 2013 to 2015, we had permission to the Japan Society of Obstetrics and Gynaecology, and obtained the data on all mothers who delivered births after 22 gestational weeks at 39 cooperating hospitals in 23 Tokyo wards from the Japan Perinatal Registry Network database. We collected fine particle on a filter each day at one fixed monitoring site, and analysed carbon and ion components of $PM_{2.5}$. The average concentrations of $PM_{2.5}$ and its components over the 3-month before pregnancy, the first trimester (0-13 gestational weeks) and the second trimester (14-27 weeks) were calculated, and assigned to each mother. We applied a multi-level logistic regression analysis.

RESULTS: of the 83,319 mothers (mean age at delivery = 33.7 years), the proportion of GDM was 4.8%. The median concentration of total $PM_{2.5}$ over the first trimester was 16.1 (interquartile range (IQR) = 3.6) μg/m³. When we simultaneously included three exposure windows of total $PM_{2.5}$, only exposure over the first trimester was associated with GDM (odds ratio per IQR = 1.09, 95%CI = 1.02-1.16). for specific components, we observed the association between exposure to carbon constituents over the first trimester and GDM.
CONCLUSION: Our findings provided the additional evidence for the association between maternal exposure to $PM_{2.5}$ and GDM.

P-1196 Exposure to ambient sulfur dioxide during gestation and risk of preterm birth among people in North Carolina, 2003-2014

Adrien Wilkie[1,2], Thomas Luben[3], Kristen Rappazzo[3], Kristen Foley[4], Courtney Woods[5], Marc Serre[5], David Richardson[2], Julie Daniels[2]

[1]Oak Ridge Institute for Science and Education (ORISE) Postdoctoral Fellow at US EPA, Research Triangle Park, USA, [2]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA, [3]USA Environmental Protection Agency, Office of Research and Development, Center for Public Health & Environmental Assessment, Research Triangle Park, USA, [4]USA Environmental Protection Agency, Office of Research and Development, Center for Environmental Measurement and Modeling, Research Triangle Park, USA, [5]Department of Environmental Science and Engineering, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA

BACKGROUND AND AIM: Coal-fired power plants are major contributors of ambient sulfur dioxide (SO2) air pollution. Epidemiological literature suggests an adverse association between SO2 exposure during gestation and preterm birth (PTB; <37 weeks completed gestation). PTB is strongly associated with infant mortality and increased risk for later life morbidities. We investigated associations between SO2 and PTB in North Carolina and evaluated whether the associations were modified by race/ethnicity.

METHODS: We assembled a retrospective, administrative cohort of singleton births in North Carolina from 2003-2014. We used USEPA CMAQ data to assign SO2 gestational exposures to eligible births for the entire pregnancy and trimesters. We used multivariable generalized linear regression to estimate risk differences (RD (95%CI)) per 1-ppb increase in SO2, adjusted for gestational parent education, marital status, and season of conception. Multi-pollutant models were additionally adjusted for criteria air co-pollutants (CO, O3, PM2.5, NO2).

RESULTS: The median SO2 across exposure windows was ~3.5 (IQR: 4) ppb. The overall baseline risk for PTB was 8800 per 100,000 live births. When stratified by race/ethnicity, the baseline risk for PTB was 12200, 7900, and 7100 per 100,000 live births among non-Hispanic Black, non-Hispanic white, and Hispanic births, respectively. Regardless of exposure window, SO2 was adversely associated with PTB with the strongest associations observed for the entire pregnancy period. RDs per 1-ppb increase in SO2 averaged across the entire pregnancy were 133.5 (95%CI: 117.0, 149.9) and 195.7 (171.6, 219.7) per 100,000 live births for single- and multi-pollutant models, respectively. for multi-pollutant models, we observed similar RDs for non-Hispanic Blacks (239.4 (200.7, 278.2)) and non-Hispanic whites (211.5 (182.4, 240.7)) with smaller RDs for Hispanics (119.8 (80.7, 158.9)).

CONCLUSIONS: Across exposure windows, the results for our adjusted single- and multi-pollutant models showed adverse associations between SO2 and PTB, with some evidence of effect measure modification by race/ethnicity.

KEYWORD: PTB

P-1197 Ambient temperature and preterm birth risk in New York City: A time-series analysis

Ariel Yuan[1], Kathryn Lane[1], Carolyn Olson[1], Kazuhiko Ito[1]
[1]*New York City Department of Health and Mental Hygiene, New York, USA*

BACKGROUND AND AIM: Recent studies suggest an association between daily variation in ambient temperature during pregnancy and preterm birth (PTB). Our objective is to examine the short-term effects of heat and cold on PTB risk from 2008 to 2016 in New York City (NYC).

METHODS: We applied quasi-Poisson regression with distributed lag nonlinear models to estimate the cumulative relative risk (CRR) of daily counts of spontaneous PTB (<37 weeks gestation) and outdoor temperature, and to estimate the fraction of PTBs attributable to temperature, by season, using NYC Vital Statistics birth records and National Weather Service daily temperature data at LaGuardia airport. Models were adjusted for within-season trends and daily number of pregnant people at risk for preterm delivery. Heat and cold were defined as the 95th versus 50th percentile of maximum temperature during the warm season and 5th versus 50th percentile of minimum temperature during the cold season, respectively. Maternal race/ethnicity was assessed for effect modification.

RESULTS: Our analysis consisted of 38,593 spontaneous PTBs. Heat was not associated with PTB during the warm season [CRR: 0.98 (95% CI: 0.92, 1.05)]. There was a nonlinear association between cold and PTB. During the cold season, the CRR was 1.08 (0.99, 1.17) for cold up to three days before delivery (lag 0-3). The estimated fraction of PTBs attributable to cold was 9.3% (-0.6%, 17.4%), which corresponded to 81 (-2, 154) cold-attributable PTBs over the 9-year study period. Among non-Hispanic Blacks, the CRR was 1.20 (1.04, 1.39) for cold over lag 0-3 days, and an estimated 23.2% (10.3%, 34.3%) of non-Hispanic Black PTBs, equivalent to 69 (29, 105) PTBs, were attributable to cold.

CONCLUSIONS: Heat had no measurable impact. Cold potentially increased risk of PTB. Our finding for the impact of cold on non-Hispanic Black PTBs warrants additional research.

P-1199 The association of congenital heart defects with prenatal exposure to air pollutants: An umbrella review

Sophie Michel[1], Aishwarya Atmakuri[2], Ondine Solveig Von Ehrenstein[1,3]
[1]Department of Epidemiology, UCLA School of Public Health, University of California, Los Angeles, USA, [2]Department of Molecular, Cell, and Developmental Biology, UCLA College of Life Sciences, University of California, Los Angeles, USA, [3]Department of Community Health Sciences, UCLA School of Public Health, University of California, Los Angeles, USA

BACKGROUND AND AIM: for idiopathic congenital heart defects (CHD), air pollution during fetal development is a potential risk factor. However, findings of previous epidemiological studies and consequently of systematic reviews, have been mixed. We aimed to synthesize and evaluate the extant evidence on associations between gestational exposure to air pollutants and CHD subtypes, using a systematic review of reviews approach ("umbrella review").

METHODS: We systematically searched PubMed, Embase, and Epistemonikos for published and unpublished systematic reviews. The search was supplemented by the use of internet search engines and hand-searching of reference lists. The Risk of Bias in Systematic Reviews ("ROBIS") tool was used to evaluate included systematic reviews.

RESULTS: We identified ten systematic reviews, including eight meta-analyses. Moderately strong evidence for an increased risk of coarctation of the aorta following prenatal exposure to NO2 was provided by five reviews, which reported statistically homogeneous pooled odds ratios of 1.10 to 1.20 (95% confidence interval range: 0.99 to 1.41). Also, there was limited evidence for positive associations between SO2 and coarctation of the aorta, PM10 and atrial septal defects, NO2 and pulmonary artery and valve anomalies, and for both, PM2.5 and NO2 and Tetralogy of Fallot. Findings for other pollutant-CHD associations were inconsistent. Based on the ROBIS tool, a high or unclear risk of bias rating was assigned to eight out of ten reviews.

CONCLUSIONS: Beyond the increased risk of coarctation of the aorta following exposure to NO2, a clear pollutant-outcome pattern was not identified. These incoherent findings may partly be explained by differences in methods used across the reviews (e.g., inclusion criteria) as well as between individual studies (e.g., exposure and outcome assessment methods). Further establishment of and adherence to systematic review methods for environmental exposures and children's health may improve the validity and consistency of future systematic review findings.

P-1201 Metabolome-wide association study of prenatal exposure to air pollution and adverse birth outcomes in the Atlanta African American Maternal-Child cohort

Zhenjiang Li[1], Anne L Dunlop[2], Jeremy A Sarnat[1], Haoran Cheng[1], Youran Tan[1], Dana Boyd Barr[1], Anke Huels[3], Alicia Smith[2], Carmen Marsit[1], Dean P Jones[4], Donghai Liang[1]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Department of Gynecology and Obstetrics, School of Medicine, Emory University, Atlanta, USA, [3]Department of Epidemiology, Rollins School of Public Health, Emory University, Atlanta, USA, [4]Department of Medicine, School of Medicine, Emory University, Atlanta, USA

BACKGROUND: African Americans (AA) are disproportionately exposed to high air pollution and elevated risks of adverse birth outcomes, while the underlying mechanisms are still largely unknown. We aimed to address the knowledge gaps by investigating the associations between air pollution exposures, perturbations in maternal metabolome, and preterm (PTB) and early term birth (ETB).

METHODS: In 288 participants from the Atlanta AA Maternal-Child cohort we performed metabolomic profiling using high-resolution mass spectrometry with liquid chromatography in early gestation serum samples. Using spatiotemporally-resolved machine learning models, we estimated individual residential exposures to nitrogen dioxide, fine particulate matters, and ozone during the first trimester and one-year before conception. Using the meet-in-the-middle approach, we investigated whether the maternal metabolic perturbations associated with air pollution are also associated with PTB and/or ETB.

RESULTS: After quality control, 13,980 and 11,106 metabolic features were extracted from HILIC and C18 chromatography columns, respectively. In the HILIC column, 95 and 190 metabolic features were associated with at least one air pollutant (false positive discovery corrected $q<0.2$) during the first trimester and one-year before conception, respectively, while 3 and 4 features were associated with PTB and ETB. From C18, 243 and 48 features were associated with first trimester and one-year before conception exposures, while 5 and 1 were associated with PTB and ETB, respectively. Perturbations in purine metabolism were associated with both air pollution and PTB in pathway enrichment analysis. Using chemical annotation, we confirmed inosine and inosinic acid, which were enriched in purine metabolism and involved in DNA damage and repair.

CONCLUSIONS: The findings suggested a potentially critical role of purine metabolism in connecting air pollution exposures and PTB, which may support future development of sensitive biomarker and targeted interventions to reduce adverse birth outcomes induced by air pollution exposures.

P-1203 Cadmium may affect testosterone levels as a hormone-like disruptor in adult males

Yidan Qiu[1,2], Yuebin Lv[1], Miao Zhang[1], Saisai Ji[1], Bing Wu[1,3], Feng Zhao[1], Yingli Qu[1], Qi Sun[1], Yanbo Guo[1,4], Yuanduo Zhu[1], Xiao Lin[1], Xulin Zheng[1,3], Zheng Li[1], Hui Fu[1], Yawei Li[1], Haocan Song[1], Yuan Wei[1,4], Liang Ding[1], Guangdi Chen[5], Ying Zhu[1], Zhaojin Cao[1], Xiaoming Shi[1]

[1]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]Department of Big Data in Health Science, School of Public Health, Zhejiang University, Hangzhou, China, [3]Center for Global Health, School of Public Health, Nanjing Medical University, Nanjing, China, [4]Department of Epidemiology and Biostatistics, School of Public Health, Jilin University, Changchun, China, [5]Institute of Environmental Health, School of Public Health, and Bioelectromagnetics Laboratory, School of Medicine, Zhejiang University, Hangzhou, China

BACKGROUND AND AIM: Sex hormones play an important role in human health, and sex hormone disorders can cause a series of relevant consequences. Cadmium is ubiquitous in the environment, while little is known on the relationship between cadmium exposure and sex hormones in adult males. The purpose of this study is to explore the potential association between cadmium exposure and serum testosterone as well as serum testosterone to serum estradiol ratio (T/E_2) among Chinese adult males.

METHODS: Adult male aged ≥18 years old who participated in China National Human Biomonitoring program from 2017 to 2018 were surveyed. Blood cadmium, urine cadmium and urine cadmium adjusted with creatinine were measured, serum testosterone and serum estradiol were measured, and T/E_2 was calculated. Multiple linear regression models were used to analyze association of cadmium exposure with serum testosterone and T/E_2 in adult males.

RESULTS: Among Chinese adult males ≥ 18 years old, the weighted geometric means (95% CI) of blood cadmium, urine cadmium and urine cadmium adjusted with creatinine levels were 1.23 (1.12, 1.35) μg/L, 0.63 (0.56, 0.71) μg/L and 0.53 (0.47, 0.59) μg/g, respectively. The geometric means (95% CI) of serum testosterone and T/E_2 were 18.56 (17.92, 19.22) nmol/L and 143.86 (137.24, 150.80). After adjusting for all covariates, tertiles of cadmium exposure were positively associated with log-transformed serum testosterone (lgT) (all Ptrend < 0.05). Moreover, tertiles of cadmium exposure were positively associated with log-transformed serum testosterone to serum estradiol ratio [$lg(T/E_2)$] (all Ptrend < 0.05).

CONCLUSIONS: In Chinese adult males, cadmium exposure may affect serum testosterone and T/E_2 as a hormone-like disruptor.

P-1211 Urinary biomarkers of inorganic arsenic exposure, inorganic arsenic metabolism, and birth weight in Tacna, Peru, 2019

Diego Fano-Sizgorich[1,2], Matthew O. Gribble[4], Dana B. Barr[3], Cinthya Vasquez-Velasquez[1], Julio Aguilar[6], Claudio Ramirez[6], Jeffrey K. Wickliffe[4], Maureen Lichtveld[5], Gustavo F. Gonzales[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Centro Latinoamericano de Excelencia en Cambio Climático y Salud, Universidad Peruana Cayetano Heredia, Peru, [3]Emory University, Atlanta, USA, [4]University of Alabama at Birmingham, Birmingham, USA, [5]University of Pittsburgh, Pittsburgh, USA, [6]Universidad Nacional Jorge Basadre Grohmann, Peru

BACKGROUND AND AIM: Arsenic exposure during pregnancy has been related to adverse birth outcomes such as low birthweight. The province of Tacna is located in southern Peru. It is characterized by elevated arsenic levels in drinking water, nonetheless, its mean birth weight is greater than the country's average. Thus the aim of this study was to evaluate the effect of urinary arsenic species on birth weight in Tacna pregnant women in 2019.

METHODS: 160 pregnant women ≤24 weeks were recruited from different health centers of Tacna, and followed up to delivery. First morning voids of urine were sampled in the second and third trimester; they were encouraged to avoid consuming seafood at least three days before sampling. Arsenic species (AsIII, AsV, MMA, DMA and arsenobetaine) were analyzed by ICP-MS. Birth outcomes data was obtained from the clinical records of Hospital Hipólito Unanue. Inorganic arsenic exposure was measured as the sum of inorganic and methylated species in urine, adjusted for arsenobetaine. Inter-individual differences in arsenic toxicokinetics were measured using the principal components of the relative concentrations of inorganic, methylated, and dimethylated arsenic in urine. We considered inorganic arsenic exposure, and arsenic toxicokinetics, individually and with an interaction term as predictors of birth weight.

RESULTS: Mean birth weight was 3618.71g, while mean tAs, iAs, MMA and DMA were 41.62, 3.52, 2.49, and 35.61µg/L, respectively. The estimate of the beta coefficient for the association of arsenic with birth weight was 0.21 (95%CI -2.31;2.74) for inorganic arsenic, while for arsenic toxicokinetics it was11.88 (95%CI -22.35;46.12), and for the interaction between them was 0.33 (95%CI -0.83;1.49).

CONCLUSIONS: In this population, we did not find evidence that arsenic exposure affected birth weight. This null association could be due to study limitations as sample size or factors not measured.

KEYWORDS: Arsenic, Birth weight, Peru, Latin America

P-1215 Residential greenspace and birth outcomes in the Chemicals in Our Bodies cohort, San Francisco, California

Lara Cushing[1], Hasibe Caballero-Gomez[1], Ana Pelegrini Guimaraes[2], Nicholas Depsky[3], Stephanie Eick[4], Tracey Woodruff[5], Rachel Morello-Frosch[3]

[1]University of California Los Angeles, Los Angeles, USA, [2]San Francisco State University, San Francisco, USA, [3]University of California Berkeley, Berkeley, USA, [4]Emory University, Atlanta, USA, [5]University of California San Francisco, San Francisco, USA

BACKGROUND AND AIM: Evidence from prior studies is inconclusive regarding the association between residential proximity to greenspace and birth outcomes. Psychosocial stress increases the risk of adverse birth outcomes and may modify associations with greenspace. We evaluated the effects of residential greenspace on gestational age and fetal growth and whether they differed with experiences of psychosocial stressors.

METHODS: Chemicals in Our Bodies is a demographically diverse prospective cohort of pregnant people in San Francisco, California (N = 815). Three measures of greenspace were constructed using the birth parent's residential address and secondary data: normalized difference vegetation index (NDVI) and percent green or blue space within 500m, and Euclidean distance to the nearest park. We used linear regression to estimate the association between quartiles of greenspace measures, completed gestational week and birthweight for gestational age z-scores (BWz), adjusting for parental age, education, smoking, parity, food insecurity, race/ethnicity, nativity, traffic within 500m, and noise. We stratified by perceived stress and depression.

RESULTS: Comparing quartile 1 vs. 4, NDVI and percent green and blue space were not strongly associated with differences in mean completed weeks of gestation (β=-0.05 [95% confidence interval -0.57, 0.48] and 0.09 [-0.39, 0.57]) or mean BWz (β=-0.07 [-0.35, 0.21] and -0.11 [-0.36, 0.14]). Low NDVI (quartile 1 vs. 4), low percent green and blue space (quartile 1 vs. 4), and high distance to nearest park (quartile 4 vs. 1) were weakly associated with reductions in gestational age among parents reporting high levels of stress or depression (β=-0.73 [-2.83, 1.36], -1.31 [-3.47, 0.85], and -0.47 [-1.92, 0.99] weeks). Associations were slightly stronger when we considered 1km buffer distances, but still not statistically significant.

CONCLUSIONS: We did not find strong evidence that residential greenspace is associated with reductions in gestational age or birthweight in this study population.

KEYWORDS: nature, urban, perinatal

P-1217 Maternal Vitamin D levels modify the association between pre-pregnancy Triclosan exposure and neonatal anogenital distance

Yan Zhang[1], Yunjie Ren[1], Yu Gao[1], Ying Tian[1]
[1]*School of Public Health, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

BACKGROUND AND AIM: Triclosan (TCS) is widely used as an antibacterial agent in consumer products and is suspected of having endocrine-disrupting properties, limited epidemiological studies examined the developmental effects of TCS exposure before pregnancy. Meanwhile, Vitamin D deficiency is a global health issue and the consequences of vitamin D deficiency during pregnancy cannot be underestimated. We investigated association between maternal TCS exposure and anogenital distance (AGD) and other genital measurements in infants at birth after considering maternal vitamin D status.

METHODS: Participating 258 women were recruited from Shanghai Birth Cohort between 2012 and 2013. TCS concentration was quantified from maternal urine samples collected before pregnancy. Vitamin D was measured by maternal plasma during early pregnancy. A standardized measure of AGD was obtained in infants at birth. Anogenital index (AGI) was defined as AGD divided by weight (kg) at examination. Effect modification by Vitamin D was estimated.

RESULTS: We found no significant associations between maternal TCS and AGD in male or female infants. However, after stratified by maternal plasma vitamin D status (deficiency (<20ng/ml) versus insufficiency or sufficient (≥20 ng/mL)), per unit increase in maternal lg concentration of TCS, AGI increased on average by 0.23 in male infants (95% confidence interval (CI): 0.02, 0.45) when maternal VD concentration was lower than 20 ng/mL. No significant association was observed between maternal TCS and AGD in male infants when VD concentration is higher than 20 ng/mL. Furthermore, no significant association of maternal TCS with AGD or AGI was found in female infants.

CONCLUSIONS: These data support the hypothesis that maternal TCS exposure at environmental levels can adversely affect male reproductive development especially when maternal Vitamin D status is deficiency. Further prospective cohort studies with longitudinal measures are warranted to confirm these findings.

KEYWORDS: triclosan, Vitamin D, anogenital distance, anogenital index, birth cohort

P-1219 Proximity to restorative environment: Perception vs. Reality

Seung-Ah Choe[1], Chae-Bong Kim, Seyoung Kim, Tammy Kim
[1]*Korea University, Seongbuk-gu, Republic of Korea*

Proximity to restorative environment is known to be associated with health outcomes. for couples who are trying to conceive, neighborhood environment may affect reproductive function. This study assessed the association of duration of infertility with self-perceived and actual restorative environment, respectively. We analyzed the data of 500 participants of PRegnancy and UrbaN Environment (PRUNE) study, which is an ongoing mobile-based prospective cohort study of infertile couples. We assessed the perceived proximity to park and blue space (river, lake, stream, etc.) and actual environment of home address (NDVI within 500m and distance to blue space). Most of participants were women (64.9%) and 37 years and beyond (50.8%). Duration of infertility was ≥ 2 years in 167 (40.3%). Mean distance to blue space was shorter when the participants reported proximity of blue space, while mean NDVI was not different according to the perceived proximity. When adjusting for age and body mass index, perceived proximity to blue space was associated with lower risk of infertility for ≥ 2 years (relative risk = 0.78, 95% confidence interval: 0.62, 0.97). Associations of infertility for ≥ 2 years with perceived proximity to park, NDVI, and actual distance to blue space were close to null. In a sample of infertility couples living in urban area, we observed a positive association between perceived proximity to blue space and duration of infertility which was not replicated for actual distance. To optimize reproductive health, interventions to improve perceived environment would be necessary.

P-1227 Health risk assessment of phthalates exposure through lipid peroxidation in children with asthma

I-Jen Wang[1], Jung-Wei Chang[2], Wan-Ting Chang[3], Po-Chin Huang[3]
[1]Department of Pediatrics, Taipei Hospital, Ministry of Health and Welfare; School of Medicine, National Yang-Ming University; China Medical University, Taiwan, [2]Institute of Environmental and Occupational Health Sciences, School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan, [3]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli, Taiwan,

BACKGROUND: Global prevalence of asthma in children has dramatically increased in the past decades. Recent studies revealed that Taiwanese children are still exposed to considerable amounts of phthalates after the 2011 incident of phthalates-tainted food products. Up-to-date findings indicated that phthalates may increase malondialdehyde (MDA), a lipid peroxidation marker, in asthma patients. The role of phthalates in the increased occurrence of childhood asthma through lipid peroxidation remains unclear. We want to assess the association between phthalates exposure and MDA in children with asthma.

METHODS: We recruited 125 children with clinically-diagnosed asthma and around 98 controls from Taipei Hospital since January 2019. Participants provided urine specimen and questionnaire. Eleven phthalate metabolites and MDA were analyzed by liquid chromatography tandem-mass spectrometry (LC-MS/MS) and ELISA, respectively. Pearson correlation and related statistical method were used to analyze the relationship of urinary phthalate metabolites or MDA in asthma children.

RESULTS: BMI in asthma children was significantly higher than that in control (p=0.005) whereas no similar phenomena was observed for other demographic factors. Mother ever had cigarette smoking in pregnancy and current burn incense at home in the case group were marginally significantly higher than those in control. Meanwhile, the median levels of urinary MEHP (72.18 v.s 68.81 ng/mL), MiNP (28.75 v.s 23.51 ng/mL), and MDA (6.87 v.s. 5.86) in asthma children were higher than those in control, though failed to reach statistical significance. Age was positively correlated with urinary MDA (r=0.159, p=0.018) and MEP (r=0.13, p=0.058). Urinary MEP was highly correlated with the other phthalate metabolites which indicated a common exposure source.
CONCLUSION: Certain phthalates may increase lipid peroxidation markers in asthma children.

KEYWORDS: Phthalate metabolites; lipid peroxidation; asthma.

P-1232 Psychosocial stress exposure and lung function in childhood: effect modification by child sex

Nadya Rivera[1], Hector Lamadrid-Figueroa[2], Adriana Mercado Garcia[3], Cecilia Sara Alcala[1], Lourdes Schnaas[4], Carmen Hernandez[4], Martha Maria Téllez-Rojo[3], Robert O. Wright[1,5,6], Maria Jose Rosa[1], Marcela Tamayo-Ortiz[7]
[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Center for Population Health Research of National Institute of Public Health (INSP), Cuernavaca, Mexico, [3]Center for Nutrition and Health Research of National Institute of Public Health (INSP), Morelos, Mexico, [4]National Institute of Perinatology, Mexico City, Mexico, [5]Department of Pediatrics, Icahn School of Medicine at Mount Sinai, New York, USA, [6]Institute for Exposomic Research, Icahn School of Medicine at Mount Sinai, New York, USA, [7]Mexican Institute of Social Security (IMSS), Mexico City, Mexico

BACKGROUND: Psychosocial stress is linked with adverse childhood respiratory outcomes, but the influence of exposure timing and sex differences has not been completely elucidated.
Aim: Examine the association between prenatal and concurrent maternal stress and lung function in children and explore sex differences.

METHODS: Analyses included 283 mother-child pairs from the Programming Research in Obesity, Growth, Environment and Social Stressors cohort in Mexico City. Lung function was tested at ages 8-11 years and age, height and sex adjusted z-scores were estimated for FEV1, FVC, FEF25-75% and FEV1/FVC. Psychosocial stress during pregnancy and concurrent to the lung function was assessed using the Crisis in Family Systems Revised questionnaire. Exposure to stress during both periods was categorized as low prenatal-low current, low prenatal-high current, high prenatal-low current and high prenatal-high current. Effect modification by sex was examined with interaction terms and in stratified analyses. Models were adjusted for maternal age and education at enrollment and concurrent report of a smoker in the home.

RESULTS: We found no associations between stress and lung function in our main models. There was a significant interaction between stress and sex in relation to FEV1 and FVC z-scores. In stratified models, low prenatal-high current stress was associated with lower percent predicted FEV1 in males (β: -0.509, 95%CI [-0.94, -0.08]) but not in females (β: 0.11, 95%CI [-0.35, 0.56]) when compared to low prenatal-low current stress. Low prenatal-high current stress was associated was associated with lower percent predicted FVC in males (β: -0.56, 95%CI [-0.96, -0.16]) but not in females (β: 0.31, 95%CI [-0.16, 0.78]) when compared to low prenatal-low current stress.

CONCLUSIONS: Time varying associations between stress children's lung function are sex-dependent and greater in males. Results highlight the importance of considering the emotional environment and the susceptibility by sex.

KEYWORDS: stress, respiratory, children's health

P-1234 Incident COPD and Its Disparities Associated with Low-concentration Air Pollution in American Older Adults: A National Cohort Analysis

Tszshan Ma[1], Haisu Zhang[1], Joel Schwartz[2], Qian Di[3], Weeberb J. Réquia[4], Howard H Chang[5], Stefanie Ebelt[1], Kyle Steenland[1], Christine Ekenga[1], Noah Scovronick[1], Jeremy A. Sarnat[1], Liuhua Shi[1]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [3]Vanke School of Public Health, Tsinghua University, Beijing, China, [4]School of Public Policy and Government, Fundação Getúlio Vargas, Brasília, Brazil, [5]Department of Biostatistics and Bioinformatics, Rollins School of Public Health, Emory University, Atalnta, USA

BACKGROUND: Risk of air pollution-related Chronic Obstructive Pulmonary Disease (COPD) and corresponding disparities associated with air pollutant exposures are less clear at concentrations below current National Ambient Air Quality Standards (NAAQS).

METHODS: We constructed a national U.S. population-based cohort of those aged ≥65 from the Medicare Chronic Conditions Warehouse (2000-2016), combined with high-resolution population-weighted air pollution datasets, to investigate the association of long-term exposure to low-level air pollution and incident COPD. We defined four distinct low-exposure sub-cohorts comprised of individuals who were always exposed to low-levels of: (1) PM2.5 (annual mean ≤12-μg/m³), (2) NO2 (annual mean ≤53-ppb), (3) O3 (warm-season mean ≤50-ppb), and (4) low levels of all three air pollutants. We further tested effect modification by individual- and community-level characteristics.

RESULTS: of the 18.8 million individuals, 64.2% (12.1-million), 99.3% (18.7-million), 75.4% (14.2-million), and 54.1% (10.2-million) were always exposed to low-level annual PM2.5, NO2, O3, and all three air pollutants, respectively. Among the single-pollutant low-exposure cohorts, a 5-μg/m³ increase in PM2.5, 5-ppb increase in NO2, and 5-ppb increase in warm-season O3 were associated with an increase in COPD rate ranging between 9-12%, 1-2%, and 11-12%. Associations with each individual pollutant were also significant in the cohort exposed to low-levels of all three pollutants. There was evidence of linearity in concentration-response relationships for NO2 and O3 at levels below the current NAAQS. for PM2.5, there was a sharp increase in risks at levels above 10-μg/m³. Further, individuals in communities with lower household incomes, lower educational attainment, and lower numbers of active doctors experienced higher risk.

CONCLUSIONS: Our study suggests exposures to low-level PM2.5, NO2, and warm-season O3 were associated with incident COPD. Subgroup differences suggest individual and contextual factors contributed to COPD disparities under effects of air pollutant exposures.

KEYWORDS: Chronic obstructive pulmonary disease (COPD), air pollution, low concentration, disparities

P-1241 Associations between exposure to ambient fine particulate matter (PM2.5) and prevalence of chronic respiratory disease in Senegalese adults: Results from the demographic health survey (DHS) 2011

Bailey Glenn[1], Youssef Oulhote[1], Lisa Chasan-Taber[1], Leon M. Espira[2], Christopher S. Crowe[3], Peter S. Larson[1,3,4]
[1]Department of Biostatistics and Epidemiology, School of Public Health and Health Sciences, University of Massachusetts, Amherst, USA, [2]Center for Global Health Equity, University of Michigan, Ann Arbor, USA, [3]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, USA, [4]Social Environment and Health Program, Survey Research Center, Institute for Social Research, University of Michigan, Ann Arbor, USA

BACKGROUND AND AIM: The prevalence of chronic respiratory conditions such as asthma and chronic bronchitis has been increasing in Africa over the past decade. Recent studies show that exposure to air pollution is associated with increased risk of chronic respiratory diseases. However, very few studies have been conducted in sub-Saharan Africa using estimated measurements of particulate matter (<2.5 um; PM2.5). The aim of our study is to investigate the association between PM2.5 exposure and prevalence of asthma/chronic bronchitis in Senegal.

METHODS: This study used data from the Demographic and Health Survey (DHS 2011 collected from October 2010 to April 2011 throughout Senegal. Using their geographic location of survey clusters, we linked data for 19,843 Senegalese adults to remotely sensed and gridded annual concentrations of PM2.5. We estimated covariate-adjusted associations of PM2.5 with prevalence of self-reported asthma/chronic bronchitis using logistic regressions while accounting for survey weights and clustering. We also evaluated potential effect modification by gender.

RESULTS: The prevalence of asthma/chronic bronchitis was 2.99%.The adjusted association between PM2.5 and asthma/chronic bronchitis prevalence was 1.03 (95%CI: 0.99 – 1.06). The association between PM2.5 and asthma/chronic bronchitis significantly differed by gender (p=0.008) with stronger associations in males (prevalence odds ratio [pOR] = 1.09; 95%CI: 1.03-1.15), compared to females (pOR = 1.01; 95%CI: 0.97 – 1.05).

CONCLUSIONS: Our results suggest that increasing levels of ambient exposure to PM2.5 puts individuals at a higher risk for chronic respiratory diseases, especially men even when taking possible indoor exposures to air pollutants into account. These findings have significant policy implications and should be built upon in future research using more refined measures of PM and prospective designs.

P-1243 Effects of smoking cessation on respiratory health and related chronic diseases

Xu Xiaocheng[1], Zhanlu Lv[2], Tiansen Zou[1], Han Zhang[1], Lingchuan Guo[2], Bin Luo[3], Jinliang Zhang[1]

[1]State Key Laboratory of Environmental Criteria and Risk Assessment, Chinese Research Academy of Environmental Sciences, Beijing, China, [2]Center for the Risk Assessment and Research, Chinese Research Academy of Environmental Sciences, Beijing, China, [3]Institute of Occupational Health and Environmental Health, School of Public Health, Lanzhou University, Lanzhou, China

OBJECTIVE: This study aims to understand the effects of smoking cessation on respiratory symptoms and chronic diseases.

METHODS: From 2015 to 2018, 1583 male residents aged 18-70 from 7 counties of Huaihe River Basin were selected as participants. Logistic regression model was used to analyze the effects of smoking or smoking cessation on respiratory symptoms and chronic diseases.

RESULTS: The smoking rate was 49.3%, and the smoking cessation rate was 26.3%. The prevalence rates of respiratory symptoms and chronic diseases was various 3.3% to 20.0%. Compared with current smokers, never smokers had a lower risk of cough, chronic cough, expectoration, chronic expectoration, wheezing, shortness of breath, and bronchial asthma/chronic bronchitis (OR=0.25~0.62), and smokers who quit smoking had a lower risk of cough (OR=0.63), but a higher risk of shortness of breath, hypertension, coronary heart disease/stroke, and diabetes than current smokers (OR= 1.44~2.40). Smokers who quit smoking due to illness had a higher risk of wheezing, shortness of breath, bronchial asthma/chronic bronchitis, coronary heart disease/stroke, and chronic gastritis/gastrointestinal ulcer (OR=1.85~2.62), while smokers who quit smoking for other reasons had lower risks of cough (OR=0.52), chronic cough (OR=0.20) and expectoration (OR=0.53), but higher risks of hypertension (OR=1.54) and coronary heart disease/stroke (OR=2.20) than current smokers. All the above were statistically significant (P<0.05).

CONCLUSIONS: Smoking cessation without illness could reduce the risk of respiratory symptoms and chronic diseases in rural male of Huaihe River Basin. Therefore, effective strategies are needed to encourage current smokers to quit.

KEYWORDS: Huaihe River Basin; smoking cessation , rural male; respiratory symptoms; chronic diseases

P-1244 Environmental impact of microbes on Awba dam: it's effect on ecotourism

Taiwo Alawode, Funmilola Ajani, Victoria Adetunji
[1]*University of Ibadan, Ibadan, Nigeria*

BACKGROUND AND AIM: Recreational use of water is often given inadequate consideration and care. This is of particular concern as the recreational use of water is becoming popular in Nigeria. Many of these are increasingly contaminated by domestic sewage and industrial effluents. This study is therefore relevant in assessing the environmental impact of microbes on ecotourism in Awba dam.

METHODS: A total of nine water (n=9) and soil (n= 9) samples were collected at entry, middle and the end of the Awba dam for heavy metal analysis and microbial assay. Total aerobic plate count, Isolation and characterization of strains was
done using standard methods. The presumptive E. coli isolates were subjected to agglutination tests with specific E. coli O157:H7 . for the antibiotic sensitivity test, the Bauer-Kirby disc diffusion
method was used to test the sensitivity of the isolates. Statistical analysis of ANOVA was used and Duncan multiple range test was used to separate the means.

RESULTS: All the values obtained for the total aerobic count and total coliform count for soil and water were higher than EPA recommended value for recreational waters. for the antibiotic Sensitivity Profile, isolates from Awba dam showed the highest sensitivity (16.17mm) to ciprofloxacin while lowest was with Augmentine (8.25mm). Generally, E.coliO157:H7
isolates were highly sensitive to Oflatoxin and Ciproflaxin(93.3%) while the isolate was completely resistant to Ampicilin and Cefuroxime.

CONCLUSIONS: The presence of E.coliO157:H7 in the dam
can make the dam unfit for recreational activities and also for the community household chores, if not well treated. The University management should device means of controlling
waste water that enters into the dam by providing alternate channels of discharge to reduce the growth and spread of the microbes in the dam.

P-1251 Nitrate Ingestion from Drinking Water and Ovarian Cancer Risk in the Agricultural Health Study

Samantha Ammons[1], Jessica Madrigal[1], Cherrel K. Manley[2], Johnathan N. Hofmann[1], Dale Sandler[3], Laura E. Beane Freeman[1], Rena R. Jones[1], Mary H. Ward[1]

[1]National Cancer Institute, National Institutes of Health, Bethesda, USA, [2]Department of Epidemiology, University of North Carolina Chapel Hill Gillings School of Public Health, Chapel Hill, USA, [3]Epidemiology Branch, Chronic Disease Epidemiology Group, National Institute of Environmental Health Sciences, National Institutes of Health, Durham, USA

BACKGROUND AND AIM: N-nitroso compounds (NOCs) formed endogenously after nitrate/nitrite ingestion cause ovarian cancer in animals. Few epidemiologic studies have evaluated the association of drinking water nitrate with ovarian cancer risk, and the only previous investigation observed increased risks with higher intake.

METHODS: We evaluated nitrate exposure from drinking water and ovarian cancer risk in the Agricultural Health Study, a cohort of pesticide applicators and their spouses in Iowa and North Carolina. for the enrollment water source (1993-1997; N=29,408), we computed average nitrate concentrations for women on public water supplies (20% of participants) from historical monitoring data and estimated nitrate concentrations in private wells (76%) using random forest models; 4% used other water sources and were excluded. We used Cox regression models adjusted for age, body mass index, smoking status, and menopausal status to estimate hazard ratios (HR) and 95% confidence intervals (CI) for nitrate quartiles and the 90th percentile. Among those with dietary data (collected at first follow-up; N=13,465), we calculated HRs for < and ≥ median nitrate concentration (1.47 mg/L), stratified by median dietary intakes of vitamin C (145.1 mg/day), as higher intake decreases endogenous NOC formation.

RESULTS: We identified 122 ovarian cancer cases through 2018 (Iowa) and 2014 (North Carolina). Risk was elevated (HR=1.67, CI:0.82–3.37, P-trend=0.19) for women in the 90th percentile (≥6.81 mg/L NO3-N) versus the lowest quartile (≤0.75 mg/L). The association with higher average nitrate exposure (> median) was stronger among women with low vitamin C intake (HR<median=2.20, CI:0.77-6.27) versus those with high vitamin C intake (HR>median=1.14, CI:0.58-2.25), although the interaction was not significant (P-interaction=0.28).

CONCLUSIONS: Although we cannot rule out the possibility our findings are due to chance, they suggest that higher average nitrate levels in drinking water may increase ovarian cancer risk and that vitamin C intake may modify this relationship.

KEYWORDS: nitrate, ovarian cancer

P-1258 Environmental influences and prediction of *Escherichia coli* concentration in freshwater recreational beaches in Southern Ontario

Johanna Sanchez[1], Jordan Tustin[1], Cole Heasley[1], Mahesh Patel[2], Jeremy Kelly[3], Anthony Habjan[3], Ryan Waterhouse[3], Ian Young[1]

[1]Ryerson University, Toronto, Canada, [2]Toronto Public Health, Toronto, Canada, [3]Niagara Region Public Health, Niagara Region, Canada

BACKGROUND AND AIM: The concentration of *Escherichia coli* is used in Canada as an indicator of fecal pollution in freshwater recreational beaches, and is associated with recreational water illness among beachgoers. This study examines the environmental predictors of *E. coli* in Toronto and Niagara Region beaches to inform beach monitoring programs and reduce beachgoer illness risks.

METHODS: Our first objective used advanced analytical methods to examine region-specific environmental predictors of *E. coli* at 18 beaches in Toronto and Niagara Region. Mixed-effects models investigated regional differences, while the application of path analysis identified intervariable relationships and pathways associated with *E. coli* in Niagara Region. Our second objective involves the development of region-specific predictive models using a novel Bayesian Network approach to provide real-time assessments of beach water E. coli concentrations in our study regions.

RESULTS: *E. coli* observations were collected from 2007-2019 for Toronto and 2011-2019 for Niagara Region. In the mixed-effects analysis, substantial clustering of *E. coli* values at the beach level was observed in Toronto, while minimal clustering was seen in Niagara, suggesting an important beach-specific effect in Toronto beaches. Air temperature and turbidity were positively associated with *E. coli* in all models in both regions. In the path analysis, we found that water turbidity was an important mediator for the indirect effect of environmental variables overall and in beach-specific models. Results from these analyses informed the development of region-specific Bayesian Network predictive models, which are currently being tested and finalized.

CONCLUSIONS: Poor beach water quality could result in an increased risk of recreational water illness among the beachgoers. The development of accurate predictive models will guide beach managers in decision-making and risk communication to reduce recreational water illness risks among beachgoers.

KEYWORDS: *E. coli*, water quality, recreational water illness

P-0007 Epigenome-wide DNA methylation assists early intervention of Coronary Heart Disease with machine learning models

Yike Shen[1], Feng Gao[1], Arce Domingo-Relloso[1,2,3], Allison Kupsco[1], Marianthi-Anna Kioumourtzoglou[1], Karin Haack[4], Maria Tellez-Plaza[2], Jason G. Umans[5,6], Amanda M. Fretts[7], Ying Zhang[8], Shelley A. Cole[4], Haotian Wu[1], Andrea A. Baccarelli[1], Ana Navas-Acien[1]

[1]Department of Environmental Health Sciences, Columbia University, New York, USA, [2]Department of Chronic Diseases Epidemiology, Carlos III Health Institute, Madrid, Spain, [3]Department of Statistics and Operations Research, University of Valencia, Valencia, Spain, [4]Population Health Program, Texas Biomedical Research Institute, San Antonio, USA, [5]Department of Biostatistics, Columbia University, New York, USA, [6]Georgetown-Howard Universities Center for Clinical and Translational Science, Washington DC, USA, [7]Department of Epidemiology, University of Washington, Seattle, USA, [8]Department of Biostatistics and Epidemiology, The University of Oklahoma Health Sciences Center, Oklahoma City, USA

BACKGROUND AND AIM: Studies have shown American Indian communities have a disproportionally high rate of coronary heart disease (CHD) compared with other ethnic groups. Microarrays for epigenome-wide DNA methylation data have enabled researchers to model a large number of methylation sites to investigate their associations with incident CHD. However, accurate prediction of CHD from high-dimensional epigenome-wide DNA methylation data is challenging. We aim to develop a workflow to accurately predict CHD up to 30 years prior to diagnosis assist early disease intervention.

METHODS: The associations of CHD with epigenome-wide DNA methylation data were first screened using elastic-net penalized cox proportional hazard models based on a previous epigenome-wide association study to identify noteworthy CpG sites. The selected significant CpG sites were then input into our autoencoder deep learning model to learn the latent space representation (embeddings). The learned embeddings were then input to multiple machine learning models (i.e., logistic regression, support vector classifier, random forest, gradient boosted decision tree, and fully connected neural networks) to predict CHD. We also performed the same prediction on raw features.

RESULTS: Using our developed method, we achieved the state-of-the-art prediction accuracy of binary CHD outcome (best AUROC=0.872) with DNA methylation and clinical features using autoencoder combined with support vector classifier model (AE-SVC_DNAm+clinical), which is better than previous studies. Results showed that DNA methylation features alone had high prediction accuracy (best AUROC=0.867), clinical features alone had poor performance (best AUROC =0.692), and that AE-SVC_DNAm+clinical only increased the prediction results incrementally. Additionally, using the learned embedding increased the overall stability of our prediction results over raw input features.

CONCLUSIONS: Our data-driven method is highly effective in accurately predicting CHD up to 30 years in the Strong Heart Study population. We suggest using this workflow in future disease predictions from the high-dimensional DNA methylation data.

P-0022 Stratification score matching: Assessing the association of phthalates on asthma using the Human Health Exposure Analysis Resource (HHEAR) Data Repository

Stefanie Busgang[1], Matthew J. Mazzella[1], Moira Bixby[1], Parita Ratnani[1], Marissa Hauptman[2,3], Wanda Phipatanakul[2,4], Kelly Hunt[5], Susan L. Teitelbaum[1], Chris Gennings[1]

[1]Icahn School of Medicine at Mount Sinai, Department of Environmental Medicine and Public Health, New York, USA, [2]Harvard Medical School, Boston, USA, [3]Boston Children's Hospital, Division of General Pediatrics, Boston, USA, [4]Boston Children's Hospital, Division of Allergy and Immunology, Boston, USA, [5]Medical University of South Carolina, Charleston, USA

BACKGROUND AND AIM: The role of certain environmental exposures may be related to the onset, severity, or progression of disease, or any combination. The assessment of exposures in relation to severity may suggest unanticipated inverse associations, perhaps due to complex confounding issues. Such was the case when assessing phthalates on asthma control among children ages 4-14, all diagnosed with asthma. To better disentangle the potential role of phthalates on asthma, we sought to use stratification score (SS) methods to find comparable controls.

METHODS: Publicly available data from the HHEAR Data Repository were used to identify studies with 9 specified phthalates measured in children ages 4-14 between 2014-2018. Multivariate control charts (MCCs) were used to determine if phthalates measured in common quality control samples were comparable across studies. SSs were calculated as the probability of having asthma, conditioned on age, sex, race, ethnicity, and body mass index percentile. Controls were matched to cases using 1:1 SS matching and differences in log2 transformed specific-gravity corrected phthalate concentrations within pairs were assessed using paired t-tests. We repeated our matching algorithm 50 times and reported the distribution of effect estimates.

RESULTS: MCCs indicated phthalate measures from our studies of interest fell within acceptable bounds of variability and thus were combinable. On average, 101 of 139 eligible cases were matched across repetitions of matching. Compared to controls, cases had significantly higher concentrations for 7 phthalates, borderline significantly higher concentration for 1 phthalate and a significantly lower concentration for 1 phthalate. Consistent with the original study findings, differences between pairs tended to be higher or no different among well controlled asthmatics pairs compared to differences among poorly controlled asthmatics pairs.

CONCLUSIONS: Most phthalates were higher among asthmatic compared to non-asthmatic children. This study warrants further investigation into phthalate exposure sources used to reduce asthma symptoms.

KEYWORDS: phthalates, asthma, matching

P-0023 Exploring exposure-outcome relationships inside the VA Normative Aging Study using graph learning

Feng Gao[1], Marianthi-Anna Kioumourtzoglou[1], Pantel Vokonas[2,3], Avron Spiro III[2,4], Andrea Baccarelli[1], Yike Shen[1]
[1]Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, USA, [2]Normative Aging Study, VA Boston Healthcare System, Boston, USA, [3]Department of Medicine, Boston University School of Medicine, Boston, USA, [4]Department of Epidemiology, Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: Contemporary health sciences draw on large-scale longitudinal studies to understand the impact of lifestyle factors and environmental exposures on the risk of disease and identify potential underlying mechanisms. While there are extensive studies on associations between exposures and outcomes, the relationships among different studies within a single cohort are less studied. A database that summarizes those relationships is important towards unifying existing knowledge and inferring new information. In this study, we aim to construct an exposure-outcome network database across multiple publications in the Veterans Affairs Normative Aging Study (NAS) to explore its various applications including discovering core exposures/outcomes and hypothesis generation.

METHODS: NAS is a well-studied ongoing longitudinal study of aging in men followed since 1963. A network or a graph G can be constructed consisting of n nodes V and edges W, with each node representing an exposure E, or an outcome O. Two nodes are only connected by an edge w if their association has been studied. The core exposures/outcomes and communities of the network are retrieved with graph learning methods. Finally, we studied the dynamic changes of network structures.

RESULTS: We collected over 130 peer-reviewed exposure-outcome related publications in the last decade with title/abstract keyword “Normative Aging Study” in PubMed. We then constructed a network database describing the exposure-outcome relationship. We identified key exposures of interest, such as short- and long-term air pollution and its components, and key outcome nodes such as DNA methylation and lung function through network analysis. We also demonstrated the possibility of using the constructed network towards hypothesis generation.

CONCLUSIONS: We constructed a graph/network database to describe the relationship between exposures and outcomes across multiple studies inside the NAS cohort. Utilizing the graph learning methods, we demonstrated various applications including identifying key exposure/outcomes as well as hypothesis generation.

P-0026 The PFAS-Tox Database: A systematic evidence map of health studies on per- and polyfluoroalkyl substances

Julia Varshavsky[1], Anna Reade[2], Carol Kwiatkowski[3,4], Francheska M. Merced-Nieves[5], Haleigh Cavalier[6], Kim Schultz[7], Taylor Wolffe[8], Katherine E. Pelch

[1]Northeastern University, Boston, USA, [2]Natural Resources Defense Council, San Francisco, USA, [3]Green Science Policy Institute, Berkeley, USA, [4]North Carolina State University, Raleigh, Raleigh, [5]Icahn School of Medicine at Mount Sinai, New York, USA, [6]New York University School of Medicine, New York, USA, [7]Independent Consultant, [8]Lancaster University, Lancaster, UK, [9]University of North Texas Health Science Center, Fort Worth, USA

BACKGROUND AND AIM: PFAS (per-and polyfluoroalkyl substances) is a large class of synthetic chemicals used widely in consumer products and industrial processes. Health and toxicology literature on PFAS has increased dramatically in the last decade, and many key stakeholders could benefit from efficient access to the data. We aimed to create a systematic evidence map (SEM) of health and toxicological research on 29 PFAS that would be easily accessible for diverse audiences.

METHODS: We published a protocol a priori and conducted a PubMed database search of peer-reviewed literature through January 25, 2021. Studies were screened for inclusion and exclusion according to the Populations, Exposures, Comparators, and Outcomes (PECO) statement. Inclusion criteria were intentionally broad and included any human, animal, and/or in vitro study that investigated exposure to one of the 29 PFAS of interest and a human health or toxicological effect. Study details were extracted, with meta-data made freely available in the online, interactive SEM at https://pfastoxdatabase.org.

RESULTS: Over 15,000 studies were retrieved from the literature search. After manual screening, 1,067 studies (505 human, 385 animal, and 220 in vitro) were identified and included as investigating health or toxicological effects of one or more PFAS of interest. Most human studies were cross-sectional (48%) or cohort (39%), with body weight/size/growth (n=195), reproductive (n=158), endocrine (n=149), and metabolic/digestive systems (n=143) examined as the most common health outcome categories.

CONCLUSIONS: The PFAS-Tox Database is a useful tool for searching, filtering, and identifying peer-reviewed research on the health and toxicological effects of PFAS. The SEM provides examples of data gaps and clusters revealed by the database and will support scientists, regulatory agencies, and individuals with tools to advance future research efforts, systematic reviews, regulatory risk assessments, and cross-disciplinary coordination on the health effects of PFAS exposure.

KEYWORDS: PFAS, epidemiology, toxicology, systematic review, risk assessment

P-0040 Longitudinal Associations of Air Pollution with Body Size and Composition in Midlife Women: The Study of Women's Health Across the Nation

Xin Wang[1], Carrie Karvonen-Gutierrez[1], Ellen Gold[2], Carol Derby[3], Gail Greendale[4], Xiangmei Wu[5], Joel Schwartz[6], Sung Kyun Park[1]

[1]University of Michigan, Ann Arbor, USA, [2]University of California, Davis, Davis, USA, [3]Albert Einstein College of Medicine, Bronx, USA, [4]University of California, Los Angeles, Los Angeles, USA, [5]California Environmental Protection Agency, Oakland, USA, [6]Harvard University, Boston, USA

BACKGROUND AND AIM: Exposure to air pollution has been suggested to be associated with obesity recently; however, epidemiologic evidence is still limited and has heavily focused on body mass index (BMI). We examined associations of fine particulate matters (PM2.5), nitrogen dioxide (NO2), and ozone (O3) with longitudinal measures of body size and composition including weight, BMI, waist circumference, fat mass, lean mass, and proportion fat mass in midlife women.

METHODS: The study population included 1,654 White, Black, Chinese and Japanese women from the Study of Women's Health Across the Nation, with the median age of 49.6 years and a total of 10,370 repeated observations followed from 2000 to 2008. Annual air pollution exposures were assigned by the residential addresses linked with hybrid estimates of air pollutant concentrations at 1-km2 resolution. Body size was measured objectively and body composition was measured using the dual-energy X-ray absorptiometry (DXA) at approximately annual visits. Linear mixed effects models were used to examine the associations between air pollution and body size and composition measures.

RESULTS: After adjusting for potential confounders, an interquartile range (IQR) increase in PM2.5 concentrations (4.5 μg/m3) was associated with 4.53% (95%CI:3.85%,5.22%) higher fat mass, 1.10% (95%CI:0.95%,1.25%) higher proportion fat mass, and 0.39% (95%CI:-0.77%,-0.01%) lower lean mass. An IQR increase in NO2 (9.5 ppb) was associated with 3.39% (95%CI:2.68%,4.10%) higher fat mass, 0.94% (95%CI:0.78%,1.10%) higher proportion fat mass, and 0.86% (95% CI:-1.26%,-0.45%) lower lean mass. Similar associations were also observed for O3. Physical activity was found to modify the associations of PM2.5 and NO2 with body size and composition: weaker associations were observed in participants who engaged in more physical activity.

CONCLUSIONS: PM2.5, NO2, and O3, are adversely associated with body composition, including higher fat mass, higher proportional fat mass, and lower lean mass, highlighting its potential role in contributing to obesity.

P-0043 Associations between traffic-related air pollution and cognitive function in Australian urban settings: the moderating role of diabetes status

Rachel Tham[1,2], Amanda J Wheeler[2,3], Alison Carver[2], David Dunstan[4,5], David Donaire-Gonzalez[2], Kaarin J Anstey[6,7], Jonathan E Shaw[5,8,9], Dianna E Magliano[5], Erika Martino[1], Anthony Barnett[2], Ester Cerin[2,5,10,11]

[1]University of Melbourne, Melbourne, Australia, [2]Australian Catholic University, Melbourne, Australia, [3]University of Tasmania, Hobart, Australia, [4]Deakin University, Melbourne, Australia, [5]Baker Heart and Diabetes Institute, Melbourne, Australia, [6]University of New South Wales, Sydney, Australia, [7]Neuroscience Research Australia, Sydney, Australia, [8]Monash University, Melbourne, Australia, [9]La Trobe University, Melbourne, Australia, [10]University of Hong Kong, Sandy Bay, Hong Kong, [11]The Arctic University of Norway, Tromso, Norway

BACKGROUND: Traffic-related air pollution (TRAP) is associated with poorer cognitive function and higher incidence of diabetes in older adults, but little is known about whether diabetes moderates the impact of TRAP on older adult cognitive function.

METHODS: We analysed cross-sectional data from 4141 adults who participated in the Australian Diabetes, Obesity and Lifestyle (AusDiab) study in 2011-2012. TRAP exposure was estimated using major and minor road density (100m/km²) within residential buffers: 200, 300, 500, 1000 and 1600 metres. Cognitive function was assessed with validated psychometric scales: California Verbal Learning Test (memory) and Symbol–Digit Modalities Test (processing speed). Diabetes status was measured using an oral glucose tolerance test. Missing data were imputed. Associations of TRAP with cognitive function and the moderating effects of diabetes on these associations were estimated using generalised additive mixed models adjusted for age, sex, English-speaking background, socioeconomic status, education, living arrangement, employment status, neighbourhood self-selection indices, urban density, neighbourhood greenspace and land-use mix. Results are reported as regression coefficients, β, per single unit increase in TRAP measures.

RESULTS: We observed positive associations between 200, 1000 and 1600m TRAP and memory (β=0.003, p=0.008; β=0.003, p=0.018; β=0.004, p=0.015 respectively) but not processing speed. Minor road density was not associated with cognitive function, while major road density showed positive associations with memory and processing speed among 1000 and 1600m buffers (β=0.010, p=0.038; β=0.014, p=0.026). Within a 300m buffer the relationship between TRAP and memory tended to be positive in people without diabetes (β=0.005; p=0.062), but negative in people with diabetes (β=-0.013; p=0.026); and negatively associated with processing speed in people with diabetes only (β=-0.047; p=0.059).

CONCLUSIONS: In Australian urban areas, higher TRAP exposure may be positively associated with cognitive function in urban dwelling people, but this benefit may not extend to people living with diabetes in urban settings.

P-0045 Short-term exposure to PM2.5 and daily all-cause dementia and Alzheimer´s disease mortality in Connecticut: a time-stratified case-crossover study

Chengyi Lin[1,2], Emily Goddard[2,3], Kevin Chan[4], Yiqun Ma[1,2], Qian Di[5], Carolyn A. Fredericks[6], Kai Chen[1,2]
[1]Department of Environmental Health Sciences, Yale School of Public Health, New Haven, USA, [2]Yale Center on Climate Change and Health, Yale School of Public Health, New Haven, USA, [3]Department of Social and Behavioral Sciences, Yale School of Public Health, New Haven, USA, [4]Yale College, New Haven, USA, [5]Vanke School of Public Health, Tsinghua University, Beijing, China, [6]Department of Neurology, Yale University, New Haven, USA

BACKGROUND: While emerging studies have examined long-term exposure to fine particulate matter ($PM_{2.5}$) and its association with various measures of morbidity of dementia and Alzheimer´s disease (AD), evidence on short-term $PM_{2.5}$ exposure and mortality caused by dementia or AD is sparse.

METHODS: We applied a time-stratified case-crossover design using conditional logistic regression to assess the association between ambient $PM_{2.5}$ concentrations and daily all-cause dementia and AD mortality in Connecticut between 2005 to 2016, while adjusting for mean air and dewpoint temperature. Our analysis included cases whose principal cause of death was all-cause dementia or AD. The daily 24-hour average $PM_{2.5}$ concentration was obtained from a well-validated model and the individual-level exposure was assigned based on the modeled $PM_{2.5}$ level in a 1 × 1 km^2 grid which contains the residential address. We also explored potential effect modification by age and sex groups.

RESULTS: A total of 28,736 all-cause dementia deaths occurred during our study period, among which 9,826 were specially coded as AD deaths. A 10 $\mu g/m^3$ increase in the 2-day moving average of ambient $PM_{2.5}$ was significantly associated with all-cause dementia (Odds Ratio [OR] =1.06, 95% confidence interval [CI]: 1.03, 1.09) and AD (OR=1.07, 95% CI: 1.02, 1.12). We did not find effect modification by age (<80 years vs. ≥ 80 years) in all-cause dementia or AD. The estimated effect of $PM_{2.5}$ was higher among the female subgroup compared to the male subgroup (P-value = 0.03) for mortality caused by all-cause dementia but not for AD.

CONCLUSIONS: Our study suggests a significant association between short-term exposure to $PM_{2.5}$ and an increase in mortality risks of all-cause dementia and AD. Further research is warranted on mechanisms that can explain the relationship between short-term $PM_{2.5}$ exposure and mortality risks of dementia.

KEYWORDS: $PM_{2.5}$; dementia; Alzheimer´s disease; mortality; short-term; case-crossover

P-0047 Para-dichlorobenzene exposure and serum α-Klotho levels among US participants in their middle and late adulthood

Yudan Wei[1], Jianmin Zhu[2]
[1]Mercer University School of Medicine, Macon, USA, [2]Fort Valley State University, Fort Valley, USA

BACKGROUND AND AIM: Para-dichlorobenzene (p-DCB) is a volatile compound commonly used as pest repellent and air deodorant in the home and public buildings. There has been an increasing concern about its metabolic and endocrine effects. The aim of the present study was to explore the relation between p-DCB exposure and serum levels of soluble α-Klotho, an anti-aging hormone, in US adults.

METHODS: A nationally representative subsample of 1485 adults 40-79 ages in the 2013-2016 National Health and Nutrition Examination Survey was analyzed for the association between urinary concentrations of 2,5-dichlorophenol (2,5-DCP), the major metabolite of p-DCB, and serum α-Klotho levels using multiple general linear models, adjusting for potential confounders. Age- and sex-specific analyses were further conducted.

RESULTS: The weighted geometric mean of urinary 2,5-DCP was 2.43 μg/L and the weighted mean of serum α-Klotho was 831.97 pg/mL in the study participants during 2013-2016. After adjusting for potential confounders, urinary 2,5-DCP was significantly associated with decreased serum levels of α-Klotho (regression coefficient β=-9.88; p=0.0133) in the total study population. When age- and sex-specific analyses being conducted, a significantly inverse association was found in older adults aged 60-79 years (β=-20.52; p<0.0001) and in males (β=-13.81; p=0.0097), but not in the middle ages (40-59 years) and in females. The strongest association was observed in older (60-79 years) male participants, with a 25.25 pg/mL reduction of α-Klotho levels per 1-unit increase of 2,5-DCP concentrations (p=0.0007). No statistically significant associations with α-Klotho levels were observed for urinary 2,4-dichlorophenol, another dichlorophenol pesticide.

CONCLUSIONS: Our study demonstrates a relation between p-DCB exposure, measured as 2,5-DCP, and decreased α-Klotho levels in older men. Additional studies would further explore these interactions and elucidate the pathogenesis of the potential effects of p-DCB exposure on aging.

P-0048 Associations between Air Pollution and Gait Speed in Older Adults

Boeun Kim, Anjum Hajat, Joel D. Kaufman, Cindy S. Leary, Erin Semmens, Annette Fitzpatrick
[1]*Johns Hopkins University, Baltimore, USA*

BACKGROUND AND AIM: Air pollution is widely recognized as a threat to public health, particularly among older adults. Long-term exposure to air pollution may impact gait speed trajectories over time, as gait speed is a marker of physical and cognitive decline. This study examined the relationship between long-term air pollution exposure and gait speed decline among older adults and evaluated whether cardiovascular disease (CVD) status modified the effect.

METHODS: We analyzed data from 3,022 older adults residing in the US followed from 2000 to 2008. Long-term exposure to fine particulate matter (PM2.5) and nitrogen dioxide (NO2) prior to study enrollment was estimated using state-of-the-art prediction models. Gait speed at usual and rapid pace was assessed annually using a 15-foot timed walk test. Mixed-effects models were fitted adjusting for sociodemographic variables overall and in those with and without CVD.

RESULTS: Greater long-term PM2.5 and NO2 exposure was related to faster gait speed decline. One interquartile range (IQR) higher 5-year PM2.5 exposure (2 μg/m3) prior to the study enrollment was related to 0.048 m/s decline in usual gait speed (95% CI: -0.084, -0.024) and an IQR higher 5-year NO2 exposure (6.5 ppb) was associated with 0.078 m/s decline in usual gait (95% CI: -0.120, -0.042) and 0.042 m/s decline in rapid gait (95% CI: -0.078, -0.006) over the 6-year period. Longitudinal association between air pollution (5- and 10-year average PM2.5 and NO2) and rapid gait speed decline was significant only in individuals with CVD.

CONCLUSIONS: Long-term exposure to air pollution appears to be associated with faster gait speed decline among older adults in the US. Policies to reduce the emission of air pollutants and interventions to avoid air pollution exposure could contribute to the reduction in the burden of preventable institutionalization and hospitalization.

P-0050 Incident Dementia and Long-Term Exposure to Constituents of U.S. Fine Particle Air Pollution: A National Cohort Study

Liuhua Shi[1], Qiao Zhu[1], Yifan Wang[1], Hua Hao[1], Haisu Zhang[1], Joel Schwartz[2], Heresh Amini[3], Aaron van Donkelaar[4], Randall Martin[4], Kyle Steenland[1], Jeremy Sarnat[1], Tszshan Ma[1], Haomin Li[1], Howard Chang[1], Jeremiah Liu[2], Rodney Weber[5], Pengfei Liu[5]

[1]Emory University, Atlanta, USA, [2]Harvard T.H. Chan School of Public Health, Boston, USA, [3]University of Copenhagen, Copenhagen, Denmark, [4]Washington University at St. Louis, St. Louis, USA, [5]Georgia Institute of Technology, Atlanta, USA

BACKGROUND: Growing evidence suggests that PM2.5 likely increases the risks of neurological disorders, yet little is known about the relative contributions of different constituents. Understanding constituent-specific effects are critical to targeting emission reductions of specific sources with the greatest health protection.
METHOD: We conducted a nationwide population-based cohort study (2000-2017), by integrating the Medicare Chronic Conditions Warehouse database and two sets of high-resolution, multiple-species, air pollution datasets to investigate the impact of long-term exposure to PM2.5 constituents on incident dementia and Alzheimer's disease (AD). and home health-care claims. Hazard ratios for dementia and AD were estimated using single- and multi-constituent Cox proportional hazards models, and penalized splines were used to evaluate potential nonlinear concentration-response relationships.

RESULTS: of the 18.5 million dementia and 19.2 million AD individuals within these cohorts, 31.5% and 14.6% developed dementia and AD events, respectively. From the single-pollutant models, an interquartile range (IQR) increase in PM2.5 mass was associated with an increase in dementia incidence ranging between 6-7% using two exposure datasets. for different PM2.5 constituents, associations remained significant in black carbon (BC), organic matter (OM), sulfate (SO42−), and ammonium (NH4+). Incident dementia was observed to have the strongest association with increases in exposure to SO42− and BC (10-11% increase and 4-6% per IQR increase, respectively). Effect estimates for AD were even larger. for both endpoints, all constituents had largely linear concentration-response relationships in the low exposure range, but most tailed off at high exposure concentrations, particularly for AD.

CONCLUSIONS: Our study suggests that long-term exposure to PM2.5 is significantly associated with increased incident dementia and AD, and that the different PM2.5 constituents may elicit differential neurotoxicity. Reduction of PM2.5 emissions, especially for the main sources of BC and SO42−, may reduce the burden of dementia or AD in the aging US population.

P-0058 Long-term Ozone Exposure and Incident Frailty in Older Adults: Findings from a Prospective Cohort Study in Chinese Elderly

Yuebin Lv[1], Qingyang Zhu[2], Lihong Ye[1,3], Meijie Jiang[4], Jinhui Zhou[1], Yuan Wei[1,5], Chenfeng Li[1,6], Chen Chen[1], Yidan Qiu[1,7], Jun Wang[1], Juan Zhang[3], John S.Ji[8], Xu Gao[4], Yang Liu[2], Xiaoming Shi[1,9]

[1]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [3]School of Population Medicine and Public Health, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [4]Department of Occupational and Environmental Health Sciences, School of Public Health, Peking University, Beijing, China, [5]Department of Hygienic Inspection, School of Public Health, Jilin University, Jilin, China, [6]School of Public Health, Anhui Medical University, Anhui, China, [7]Department of Public Health, Zhejiang University, Zhejiang, China, [8]Vanke School of Public Health, Tsinghua University, Beijing, China, [9]Center for Global Health, School of Public Health, Nanjing Medical University, Jiangsu, China

BACKGROUND AND AIM: Studies have linked elevations in short-term ozone exposure to acute adverse health outcomes. In this study, we aimed to explore whether long-term ozone exposure was linked to the development of frailty in older adults.

METHODS: A total of 15,734 participants aged ≥65-year-old and were free of frailty were included in Chinese Longitudinal Healthy Longevity Survey (CLHLS) from 2005 to 2018. Frailty was defined by a frailty index (FI) ≥0.25, which was measured by 39 health deficits. Personal ozone exposures were estimated using full-composition annual ozone covering all of China at a 0.05° resolution. County-level ozone-related burden of frailty in China was calculated by warm season hazard ratio of frailty.

RESULTS: During 78,588 person-years follow-up, 3587 incident frailties were documented. In competing risk models, each 10-μg/m³ increase in baseline warm-season (May to October) and yearly ozone exposure corresponded to 6.9% and 12.1% higher risk of incident frailty, the hazard ratios were 1.069 (1.035-1.104) and 1.121 (1.063-1.182), respectively. Monotonically increasing dose-response of warm-season and yearly ozone exposure with incident frailty and FI score were observed. With the dramatic population aging and increasing ozone exposure simultaneously in China, it was estimated that the burden of warm season ozone related incident frailty among the population aged ≥65-year-old in China were 1,818,729 and 3,700,237 cases in 2010 and 2020, respectively, and there will be 4,806,037 incident frailties in 2030.

CONCLUSIONS: This nationwide prospective cohort study established that long-term ozone exposure was associated with incident frailty and contributed to an enormously significant and increased disease burden for the older adults, suggesting that controlling ozone exposure may be a priority area for air quality regulations in China in next decade that may yield substantial health benefits.

P-0059 Associations of peak season ozone with blood pressure among older adults without hypertension in a high exposure country: evidence from the Chinese Longitudinal Healthy Longevity Survey from 2005 to 2018

Jinhui Zhou[1], Qingyang Zhu[2], Lihong Ye[1,3], Yidan Qiu[1,4], Bing Wu[1,5], Chen Chen[1], Jun Wang[1], Yuan Wei[1,6], Xulin Zheng[1,5], Yuebin Lv[1], Yang Liu[2], Xiaoming Shi[1,5]

[1]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]Department of Environmental and Occupational Health, Emory University, Atlanta, USA, [3]School of population medicine and public health, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [4]Department of Public Health, Zhejiang University, Hangzhou, China, [5]Center for Global Health, School of Public Health, Nanjing Medical University, Nanjing, China, [6]School of Public Health, Jilin University, Changchun, China

BACKGROUND AND AIM: Evidence based on long-term prospective cohort studies is lacking to investigate the association between ambient ozone (O3) and blood pressure among older adults. We aim to evaluate the associations of peak season O3 with change of blood pressure in a long-term cohort study among older adults without hypertension.

METHODS: We included 5940 older adults aged ≥65 years and with repeated measurements of blood pressure from 2005 to 2018 in 23 provinces of China, estimated monthly O3 exposures at 0.05 ° ×0.05 ° resolution were matched to each participant. Peak season O3 exposure was measured as the average from April to September. Outcomes include blood pressure measurements of SBP, DBP, PP and MAP. Linear mixed models were performed to evaluate the associations between O3 exposures and blood pressure. Natural splines were applied to explore the potential non-linear concentration-response associations.

RESULTS: In this study, peak-season O3 ranges from 72.6 to 151.7 μg/m3 in China. In fully adjusted model, per 10 μg/m3 increase in peak season O3 was associated with increases of 2.46 mmHg (95% confidence interval [CI]: 1.85-3.06) in SBP, 2.46 mmHg (95%CI: 1.94-2.99) in PP and 0.74 mmHg (95%CI: 0.38-1.11) in MAP, but non-significant decrease in DBP. Female, ethnic minorities, and older adults who were not in marriage, underweight, with medium or low income levels were susceptible to O3 exposure. Non-linear curves indicated that the effect of O3 exposure on SBP, PP and MAP were monotone increasing, with faster increase in risk magnitude before WHO interim target 1 at 100 μg/m3, but slow down thereafter.

CONCLUSIONS: The study added evidence to support the World Health Organization interim targets for peak-season O3, however, lower interim targets should be set to maintain healthy blood pressure among populations in countries with high O3 concentrations.

P-0060 Association of blood mercury exposure with depressive symptoms in the Chinese oldest old

Jiahui Xiong[1,2], Yuebin Lv[1], Yuan Wei[1,3], Zuyun Liu[4], Xinwei Li[1,3], Yang Liu[1,3], Feng Zhao[1], Chen Chen[1], Heng Gu[1], Jun Wang[1], Xulin Zheng[1,5], Kai Xue[1,3], Yidan Qiu[1,4], Tong Shen[2], Xiaoming Shi[1,2]

[1]National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]Anhui Medical University, Hefei, China, [3]Jilin University, Changchun, China, [4]Zhejiang University, Hangzhou, China, [5]Nanjing Medical University, Nanjing, China

Background:Depressive symptoms have a significant impact on the quality-of-life among the oldest old. Current research on the association of blood mercury with depressive symptoms has mainly targeted the general population. However, it is unclear whether this association is present at the oldest old.

Objective:The aim of this study was to investigate the association of blood mercury exposure with depressive symptoms in the oldest old.

Methods:We used data from the Healthy Aging and Biomarker Cohort Study carried out in 2017-2018, with 1567 participants aged ≥80 years were eligible for analysis. Blood mercury levels were measured by inductively coupled plasma mass spectrometry (ICP-MS). The CES-D10 depression scale was used to assess depressive symptoms. Multivariable logistic regression models were used to examine the association between blood mercury levels and depressive symptoms. We also used restricted cubic splines (RCS) to assess the linear or nonlinear association of blood mercury with depressive symptoms.

Results:The mean age of the 1567 participants was 91.8 years, while the geometric mean concentration of blood mercury was 1.17 μg/L. Multivariable logistic regression analysis showed a statistically significant positive association of blood mercury with depressive symptoms after adjustment for covariates. The odds ratios of blood mercury for depressive symptoms in the second and third tertiles were 1.88 (1.37-2.56) and 1.51 (1.11-2.04), respectively, compared with that measured in the first tertile. The RCS model showed that there was a non-linear association between blood mercury level and depressive symptoms.

CONCLUSIONS: Among the oldest old, we found blood mercury levels are associated positively with depressive symptoms, highlighting the importance of appropriately managing their exposure to mercury.

P-0061 Accelerated aging modifies impact of ozone on QT interval and markers of inflammation in healthy humans

William Weston[1], Marie-Abele Bind[2], Robert Devlin[1], Cavin Ward-Caviness[1]
[1]Center for Public Health and Environmental Assessment, USA Environmental Protection Agency, Chapel Hill, USA, [2]Department of Statistics, Harvard University, Cambridge, USA

BACKGROUND AND AIM: Older individuals often have increased health risks from environmental exposures, but this has been rarely investigated using molecular measurements of biological age. DNA methylation can be used to measure biological age and epigenetic age acceleration (EAA) in subjects. EAA accurately predicts mortality and chronic disease risk; however, it is unknown whether EAA modifies responses to environmental exposures. Here, we investigated whether cardiovascular and inflammatory responses to ozone are modified by EAA.

METHODS: LAMARCK was a controlled exposure study where 17 healthy participants were exposed to 0.3-ppm ozone or to clean air for two hours in a randomized single-blind crossover study design. Functional cardiopulmonary measures (n=3) and inflammation biomarkers (n=5) were collected immediately before and 24-hours after exposures. Epigenetic age was estimated using the Horvath method on cells that were collected from BALFs 24 hours after exposure. All outcomes were normalized to their pre-exposure values. We used mean and quantile regression to examine if EAA (calculated as epigenetic age – chronological age) measured during clean air exposure is associated with the estimated causal risk difference (CRD; Ozone – Clean Air) of cardiopulmonary and inflammatory outcomes. Regression models were evaluated with and without outliers to determine model consistency. Results are presented as percentage change relative to the mean value measured during air exposure.

RESULTS: Mean and median regression results were concordant. for mean regression, one-year higher EAA was associated with a 0.44% (95% confidence interval = 0.13%, 0.75%) increase in the CRD for QT interval in response to ozone exposure. One-year higher EAA was also associated with a -15.3% (95% confidence interval = -23.2%, -7.41%) change in the CRD for C-reactive protein in response to ozone. No other associations were observed.

CONCLUSIONS: Accelerated aging in the lung is associated with prolonged QT interval and depressed inflammatory response during short-term ozone exposure.

P-0064 Air Pollution and Trajectories of Positive and Negative Affect in Older Women

Andrew Petkus[1], Susan Resnick[2], Xinhui Wang[1], Lauren Salminen[1], Joshua Millstein[1], Daniel Beavers[3], Mark Espeland[3], Margaret Gatz[1], Joel Kaufman[4], Stephen Rapp[3], Jiu-Chiuan Chen[1]

[1]University of Southern California, Los Angeles, USA, [2]National Institute on Aging, Baltimore, USA, [3]Wake Forest School of Medicine, Winston-Salem, USA, [4]University of Washington, Seattle, USA

BACKGROUND AND AIM: Exposure to ambient air pollution, including PM2.5 (particulate matter <2.5 μm) and NO2 (nitrogen dioxide), is associated with depressive symptoms in older adulthood. Depression is characterized by low positive affect and high negative affect. Elucidating how exposure may differentially impact the emotional dimensions underlying depressive symptoms will deepen our understanding of the link between air pollution neurotoxicity and emotional health of older adults. Here we examined associations between air pollution and longitudinal trajectories of positive and negative affect in older women.

METHODS: Women (N=2,114; baseline age=73.3±3.8 years), enrolled in the Women's Health Initiative Study of Cognitive Aging (2000-2010), completed up to nine annual assessments with the Positive and Negative Affect Schedule (PANAS). Three-year average annual mean concentrations (scaled by interquartile range [IQR]) of ambient PM2.5 (in μg/m3; IQR=3.64 μg/m3) and NO2 (in ppb; IQR=10.35 ppb) before baseline were estimated at participants' addresses via spatiotemporal models. Latent-class mixture models were constructed to identify subgroups of women with similar trajectories of positive or negative affect over time. Multinomial logistic regressions were used to examine whether exposures predicted latent-class membership, adjusting for sociodemographic, lifestyle, and clinical characteristics.

RESULTS: Two latent trajectories of positive affect (PA) were identified: (high-stable PA: 95% and decreasing PA: 5%). Higher exposure to NO2 (OR = 1.55, p=.008), but not PM2.5 (OR=1.23, p=.212), was significantly associated with increased odds of being classified as having decreasing PA relative to high-stable PA. Four latent trajectories of negative affect (NA; minimal-stable: 27%; mild-stable: 46%; moderate-stable:21%; and moderate-decreasing: 6%) were identified. Neither NO2 nor PM2.5 was predictive of latent class membership of NA trajectories.

CONCLUSIONS: Exposure to NO2 may contribute to reduction of PA in older adulthood. Future studies should examine brain structures and neural networks as well as behavioral mechanisms underlying PA changes associated with air pollution neurotoxicity in late life.

P-0066 Narrative Review of Long-Term Exposure to Traffic-Related Air Pollution on Dementia and Related Outcomes in Older Adults

BACKGROUND AND AIM: As part of an extensive systematic review on the associations of important clinical health outcomes with exposure to traffic-related air pollution (TRAP), an independent Panel appointed by the Health Effects Institute considered the emerging literature on dementia-related outcomes and Parkinson's disease, two areas of significant public health interest.

METHODS: The Panel systematically searched the PubMed and LUDOK electronic databases for observational epidemiological studies from 1980 through 2019 on long-term exposure to TRAP and dementia-related outcomes and Parkinson's disease prevalence in the general population. Study selection and data extraction were conducted according to a defined protocol, and a novel framework was used to identify which studies provided information on TRAP exposure. Conclusions regarding the level of confidence in the presence of an association were based on a narrative assessment. The Panel decided a priori not to conduct formal confidence and risk of bias assessments and meta-analyses because this is an emerging area of research.

RESULTS: The Panel reviewed 15 studies on dementia-related outcomes and six studies of Parkinson's disease. Evidence for an association of dementia-related outcomes with TRAP was mixed; studies of cognition and incident dementia generally found adverse associations while findings on cognitive decline were null. Evidence for an association of TRAP with Parkinson's disease was inconsistent with some potential for systematic bias. Limitations of the body of literature included its small size, potential for bias due to outcome misclassification, selection and attrition bias, and adjustments for confounding that did not align with plausible pathways between TRAP exposure and outcomes.

CONCLUSIONS: The Panel's confidence in the association of TRAP with dementia-related outcomes was low to moderate, while confidence in the association with Parkinson's disease was low. Future systematic reviews will benefit from the continued growth in this literature.
KEYWORKS: narrative review, traffic-related air pollution, dementia, cognitive decline

P-0067 Long-Term Air Pollution Exposure and Loss of Independence in the U.S.

KEYWORDS: Air pollution, personal help, disability

BACKGROUND AND AIM: Disabilities, especially those that result in lost independence, can result in high emotional and economic burdens to individuals and families. Although air pollution is a well-established risk factor for chronic disease, its impacts on disability are only recently being considered and current studies have not focused on lost independence. We examined associations between air pollution and receiving help for disability, in a nationally representative cohort, focusing on the highest degree of limitations.

METHODS: We used biennial self-reported data between 2006 and 2016 on receiving personal help with six activities of daily living (ADL) and five instrumental activities of daily living (IADL) or living in the nursing home due to health and memory problems from participants>50 years in the Health and Retirement Study. Using spatiotemporal models, we predicted 10-year average PM2.5, PM10-2.5, NO_2, and O_3 concentrations at participant addresses before each interview. Associations with first receipt of help due to disability were estimated with Cox models, adjusting for individual demographics, area-level characteristics, and temporal and geographic trends.

RESULTS: During 6.8±3.0 years of follow-up, 31.7% of our 20,800 participants reported newly receiving help due to disability. We observed a 4% (HR: 1.04 per 3.2 μg/m³, 95%CI: 0.99, 1.10) and 6% (HR: 1.06 per 6.73 ppb, 95%CI: 1.02, 1.11) greater rate of receiving help due to disability per inter-quartile range higher long-term PM2.5 and NO_2 concentrations, respectively. In contrast, PM10-2.5 and O_3 concentrations were not associated with increased rates of receiving help.

CONCLUSIONS: This prospective study of older U.S. adults provides evidence that air pollution is associated with an increased need for help due to disabilities, though this association varied across pollutants. Controlling air pollution might potentially divert or delay individuals from needing care in late life and prolong/enhance their ability to live independently.

P-0069 Heterogeneous impact of air pollution exposures on cognitive trajectories in Women's Health Initiative Memory Study in Younger Women

Xinhui Wang[1], Andrew Petkus[1], Lauren Salminen[1], Joshua Millstein[1], Daniel Beavers[2], Mark Espeland[2], Margaret Gatz[1], Susan Resnick[3], Joel Kaufman[4], Stephen Rapp[2], Jiu-Chiuan Chen[1]

[1]University of Southern California, Los Angeles, USA, [2]Wake Forest School of Medicine, Winston-Salem, USA, [3]National Institute on Aging, Baltimore, USA, [4]University of Washington, Seattle, USA

BACKGROUND AND AIM: Late-life exposure to ambient air pollutants is a risk factor for dementia, but little is known about the associations between midlife exposure and cognitive aging. We examined the effects on trajectories of general cognitive ability and episodic memory in older adulthood, comparing midlife and late-life exposures.

METHODS: Using regionalized universal kriging models applied to the residences of women (n=881; aged 62-71) enrolled in the Women's Health Initiative Memory Study in Younger Women (WHIMS-Y) in 2009, we estimated the annual PM2.5 (particulate matter<2.5μm) and NO2 (proxy for traffic-related pollutants) aggregated exposures to 3-year averages for midlife (aged 50-59, 12 years before WHIMS-Y inception) and late-life (at WHIMS-Y inception). General cognitive ability and episodic memory were assessed annually (2009-16) respectively by modified Telephone Interview for Cognitive Status (TICSm) and California Verbal Learning Test (CVLT). Linear mixed effect models were used to examine exposure effects adjusting for socio-demographic, lifestyle, and clinical covariates and time-varying propensity scores.

RESULTS: The average performance in TICSm and CVLT improved over time (both slope=0.15/year, p<0.001). Women with higher midlife exposures had worse baseline CVLT scores, with associations statistically significant for PM2.5 (β0,midlifePM2.5=-0.58 per IQR=3.43μg/m3, p=0.02), but not for NO2 (β0,midlifeNO2=-0.44 per IQR=9.23ppb, p=0.13). Women with higher midlife exposures had less improvement in CVLT performance over time, but the associations were non-significant. Associations between late-life exposures and CLVT trajectories and between both midlife or late-life exposures and TICSm trajectories were non-significant.

CONCLUSIONS: Among women aged 62-71 with positive trajectories suggesting considerable cognitive resilience, greater midlife PM2.5 exposure was associated with lower episodic memory with no appreciable impacts on trajectory afterwards. However, recent late-life exposures were not associated with cognitive trajectories. Results suggested the adverse midlife exposure effects may not contribute to the neuropathological processes underlying cognitive decline in late-life.

KEYWORDS: Air pollution, midlife exposure, cognitive trajectory

P-0071 Residential green space, air pollution, public facility and mortality among older adults in Beijing: a longitudinal cohort study

Hui Miao[1], Yucheng Wang[1], John Ji[1]
[1]*Tsinghua University, Beijing, China*

BACKGROUND AND AIM: Urban environment is influential towards healthy aging in China. We aimed to describe trends of greenness and air pollution in Beijing, and explore their association with mortality among the elderly.

METHODS: This study included 800 participants (mean age=88.7, SD=11.1) in China Longitudinal Healthy Longevity Survey (CLHLS) who entered the cohort in 2000, 2002, 2005 and 2008 and lived in Beijing. Residential greenness was measured as satellite-derived Normalized Difference Vegetation Index (NDVI) in 1250m-radius-buffer around individual residence; cumulative NDVI was used. Last-one-year residential PM2.5, NO2 and last-peak-season O3 were obtained from both monitors and estimating models. Counts of medical, recreational and sports facilities in 5km-radii-buffers around residence were calculated. We examined the association of NDVI, PM2.5, NO2, O3, and 10-year change in NDVI and PM2.5 with mortality using Cox models, adjusted for demographic, socioeconomic and lifestyle covariates, and counts of public facilities.

RESULTS: NDVI in Beijing increased from 0.38 in 2000 to 0.45 in 2019. PM2.5 and NO2 concentration showed an inverse-U trend, with a turning point in 2013. In fully-adjusted models, 0.1-unit increase of NDVI was associated with lower mortality (HR[95%CI]: 0.656[0.485,0.885]), and similar association was found with per 10μg/m3 increase of O3 (HR[95%CI]: 0.882[0.781,0.995]). Moreover, living with increasing NDVI in the past decade was beneficial for health (HR[95%CI]: 0.402 [0.231,0.698]). Living with decreasing PM2.5 had 88% lower mortality (HR[95%CI]: 0.121[0.039,0.372]), while increasing PM2.5 had an increase of risk by 783% (HR[95%CI]: 8.831[4.688,16.635]), comparing with those living with stable exposure in the past decade. PM2.5, NO2 and accessibility to facilities were inconsistently associated with mortality.

CONCLUSIONS: In Beijing, greenness increased over decades, and air pollution started to reduce in recent years. Besides level of residential greenness and air pollution, change in these factors also matter to elderly health.

P-0073 Association of exposure to multiple essential trace elements with frailty in Chinese elderly

Lin Meng[1], Fanjia Guo[2], Yaoyao Lin[1], Mingjuan Jin[2], Jianbing Wang[3], Mengling Tang[1], Kun Chen[2]
[1]Department of Public Health, Fourth Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [2]Department of Public Health, Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [3]Department of Public Health, National Clinical Research Center for Child Health of Children's Hospital, Zhejiang University School of Medicine, China

BACKGROUND AND AIM: Deficiency and excessive intake of essential trace elements can cause a variety of adverse outcomes. This study aims to describe the levels of 6 essential trace elements, to analyze the combined and interactive effects of 6 essential trace elements on frailty and to evaluate the association between essential trace elements and frailty in the elderly in a community in Zhejiang province, China.

METHODS: Frailty was assessed by FRAIL Scale. Essential trace elements including chromium (Cr), manganese (Mn), iron (Fe), copper (Cu), zinc (Zn) and selenium (Se) were analyzed in whole blood after acid dilution pretreatment using inductively coupled plasma mass spectrometry (ICP-MS). Ordinal logistic regression models and restricted cubic spline (RCS) were used to analyze the independent association between elements and frailty. Bayesian kernel machine regression (BKMR) models was used to examine combined and interactive effects of 6 essential trace elements on frailty.

RESULTS: Participants were determined following inclusion and exclusion criteria, and 4.2% of them were considered frail. Ordinal logistic regression models indicated that Se was inversely associated with frailty while Cu was positively associated with it. RCS showed U-shaped association between Cr, Mn and Zn and frailty, showed L-shaped association between Se and frailty, while the risk of frailty increased in a Cu dose-dependent manner, decreased in a Fe dose-dependent manner. BKMR models showed similar results, the inverse association between Cr and frailty was stronger when the remaining at lower levels. Exposure to all 6 trace elements was negatively associated with frailty.

CONCLUSIONS: Deficiency and excessive intake of Mn and Cr would increase the risk of frailty, and all 6 essential trace elements mixed exposure was negatively associated with frailty.

KEYWORDS: Essential trace elements, frailty, BKMR, multiple-exposure

P-0074 Associations of cumulative exposure to metal mixtures with metabolic dysfunction-associated fatty liver disease in a Chinese aged population

Fanjia Guo[1], Lin Meng[2], Yaoyao Lin[2], Mingjuan Jin[1], Jianbing Wang[3], Mengling Tang[2], Kun Chen[1]
[1]Department of Public Health, Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [2]Department of Public Health, Fourth Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [3]Department of Public Health, National Clinical Research Center for Child Health of Children's Hospital, Zhejiang University School of Medicine, Hangzhou, China

BACKGROUND AND AIM: Few studies have demonstrated the potential effects of metal mixtures on metabolic dysfunction-associated fatty liver disease (MAFLD). Here, we examined the associations between whole blood metal mixtures and prevalence of MAFLD among an aged population in China.

METHODS: a cross-sectional study of community-dwelling elderly adults were conducted in China. Whole blood concentrations of fourteen metals were measured by inductively coupled plasma mass spectrometry (ICP-MS). MAFLD was ascertained based on ultrasonographic evidence of hepatic steatosis and the presence of overweight/obesity, type 2 diabetes mellitus, or metabolic dysregulation. We performed logistic regression and restricted cubic spline (RCS) models to independently estimate the associations between metal concentrations and MAFLD prevalence. Environmental Risk Score (ERS) constructed by adaptive elastic net (AENET) and Bayesian kernel machine regression (BKMR) analysis were utilized to examine joint effects of metal mixtures and metal interactions on MAFLD.

RESULTS: In the models adjusting for multiple covariates, lower blood copper and higher selenium, iron and mercury were significantly associated with the elevated prevalence of MAFLD. Non-linear effects of copper, iron, magnesium, manganese and selenium on MAFLD were observed in RCS models. Similar metals (copper, selenium, zinc, iron, cadmium and mercury) were selected as crucial predictors for MAFLD prevalence by AENET and BKMR models. The association between ERS and MAFLD was estimated and the ERS was significantly associated with the elevated OR for MAFLD.

CONCLUSIONS: Our findings provide evidence that exposure to blood copper, iron, selenium and mercury are associated with the prevalence of MAFLD. Multiple metals exposure may adversely affect MAFLD, with copper, selenium, zinc, iron, cadmium and mercury being the major contributors. Further researches are needed to clarify the cumulative effects of metal mixture in a larger population.

P-0075 Association between whole blood essential trace elements and cognitive function in the elderly

Yaoyao Lin[1], Lin Meng[1], Fanjia Guo[2], Mingjuan Jin[2], Jianbing Wang[3], Mengling Tang[1], Kun Chen[2]
[1]Department of Public Health, Fourth Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [2]Department of Public Health, Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [3]Department of Public Health, National Clinical Research Center for Child Health of Children's Hospital, Zhejiang University School of Medicine, Hangzhou, China

BACKGROUND
Essential trace elements (ETEs) are important for keeping nervous system function. The evidence of associations between ETEs and cognitive function among the elderly was limited. Therefore, we aimed to investigate the individual and joint association between ETEs and cognitive function among the elderly.

METHODS: An elderly population from Yiwu cohort in China was available for this study. Whole blood chromium (Cr), manganese (Mn), copper (Cu), and selenium (Se) concentrations were measured by inductively coupled plasma mass spectrometry (ICP-MS). Cognitive function was assessed using the Mini-Mental State Examination (MMSE), consisting of five specific-cognitive domains of orientation, registry, attention and calculation, recall, and language and praxis. Linear regression, restricted cubic spline (RCS) analysis, and Bayesian kernel machine regression (BKMR) were performed to explore the individual and joint associations between ETEs and cognitive function.

RESULTS: Linear regression showed that high-level Cr was positively associated with MMSE score compared to the lowest quartile, especially with recall. Further RCS analysis found an inverted-U-shaped association between Cr and MMSE score. Se was positively associated with MMSE score and particularly with registry. BKMR model showed that ETEs mixture was positively associated with cognitive function, and Se was the most important contributor within the mixture. Therefore, Se demonstrated a positive additive effect on the associations for other ETEs with cognitive function.

CONCLUSIONS: Low and high levels Cr were associated with poor cognitive function, indicating that exploring an appropriate range of Cr concentration is important. Se was positively associated with cognitive function and was the most important contributor to the association between ETEs mixture and cognitive function. Moreover, Se presented the additive effect for other ETEs. Thus, it should be considered the joint effect of ETEs mixture. Our findings provided the evidence to protect cognitive function by supplementing ETEs.

P-0076 The Interactive Effects of Ambient Air Pollution and Residential Greenness on Overweight and Obesity in Older Adults: Findings from the Chinese Longitudinal Healthy Longevity Survey

Lihong Ye[1], Yuebin Lv[2], Jinhui Zhou[2], Juan Zhang[1], Xiaoming Shi[2]

[1]School of Population Medicine and Public Health, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [2]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, China

BACKGROUND AND AIM: Air pollution [e.g., Fine particulate matter < 2.5 μm (PM2.5)] is a risk factor for frailty, while there were limited ways to overcome it. Currently, cross-sectional studies of the European population found an inverse association of residential greenness with body mass index (BMI). However, in older Chinese adults, there was inconsistent evidence regarding the association between residential greenness and overweight/obesity. Additionally, the interaction of residential greenness and PM2.5 concentration on overweight/obesity remains unknown. This cohort study aimed to evaluate the interactive effects of normalized difference vegetation index (NDVI) and PM2.5 exposure on overweight/obesity among older Chinese adults.

METHODS: The study included a total of 23,431 participants aged ≥65-year-old from 2000 to 2018 wave of the Chinese Longitudinal Healthy Longevity Survey. The baseline NDVI for each participant was calculated, based on a region within 1000 m radius around their residence. PM2.5 concentration was calculated using 3-year average concentrations in 1 km×1 km grid resolution. The overweight/obesity was defined based on BMI ≥24.0 during follow-up. Cox proportional hazards models were used to estimate the effects of NDVI, PM2.5, and their interaction on overweight/obesity.

RESULTS: During 117,240 person-years follow-up, 2622 incidents of overweight/obesity were documented. The hazard ratio of overweight/obesity was 0.95 [95% confidence interval (95% CI): 0.92~0.99] for each 0.1-unit increase in baseline NDVI, 1.16(1.13~1.19) for each 10 μg/m³ increase in 3-year average PM2.5, and 1.04 (1.02~1.06) for the interaction term. In the sensitivity analyses, the interaction of NDVI and PM2.5 on BMI remained significant.

CONCLUSIONS: This nation-wide prospective cohort study revealed the interaction effect of greenness and air pollution on overweight/obesity, which deserve the potential to lead to the lobbying of governments to determine new ways to reduce the burden of PM2.5 air pollution for older Chinese adults.

P-0081 Multiple air pollutants co-exposure and health among the older adults in China

John Ji[1], Linxin Liu[1], Yi Zeng[2,3]
[1]Tsinghua University, Beijing, China, [2]Peking University, Beijing, China, [3]Duke University, Durham, USA

BACKGROUND AND AIM: We aim to examine the association between ambient air pollutants defined by the WHO guideline AQG (PM2.5, NO2, O3) and mortality, cognitive function, and activities of daily living (ADL) disability in Chinese older adults.

METHODS: We used the 2008-2018 cohort of the Chinese Longitudinal Healthy Longevity Study (CLHLS). We included 11 835 participants, covering 23 provinces of China. We ran the Cox proportional hazards model to examine the association between the ambient air pollutants exposure and all-cause mortality, generalized estimating equation to test the association between air pollutants and repeatedly measured cognitive function and ADL disability.

RESULTS: The participants had a mean age of 87 (SD:11) and 57% were females. The annual average PM2.5, NO2, and O3 were higher in northern China than in southern China. The proportion exposed under the AQG level in the last year was 0% for PM2.5, 23.7% for NO2, and 0.7% for O3. Each 10 μg/m3 increase in PM2.5 was associated with higher mortality risk in both the single-pollutant and three-pollutant model [hazard ratio: 1.17, 95% confidence interval (CI): 1.15-1.19]. NO2 was not significantly associated with mortality risk and O3 was protective for mortality in three-pollutant model. Each 10 μg/m3 increase in O3 was associated with higher odds of cognitive impairment [Odds ratio (OR): 1.04, 95% CI: 1.01-1.07] in three-pollutant model. Each 10 μg/m3 increase in PM2.5 and NO2 were both associated with higher odds of ADL disability [OR (95% CI): 1.03 (1.01, 1.06) and 1.24 (1.20, 1.28) respectively] in three-pollutant model.
CONCLUSION: China has diverse air pollution levels depending on geographical areas, and do not meet WHO AQG in the majority of regions. PM2.5 was dominant for mortality outcome, while O3 and NO2 were dominant for cognitive impairment, and ADL disability outcomes, respectively.

KEYWORDS: Air pollution, mortality, cognitive function, ADL, China

P-0082 Interactive effects of physical activity and air pollution on incident dementia

Wei Xu[1], Jason Fletcher[1], Kristen Malecki[1], Ozioma Okonkwo[1]
[1]*University of Wisconsin Madison, Madison, USA*

BACKGROUND AND AIM: Accumulating evidence suggests that physical activity reduces dementia risk, but the extent to which this can be offset by residential air pollution is unknown. The aim is to determine whether residential air pollution attenuates the beneficial effects against the risk of incident dementia induced by regular physical activity.

METHODS: A population-based longitudinal study that included adults aged between 40 and 74 years without dementia at baseline. Participants were recruited to the UK Biobank study between 2006 and 2010 and followed up for an average of 9.0 years. Physical activity was categorized into regular and non-regular and residential overall air pollution with Q1 (lowest quartile, 25.6-43.6 μg/m3) to Q4 (highest quartile, 60.8-280.1 μg/m3) exposure categories. Associations between physical activity and air pollution and risk of incident dementias were assessed using Cox proportional hazards regression models.

RESULTS: 502 222 individuals (mean [SD] age, 56.5 [8.1] years; 45.6% were women) were included in the study, among which 2 502 individuals were subsequently diagnosed with all-cause dementia. Results of main effects indicate that not engaging in regular physical activity was associated with a 15% increase in dementia risk (adjusted hazard ratio, 1.15; 95%CI, 1.05-1.26) while exposure to the highest level of air pollution was associated with a 29% increase in the risk (adjusted hazard ratio, 1.29; 95%CI, 1.14-1.46). Hazard ratios associated with no regular physical activity decreased as air pollution increased; however, there was no significant interaction between the two factors (p = .05).

CONCLUSIONS: Among mid-age adults without dementia, regular physical activity was significantly associated with lower dementia risk and higher air pollution were significantly associated with higher risk. Although the benefit of physical activity was smaller among participants exposed to higher air pollution, we found no significant interaction effects.

KEYWORDS: air pollution; physical activity; incident dementia

P-0083 Mapping the complex systems that connects the urban environment to cognitive decline in older adults: a group model building study

Ione Avila-Palencia[1], Leandro Garcia[1], Claire Cleland[1], Bernadette McGuinness[1], Conor Meehan[2], Ruth F. Hunter[1]
[1]*Centre for Public Health, School of Medicine, Dentistry and Biomedical Sciences, Queen's University Belfast, Belfast, UK,* [2]*Innovation Lab of the Northern Irish Civil Service, Belfast, UK*

BACKGROUND AND AIM: The number of people living with dementia and Mild Cognitive Impairment (MCI) is increasing. A supportive urban environment can prevent or delay the progress of cognitive decline. There is evidence for the existence of mechanistic pathways between the urban environment and cognitive decline, but the interrelations between these pathways are unclear. In this study, we aimed to map the mechanistic pathways by which urban environment factors impact cognitive decline in older adults.

METHODS: This study was part of the Supportive environments for Physical and social Activity, healthy ageing and CognitivE health (SPACE) project. A 2-day workshop with the SPACE investigators was conducted based on the Group Model Building (GMB) methodology. The workshop aimed to create a causal-loop diagram (CLD) that identifies established and potential urban environment, lifestyle, health, and physiological determinants of cognitive decline in older adults. A facilitation team guided the activities. The workshop was held online following appropriately adapted scripts. After the workshop, the modelling team reviewed the CLD to ensure that main potential causal pathways and mechanisms were captured.

RESULTS: During the workshop, 12 experts from 10 different disciplines identified 83 factors and 221 connections between them. After review, the CLD presented 50 factors and 154 connections. All factors were classified in 10 main groups: urban design, social environment, travel behaviours, urban design by-products, lifestyle, disease/physiology, mental health conditions, exogenous factors, and cognitive decline outcomes. The main output was a CLD of the complex system of how the urban environment can influence cognitive decline in older adults.

CONCLUSIONS: The CLD detailed the plausible causal pathways between the urban environment and cognitive decline. Our findings suggested that GMB can engage experts and help them view problems through the lens of complex systems.

P-0085 Air pollution protective measures at personal-level affecting health outcomes: A systematic review and meta-analysis

Surabhi Shah[1], Eunji Kim, Kyoung-Nam Kim, Eunhee Ha
[1]*Ewha Womans University College of Medicine, Seoul, Republic of Korea*

BACKGROUND: Evidence for the effect of health-protective measures from air pollution at the individual level is relatively scarce. We performed a systematic review and meta-analysis to investigate the effect of personal protective measures for air pollution on various health outcomes.

METHODS: We searched PubMed, Scopus, and Web of Science to find randomized controlled trial studies investigating the effect of personal protective measures for air pollution on health outcomes. Two authors independently searched and selected studies, extracted information, and assessed each study's quality and risk of bias. Meta-analyses were performed when three or more studies were available for specific pair of protective measure and health outcome.

RESULTS: Lung function was higher in groups applying air purifiers than control groups with sham/no filter: forced expiratory volume in 1 second (FEV1) by 0.25 L [95% confidence intervals (CI): 0.01, 0.49]. The application of air-purifying respirators was associated with increased heart rate variability: the root mean square of successive differences between normal heartbeats (rMSSD) by 0.36 (95% CI: 0.13, 0.59). for other pairs of measures and health outcomes, evidence was insufficient.
CONCLUSION: Our findings suggest that air purifiers and air-purifying respirators can serve as an efficient protective measure for respiratory and cardiovascular health, respectively.

KEYWORDS: air pollution, personal-level protective measures

P-0092 Association between Long-Term Ambient PM2.5 Exposure and Cardiovascular Outcomes among U.S. Hemodialysis Patients

Yuzhi Xi[1,2,3], David Richardson[3], Abhijit Kshirsagar[4,5], Timothy Wade[6], Jennifer Flythe[4,5], Eric Whitsel[3,5], Ana Rappold[6]
[1]Emory University, Atlanta, USA, [2]Oak Ridge Institute for Science and Education at the USA Environmental Protection Agency, National Health and Environmental Effects Research Laboratory, Environmental Public Health Division, Research Triangle Park, USA, [3]Department of Epidemiology Gillings School of Global Public Health UNC Chapel Hill, Chapel Hill, USA, [4]University of North Carolina Kidney Center, Division of Nephrology and Hypertension, Department of Medicine, Chapel Hill, USA, [5]Department of Medicine,School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, USA, [6]USA Environmental Protection Agency, Center for Public Health and Environmental Assessment, Research Triangle Park, USA

BACKGROUND AND AIM: Ambient PM2.5 is a ubiquitous air pollutant with established adverse cardiovascular (CV) effects. However, quantitative estimates of PM2.5 exposure associations on CV outcomes in susceptible populations are limited. This study assessed the impact of long-term PM2.5 on CV events and cardiovascular disease (CVD)-specific mortality among patients receiving maintenance in-center hemodialysis (HD).

METHODS: We conducted a retrospective cohort study with 314,079 adult kidney failure patients initiating HD between 2011 and 2016 identified from the United State Renal Data System. Estimated daily ZIP code-level PM2.5 concentrations were used to calculate each participant's annual-average PM2.5 exposure based on the dialysis clinics visited during the 365 days prior to the outcome. CV event and CVD-specific mortality were ascertained based on ICD-9/ICD-10 diagnostic codes and recorded cause of death from form 2746. Discrete time hazards models were used to estimate hazards ratios (HRs) per 1 µg/m3 in annual-average PM2.5 adjusting for temperature, humidity, day of the week, season, age at baseline, race, employment status, and geographic region. Effect measure modification was assessed for age, sex, race, and baseline comorbidities.

RESULTS: Annual-average PM2.5 of 1 µg/m3 was associated with increased hazard rates in CV events (HR: 1.02, 95% CI: 1.01, 1.02) and CVD-specific mortality (1.02, 95% CI: 1.02, 1.03). The association was more pronounced for people who initiated dialysis at an older age, had COPD at baseline, or were Asian. Evidence of effect modification was also observed across strata of race, and other baseline comorbidities.

CONCLUSIONS: Long-term ambient PM2.5 exposure was positively associated with CV outcomes among patients receiving maintenance in-center HD. Patients who had advanced age, COPD, or reported to be Asian, appeared to be more susceptible to long-term PM2.5 adverse effects.

KEYWORDS: Air pollution, long-term, vulnerable population, dialysis patients

P-0095 Short-Term Coarse Particulate Exposure and Daily Cardio-Respiratory Hospital Admissions in the Helsinki Capital Region

Enembe Okokon[1], Pekka Tiittanen[2], Timo Lanki[2,3]
[1]University of Calabar, Calabar, Nigeria, [2]Finnish Institute for Health and Welfare, Kuopio, Finland, [3]University of Eastern Finland, Kuopio, Finland

BACKGROUND AND AIM: Short-term exposure to coarse inhalable particles (2.5 µg/m3>PMcoarse<10 µg/m3) has been suggested to increase the risk of respiratory disease independently of fine particles, but studies present mixed findings which are even less clear for other outcomes.
This study aims to assess the relationship between short-term exposure to PMcoarse and total admissions for cardio-pulmonary diseases.

METHODS: We conducted a seventeen-year (01/2001-12/2017) time-series study of the daily admissions for cardio-respiratory disease in relation to the mean levels of coarse particles. We obtained air pollution data from the Helsinki Region Environmental Services Authority, meteorological data from the Finnish Meteorological Institute, and hospital exit records from the Finnish Institute for Health and Welfare. We modelled the association between particles and cardiorespiratory admissions using log-linked quasi-Poisson regression. Penalised splines were used to adjust for the time-trend and the meteorological variables. These models were also adjusted for the weekday, pollen concentration, and influenza outbreaks. Different lag structures were explored in both single-pollutant and multipollutant models. The multipollutant models were simultaneously adjusted for PM2.5, NO2, and O3.

RESULTS: The mean(standard deviation) concentration of PMcoarse was 6.6(5.9) (µg/m3), while the mean (standard deviation) daily numbers of cardiovascular and respiratory admissions were 25.9(7.3) and 21.3(7.4), respectively. A 10 µg/m3 increase in the same day PMcoarse was associated with a 1.7% (95% CI, 0.4%—3.1%) and a 1.9% (95% CI, 0.5%—3.4%) excess daily risk of respiratory admissions in the single-pollutant and multipollutant models, respectively; same-day excess cardiovascular admissions risks were 0.6% (95% CI, -0.5%—1.7%) and 0.3% (95% CI, -0.9%—1.4%) in similar models.

CONCLUSIONS: Short-term exposure to PMcoarse can increase respiratory admission risks independently of co-pollutants but has a less determinate effect on cardiovascular admissions. A guideline framework should be considered for PMcoarse.

KEYWORDS: Coarse Particles, Cardiovascular Admissions, Respiratory Admissions, Time-Series, Fine Particles

P-0096 Particulate matter, albumin/creatinine ratio, and chronic kidney disease in a prospective cohort study

Ta-Yuan Chang[1], MS Ai-Hua Lee[1], MS Zhi-Ling Lin[1], Tsai-Chung Li,[1], Chiu-Shong Liu[2], Cheng-Chieh Lin[1]
[1]China Medical University, Taichung, Taiwan, [2]China Medical University Hospital, Taichung, Taiwan

BACKGROUND: Many studies have investigated the association between exposure to particulate matter (PM) and kidney dysfunction, but the relationship is inconsistent due to the variations in exposure assessment, the use of renal-function indices, and study design.
OBJECTIVES: This study elucidated the associations between exposure to PM10, PM2.5, and PM1 with albumin/creatinine ratio (ACR) and the incidence of chronic kidney disease (CKD) in a community-based cohort in Taiwan.

METHODS: A total of 704 residents living in Taichung were recruited as study subjects at the baseline of 2004 and followed up to the end of 2018. Questionnaire and health examination was used to collect personal information and renal-function indices at baseline and follow-up. Land-use regression models were established to predict individual levels of PM10, PM2.5, and PM1 annually during studying periods. The multivariable linear regression and Cox regression were conducted to investigate the associations between PM exposures, ACR, and the incident CKD (creatinine-based estimated glomerular filtration rate, [eGFRcr] < 60ml/min/1.73m2).

RESULTS: We found that an increase of 1 μg/m3 in PM10, PM2.5, and PM1 was associated with the decreased ACR of 1.10±1.14 mg/g (p=0.080), 4.66±2.17 mg/g (p=0.032), and 6.05±2.82 mg/g (p=0.032), respectively. The similar associations were identified for the cumulative exposure of 1 μg/m3-year to PM10, PM2.5, and PM1, which decreased the ACR of 0.14±0.10 mg/g (p=0.157), 0.55±0.27 mg/g (p=0.040), and 0.72±0.35 mg/g (p=0.040), respectively. Per 1 μg/m3 increase in PM10, PM2.5, and PM1 was associated with the elevated risk of 1.07-fold (95% confidence interval [CI]=1.00-1.15, p=0.055), 1.19-fold (95% CI=1.04-1.37, p=0.011), and 1.26-fold (95% CI=1.05-1.50, p=0.011) in the incident CKD, respectively.

CONCLUSIONS: The present study showed that exposure to PM2.5 and PM1 was associated with the decreased renal function to increase the risk of developing CKD.

P-0097 Fine particulate matter infiltration at skilled nursing facilities during wildfire season in the Western USA

Ethan Walker[1], Luke Montrose[2], Curtis Noonan[1]
[1]*Center for Population Health Research, University of Montana, Missoula, USA,* [2]*Department of Public Health and Population Science, Boise State University, Boise, USA*

BACKGROUND AND AIM: Wildfire air pollution is a growing public health concern as wildfires increase in size, intensity, and duration in the USA (US). Residents of skilled nursing facilities (SNFs) are vulnerable to wildfire smoke due to common pre-existing health conditions and advanced age of these populations. We assessed the impact of wildfire smoke on SNFs by estimating ambient fine particulate matter ($PM_{2.5}$) infiltration into SNFs during wildfire season.

METHODS: We measured continuous outdoor and indoor $PM_{2.5}$ concentrations from July-October 2021 at six SNFs in the US states of Idaho and Montana using PurpleAir monitors. We calculated infiltration efficiency (range 0-1; higher values indicate more ambient $PM_{2.5}$ infiltration to the indoor environment) at each facility using paired outdoor/indoor $PM_{2.5}$ samples in a validated recursive modeling approach. Analyses were conducted separately for each facility, by time of day (8am-5pm work hours versus after hours), and by days impacted by wildfire smoke.

RESULTS: Median outdoor $PM_{2.5}$ at the SNFs ranged from 7.9 $\mu g/m^3$ (25th percentile=4.4, 75th percentile=21.6) to 16.0 $\mu g/m^3$ (25th percentile=7.4, 75th percentile=30.6). Median indoor $PM_{2.5}$ at the SNFs ranged from 2.1 $\mu g/m^3$ (25th percentile=1.7, 75th percentile=3.9) to 8.4 $\mu g/m^3$ (25th percentile=2.0, 75th percentile=15.8). Infiltration efficiency at the facilities ranged from 0.13 (95% Confidence Interval: 0.10, 0.18) to 0.74 (95% Confidence Interval: 0.64, 0.85). Infiltration efficiency was similar during work hours versus after hours, but was higher during wildfire-impacted days than non-wildfire-impacted days for all but one facility.

CONCLUSIONS: The high variability of indoor $PM_{2.5}$ and infiltration efficiency across the facilities suggests that indoor exposures to wildfire smoke may be a modifiable risk factor for SNF residents. Future work will assess building characteristics and behavioral factors among residents and staff that may be related to wildfire smoke infiltration.

KEYWORDS: smoke, wildfires, indoor air pollution, vulnerable populations, infiltration efficiency, $PM_{2.5}$

P-0099 Educational intervention to promote air pollution knowledge and personal exposure mitigation strategies using wearable sensors

Trang VoPham[1,2], Eric S. Kim[3,4,5], Francine Laden[6,7,8], Jaime E. Hart[6,8]

[1]Epidemiology Program, Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, USA, [2]Department of Epidemiology, University of Washington, Seattle, USA, [3]Department of Psychology, The University of British Columbia, Vancouver, Canada, [4]Human Flourishing Program, Harvard Institute for Quantitative Social Science, Harvard University, Cambridge, USA, [5]Lee Kum Sheung Center for Health and Happiness, Harvard T.H. Chan School of Public Health, Boston, USA, [6]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [7]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [8]Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, USA

BACKGROUND AND AIM: Although strategies to reduce air pollution have focused on policy regulations and population-level controls, personal exposure mitigation is an approach that has not been well-explored. The aim of this study was to determine the feasibility of conducting an educational intervention to promote knowledge regarding air pollution, its health effects, and preventive behaviors.

METHODS: We recruited participants from Seattle, Washington from September-November 2021 for a 5-week study. Participants were asked to use Plume Labs Flow 2 wearable air pollution sensors, watch educational videos (intervention at week 3), and receive Air Quality Index (AQI) alerts. Questionnaires were administered pre- and post-intervention to assess air pollution knowledge and Health Belief Model (HBM) constructs for perceived susceptibility, severity, benefits, barriers, cues to action, and self-efficacy. McNemar and signed-rank tests were used to determine pre- and post-intervention differences.

RESULTS: A total of n=20 participants were included in this study (n=18 were never-smokers). Participants were knowledgeable regarding air pollution (≥35% of participants responded correctly to any given knowledge item at baseline). There was an increase in knowledge of AQI (of the 7 participants who answered incorrectly at pre-intervention, 6 answered correctly at post-intervention; p=0.01). There were no differences in HBM constructs, although pre-intervention responses showed participants perceived air pollution as a personal health threat (perceived severity mean score 8.7 ± 1.3; score range 1-10). Post-intervention personal NO2 levels (mean 11.62 ppb ± 5.89) were lower compared to pre-intervention levels (mean 13.49 ppb ± 3.00) (p=0.02). There were no differences in VOCs, PM1, PM2.5, or PM10 exposures at post-intervention.

CONCLUSIONS: This study demonstrated high feasibility in conducting an educational intervention to promote air pollution knowledge and reduce NO2 exposure. Future research could scale this intervention to subgroups disproportionately impacted by air pollution (e.g., vulnerable populations).

KEYWORDS: intervention; air pollution; sensors; wearables; behavioral science

P-0107 A hybrid model for estimating number concentrations of ultrafine particles in central Taiwan

BACKGROUND AND AIM: The epidemiological studies for assessing ultrafine particles (UFP) and health effects are scarce. The reasons are that the instrument for measuring UFP is expensive and the previous studies generally relied on a small number of fixed monitoring stations or short-term measurements. Modeling is a cost-effective measure to precisely estimate personal concentration in large-scale epidemiological studies, while the previous UFP estimation generally relied on the land-use regression model (LUR) and lacked temporal resolution. In this study, we conducted in-situ measurements for UFP in Taichung city, Taiwan, and developed a UFP estimation model by using machine learning algorithms.

METHODS: A scanning mobility particle sizer (SMPS Model 5.500, GIMM Aerosol Technik, Gmbh, Germany) was used to measure UFP number concentrations hourly in two sites (urban and rural sites) from 2017 to 2021. Random forest, XGBoost, and deep neural network were used to build the model. Ten-fold cross-validation was used to evaluate model performance. Coefficient of determination (R^2) and normalized root mean square error (nRMSE) were utilized to compare models.

RESULTS: A total of 1488 observations were collected. The average number concentrations of UFP was 23505.4±14643.9 (mean±sd). The XGBoost model had the best performance with a fitting R^2 of 1.00 (nRMSE: 0.20%) and a cross-validation R^2 of 0.63 (RMSE: 3.84%). The top important variables were temperature, surface pressure, Julian date, nitrogen dioxide, wind direction (X direction), fine particulate matter, sulfur dioxide, relative humidity, ozone, year, and aerosol optical depth (AOD).

CONCLUSIONS: Our results provided basic descriptions of UFP in Taiwan and identified several important features for UFP. Although the XGBoost model displayed overfitting, it still outperformed the previous models and provided accurate estimates. These estimates can be used to assess both the short-term and long-term effects of UFP on health outcomes.

KEYWORDS: Aerosol optical depth, estimation model, machine learning, ultrafine particles

P-0113 Household Cooking Fuel Choices and Associated Factors in a Rural and Peri-Urban Community in Western Kenya

Judith Mangeni[1], Diana Menya[1], James Mwitari[2], Matt Shupler[3], Rachel Anderson de Cuevas3[3], ms Edna Sang[1], Esilaba Anabwani[1], Noelle Sutton[1], Emily Nix[3], Sarah Ronzi[3], Dan Pope[3], Elisa Puzzolo[3], Kwaku Poku Poku Asante[4]
[1]Moi University, Eldoret, Kenya, [2]Kenya Medical Research Institute, Nairobi, Kenya, [3]University of Liverpool, Liverpool, UK, [4]Kintampo Health Research Centre., Kintampo, Ghana

BACKGROUND AND AIM
Polluting fuels such as biomass and kerosene are used for cooking by approximately 85% of the population in sub-Saharan Africa (SSA) despite the well-known associated adverse health effects. Many governments across SSA aim to scale up domestic use of liquefied petroleum gas (LPG), a cleaner-burning fuel in terms of black carbon and fine particulate matter emissions, to promote public health and protect the environment by reducing deforestation. We sought to determine factors associated with household fuel choice in-order to make recommendations that could promote uptake of LPG in rural and peri-urban settings within Uasin Gishu County.

METHODS: The study was part of the CLEAN-Air(Africa) project designed to address barriers to transitioning populations way from reliance on polluting biomass for cooking. A quantitative survey was administered to over 2000 households in peri-urban and rural sub-counties of Uasin Gishu County, West Kenya, to determine cooking characteristics and factors associated with the primary cooking fuel choice (biomass versus LPG).

RESULTS: We found that the majority (72%) of the households still use biomass as a primary fuel while about one third use clean fuels. Predictors for use of clean fuel include; residing in a peri-urban area (aOR 2.5,C.I: 1.933-3.162), education (aOR: 1.9, C.I 1.095-3.602), connection to electricity (aOR: 2.2, C.I: 1.649 -3.189), regular income (aOR:1.4,C.I: 1.117-1.886). Supply factors such as the ease of accessing refills affects duration of LPG use.

CONCLUSIONS: Urbanization at a sub-county level may lead to increases in the use of LPG for cooking. Socio-economic factors and LPG supply factors also predict LPG use. Policies that would increase the availability of LPG to rural communities need to be enacted in order to reduce the time and transportation costs that are likely to affect access and hence low usage.

P-0121 Particle Radioactivity: A potential driving factor for PM2.5 toxicity

Rebecca Stern[1], Petros Koutrakis[1], Haroula Baliaka[2], Man Liu[1], Choong Min Kang[1], Spyros Pandis[2], Athanasios Nenes[2], Carol Zilli Vieira[1], Longxiang Li[1]
[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]University of Patras, Patras, Greece

BACKGROUND AND AIM: Fine particulate matter (PM2.5) is associated with adverse human health outcomes. However, little is known about the mechanism(s) for the toxicity or which components of the PM2.5 cause the health effects. The ability of particles to cause oxidative damage may play a role.

METHODS: We evaluated the associations between the oxidative potential (OP) of PM2.5 particles (N=60) as measured by the dithiothreitol (DTT) assay, and different properties of these particles, including α- and β-activity, PM2.5 mass, and chemical components.

RESULTS: We found that Pearson correlation coefficients (r) between OP and the different variables were the strongest for α- and β-activities (Pearson's r=0.49 and 0.47, respectively), with a weaker correlation for PM2.5 mass (Pearson's r=0.33). Correlations between OP and the 25 PM2.5 elemental concentrations were weaker, ranging from 0.32 for Zinc to -0.21 for Barium. Bivariate regression models including radiation (either α- or β-activity) and one other variable (mass or chemical component) showed that only the radiation component was a significant predictor ($p<0.001$). None of the PM2.5 mass and elemental concentrations were significant.

CONCLUSIONS: The findings here suggest that radionuclides play a role in the toxicity of the particles. Gross α- and β-activity may help explain the association found between PM2.5 and detrimental health outcomes. This is the first study to link particle radioactivity to an oxidative stress assay.

P-0124 Causal relationship between PM 2.5 and diabetes mellitus: Two sample Mendelian Randomization using MR-Base platform

Eunji Kim[1], Joyce Mary Kim[1], Whanhee Lee[1], Jongmin Oh[1], Eunhee Ha[1]
[1]*Ewha Womans University, Seoul, Republic of Korea*

BACKGROUND AND AIM: Many studies have shown air pollution has emerged as one of the major environmental risk factors for diabetes mellitus; however, studies on the causal relationship between air pollution and diabetes mellitus based on genetic approaches are scarce. The study estimated the causal relationship between diabetes and fine particulate matter (PM2.5) using Mendelian randomization (MR).

METHODS: We collected genetic data from European ancestry publicly available genome wide association studies (GWAS) summary data through the MR-BASE repository. The IEU GWAS information output (PM2.5) from the Single nucleotide polymorphisms (SNPs) GWAS pipeline using pheasant-derived variables (Consortium=MRC-IEU, sample size: 423,796). The annual estimates of PM2.5 (2010) were modeled for each address using a Land Use Regression model developed as part of the European Study of Cohorts for Air Pollution Effects. Diabetes GWAS information (Consortium=MRC-IEU, sample size: 461,578) were used, and the genetic variants were used as the instrumental variables (IVs). We performed three representative MR

METHODS: Inverse Variance Weighted regression (IVW), Egger, and Weighted median for causal inference using genetic variants. Furthermore, we used a novel method called MR Mixture to identify outlier SNPs.

RESULTS: From the IVW method, we revealed the causal relationship between PM2.5 and diabetes (Odds ratio [OR]: 1.041, 95% CI: 1.008-1.076, p=0.016), and the finding was substantiated by the absence of any directional horizontal pleiotropy through MR-Egger regression (β=0.016, p=0.687). From the IVW fixed-effect method (i.e. one of the MR Mixture methods), we excluded outlier SNP (rs1537371) and showed the best predictive model (AUC=0.72) with a causal relationship between PM2.5 and diabetes (OR: 1.028, 95% CI: 1.006-1.049, p=0.012).

CONCLUSIONS: We identified the hypothesis that there is a causal relationship between PM2.5 and diabetes in the European population, using MR methods.

KEYWORDS: Causal relationship; Particulate matter; Diabetes; Mendelian Randomization

P-0125 Short-term effects of fine particulate matter constituents on pulmonary function among adolescents

Yoshiko Yoda[1], Hiroshi Takagi[2], Takeshi Ito[2], Junko Wakamatsu[2], Ryohei Nakatsubo[3], Yosuke Horie[3], Takatoshi Hiraki[3], Satoru Kobayashi[1], Masayuki Shima[1]

[1]Hyogo Medical University, Nishinomiya, Japan, [2]National Institute of Technology, Yuge College, Kamijima, Japan, [3]Hyogo Prefectural Institute of Environmental Sciences, Kobe, Japan

BACKGROUND: Expose to fine particle matter (PM2.5) has been associated with adverse effects on pulmonary function. Especially, it has been recently focused on the effects of PM2.5 constituents on human health. However, it is unclear whether healthy adolescents are affected by the expose to PM2.5 constituents in daily life. We investigated the association between PM2.5 constituents and pulmonary function in healthy adolescents.

METHODS: We conducted a panel study for about one month, in every spring and fall from 2014 to 2016, in Yuge Island, Japan. Pulmonary function measurements were conducted every morning in 48 healthy adolescents. PM2.5 samples were collected every 24 h during the study period, and the concentrations of 27 constituents in PM2.5 were analyzed. Mixed effects model were used to estimate the associations of pulmonary function with the average concentrations of PM2.5 constituents for 24h before a pulmonary function measurements.

RESULTS: The mean (SD) of PM2.5 mass concentration was14.9 (7.5) μg/m3 during the study period. A total of 4155 pulmonary function measurements were conducted by 48 healthy students. The peak expiratory flow (PEF) decreased significantly in relation to increases in concentrations of 12 constituents in PM2.5. The largest decrease of PEF with an interquartile range increase was observed for potassium (-4.01L/min [95% confidence interval: -6.07, -1.94]). The force expiratory volume in 1 s (FEV1) also decreased significantly in relation to increases in 11 constituents in PM2.5, and potassium had the most prominent effects among the constituents in PM2.5.

CONCLUSIONS: Our results suggest that many constituents in PM2.5 were associated with significant reduction in pulmonary function among healthy adolescents. Further studies are needed to clarify the source of the constituents in PM2.5 that affect respiratory system, and the reduction of the substances is desired to prevent the health effects of PM2.5.

P-0128 Triggering of ST-elevation myocardial infarction by ultrafine particles in New York: changes following Tier 3 vehicle introduction

Catherine Yount[1], Philip K Hopke, Mark Utell, Sally W Thurston, Frederick Ling, Yunle Chen, David Chalupa, Shao Lin, Xinlei Deng, David Q Rich
[1]*University of Rochester, Rochester, USA*

BACKGROUND AND AIM: Previously, we found increased rates of ST-elevation myocardial infarction (STEMI) associated with increased ultrafine particle (UFP; <100nm) concentrations in the previous few hours in Rochester, New York. Rates were higher after air quality policies and a recession reduced pollutant concentrations (2014-2016 versus 2005-2013), suggesting PM composition had become more toxic. Tier 3 light duty vehicles, which should produce less primary organic aerosols and oxidizable gaseous compounds, likely making PM less toxic, were introduced in 2017. Because of this, we hypothesized we would observe a lower relative STEMI rate in 2017-2019 than 2014-2016.

METHODS: Using STEMI events treated at the University of Rochester Medical Center (2014-2019), local UFP and other pollutant concentrations, a case-crossover design, and conditional logistic regression models, we separately estimated the rate of STEMI associated with increased UFP and other pollutants in the previous hours and days in the 2014-2016 and 2017-2019 periods.

RESULTS: An increased rate of STEMI was associated with each 3121 particles/cm3 increase in UFP concentration in 2014-2016 (lag hour 0: OR=1.23; 95% CI = 1.08, 1.41), but not in 2017-2019 (OR=0.93; 95% CI = 0.79, 1.09). There were similar patterns for black carbon, UFP11-50nm, and UFP51-100nm. In contrast, increased rates of STEMI were associated with 0.6ppb increases in SO2 concentrations in the previous 120 hours in both periods (2014-2016: OR=1.25, 95% CI = 1.00, 1.36; 2017-2019: OR=1.22, 95% CI = 0.88, 1.68).

CONCLUSIONS: Greater rates of STEMI were associated with short term increases in concentrations of UFP and other motor vehicle related pollutants before Tier 3 introduction (2014-2016), but not afterwards (2017-2019). This change may be due to changes in PM composition, to increased exposure misclassification and greater underestimation of effects from 2017-2019, and/or changes in therapeutic approaches such as preventive aspirin use.

KEYWORDS: myocardial infarction, air pollution, ultrafine particles, case-crossover

P-0129 Ambient fine particulate matter exposure and risk of incident breast cancer in the NIH-AARP Diet and Health Study

Alexandra White[1], Jared Fisher[2], Neal Freedman[3], Joel Kaufman[4], Debra Silverman[2], Rena Jones[2]
[1]Epidemiology Branch, National Institute of Environmental Health Sciences, Research Triangle Park, USA, [2]Occupational and Environmental Epidemiology Branch, National Cancer Institute, Rockville, USA, [3]Metabolic Epidemiology Branch, National Cancer Institute, Rockville, USA, [4]Environment and Occupational Health Sciences, University of Washington, Seattle, USA

BACKGROUND AND AIM: Fine particulate matter (PM2.5) has been inconsistently associated with breast cancer risk, however few studies have considered historic exposure levels which may be more relevant given the long latency of breast cancer.

METHODS: Outdoor residential PM2.5 concentrations were estimated using a nationwide spatiotemporal model for women in the NIH-AARP Diet and Health Study, a cohort located in 6 states (California, Florida, Louisiana, New Jersey, North Carolina, and Pennsylvania) and 2 metropolitan areas (Atlanta, Georgia, and Detroit, Michigan) and enrolled in 1995-1996. Annual average PM2.5 concentrations were estimated for a 5-year historical period 10 years prior to enrollment (1980-1984). We used Cox regression to estimate adjusted hazard ratios (HRs) and 95% confidence intervals (95% CIs) for the association between a 10µg/m3 increase in PM2.5 and incident breast cancer risk overall and by estrogen receptor (ER) status and extent of the tumor (invasive vs. ductal carcinoma in situ (DCIS)). Models were adjusted for age, body mass index, race/ethnicity, smoking status and catchment area. We also conducted analyses stratified by catchment area.

RESULTS: With follow-up through 2011, 13,246 breast cancer cases were diagnosed. A 10ug/m3 increase in PM2.5 was significantly associated with overall breast cancer risk (HR=1.07, 95% CI:1.01-1.13). No significant differences were observed between invasive tumors and DCIS (p-for-heterogeneity=0.40). The association was evident for ER+ tumors (HR=1.09, 95% CI:1.02-1.17), but not ER- tumors (HR=0.97, 95% CI:0.80-1.17; p-for-heterogeneity=0.31). Overall breast cancer HRs were >1 across all cohort catchment areas; ranging from a HR=1.47 (95%CI: 0.73-3.00) for Georgia to a HR=1.04 (95% CI:0.97-1.11) for California (p-for-heterogeneity=0.66).

CONCLUSIONS: In this large U.S. cohort with historical air pollutant exposure, PM2.5 was associated with ER+ breast cancer risk. Future work should consider region-specific associations and the potential contribution of PM2.5 chemical constituency in modifying the observed association with breast cancer.

KEYWORDS: breast cancer, outdoor air pollution

P-0135 Source apportionment of ambient PM2.5 using positive matrix factorization (PMF) model in Cape Town, South Africa

Anna Alfeus[1], Adewale Adeyemi[2], Joyce Shirinde[2], Peter Molnar[3], Johan Boman[4], Philip Hopke[5], Janine Wichmann[2]
[1]University of Namibia, Oshakati, Namibia, [2]School of Health System and Public health, University of Pretoria, Pretoria, South Africa, [3]Department of Occupational and Environmental Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, SE-405 30 Götenborg, Sweden, [4]Department of Chemistry and Molecular Biology, University of Gothenburg, SE-412 96 Götenborg, Sweden, [5]Department of Public Health Sciences, University of Rochester School of Medicine and Dentistry, Rochester, USA

BACKGROUND AND AIM: Particulate matter (PM) with an aerodynamic diameter <2.5µm (PM2.5) is an indicator of air pollution that threatens global population health. In 2017, exposure to PM2.5 was attributed to 2.9 million premature deaths and 83 million DALYs globally. The dearth of data on PM2.5 sources and quantification presents a significant gap in knowledge for Africa and South Africa in particular. This study identified the sources and their contributions to ambient PM2.5 in Cape Town, South Africa.

METHODS: PM2.5 samples were collected every third day for 121 days in an urban background site in the Kraaifontein suburb in Cape Town. Filters were analyzed for black carbon, organic carbon, and trace elements using Model OT21 Optical Transmissometer and a Xepos 5 Energy-dispersive x-ray fluorescence (EDXRF) spectrometer, respectively. Concentration and uncertainty data for PM2.5, BC, OC, and trace elements (S, Cl, Si, K, Ca, Ti, V, Fe, Ni, Cu, Zn, As, Se, Br, Sr, Sb, Ba, Pb, U) were used in the PMF, version 5.0 from the US Environmental Protection Agency to identify sources by markers.

RESULTS: The mean PM2.5 concentration was 13.4 ± 8.2 µg/m3 (1.2 to 39.1µg/m3) above the stipulated WHO air quality guideline of 5µg/m3. The PM2.5 mean seasonal concentration were 17.37µg/m3 (spring), 16.1 µg/m3 (winter), 11.25 µg/m3 (autumn) and 9.12 µg/m3 (summer). Sulfur had the highest mean concentration of 346.95ng/m3 followed by chlorine (288.21ng/m3) then silicon (204.52ng/m3). Uranium had the lowest mean concentration of 0.62ng/m3. Seven sources of PM2.5 were quantified including point source emission (24.6%), biomass burning (22.3%), traffic emission (16.8%), secondary sulphate (13.1 %), sea salt (9.3%), diesel combustion (8.4%) and crustal sources (5.5%).

CONCLUSIONS: The main PM2.5 emitters are combustion sources. Therefore abatement strategies should focus on improving the combustion processes.

P-0139 Chronic exposure to air pollution and semen quality in an Asian population

Yiqian Zeng[1], Cui Guo[1], Jinjian Chen[1], Xianglin Wei[1], Xiangqian Lao[1,2]
[1]The Chinese University of Hong Kong, Hong Kong, China, [2]Shenzhen Research Institute of the Chinese University of Hong Kong, Shenzhen, China

BACKGROUND AND AIM: Evidence concerning the association between air pollution and semen quality is sparse, and findings in previous studies remain inconsistent. This study aims to investigate the associations between exposure to ambient air pollution and semen quality in Asia.

METHODS: A cross-sectional study was conducted among 7,658 male participants (aged ≥15 years) who participated in a standard medical examination program in Taiwan and Hong Kong between 2000 and 2018. The 2-year average concentration of $PM_{2.5}$, NO_2, and O_3 was estimated at each participant's address using satellite-based spatial-temporal models. Semen quality was assessed according to the WHO 1999 guidelines, including sperm concentration, total motility, progressive motility, and morphology. Generalized linear mixed models were used to examine the association between air pollution and sperm quality, with a region-level random intercept used in all models to control within-region clustering effects.

RESULTS: Every 10 ug/m³ increase in NO_2 was associated with a decrease of -1.72% [95% confidence interval (CI): -2.68% to -0.75%] in sperm concentration. However, each 10 ug/m³ increase in $PM_{2.5}$ and O_3 was associated with an increase of 3.13% (95%CI: 0.76% to 5.55%] and 2.88% (95%CI: 0.75% to 5.05%) in sperm concentration, respectively. In addition, each 10 ug/m³ increase in $PM_{2.5}$ was associated with a lower percentage of normal sperm morphology, with a coefficient of -1.54 (95%CI: -2.41 to -0.68). There were no consistent associations between air pollution and other semen parameters.

CONCLUSIONS: We found that exposure to ambient NO_2 was associated with a lower level of sperm concentration and exposure to ambient $PM_{2.5}$ was associated with a lower level of normal sperm morphology. Further studies are warranted to validate our findings.

KEYWORDS: Air pollution, ozone, male infertility, semen quality

P-0145 Associations between long-term air pollution exposure and physical function in older adults

Tzu-Hsuan Liu[1], Yuan-Ting C. Lo[1], Yann-Yuh Jou[2], Han-Bin Huang[1]
[1]School of Public Health, National Defense Medical Center, Taipei, Taiwan, [2]Health Promotion Administration, Ministry of Health and Welfare, Taipei, Taiwan

BACKGROUND AND AIM: Epidemiological studies concerning the relations between exposure to air pollutants especially in ozone and disability in older adults were limited. Thus, this study aims to investigate the associations between exposure to long-term air pollution and the risk of disability among the community-dwelling older adults.

METHODS: Study participants were adopted from the third to sixth wave surveys (1996, 1999, 2003 and 2007 year) in Taiwan Longitudinal Study on Aging (TLSA) (n=2241). We estimated 1-year and 2-year exposure window for ozone levels from 1994 to 2007 by using daily concentration data at air quality monitoring stations in the administrative zone of participants' residences. The status of disability for each participant was evaluated on the activities of daily living scale (ADLs) and instrumental activities of daily living scale (IADLs). Generalized linear mixed models were used to investigate the associations between long-term ozone exposure and disability after adjusting for covariates.

RESULTS: We found that long-term (1-year moving average or 2-year moving average) ozone exposure was positively associated with the risk of disability in the elderly. for example, when the average concentration of ozone increased 1 ppb in 1-year exposure window, the risk of disability for ADL scores ≥1 and IADL scores ≥7 in the elders increased 5.4% (OR=1.054, 95% CI:1.022-1.086) and 4.3% (OR=1.043, 95%CI:1.016-1.071), respectively. As compared to quartile 1 (Q1) of 1-year moving average for ozone levels, quartile 4 (Q4) of ozone exposure was significantly associated with the risk of disability for ADL scores ≥1 and IADL scores ≥7 in older adults (OR=1.858, 95% CI:1.404-2.459 for ADL scores ≥1; OR=1.700, 95%CI:1.331-2.171 for IADL scores ≥7).

CONCLUSIONS: Our results indicated that the long-term exposure to ozone could be a risk factor of disability in older adults. More researches on the biological mechanism of ozone-disability associations are required in the future.

P-0146 Adoption of innovative energy efficiency pots to enhance sustained use of clean cooking with gas in resource-poor households in Kenya: perceptions from participants of a randomized controlled trial

Willah Simiyu[1], Elisa Puzzolo[2,3], Stephen Clayton[2], James Mwitari[1], Arthur Gohole[1], Elizabeth Muchiri[3], Dan Pope[2]
[1]Amref International University (AMIU), Nairobi, Kenya, [2]Department of Public Health, Policy and Systems, University of Liverpool, Liverpool, UK, UK, [3]The Global LPG Partnership (GLPGP), 654 Madison Avenue, New York, USA

BACKGROUND AND AIM: Initial equipment purchase and recurrent fuel costs, as well as cultural cooking preferences (including perceived fuel wastage for long cooking duration foods) are recognized barriers to adoption and use of gas and electricity for clean cooking. Scaling clean cooking is now a priority for many sub-Saharan African countries to address the substantial health burden from exposure to household air pollution from reliance on polluting solid fuels.
METHOD: To facilitate transition to clean cooking with liquefied petroleum gas (LPG) innovative cooking pots with a revolutionary new fuel saving design were tested by LPG using cooks in an informal settlement in Nairobi, Kenya who currently also used polluting fuels for their cooking. Semi-structured interviews (SSIs) were conducted with 22 of 200 cooks who took part in a randomized control trial of the pots to test the impacts of the pots on exclusive clean cooking with LPG. The SSIs explored positive and negative perceptions of the technology in aiding clean cooking and potential time savings.

RESULTS: Universal appreciation of the benefits of the pots for cooking, fuel and time saving and prestige were reported by the cooks with all cooks reporting advantages over their traditional locally available pots (Sufurias). Willingness to pay for the pots and the potential for scale in the local community was a key outcome from the thematic analysis.

CONCLUSIONS: This study highlights the potential role for energy-efficient pots as a solution to sustained /exclusive clean cooking with LPG in resource poor settings. The documented positive impacts on time and fuel savings are substantiated and contextualized through the results of this qualitative study. In addition, the findings are directly relevant to scale of the cooking pots in local markets through both import and local manufacturing.

KEYWORDS: Household Air pollution, energy-efficient pots, LPG, adoption, enhanced cookware, gas.

P-0150 Malodour and health risks in the surroundings of an animal rendering plant

Eleni Sazakli[1], Michalis Leotsinidis[1]
[1]*Lab of Public Health, Medical School, University of Patras, Patras, Greece*

BACKGROUND AND AIM. Volatile Organic Compounds (VOCs) emitted from animal rendering processes, may be hazardous and/or malodorous. This study was conducted in the vicinity of a rendering plant in Southwest Greece, during operation and after its compulsory cessation. The aim was to assess the odour annoyance and the possible carcinogenic and toxic risks, derived from VOCs in ambient air.

METHODS: VOCs were absorbed onto Tenax TA/Sulficarb sorbents via active sampling and analyzed by Thermal Desorption-Gas Chromatography-Mass Spectrometry. Odour Activity Values (OAVs) were calculated for odorants. Health risks were determined by probabilistic risk assessment. Past and present odour nuisance perceived by residents was assessed through a questionnaire.

RESULTS: A substantial reduction in ambient air concentrations of VOCs (47 %) was found after closure of the plant. Seventeen compounds totally disappeared, of which four (propanoic and butanoic acids, dimethyl trisulfide, 2-nonenal) were immensely malodorous. The total odour burden, as expressed by the sum of OAVs, decreased by 70 %. Residents reported a definite drop in the frequency, intensity, duration and annoyance of the odour. Non-specific health symptoms (nausea, respiratory problems, etc.) that participants were experiencing in the past, no longer occur. During the operation period, the cumulative Lifetime Cancer Risk (LCR) for the general population was calculated to be 10 times higher than the acceptable risk. The cumulative mean Hazard Quotient (HQ = 3.3), indicated a high risk of adverse health effects. After activity termination, LCR decreased by 3-fold, while HQ remained almost the same.

CONCLUSIONS: Three major issues, odour disturbance, cancer and toxic risks were imposed on the surrounding population by a rendering plant, which was not operating under the Best Available Techniques framework. A significant amelioration of life quality was reported by residents after activity termination.

P-0156 Pregnant women's exposure to 1-hydroxypyrene predicted by airport-related source indicators in an area with low ambient air pollution

Emily Craig[1], Yan Lin[1], Xiaodong Liu[1], Yihui Ge[1], Xiangtian Wang[1], Zhenchun Yang[1], Jessica Brunner[2], Philip Hopke[2], Sally Thurston[2], Susan Murphy[1], Emily Barrett[3], Thomas O'Connor[2], Dave Rich[2], Junfeng Zhang[1]
[1]Duke University, Durham, USA, [2]University of Rochester, Rochester, USA, [3]Rutgers University, Newark, USA

BACKGROUND: Gestational exposures to polycyclic aromatic hydrocarbons (PAHs) are associated with adverse health effects among mothers and infants. Although outdoor air pollution is a known contributor to the general population's exposures to PAHs, it is unclear whether residential proximity to local pollution sources predict PAH exposure in pregnant women, especially in areas with low-level pollution.
AIM: To determine the associations of residential proximity to vehicular traffic and a nearby airport with urinary 1-hydroxypyrene (1-OHP) among pregnant women living in Rochester, New York.

METHODS: We used 743 urine samples measured for 1-OHP (once per trimester) from a pregnancy cohort study of 313 women. We calculated the distance between participants' residences and the Rochester Airport and annual average daily traffic volumes (AADT) within different buffer distances from the residence (100m increments). Associations between 1-OHP and these proximity measures were examined using linear regressions, adjusting for age, body mass index, and smoking status.

RESULTS: Residential proximity to the airport and AADT within a 300m buffer distance were associated with 1-OHP concentrations. One IQR increase in log-distance (i.e., from 6.3 to 14.0 km) was associated with an 11.0% increase in 1-OHP concentration (95%CI: 4.4%, 17.2%), while each IQR increase in the square root of AADT was associated with an 8.3% increase in 1-OHP concentration (95%CI: 1.41%, 15.73%). We found greater increases in 1-OHP levels associated with IQR increases in residential proximity to the airport when participants lived downwind (15%) than upwind (12%) of the airport, suggesting a substantial contribution of airport-related sources to PAH exposures.

CONCLUSIONS: Emissions from an airport and local traffic activities likely contributed to increased PAH exposures among pregnant women living in a Northeastern US city with low air pollution levels (average participant exposure PM2.5 = 6.1 μg/m3).

KEYWORDS: PAH, 1-hydroxypyrene, pregnant women exposure

P-0161 Hospital admission risks and costs for neuropsychiatric disorders attributable to fine particulate matter in New York State: a community-level cross-sectional study

Jieun Min[1], Whanhee Lee[1,2], Soo In Kim[3], Eunhee Ha[1,2]

[1]Department of Environmental Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [2]Institute of Ewha-SCL for Environmental Health (IESEH), Ewha Womans University College of Medicine, Seoul, Republic of Korea, [3]Department of Psychiatry, Ewha Womans University Mokdong Hospital, Ewha Womans University College of Medicine, Seoul, Republic of Korea

BACKGROUND AND AIM Neuropsychiatric disorders are a huge and growing public health concern during the recent years. However, evidence is limited for air pollution and related excess medical costs for neuropsychiatric disorders. We aimed to investigate excess risks and costs of hospital admission for neuropsychiatric disorders associated with long-term exposure to fine particulate matter (PM2.5) in New York State and examine disproportionate impact of PM2.5 on neuropsychiatric disorders by individual characteristics.

METHODS: We collected non-elective annual hospital admission counts and costs for six neuropsychiatric disorders—fatigue, headache, behavior disorder, mood disorder, Parkinson's diseases, and epilepsy— from the Statewide Planning and Research Cooperative System (SPARCS) database from 2010 to 2016. We also obtained county-level annual average of PM2.5 from the high-quality prediction model. We performed a generalized linear mixed model to estimate the association between annual average PM2.5 and the number of annual hospital admissions for neuropsychiatric disorders and calculated the excess medical costs attributable to PM2.5 based on the estimated association.

RESULTS: We found that higher exposure to PM2.5 was associated with higher hospital admission risks of neuropsychiatric disorders, and the risk was more evident in behavior disorder and Parkinson's disease, RRs: 1.08 (95% CI: 1.02, 1.16) and 1.08 (95% CI: 1.00, 1.17). Meanwhile, the excess medical cost attributable to annual PM2.5 was the highest in mood disorder (309.8 million dollars with 95% CI: -48.4, 599.4 million dollars) and epilepsy (255.5 million dollars with 95% CI: 55.9, 405.2 million dollars).

CONCLUSIONS:This study provides the excess hospital admission risks due to exposure to long-term PM2.5 for neuropsychiatric disorders, together with the excess costs attributable to PM2.5 which have a different pattern from the estimated risks.

KEYWORDS: Fine particulate matter, PM2.5, Neuropsychiatric disorders, Economic burden.

P-0167 Individual and regional vulnerability for hospitalization with cardiovascular and respiratory diseases in association with short-term ambient PM2.5 exposure

Hyungryul Lim[1], Jonghyuk Choi[1], Sanghyuk Bae[2], Kyung-Hwa Choi[1], Xue Han[1], Mina Ha[1], Ho-Jang Kwon[1]
[1]Department of Preventive Medicine, College of Medicine, Dankook University, Cheonan, Republic of Korea, [2]Department of Preventive Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

BACKGROUND AND AIM: Short-term effect of ambient $PM_{2.5}$ exposure on cardiovascular and respiratory hospitalization has a high scientific evidence. However, further evaluation for the vulnerability in terms of individual and regional characteristics is still needed.
METHOD: We covered 166 municipalities, in which has ambient $PM_{2.5}$ monitoring sites, in Republic of Korea from 2015 to 2019. We used daily means of $PM_{2.5}$ concentration, temperature, relative humidity data, and daily hospitalization [ischemic heart disease (IHD), stroke, chronic obstructive pulmonary disease (COPD), and asthma] count data from the National Health Insurance Sharing Service. Quasi-Poisson generalized additive models for overall population and the strata [individually identified; sex, age, social economic status (SES)] in each municipality and meta-analyses using regional-level variables (over aged 65, obesity, current smoker, and greenspace rate, Gross Regional Domestic Product(GRDP) per capita, employment rate, and untreated medical need rate) were implemented.

RESULTS: The pooled risk according to increase of 10 $\mu g/m^3$ of $PM_{2.5}$ concentration was increased by 0.62% (95%CI, 0.44–0.81), 0.16% (95%CI, -0.09–0.40), 0.75% (95%CI, 0.49-1.02) and 0.59% (95%CI, 0.32–0.86) based on the model with 0-1 lag day exposure, for IHD, stroke, COPD, and asthma, respectively. We found higher risks in female for IHD (0.76%), male for COPD (1.19%), in lower SES for IHD (0.88%) and stroke (0.47%), and in older group aged 65 or more for IHD (0.97%), stroke (0.36%), COPD (1.31%), and asthma (1.85%). In the regions with higher rates of older group over aged 65, obesity,and GRDP per capita, the higher risks were shown for IHD, stroke, and asthma, while in the regions with lower employment rate, those were for IHD, stroke, and COPD.

CONCLUSIONS: We explored to identify the vulnerable factors in terms of individual and regional characteristics.

BACKGROUND: In 2019, household air pollution from combustion related to household energy needs (e.g., cooking) was estimated to be responsible for 2.3 million premature deaths globally, including nearly 400,000 from chronic respiratory diseases. In rural Honduras, we demonstrated substantially reduced personal fine particulate matter [PM2.5] concentrations following a 3-year wood-burning Justa stove (engineered combustion chamber and chimney) intervention (e.g., 24-hour PM2.5 median [25th, 75th percentiles]: Justa, 43 [27, 73]; traditional stove, 81 [50, 141] µg/m3). We evaluated the impact of the intervention and PM2.5 and black carbon (BC) concentrations on fractional exhaled nitric oxide (FeNO), a noninvasively collected biomarker of eosinophilic airway inflammation previously associated with exposure to ambient air pollution.

METHODS: With 6 visits per household over 3 years, the individual-level, stepped-wedge randomized controlled trial was conducted among 230 primary female cooks aged 24-59 years and using traditional stoves at baseline. In addition to 24-hour gravimetric personal and kitchen PM2.5 and BC concentrations, we longitudinally assessed FeNO levels with the NIOX Vero device at each visit in a random sample of 90 participants. Among participants reporting no use of anti-inflammatory medications, we explored FeNO impacts of the intervention in intent-to-treat (adjusted for time trends) and exposure-response (adjusted for potential confounders) linear mixed effect models (n=414 observations).

RESULTS: We did not observe an effect of the intervention on FeNO levels (3% higher geometric mean among those assigned to the Justa compared to the traditional stove, 95% confidence interval [CI]: -12%, 21%). Associations between pollution concentrations and FeNO were consistent with the null association (e.g., we observed a difference of 4% lower FeNO per 1-unit higher log-transformed personal PM2.5, 95% CI: -9%, 1%).

CONCLUSIONS: Evidence from ambient and HAP studies regarding associations with FeNO is inconsistent, and may be attributable to differing study populations, exposures, and FeNO measurement procedures.

P-0173 Long-term trends in mortality risks associated with short-term exposure to air pollution in 10 Japanese cities between 1977 and 2015

BACKGROUND AND AIM: Short-term associations between air pollution and mortality have been well reported in Japan, but the historical changes of mortality risks remain unknown while Japan undergoes rapid aging. We examined temporal changes in the mortality risks associated with short-term exposure to four criteria air pollutants in selected Japanese cities.

METHODS: We collected daily mortality data for non-accidental causes (n=5,748,206), cardiovascular (n=1,938,743) and respiratory diseases (n=777,266), and air pollutants – SO_2, NO_2, suspended particulate matter (SPM) and oxidants (Ox) – of 10 cities from 1977 to 2015. We performed a two-stage analysis with 5-year stratification to estimate the relative risk (RR) of mortality per 10 unit increase in 2-day moving average of air pollutant concentrations. In the first stage, city-specific associations were assessed using a quasi-Poisson generalized linear regression model. In the second stage, the city-specific estimates were pooled using a random-effects meta-analysis. Ratio of relative risks (RRR) was computed to examine temporal changes.

RESULTS: Average concentrations in each stratified period decreased for SO_2, NO_2, and SPM (14.2–2.3 ppb, 29.4–17.5 ppb, 52.1–20.6 μg/m³, respectively) but increased for Ox (29.1–39.1 ppb), over the study period. When stratifying the analysis by every 5 years, the estimated risks of non-accidental mortality with these pollutants remained positive but did not show any clear trend. Meanwhile, the risk of respiratory mortality with SPM had increased (RRR of the latest period to that of the earliest period: 1.008, 95% CI: 1.002–1.015). The risks posed by these pollutants were slightly to moderately heterogeneous for the different cities.

CONCLUSIONS: The respiratory mortality risk per 10 unit increase of SPM concentration was significantly higher in the latest period than in the earliest period. Other pollutant–mortality associations indicated either decrease or non-significant risk change in Japan between 1977 and 2015.

P-0174 Long-Term Association of Air Pollution and Incidence of Lung Cancer in American Elderly Population: A National Study in Medicare Cohort

Cristina Su Liu[1], Mahdieh Danesh Yazdi[1], Xinye Qiu[1], Edgar Castro[1], Yaguang Wei[1], Qiao Zhu[2], Haomin Li[2], Joel D. Schwartz[1], Liuhua Shi[2]

[1]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [2]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA

BACKGROUND AND AIM: Despite growing evidence of the association of fine particulate matter [PM2.5] to an increased risk of lung cancer mortality, few studies have investigated associations of multiple pollutants simultaneously. We aim to investigate the long-term effects of PM2.5, nitrogen dioxide [NO2], and warm-season (i.e. May to October) ozone [O3] on lung cancer incidence in a large national cohort.

METHODS: We conducted a prospective study in a nationwide cohort with Medicare beneficiaries (aged ≥ 65 years) enrolled in the fee-for-service program in the contiguous US from 2000 to 2016. Air pollution exposure was averaged across three years and assigned to each subject based on their ZIP code of residence. We fitted single-, bi-, and tri-pollutant Cox proportional hazards models to estimate the hazard ratios (HRs) for lung cancer incidence, adjusted for potential confounders.

RESULTS: Over the study period, we identified 172,371 lung cancer cases (n= 12,827,068). We found a significant increase in lung cancer risk for all three pollutants in the single-pollutants model. HRs associated with 1 μg/m3 increase in PM2.5 (μg/m3) was 1.015 (1.013, 1.018), and with 1 ppb increase in NO2 and O3 was 1.013 (1.012, 1.014) and 1.007 (1.006, 1.009) respectively. In bi- and tri-pollutant models, we observed potential confounding by NO2 on PM2.5¬, which was no longer significantly associated with lung cancer incidence. Subgroup analysis revealed significantly stronger effects for PM2.5 for those who were men, aged ≥ 75 years, black, eligible for Medicaid, and living in neighborhoods at the lowest quartile of median household income.

CONCLUSIONS: Long-term exposure to elevated concentrations of PM2.5, NO2, and O3 was significantly associated with an increased risk of lung cancer incidence among the Medicare population. Improving air quality in the US could yield substantial health benefits for the aging American population.

P-0177 Estimate High-Spatial Resolution of Ground-Level Ozone in Korea during 2001-2020 using Ensemble Model

Dohoon Kwon[1], Whanhee Lee[2,3], Cinoo Kang[1], Insung Song[1], Jieun Min[1], Jieun Oh[1], Jeongmin Moon[1], Jinah Park[1], Ho Kim[1]

[1]Graduate School of Public Health, Seoul National University, Seoul, Republic of Korea, [2]Departmemt of Environmental Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [3]Institute of Ewha-SCL for Environmental Health (IESEH) College of Medicine, Ewha Womans University, Seoul, Republic of Korea

BACKGROUND AND AIM: Estimating ground-level ozone concentrations with high spatial resolution is crucial to assess the adverse health effects associated with exposure to ozone. Despite its importance, there is no study estimating high spatial resolution of ozone concentration in Korea. This study aims to estimate monthly average of daily maximum 8 hours (8 h) ozone at a resolution of 1 km × 1 km across Korea from 2001 to 2020.

METHODS: This study used an ensemble model that integrated multiple machine learning algorithms (random forest, light gradient boosting, and neural network) to estimate monthly average of daily maximum 8 h ozone at a resolution of 1 km × 1 km across the contiguous Korea. We used a generalized additive model that accounted for geographic difference to combine ozone estimates from random forest, light gradient boosting, and neural network. The three machine learning models include multiple predictors with satellite data, meteorological variables, spatially weighted ground-level air pollutants, land-use variables, reanalysis datasets for meteorological variables, and others.

RESULTS: Total number of monitoring stations for ozone was 480 during the period 2001-2020. In the total area, our ensemble model showed a 10-fold cross-validated R2 of 0.840 during the entire study period. Urban areas showed the better prediction performance (R2 of 0.842), compared to the non-urban areas (R2 of 0.764).

CONCLUSIONS: This study can provide the high-resolution ozone prediction estimates with excellent performance, and our estimates can be used to estimate the more precise health impacts attributable to ozone.

P-0178 Long-term and short-term exposures to ambient ozone and sleep quality in China

Yao Zhang[1], Limei Ke[1], Xindong Ma[1], Qian Di[1]
[1]*Tsinghua University, Beijing, China*

BACKGROUND: Compelling evidence has documented that ground-level ozone has various adverse health impacts, causing elevated mortality and morbidity. However, few studies have focused on the effect of ozone on sleep quality.
METHOD: We assessed the causal relationship between short-term and long-term exposure to ozone and sleep quality in a national representative sample from the China Family Panel Study, using a difference-in-difference study design. We further followed ninety healthy Chinese adults from September 2020 to June 2021, ascertained their daily ozone exposure, and measured average daily accelerometer-based sleep architecture and resting-state EEG signals in 4 one-week-long sessions.

RESULTS: In the national sample, we found that every 1-□g/m3 increase in yearly and monthly ozone exposure was causally associated with 0.0047 (p = 0.047) and 0.0021 (p = 0.014) hours decline in night-time sleep duration, respectively. In the small sample with objective sleep measurements, we found that every 1-□g/m3 increase in daily ozone exposure was associated with 0.19 minutes decrease in night-time sleep duration (p = 0.031), 0.058 percentage decrease in sleep efficiency (p < 0.001), 0.071 minutes increase in sleep latency (p = 0.007) and 0.20 minutes increase in wake after sleep onset (p = 0.0016) in a quasi-linear pattern. Interestingly, we also found that short-term ozone exposure was directly associated with altered EEG pattern, with sleep quality playing as a potential mediating role.

CONCLUSIONS: This study indicates that long-term and short-term ozone exposure has adverse impact on sleep health and might impair brain functioning. More hidden adverse health effects of ozone are worth exploring.

P-0179 Exposure to outdoor $PM_{2.5}$ and Risk of Upper Gastrointestinal Cancers in a Large Prospective U.S. Cohort

Natalie Prtichett[1,2], Jared Fisher[1], George Gray[3], Joel Kaufman[2], Debra Silverman[1], Sandy Dawsey[1], Rena Jones[1]
[1]National Cancer Institute (U.S.), Rockville, USA, [2]University of Washington, Seattle, USA, [3]George Washington University, Washington, USA

BACKGROUND AND AIM: Studies of outdoor air pollution and upper gastrointestinal (UGI) cancers are limited, and few have evaluated heterogeneity in effects by histologic subtype. We investigated the relationship between ambient fine particulate matter ($PM_{2.5}$) and UGI cancer risk in a large prospective cohort.

METHODS: Our analysis included 456,472 participants of the NIH-AARP Diet and Health Study in 6 U.S. states (California, Florida, Louisiana, New Jersey, North Carolina, and Pennsylvania) and 2 metropolitan areas (Atlanta, Georgia and Detroit, Michigan). We used annual estimates from a historical spatiotemporal model to assess average residential $PM_{2.5}$ concentrations during a 15-year period (1980-1994) prior to enrollment in 1995-1996. We used Cox regression to estimate hazard ratios and 95% confidence intervals (HR [CI]) for risk of incident UGI (esophageal and gastric) cancers overall and by histologic subtype per 10µg/m3 increase in $PM_{2.5}$. Models were adjusted for age, smoking, alcohol intake, body mass index (BMI), race/ethnicity, and catchment area and separately adjusted for residential nitrogen dioxide (NO_2) concentrations. We ran models stratified by smoking status, sex, and BMI, and evaluated statistical interaction via Wald tests.

RESULTS: We found no overall $PM_{2.5}$-UGI cancer association in follow-up through 2011 (N=2,352 cases). Increased risk of esophageal squamous cell carcinoma (N=244) was suggested (HR:1.50 [0.95-2.37] per 10µg/m^3) and stronger among men (HR=1.80 [1.06-3.07]) than women (HR=1.01 [0.50-2.09]), although the interaction was non-significant (p-interaction=0.4). There was no association with esophageal adenocarcinoma (n=774). We observed a small, nonsignificant increased risk for gastric noncardia adenocarcinoma (n=898; HR=1.06 [0.84-1.35]); risk of gastric cardia adenocarcinoma (N=577) was increased only among never smokers (p-interaction=0.01). There were no differences in relationships by BMI, and NO_2 adjustment did not change associations.

CONCLUSIONS: Our novel investigation provides evidence of a relationship between $PM_{2.5}$ and specific UGI cancer subtypes. Stratified findings suggest important areas for future research.

P-0184 Long-term air pollution exposure and the incidence of cardiovascular diseases among American elderly population

Tingfan Jin[1], Qian Di[2], Weeberb J. Réquia[3], Mahdieh Danesh Yazdi[1], Edgar Castro[1], Qiao Zhu[4], Yifan Wang[4], Haisu Zhang[4], Liuhua Shi[4], Joel Schwartz[1]

[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Vanke School of Public Health, Tsinghua University, Beijing, China, [3]School of Public Policy and Government, Fundação Getúlio Vargas, Brazil, [4]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA

BACKGROUND AND AIM: Numerous studies have linked PM2.5, NO2, and ozone with cardiovascular diseases. Fewer studies have examined the multi-pollutant effects and effects at low pollutant levels, as well as potential effect modifications.

METHODS: Our study population included all Medicare enrollees continuously enrolled in the fee-for-service (FFS) program and both Medicare part A and part B in the contiguous U.S. from 2000 to 2016. We looked at the association between population-weighted ZIP code level annual average PM2.5, NO2, and warm-season ozone (May-October) and the first diagnosis of atrial fibrillation (AF), congestive heart failure (CHF), and stroke using Cox proportional hazards models. We adjusted for individual demographic characteristics and area-level covariates. We further examined these associations at low pollutant levels (PM2.5: <10 µg/m3¬, <8 µg/m3; NO2: <25 ppb, <18 ppb; warm-season ozone: <50 ppb, <40 ppb) and potential modifications by race and comorbidities (diabetes, hypertension, hyperlipidemia).

RESULTS: In the full cohorts, elevated PM2.5 and NO2 levels were associated with increased incidence of AF, CHF, and stroke. for each µg/m3 increase in annual PM2.5, HRs were 1.0059 (95%CI: 1.0054, 1.0064), 1.0260 (95%CI: 1.0256, 1.0264), and 1.0279 (95%CI: 1.0274, 1.0284), respectively. for each ppb increase in annual NO2, HRs were 1.0057 (95%CI: 1.0056, 1.0059), 1.0112 (95%CI: 1.0110, 1.0113), and 1.0095 (95%CI: 1.0093, 1.0096), respectively. Each one ppb increase in warm-season ozone was associated with an increased risk of CHF (HR=1.0035, 95%CI: 1.0033-1.0037) and stroke (HR=1.0026, 95%CI: 1.0023-1.0028). The effect estimates were stronger when we restricted the analyses to low pollutant levels. We also found generally higher risks for enrollees who are black or have diabetes.

CONCLUSIONS: Long-term exposure to PM2.5, NO2, and warm-season ozone were associated with risks of cardiovascular diseases, even at low pollutant levels. These associations were modified by race and several comorbidities.

KEYWORDS: Air Pollution, PM2.5, NO2, Ozone, Cardiovascular Diseases

P-0187 Fine particulate matter (PM2.5) levels in Brits, North West province, South Africa

Boitshoko Lekwe[1], Adewale Adeyemi[1], Janine Wichmann[1]
[1]*University of Pretoria, Pretoria, South Africa*

BACKGROUND AND AIM: Air pollution is a major threat to human health globally. In 2021, the World Health Organization (WHO) reported that 7 million premature deaths, mainly from non-communicable diseases are due to air pollution. Air quality studies on PM2.5 and its composition are lacking in South Africa and Africa. In order to find ways to reduce PM2.5 sources and its associated health impact in Brits, South Africa, it is necessary to determine PM2.5 levels and its chemical composition, followed by a source apportionment study.

METHODS: 24-hour PM2.5 filter samples were collected on the roof of a home in Brits every sixth day. In total, 61 samples and 10 duplicate samples were collected during 10 May 2020 and 5 May 2021. GilAir5 pumps and PM2.5 cyclones were used in the sampling. PM2.5 levels were determined with gravimetric analysis at the Air Quality Laboratory, School of Health Systems and Public Health, University of Pretoria. The yearly average was compared to the Averages were compared across seasons.

RESULTS: The average PM2.5 level during the sampling period was 17.7 µg/m³ (range: 3.6 -52.7 µg/m³), which is higher than the yearly WHO guideline (5 µg/m³), but lower that the yearly South African standard (20 µg/m³). The 24-hour PM2.5 levels exceeded the daily WHO guideline (15 µg/m³) and daily South African standard (40 µg/m³) on 17 and 2 occasions, respectively. The highest PM2.5 levels were observed during dusty spring season (52.7 µg/m³: September 2021) and winter (43.4 µg/m³: June 2021). Possible outdoor sources include industrial and mining activities. The lowest PM2.5 level (3.6 µg/m ³) was observed in May 2021 (autumn).

CONCLUSIONS: The PM2.5 levels in Brits exceeded the yearly and daily WHO guidelines on several occasions. This may pose a public health risk to the population.

KEYWORDS: PM2.5, outdoor air pollution, South Africa.

P-0188 Source apportionment of PM2.5 and PM2.5-bound trace elements in Pretoria, South Africa

Nandi Mwase[1], Peter Molnar[2], Johan Boman[2], Janine Wichmannn[1]
[1]University of Pretoria, Pretoria, South Africa, [2]University of Gothenburg, Gothenburg, Sweden

BACKGROUND AND AIM: Source apportionment studies are an important step in understanding primary sources and contributions of fine particulate matter (PM2.5). However, there is still research needed on the topic in South Africa. The aim of this study was to identify the possible sources of PM2.5 in Pretoria, during a 46-month study period.

METHODS: PM2.5 samples were collected on the roof of the School of Health Systems and Public Health (SHSPH), University of Pretoria in Pretoria from 18 April 2017 to 12 February 2021. Gravimetric analysis was done at the SHSPH Air Quality Lab. The trace element composition was determined with X-ray fluorescence at the University of Gothenburg, Sweden. Source apportionment was conducted using the US EPA 5.0 software.

RESULTS: The average PM2.5 concentration during the 46-month study period was 21.8±17.9 µg/m3 (range 0.29–138.9 µg/m3). The identified sources and their contribution to PM2.5 were mining (43.2%), biomass/coal burning (14.2%), secondary sulphur (12.1%), road traffic (11.3%), industry/base metal (8.7%), resuspended dust (8.5%) and vehicle exhaust (2.0%). Mining and biomass burning contributed to over half of the PM2.5 and higher contributions were observed during cold winter months. South Africa primarily depends on fossil fuel burning (i.e. coal) for energy through mining and production.

CONCLUSIONS: Reduction of PM2.5 at both local level in Pretoria can be implemented through the adjustments of the national air quality management act. Particularly introducing more safe national air quality standards that could lead to lower PM2.5 levels in Pretoria.

P-0192 Patterns of fuel use, cooking practices and factors associated with the use of LPG for cooking in peri-urban Cameroon

Esong Miranda Baame[1], Humphrey Atongno[1,4], Andre Pascal Goura[1], Emmanuel Betang[1], Mathew Shupler[2], Emily Nix[2], Elisa Pozzolo[2], Daniel Pope[2], Bertrand Hugo Ngahane Mbatchou[1,3]

[1]Douala General Hospital, Douala, Cameroon, [2]University of Liverpool, Department of Public Health, Policy and Systems., Liverpool, UK, [3]University of Douala, Faculty of Medicine and Pharmaceutical Sciences., Douala, Cameroon, [4]University of Buea, Faculty of Health Sciences, Department of Public Health, Buea, Cameroon

BACKGROUND AND AIM: Over three billion people, mostly living in low and middle income countries (LMICs), are exposed to household air pollution from reliance on polluting fuels (e.g. wood, charcoal). There is a dearth of information on barriers to adoption and sustained use of clean cooking fuels, (e.g. liquefied petroleum gas (LPG)) in remote locations in sub-Saharan Africa.

METHODS: A cross-sectional demographic and fuel use survey was completed by approximately 1500 household cooks from peri-urban Mbalmayo in Central Cameroon. Stratified random sampling was conducted to identify approximately 200 clean (LPG) and 200 polluting (e.g. wood) cooking fuel users who completed in-depth surveys on individual and household characteristics that were potentially associated with cooking behavior and fuel choice.

RESULTS: Among households using solid fuels (n=196), the main reported barrier to LPG adoption included the initial cost of LPG equipment (n=87; 59%). Concerns over LPG safety were a significant concern in both users and non-users of LPG (n=366; 83.6% perceived LPG to be dangerous). Decision making over choice of cooking fuel was approximately equally split between the main cook (typically women) and the head of household (usually men); men were in charge of decision making regarding cooking fuel adoption among 41.4% (n=121) LPG users and 56.2% (n=82) of biomass users. Stacking was universal (100%) amongst LPG users, with 70% LPG use. Free secondary fuel and a distance 20-30minutes from retail point reduced LPG use by 20% and 10% respectively. Household head unemployed (O.R 2,057, p-value .000), No formal education (O.R 15.200,p-value .006), and Cost (O.R 2.489, p-value 0.000) were all associated with the non-adoption of LPG.

CONCLUSIONS: Addressing safety concerns through education, and financially supporting households (e.g. through microfinance) will considerably scale LPG adoption in peri-urban Cameroon. Policies to facilitate LPG adoption should be targeted to both genders.

KEYWORDS: LPG, clean cooking, adoption

P-0193 Long-term Total and Source-specific PM2.5 in Relation to Incident Dementia in the U.S.

Boya Zhang[1], Jennifer Weuve[2], Kenneth M. Langa[3,4,5,6], Adam A. Szpiro[7], Carlos Mendes de Leon[1], Jessica Faul[8], Jiaqi Gao[1], Joel Kaufman[9,10,11], Richard Hirth[12,13], Jennifer D'Souza[1], Sara D. Adar[1]

[1]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, USA, [2]Department of Epidemiology, 715 Albany Street, Boston University School of Public Health, Boston, USA, [3]Institute for Social Research, University of Michigan Medical School, Ann Arbor, USA, [4]University of Michigan Medical School, Ann Arbor, USA, [5]Institute for Healthcare Policy and Innovation, University of Michigan, Ann Arbor, USA, [6]Veterans Affairs Center for Clinical Management Research, Ann Arbor, USA, [7]Department of Biostatistics, University of Washington, Seattle, USA, [8]Survey Research Center, University of Michigan, Ann Arbor, USA, [9]Department of Epidemiology, School of Public Health, University of Washington, Seattle, USA, [10]Departments of Environmental and Occupational Health Sciences, and Epidemiology, University of Washington School of Public Health, Seattle, USA, [11]Department of Medicine, School of Medicine, University of Washington, Seattle, USA, [12]Department of Health Management and Policy, University of Michigan School of Public Health, Ann Arbor, USA, [13]Department of Internal Medicine, University of Michigan, Ann Arbor, USA

BACKGROUND AND AIM: Emerging, but sometimes inconsistent, associations have been observed between PM2.5 and incident dementia. One possible explanation for differing associations across studies could be differing toxicity by source. We investigated the associations of long-term exposures to total and source-specific PM2.5 with incident dementia in a national, population-based cohort.

METHODS: We used biennial data between 1998 and 2016 from participants >50 years in the Health and Retirement Study. Incident dementia was identified using a validated algorithm based on cognitive testing and informant information. We predicted 10-year average total PM2.5 at participant residences before each interview using spatiotemporal modeling. Then, we derived source-specific PM2.5 by leveraging spatially refined fractions of PM2.5 from agriculture, traffic, energy, industry, open-fire and windblown dust as estimated by GEOS-Chem. Associations with incident dementia were estimated with Cox models, adjusting for individual demographics, area-level characteristics, time, and geographic trends.

RESULTS: Among 27,857 participants, 4,105 (15%) developed dementia during follow-up. Mean PM2.5 levels were 11.5+3.7 µg/m3 overall, with the largest contributing individual sectors of agriculture (1.6+0.6) and the smallest of windblown dust (0.2+0.4). In single-source models, we observed a hazard ratio of 1.16 (95% CI: 1.05 to 1.29), 1.20 (1.01 to 1.41), 1,65 (0.98 to 2.77), 1.07 (0.94 to 1.22) and 1.07 (1.02 to 1.13) for incident dementia per 1-µg/m³ greater PM2.5 from agriculture, road traffic, non-road traffic, energy coal, and open fires, respectively. These associations remained after adjustment for the sum of PM2.5 from other sources. Associations corresponding to PM2.5 from other sources were inconsistent with adverse effects.

CONCLUSIONS: We found evidence that specific emission sources may be more important in the relationship between PM2.5 and dementia risk, suggesting the possibility of targeted interventions to reduce the burden of dementia in the future.

KEYWORDS: Air Pollution, Source-specific PM2.5, Dementia

P-0195 Forecasting greenhouse gas emissions from road traffic in 2040 across the Greater Montreal Region of Canada

Ying Liu[1], Marianne Hatzopoulou[2], Arman Gangi[2], Audrey Smargiassi[1]
[1]*University of Montreal, Montreal, Canada,* [2]*University of Toronto, Toronto, Canada*

BACKGROUND AND AIM: Road traffic is a major source of ambient air pollution and greenhouse gas (GHG) emissions in urban areas and is linked with human health impacts and climate change. Urban land-use planning and travel behavior greatly influence on-road traffic. The aim of this study was to map the spatial distributions of on-road traffic and its associated GHG emissions across the Greater Montreal Region (Canada) for the year 2040 under different population growth and land-use scenarios.

METHODS: A random forest model was developed to estimate the annual average daily traffic (AADT) for each road segment based on the 2018 traffic count data collected from in-situ monitoring stations and Google aerial images, an origin-destination travel survey, points of interest from OpenStreetMap, and sociodemographic census data. The spatial distribution of the population in 2040 was then predicted under three population growth scenarios. According to the forecasted population distributions in 2040, we modified the population-related predictors in the 2018 random forest model to map AADT distributions for 2040. Finally, vehicle induced GHG emissions in 2040 were estimated based on AADT.

RESULTS: Our random forest model performed well for AADT prediction, resulting in an R2 of 0.66 in leave-one-out cross-validation. Vehicle induced GHG emissions will increase 13.28% in 2040 compared to 2018 if population growth maintains past trends. GHG emissions will only increase 4.30% and 2.36% with 60% of the new population located within one kilometer of subway stations and with telecommuting increasing by 12.5% and 40% respectively.

CONCLUSIONS: Allocating new population in areas with transportation infrastructure and increasing telecommuting can reduce traffic-associated GHG emissions. Our modelling work demonstrates the potential influences of travel behaviors and land use planning on human health and climate change.

KEYWORDS: greenhouse gas emission, traffic count, air pollution, population, land use.

P-0197 A Review of studies using Air Q software for prediction of Air Pollution Health effects in Iran

Narges Khanjani[1], Mohammad Amin Farahmand[1], Marzieh Eslahi[1]
[1]*Kerman University of Medical Sciences, Kerman, Islamic Republic of Iran*

BACKGROUND AND AIM: Exposure to air pollutants may lead to various health effects and is a major public health issue. Concerns about these effects exist in both developed and developing countries. The Air Q software was developed to estimate the health impacts of air pollution based on reported levels of air pollutants in real world studies. In Iran several studies have been conducted to estimate human morbidity and mortality based on this software. We conducted this review to summarize articles which have predicted the effects of air pollution on human health in Iran using Air Q.

METHODS: We conducted a systematic search for relevant studies published until 24 April 2021 in Web of Science, PubMed, Scopus and SID (Scientific Information Database which includes articles in Farsi language). We applied no time or language restrictions.

RESULTS: 44 studies out of 525 identified articles met our inclusion criteria. The main air pollutants under investigation were particulate matter (PM), NO2, O3 and SO2. Most studies were conducted in metropolitan areas, such as Ahvaz (9 studies), Tehran (9 studies), and Shiraz (7 studies). In all studies the levels of most air pollutants were higher than the 2005 WHO guideline levels and were predicted to be related to considerable health effects. However, it was not possible to aggregate the results and report the total number of casualties during these years, because studies were done in different cities with fluctuating levels of multiple pollutants and in different years and time frames.

CONCLUSIONS: This systematic review showed that air pollution remains at unacceptably high levels resulting in substantial detrimental health effects in various Iranian cities. Using clean renewable energies, increasing human capital and increasing green spaces and vegetation can help improve air pollution and decrease human casualties in Iran.

KEYWORDS: Air Pollution, Air Q, Iran

P-0200 Ambient air pollutants and pulmonary function in children after COVID-19 pandemic

I-Jen Wang[1,2,3]

[1]Department of Pediatrics, Taipei Hospital Ministry of Health and Welfare, Taipei, Taiwan, [2]School of Medicine, National Yang-Ming University, Taipei, Taiwan, [3]College of Public Health, China Medical University, Taichung, Taiwan

BACKGROUND AND AIM: The acute effects of air pollutants on pulmonary function remain unclear. After COVID-19 spreads, fear drives patients away from hospitals. Smartphone applications may help asthma care. This study investigated the acute effects of ambient air pollution on pulmonary function among asthma in children by smartphone applications.

METHODS: We designed a smartphone app to provide timely support for patients with asthma. Peak expiratory flow (PEF) recordings were made twice daily and was corrected by age and gender. The severity of asthma by GINA guideline and asthma control test (ACT) test score were also monitored. Ambient air pollution parameters of particulate matter (PM), ozone(O3), oxides of nitrogen (NO2),carbon monoxide (CO), and sulfur dioxide (SO2) were measured from each nearby air monitoring station at each time while PEF recordings by linking to Global Positioning System. Allergen-specific IgE were also measured by MAST. Effects of exposure to pollutants on PEF were assessed in person-days of observations by GEE model.

RESULTS: In lag 0 (the same day), PM10, NO2, CO, and SO2 were negatively correlated with PEF (p=0.030, 0.031, 0.008, 0.017). In lag1 (one day before), NO2, CO, and SO2 were found to be correlated PEF (p=0.005, 0.010, 0.025). In lag2, PM2.5, PM10, NO2, and SO2 were associated with PEF (p=0.031, 0.023, 0.031, 0.005). Analyses stratified by mite allergen sensitization revealed that PM10, NO2, CO, and SO2 air pollutant levels negatively correlated with PEF only in mite sensitization children.

CONCLUSIONS: Exposure to air pollutants can lead to acute effects on the pulmonary function in children with asthma. Pollutants may reduce lung function and have different effects over time. Mite sensitization might modify the effect of air pollutant exposures on lung function on asthma. Smartphone applications are readily available tools to help individual air monitoring and asthma care after COVID-19 pandemic.

P-0202 Measurement of indoor and outdoor SO2 and NO2 and indoor BTEX/VOC concentrations at pre-schools in Mabopane Township, Tshwane Metropolitan Municipality, Gauteng Province, South Africa

Joyce Shirinde[1], Mandla Bhuda[1], Matome Rapatsa[1], Sean Patrick[1], Janine Wichmann[1]
[1]*University of Pretoria, Pretoria, South Africa*

INTRODUCTION: Children spend approximately 7 hours a day at pre-schools, mostly indoors. The aim of the study was to assess indoor and outdoor SO2 and NO2 and indoor BTEX/VOC at pre-schools situated in Mabopane, Tshwane Metropolitan Municipality, Gauteng Province, South Africa
Methodology: Six pre-schools in the study area were purposively selected to participate in the study. Indoor and outdoor levels of SO2 and NO2, and indoor BTEX/VOC were assessed over 24hrs for two weeks using Radiello passive samplers. Indoor temperature and relative humidity were also monitored using temperature data loggers. The outdoor temperature and relative humidity data was provided by South African Weather Services.

RESULTS: The indoor and outdoor SO2 median levels were 0.22 µg.m-3 and 1.12 µg.m-3 The indoor and outdoor NO2 median levels were 21.10 µg.m-3 and 17.22 µg.m-3, respectively. The indoor/outdoor ratios for NO2 and SO2 were 0.20 and 1.07, respectively. The infiltration factor parameter estimates of NO2 and SO2 were 0.48 and 0.01. The indoor and outdoor temperature and relative humidity levels were 2.11 °C and 22.4 °C, and 43.14% and 57%. The median concentrations of BTEX ranged from 0.5µg/m3 to 43.19µg/m3. The Kruskal-Wallis test showed that the level of benzene in the six schools differed significantly - χ^2=13.87,p-value=0.016. The levels of toluene at the six school did not differ significantly - χ^2=5.96,p-value=0.310. There was no statistically significant difference between the six schools in terms of ethylbenzene - χ^2=6.30,p-value=0.2710. The p-value for Xylene showed there was no statistically significant difference between the six schools - χ^2=6.01,p-value=0.2967..

CONCLUSIONS: The levels of outdoor NO2, SO2 and BTEX/VOC were below the South African National Ambient Air Quality Standards and WHO Air Quality Guidelines. However, they still pose a health risk for children attending pre-school in the area.

KEYWORDS: Air pollution; SO2, NO2, BTEX/VOC, Temperature; Relative humidity; South African

P-0203 Health Risk Assessment and Projection of Municipal Solid Waste Disposal in China

Jianxun Yang[1], Yunqi Liu[2], Yanyan Qiu[1], Qi Zhou[1], Miaomiao Liu[1], Jun Bi[1]
[1]Nanjing University, Nanjing, China, [2]Nanjing Foreign Language School, Nanjing, China

BACKGROUND: China's Municipal solid waste (MSW) is growing rapidly. Incineration and landfill are two main approaches of MSW disposal and both of them emit different types of ambient pollutants and threaten human health. There lacks systematic health risk assessment and projections of MSW incineration and landfill in China.

METHODS: We established the historical MSW incineration and landfill emission inventories from 2015 to 2017 and used the Gaussian Diffusion Model to simulate the spatial distribution of ambient pollutants. We then used Risk Quotients Model to assess the non-carcinogenic and carcinogenic health risks through inhalation exposure. Besides, we set seven possible MSW incineration development scenarios to predict health risk levels in 2035, considering the effect of population growth, incineration rate, waste classification and recycling, and technology progress.

RESULTS: The results show that non-carcinogenic risk caused by MSW incineration from 2015 to 2017 was lower than landfill at the national level. Both of them were meet the maximum acceptable level (HI ≤ 1). From 2015 to 2017, carcinogenic risks caused by landfill were 9.42 × 10-6, 9.40 × 10-6, 9.37 × 10-6, nine times larger than the maximum acceptable level (CR ≤ 1×10-6). Carcinogenic risks caused by incineration were 5.71 × 10-6, 7.92 × 10-6, 9.44 × 10-6, five to nine times larger than the maximum acceptable level. Projection results show that compared to the baseline scenario, through classification and recycling, changing incinerator furnace, and improving, national health risk levels will be decreased by 24%, 94% and 97%.

CONCLUSIONS: We assessed the health risks caused by MSF disposal and found MSF incineration a relatively low risk alternative disposal approach compared to waste landfill. In the future, local government should reduce MSF disposal health risks by optimizing the selection of incinerators locations, improving the garbage sorting recycling system, and strengthening information disclosure and communications.

P-0214 Demonstration project to transition from gas to electric induction stoves in affordable housing units: the 'Out of Gas' pilot study

Ashlinn Quinn[1], Annie Carforo[2], Michelle Feliciano[3], Francis Rodriguez[3], Heather Miller[1], Ricardo Piedrahita[1], Misbath Daouda[4], Darby Jack[4], Michael Johnson[1]

[1]Berkeley Air Monitoring Group, Fort Collins, USA, [2]We Act for Environmental Justice, New York, USA, [3]Association for Energy Affordability, New York, USA, [4]Columbia Mailman School of Public Health, New York, USA

BACKGROUND: Natural gas-fueled stoves are a major source of indoor residential NO_2, which has been associated with asthma exacerbations. WE ACT for Environmental Justice launched 'Out of Gas' in 2021 to investigate the feasibility of transitioning from fossil fuels to renewable energy in affordable housing. 20 families in New York City Housing Authority units in the Bronx, New York City were selected to receive electric induction stoves to replace existing gas stoves. Air pollution (primarily NO_2 and PM2.5) and stove usage are being monitored before and after the transition. The pilot will be repeated in Buffalo, NY.

METHODS: In-kitchen stationary monitoring of NO_2, PM2.5, CO_2, and CO was conducted for 7 days at baseline and after stove switch-out using the Home Health Box (Access Sensor Technologies, Fort Collins, CO). Cooking events were identified using temperature loggers (Wellzion Electronics Technology Co, China). Pollutant concentrations were analyzed during cooking vs. non-cooking times and compared to ambient levels from nearby New York Department of Environmental Conservation stations.

RESULTS: Mean (SD) [median] NO_2 kitchen concentrations at baseline (before appliance switch-out) were 47.0 (60.6) [34.6] ppb, 27.8 ppb higher than ambient levels during the monitoring period. PM2.5 concentrations were 17.2 (40.1) [7.3] $\mu g/m^3$, 7.9 $\mu g/m^3$ higher than ambient levels. Levels of both pollutants were higher during cooking, with NO_2 averaging 117.5 (125.5) [82.3] ppb during cooking versus 35.5 (25.8) [32.5] ppb otherwise. The corresponding values for PM2.5 were 33.4 (63.7) [11.5] $\mu g/m^3$ during cooking and 14.5 (33.8) [7.0] $\mu g/m^3$ otherwise. On average, cooking was associated with an increase of 63.3 ppb NO_2 and 18.3 $\mu g/m^3$ PM2.5 above baseline levels.

CONCLUSIONS: Cooking with gas stoves contributes substantially to indoor residential NO_2 and PM2.5 concentrations. Switching to efficient electric induction stoves could reduce the exposure of potentially vulnerable populations to these pollutants.

KEYWORDS: NO_2, PM2.5, cookstoves

P-0217 “[Classes] are highly affected because of the smoke”: Impacts of cooking on air pollution and health among three schools in Nairobi, Kenya

Emily Nix[1], Willah Simiyu, Arthur Gohole[2], James Mwitari[2], Matthew Shupler[1], Elisa Puzzolo[1], Federico Lorenzetti[1], Serena Saligari[1], Rachel Anderson de Cuevas[1], Margaret Nyongesa[2], Daniel Pope[1]
[1]University of Liverpool, Liverpool, UK, [2]Amref International University, Nairobi, Kenya

BACKGROUND AND AIM: Links between cooking with polluting fuels (e.g., wood, charcoal), air pollution and health are well-established. However, few studies have been conducted in schools that rely on such fuels for catering. This study presents the first investigation of air pollution, cooking, and health in schools in Nairobi, Kenya.

METHODS: We carried out an in-depth study in three schools (two primary schools and a college) in an informal settlement using wood and/or charcoal for catering. 24-hour air pollution measurements (particulate matter (PM2.5) and carbon monoxide (CO)) were collected to assess concentrations in the main kitchen and a nearby classroom, and personal exposure of the main cook. Surveys with catering staff collected data on the health impacts on air pollution. Focus groups with catering staff, teachers and senior management were used to understand impacts on health and the school environment, perspectives, and pathways for clean fuel transitions.

RESULTS: Mean 24-hr PM2.5 cook exposures ranged from 97.6 -343.7 µg/m3, and 24hr concentrations ranged from 64.9-171.7 µg/m3 and 66.3-903.9 µg/m3 in classrooms and kitchens, respectively –all exceeding WHO 24-hr air quality guidelines. Reported impacts from the pollution by catering staff included eye irritation, wheezing and headaches, leading to the frequent avoidance of smoke. Focus groups highlighted disturbance to teaching from smoke and how students experienced coughing and sneezing. While the impact of cooking with polluting fuels was understood, opportunities for fuel transitions were limited by catering needs and external organisations’ agendas.

CONCLUSIONS: Despite cooking not occurring in classrooms, minimum concentrations were similar to kitchens, suggesting students are exposed to unhealthy air pollution levels. Transitions in schools to clean fuels can likely advance health and minimize disturbances to teaching. Building awareness on links between cooking, air pollution and health and developing solutions that support schools catering needs is vital to support transitions.

P-0221 Correlation between extreme/unusual ozone events and corona effect from electric power transmission & distribution grids. Assessing the health and environmental impact of high-voltage direct current (HVDC) grid on ozone ground levels in Sao Paulo metropolitan area, Brazil.

Pedro Diaz Peralta[1], Claudia Ribeiro Pereira Nunes[1]
[1]*Yale School of the Environment- Michelle L. Bell´s Research Group, New Haven -CT, USA*

BACKGROUND AND AIM: 1- Ozone ground levels pose a risk for public health
2- The increasing ozone levels measured in parts of the metropolitan area of Sao Paulo have brought the attention of researchers. Proposed mechanisms do not provide a clear outcome for establishing root causes, and for clarifying sources of ozone. Spatial distribution of ozone also depends on wind patterns.
3- As an alternate hypothesis for explaining unusual high levels of ozone, the corona discharge from electric transmission grid, known as corona effect, can play a significative role in the absence of, or in coincidence with other concomitant factors, to explain ozone (O3) and nitric oxide (NO) unusual levels. Negative coronas emits more ozone than Positive coronas.
4- The Environmental Protection Agency- EPA, found in a report of 1973 (EPA-650/4-73-003), following a research carried out in areas of high concentration of transmission lines that "under minimal wind conditions, such transmission line concentrations can produce sizeable local ozone levels."
5- Research applies geospatial and statistical analysis with the aim of better understanding correlations between exposures and ozone levels.

METHODS: Geographic Information System (GIS)-based systems with average grid cell edge length of 10 km minimum. Global InMAP (Intervention Model for Air Pollution) with a variable resolution grid (4 km horizontal grid cell widths) in combination with GEOS- Chem simulations. Data analysis by machine-learning model.

RESULTS: Applying Predictive Machine Learning algorithm as regression models, research found that coronas could generate significant ozone levels downwind of the power line.

CONCLUSIONS: Evidence of correlation between unusual ozone measurements and location of key power electric grid transmission lines and distribution centers with potential for corona effect are found in Sao Paulo state and Sao Paulo city metropolitan area.

KEYWORDS: Corona effect, ozone, electric grids, spatial simulation, wind patterns, air pollution

P-0222 Exposure to Household Air Pollution (HAP) and measures of central hemodynamic parameters among Bangladeshi population- A cross-sectional study.

Mohammad Shahriar[1], Mahbubul Eunus[2], Shyfuddin Ahmed[3,5], Muhammad Ashique Haider Chowdhury[6], Shirmin Kader[3], Bilkis Begum[7], Rabab Shams[3], Golam Sarwar[3], Tariqul Islam[3], Dewan Alam[8], Faruque Parvez[4], Rubhana Raqib[3], Habibul Ahsan[1], Muhammad Yunus[3]

[1]Institute for Population and Precision Health, The University of Chicago, Chicago, USA, [2]UChicago Research Bangladesh (URB), Dhaka, Bangladesh, [3]icddr,b, Dhaka, Bangladesh, [4]Mailman School of Public Health, Columbia University, NY, USA, [5]Robert Stempel College of Public Health and Social Work, Florida International University, Miami, USA, [6]Department of Public Health Sciences, Biological Science Division, The University of Chicago, Chicago, USA, [7]Chemistry Division, Atomic Energy Center, Dhaka, Bangladesh, [8]School of Kinesiology and Health Science, Faculty of Health, York University, Toronto, Canada

Household Air Population (HAP) has been linked to an array of adverse health hazards, including cardiovascular mortality and morbidity. We have assessed whether household air pollution (HAP) is associated with hemodynamic parameters as part of the Bangladesh Global Environmental and Occupational Health (GEO Health) project.

We assessed central hemodynamic parameters-Systolic Blood Pressure (SBP), Diastolic Blood Pressure (DBP), and Heart rate (HR) using a standard cuff sphygmomanometer (Omron) and Mean Arterial Pressure (MAP) and Pulse Pressure (PP) using the standard formula. The exposures to particulate matter < 2.5µm (PM2.5) and Black Carbon (BC) from biomass fuel were measured for 24 hours using a personal monitor, RTI MicroPEM (RTI International, NC), among healthy, non-smoking women (n=400) and men (n=200). A multiple linear regression model adjusted for potential confounders was used to examine the association between HAP exposures and hemodynamic outcomes.

The average 24-hour PM2.5 concentration was 167.7 µgm-3 for females and 98.0µgm-3 for males. The average 24-hour concentration of BC was 14.1µgm-3 for females and 10.3µgm-3 for males. In the adjusted multivariable regression model, an 1% increase in BC resulted in a 1.6 mm of Hg reduction in MAP (95% CI: -3.24, -.03 mm of Hg, P=0.04), 2.8 mm of Hg increase in PP (95% CI: 1.55, 4.22 mm of Hg, P=0.00) and 2.6 mm of Hg reduction in DBP (95% CI: -4.09, -1.10 mm of Hg, P=0.00). No association was observed between BC and SBP as well as BC and HR. PM2.5 was not associated with any of the hemodynamic parameters even after adjusting for age, cooking duration, household income, and Body mass index (BMI).

This population-based study provides evidence that exposure to HAP (BC) is linked with central hemodynamic parameters, especially MAP and PP, which have negative implications for cardiovascular health when they become high and low.

HAP, Hemodynamics, Bangladesh

P-0228 Fine particulate matter shown to influence cytokine and chemokine levels during pregnancy

Amanda Goodrich[1], Chelsea Kelland[1,2], Heather Volk[3], Judy Van De Water[1,2], Rebecca Schmidt[1,2]
[1]University of California, Davis, Davis, USA, [2]UC Davis MIND Institute, Sacramento, USA, [3]Johns Hopkins University, Baltimore, USA

BACKGROUND AND AIM: Pregnancy is a period vulnerable to environmental exposures like air pollution that disrupt immune regulation or induce inflammatory responses.

METHODS: Participants were 148 mother–child pairs from MARBLES (Markers of Autism Risk in Babies – Learning Early Signs), a high familial risk ASD cohort. Self-reported maternal address history was obtained for the entire pregnancy period and the 3 months prior to pregnancy. Daily PM2.5 (particulate matter < 2.5 µm in diameter) exposure values were spatially interpolated from the U.S. Environmental Protection Agency's (EPA) Air Quality System (AQS) monitoring stations' locations to the residence locations using inverse distance-squared weighting. Trimester-specific PM2.5 averages were assigned. Maternal plasma samples from each trimester were quantified for 29 cytokines and chemokines using Luminex multiplex analysis technology. Cytokines and chemokines were natural log transformed and standardized. Betas and 95% confidence intervals (CIs) for an interquartile range (IQR) change in PM2.5 were estimated using confounder-adjusted linear regression.

RESULTS: Pre-pregnancy PM2.5 was associated with a statistically significant increase in first trimester IL-8, IL-1β, MIP-1β, and TNFα values and in second trimester IL-7 and EGF values, and with a statistically significant decrease in third trimester IL-10. Trimester 2 PM2.5 was associated with a statistically significant decrease in second trimester IL-12 (p40) and EGF and with third trimester GM-CSF, IL-10, and IL-15. Trimester 3 PM2.5 was associated with a statistically significant decrease in third trimester IFN-γ, IL-2, IL-1ra, and IL-5.

CONCLUSIONS: PM2.5 appears to be associated with a shift from typical cytokine and chemokine levels that differs by trimester. Future studies should examine the ramification of such changes in cytokine and chemokine profiles associated with air pollution exposure.

P-0229 Ultrafine particulate matter exposure during second year of life associated with increased risk of autism spectrum disorder in mixtures model

Amanda Goodrich[1], Michael Kleeman[1], Daniel Tancredi[1], Yunin Ludeña[1], Deborah Bennett[1], Irva Hertz-Picciotto[1,2], Rebecca Schmidt[1,2]

[1]University of California, Davis, Davis, USA, [2]UC Davis MIND Institute, Sacramento, USA

BACKGROUND AND AIM: Prenatal and early life exposure to air pollution has been shown to be associated with autism spectrum disorder (ASD) risk, but the results have been mixed and to our knowledge, no study has reported on effects of combined exposures to multiple air pollutants using a mixtures approach. We applied a multidomain, multipollutant approach to assess the association between ASD and air pollution.

METHODS: The study consisted of 484 TD children and 707 children with ASD from the CHARGE case-control study. Air pollution exposures for NO2, and Ozone, fine (PM2.5) and ultrafine (PM0.1) particles were predicted using a chemical transport model with statistical bias adjustment based on ground-based monitors. Averages were calculated for each pregnancy period (pre-pregnancy, each trimester of pregnancy, and first and second year of life) for all births between the year 2000 and 2016. The air pollution (AP) variables were natural log transformed and then standardized. We estimated individual and joint effects of AP exposure with ASD and evaluated potential interactions among AP variables for each pregnancy period, using component-wise and hierarchal Bayesian Kernel Machine Regression (BKMR) models.

RESULTS: In component-wise BKMR models that included PM0.1, NO2, and Ozone, we found a strong increasing risk of ASD in year 2 of life with increasing PM0.1 (Posterior inclusion probability, PIP, = 0.99). This held true in hierarchal models when grouped by time or by pollutant. In component-wise BKMR models that included PM2.5, NO2, and Ozone, we found that NO2 and Ozone in years 1 and 2 were associated with ASD in an inverted U shape. No robust associations were observed in the prenatal or pregnancy periods.

CONCLUSIONS: PM0.1 appears to be associated with an increased risk of ASD in year 2 of life. Future research should examine ultrafine particulate matter in relation to ASD.

P-0231 Evaluation of adult and pediatric burns from domestic fuel use at the Douala General Hospital, Cameroon

Lifafa Kange[1], Frederico Lorenzentti[2], Humphrey Atongno[1,4], Emmanuel Betang[1], Elisa Puzzolo[2], Daniel Pope[2], 1,3 Bertrand Hugo Mbatchou Ngahane[1,3]

[1]Douala General Hospital, Douala, Cameroon, [2]University of Liverpool, Department of Public Health, Policy and Systems, Liverpool, UK, [3]University of Douala, Faculty of Medicine and Pharmaceutical Sciences., Douala, Cameroon, [4]University of Buea, Faculty of Health Sciences, Department of Public Health, Buea, Cameroon

BACKGROUND AND AIM: Burns have a significant contribution to the global burden of death and disability accounting for over 300,000 deaths occurring yearly, with majority in low-and middle-income countries where solid fuels are widely used for cooking. The aim of this study was to characterize burns from domestic fuel among burns patients received at the Douala General Hospital (DGH), Cameroon

METHODS: A descriptive study involving adult and paediatric burn patients admitted in the burn unit during a 6 months period at the DGH was conducted. A consecutive sampling was used to include the participants. The Global burn registry data collection tool with closed and open ended questions was used for data collection between September 2021 and February 2022.

RESULTS: A total of 61 patients participated, with a mean age of 25.8±20.3 years; majority were aged 1 to 10 years (31.1%) and 31 to 40 years (24.6%). Majority of the participants were males with 41(67.2%) participants. Majority of the burns were due to electrical causes (n=21; 34.4%) while flame from cooking were involved in 10 subjects (16.4%). The main parts of the body involved were the trunk (75%), arms (67.2%) and legs (67.2%). Among the participants with burns from cooking, the main sites were head (90%), arms (80%) and legs (70%). The total body surface was less than 20% in 29 participants (47.5%) and 21-40% in 16 (26.2%). The mortality rate was 24.6%, although insignificant (P=0.21), this rate was higher for burns from flame cooking than burns of other causes.

CONCLUSIONS: Burn injuries are frequent in Cameroon, with cooking fuels being responsible for 16.4% of them. The related mortality rate remains very high. It is therefore necessary to create awareness and reinforce strategies to reduce the burden of burn accidents.

KEYWORDS: Burns, cooking fuel, Africa, epidemiology

P-0244 Multiple Air Pollutants Exposure and Leukemia Incidence in Tehran, Iran

Zahra Khorrami[2], Mohsen Pourkhosravani[3], Marzieh Eslahi[1], Maysam Rezapour[4], Mohammad Esmail Akbari[2], Heresh Amini[5], Seyed Mahmood Taghavi-Shahri[5], Nino Künzli[6], Koorosh Etemad[2], Narges Khanjani[1]

[1]Kerman University of Medical Sciences, Kerman, Islamic Republic of Iran, [2]Shahid Beheshti University of Medical Sciences, Tehran, Iran, [3]Shahid Bahonar University of Kerman, Kerman, Iran, [4]Mazandaran University of Medical Sciences, Sari, Iran, [5]University of Copenhagen, Copenhagen, Denmark, [6]University of Basel, Basel, Switzerland

BACKGROUND AND AIM: Leukemia is one of the most common cancers and may be associated with exposure to environmental carcinogens, especially outdoor air pollutants. The objective of this study was to investigate the association of ambient air pollution and leukemia in Tehran, Iran.

METHODS: In this ecological study, data about the residential district of leukemia cases diagnosed from 2010 to 2016 were inquired from the Ministry of Health cancer database. Data from a previous study was used to determine long-term average exposure to different air pollutants in 22 districts of Tehran. Latent profile analysis (LPA) was used to classify pollutants in two exposure profiles. The association between air pollutants and leukemia incidence was analyzed by negative binomial regression.

RESULTS: The districts with higher concentrations for all pollutants were near the city center. The incidence rate ratio (IRR) was positive but non-significant for most of the air pollutants. However, annual mean NOx was directly and significantly associated with total leukemia incidence in the fully adjusted model (IRR (95% CI): 1.03 (1.003, 1.06) per 10 ppb increase). Based on LPA, districts with a higher multiple air-pollutants profile were also associated with higher leukemia incidence (IRR (95% CI): 1.003 (0.99, 1.007) per 1 ppb increase).

CONCLUSIONS: Our study shows that districts with higher air pollution (nitrogen oxides and multi-pollutants) have higher incidence rates of leukemia in Tehran, Iran. This study warrants conducting further research with individual human data and better control of confounding.

P-0253 Association between historical redlining and neighborhood deprivation in North Carolina

Monica Jimenez[1], Danielle T Lobdell[2], Alison K Krajewski[2], Kristen M Rappazzo[2], Lynne C Messer[3], Thomas J Luben[2]
[1]Oak Ridge Institute for Science and Education (ORISE) Postdoctoral Fellow at US EPA, Chapel Hill, USA, [2]US Environmental Protection Agency, Center for Public Health and Environmental Assessment, Research Triangle Park, USA, [3]OHSU-PSU School of Public Health, Portland, USA

BACKGROUND AND AIM: In the late 1930s, the Home Owners' Loan Corporation created maps that ranked neighborhoods considered high risk for mortgage lending; these ratings denied residents, usually racial, ethnic, and religious minorities, the opportunity to become homeowners and accumulate wealth. We explored whether historical designation as a redlined neighborhood predicted contemporary (2010) neighborhood-level deprivation in North Carolina (NC) cities (Asheville, Charlotte, Durham, Greensboro, Winston-Salem).

METHODS: We examined 142 NC census tracts with historical redlining data. Because neighborhoods can be disadvantaged in many ways, a composite index representing poverty, occupation, housing, employment, and education was used for determining the relationship between neighborhood deprivation and having been previously redlined. To create the exposure, we overlayed a census tract shapefile layer on high-resolution digital maps of historical redlining, assigning a redlining rating of Best (N=15), Still Desirable (N=14), Declining (N=73), or Hazardous (N=40). The ratings were further combined to create exposure categories as follows: Best or Still Desirable (BSD, referent), Declining, Hazardous, and a combined redlined areas category that included both Declining and Hazardous (DH). Linear models estimated the associations between historical redlining ratings and contemporary neighborhood deprivation.

RESULTS: Neighborhood deprivation scores ranged from -1.78 to 2.72, with a higher score indicating worse neighborhood deprivation. When comparing the combined redlined areas (DH) to BSD areas, we observed increasing neighborhood deprivation (1.34 increase in index score [95% CI: 1.01, 1.67]). We observed increasing neighborhood deprivation score when comparing Declining or Hazardous ratings individually to BSD areas (1.24 increase in score [95% CI: 0.93, 1.55]; 1.57 increase in score [95% CI: 1.15, 1.98], respectively).

CONCLUSIONS: Results suggest that redlined neighborhoods are associated with increased neighborhood deprivation 70 years later and may contribute to disparities in exposure to detrimental environments and associated effects on health and well-being.

KEYWORDS: Redlining, neighborhood deprivation, built environment

P-0261 Reduction of noise-induced change in cardiovascular functions and subjective sensations when using passive and active hearing protection devices

Yi-Chun Lin[1], Ai-Luen Tsai[1], Chen-Peng Chen[1]
[1]*China Medical University Department of Occupational Safety and Health, Taichung City, Taiwan*

Impulse and continuous noise occur frequently in the workplace and harm the physiological and psychological capability of the workers. This study investigated how the exposure to noise of varying acoustic pressure and frequency influenced cardiovascular functions and subjective sensations of people and how the use of passive and active hearing protection devices (HPDs) reduced the impacts.
Twenty participants (10 males and 10 females) were exposed to three levels of sound for 5 min each level in the order of ascending acoustic pressure, 65, 85, or 100 dBA. The participants used either foam earplugs or electronic earplugs that compressed noise while allowing transmission of speech. The experiment was first conducted at a noise frequency of 200 Hz and repeated at 1,000 Hz. Changes in cardiovascular functions (blood pressures, heart rate, and metabolic rate) and those potentially involved in local hemodynamics (skin capillary blood flow and transepidermal water loss) of the participants were measured intermittently. Subjective perceptions of noise intensity, harshness, annoyance, and reduction in attention and short-term memory were also evaluated.
The noise exposure significantly increased the blood pressures and heart rate and the sensations of noise intensity, annoyance and sharpness. The most prominent increase was observed in the first 5 min of exposure, even though the acoustic pressure during this stage was the same as that of the background (white noise). The cardiovascular functions of the participants returned to the baseline 15 min after the exposure ended. The foam earplugs provided better reduction in sounds of low frequency whereas the electronic plugs performed better against those of high frequency.
The physiological impacts of noise exposure were determined by the physical characteristics of the noise. On-site evaluation of the acoustic environment and job requirements should be performed before HPDs were selected to manage the exposure.

KEYWORDS: Noise exposure, hearing protection devices.

P-0279 Heat Policies and AC Availability in US Prison Systems

Marjorie Segule[1], Jessica Lin[1], Joseph Allen[1], Monik Jimenez[2,3]
[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Harvard Medical School, Boston, USA, [3]Brigham and Women's Hospital, Boston, USA

BACKGROUND AND AIM: Climate change will increase the number of hot days and heatwaves leaving incarcerated populations particularly vulnerable to extreme heat due to their lack of agency and control over their heat exposure. Previous prison heat policy analysis has not utilized Heat Index to provide context for the implementation of policies or had access to air-conditioning data. We aimed to examine the coverage and gaps of US prison system heat policies and air-conditioning access.

METHODS: Prison heat policies were identified using 52 prison system (50 states, DC, and Federal Bureau of Prisons) websites and complemented by state legislation. Heat policies were analyzed using the National Weather Service's (NWS) Heat Index Calculator on maximum reported temperature values. Facility-level air-conditioning data for 18 prison systems were public or received through public records requests by UCLA's COVID-19 Behind Bars, with facility function, capacity, and heat risk collected from federal, state, and the Intercept's Climate and Punishment datasets.

RESULTS: Half of the prison systems had publicly-available heat policies (n=52), of which 81% included temperature values (n=21). 64% of heat indices using maximum indoor temperature (n=14) would be classified as "caution" and 63% of heat indices using temperatures when respite resources would be provided (e.g. extra water) (n=8) were classified as "extreme caution" by the NWS assuming 50% relative humidity. 18% of facilities (n=374) lacked AC access completely. Among these, 55% of non-air-conditioned facilities (41,000 operational capacity) are at "severe or extreme heat risk". Overall, 23% of facilities whose function includes serving heat-sensitive populations (n=202), lack any air-conditioning despite their heat risk.

CONCLUSIONS: This study emphasizes the need for national correctional temperature policies and air-conditioning requirements to protect the thermal health of those who live and work in carceral facilities.

P-0287 Modeling energy and exposure benefits through integrated ventilation upgrades and rooftop gardens in a high school in Boston, MA

Catherine Connolly[1], Sarabeth Buckley[2], Pamela Templer[3], Jacqueline Ashmore[4], Luis Carvalho[5], Nathan Phillips[6], Jonathan Levy[1], M. Patricia Fabian[1]

[1]Boston University School of Public Health, Boston, USA, [2]University of Cambridge, Cambridge, UK, [3]Boston University Department of Biology, Boston, USA, [4]Borrego Solar, San Diego, USA, [5]Boston University Department of Mathematics and Statistics, Boston, USA, [6]Boston University Earth and Environment Department, Boston, USA

BACKGROUND AND AIM: Many U.S. schools have poor indoor ventilation, impacting air quality (IAQ), which is associated with adverse learning outcomes for children (e.g. reduced cognition, academic performance). However, increased ventilation results in increased energy consumption, which conflicts with goals to lower utility bills and carbon emissions. Addressing these challenges requires innovative and sustainable solutions. We propose a novel approach to simultaneously implement indoor ventilation upgrades and rooftop gardens, and model the impacts on energy use, financial costs, and carbon cycling in a Boston, MA high school.

METHODS: We measured CO2 concentrations continuously for a week in 13 classrooms and at exhaust rooftop vents during a two-month period in Spring 2019. We calculated baseline school-level average ventilation rates and estimated the energy needed to increase indoor ventilation to reduce CO2 to recommended indoor values (i.e. <1000 ppm). We then compared to yearly modeled energy savings and carbon emissions reductions occurring through plant carbon capture at a rooftop garden.

RESULTS: The baseline median classroom CO2 concentration was 840 ppm and exceeded 1000 ppm 33% of the school day. The estimated ventilation rate during occupancy was 4 L/s/person, below the recommended 7 L/s/person. Increasing ventilation to recommended levels would increase yearly total energy, cost, and carbon emissions (1-4%). A rooftop garden would provide net decreases of energy (12%), cost (13%), and carbon emissions (23-46%) with the higher end of this range attributed to plant growth enhancement.

CONCLUSIONS: Our analyses demonstrated the potential for integrated interventions in school buildings that can improve IAQ while capturing carbon through rooftop gardens. We found that CO2 levels of concern persist in schools, but could be vented to rooftops to reduce exposures and benefit plant growth. Future studies should evaluate alternative rooftop garden configurations that yield maximal energy and carbon reduction benefits.

P-0292 The changes of lipid profiles among Chinese adults may be associated with legacy and emerging per- and polyfluoroalkyl substances: Evidence from China National Human Biomonitoring

Bing Wu[1], Yuebin Lv[1], Xiaoming Shi[1]
[1]*National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND AND AIM: In the past decade, the levels of cholesterol and lipid profiles have drastically changed. Whether these changes may be associated with legacy and emerging PFASs is worth exploring. In this study, we aimed to explore the associations of single and mixed exposure to legacy and emerging PFASs with lipid profiles in general Chinese adults.

METHODS: A total of 10855 adults aged 18 and older from China National Human Biomonitoring (CHBNM) were recruited. Weighted multiple linear regression was used in single-pollutant models to explore the associations of PFAS with lipid profiles. Qgcomp was used to explore the joint associations of 8 PFAS mixtures (PFOA, PFNA, PFDA, PFUnDA, PFHxS, PFHpS, PFOS, 6:2Cl-PFESA) with lipid profiles.

RESULTS: Single and multiple pollution models showed that legacy and emerging PFASs were positively associated with lipid profiles. The adjusted β (95% confidence intervals: CI) of log(10) transformed PFOA, PFOS, PFNA and 6:2 Cl-PFESA with TC were 0.123 (0.058, 0.187), 0.214 (0.151,0.277), 0.227 (0.159, 0.295) and 0.115 (0.066, 0.164). The adjusted estimated changes (95%CI) of PFAS mixtures with TG, TC, LDL-C, HDL-C, and non-HDLC were 0.023 (0.009, 0.037), 0.253 (0.225,0.281), 0.149 (0.125,0.174), 0.081 (0.07,0.092), and 0.172 (0.145,0.199), respectively. Qgcomp model showed that PFNA (67.7%) contributed the most to TG, PFUnDA (30.2%) contributed the most to TC, PFHpS (36.7%) contributed the most to LDLC, PFUnDA (74.8%) contributed the most to HDLC, and PFHpS (38.6%) contributed the most to non-HDLC. However, compared with legacy PFASs, 6:2 Cl-PFESA contributed less to the lipid profiles.

CONCLUSIONS: The changes of lipid profiles among Chinese adults may be associated with legacy and emerging PFASs. Compared to legacy PFASs, emerging PFASs such as 6:2 Cl-PFESA may be less harmful to lipids.

KEYWORDS: Per- and polyfluoroalkyl substances, Lipid profiles, Joint effects, emerging PFAS.

P-0297 Greenspace exposure and depressive symptoms: findings from the French CONSTANCES cohort

Mohammad Javad Zare Sakhvidi[1], Antoine Lafontaine[2], Emeline Lequy[3], Claudine Berr[4], Payam Dadvand[5,6,7], Kees de Hoogh[8,9], Danielle Vienneau[8,9], Marcel Goldberg[3], Marie Zins[3], Cédric Lemogne[10], Bénédicte Jacquemin[2]

[1]Occupational Health Department, School of Public Health, Shahid Sadoughi University of Medical Sciences, Yazd, Islamic Republic of Iran, [2]Univ Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) – UMR_S 1085, F-35000, Rennes, France, [3]Université Paris Cité, Unité "Cohortes en Population" INSERM, Université Paris Saclay, UVSQ, UMS 011, Paris, France, [4]INM, Univ Montpellier, Inserm, Montpellier, France, [5]ISGlobal, Doctor Aiguader 88, 08003, Barcelona, Spain, [6]Universitat Pompeu Fabra (UPF), Doctor Aiguader 88, 08003, Barcelona, Spain, [7]CIBER Epidemiología y Salud Pública (CIBERESP), Melchor Fernández Almagro, 3-5, 28029, Madrid, Spain, [8]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [9]University of Basel, Basel, Switzerland, [10]Service de Psychiatrie de l'adulte, AP-HP, Hôpital Hôtel-Dieu, F-75004, Paris, France

BACKGROUND AND AIM: The association between greenspace exposure and different dimensions of depression is yet to be established. We aimed to explore this association in a large population-based cohort.

METHODS: Data from the enrollment phase of the French CONSTANCES cohort (2012-2020) were analyzed cross-sectionally. Depressive symptoms were measured by the Centre of Epidemiologic Studies Depression (CES-D) questionnaire allowing to compute a total CES-D score (≥19 used as a cutoff score to identify individuals at risk for clinical depression), and including four dimensions (depressed affect, disturbed interpersonal relations, low positive affect, somatic complaints). Residential surrounding greenspace exposure was quantified using the satellite-based Normalized Difference Vegetation Index (NDVI) at 300m buffer during the enrollment year. Adjusted multiple logistic and linear regression models were developed, reported as odds ratio [OR] for dichotomized total depressive symptoms, and ß for dimension-scores, with a 95% confidence interval [CI] for an interquartile range [IQR] increase in exposure. Analyses stratified by personal and socioeconomic variables were performed.

RESULTS: In total 185,781 participants were included (age: 46.80±13.61 years, 53.5% women). Residential surrounding greenness (average NDVI: 0.53; IQR=0.28) was significantly associated with lower odds of having depressive symptoms (OR [95%CI]: 0.94 [0.90-0.99]). This exposure was also associated with a lower scores for all dimensions (ß [95% CI]: -0.043 [-0.053: -0.033]; -0.016 [-0.026:-0.006]; -0.020 [-0.030:-0.010]; and -0.019 [-0.029:-0.009] for depressed affect, disturbed interpersonal relations, low positive affect, and somatic complaints, respectively). We found suggestions for potentially stronger protective associations in men and participants with lower income.

CONCLUSION: Residential surrounding greenspace was associated with lower depressive symptoms in general, and all four dimensions especially depressed affect and somatic complaints. Considering depression prevalence, its burden, and the increasing trend of urbanization, our finding is of importance for policymakers.

P-0302 Comparing greenspace metrics and buffer methods in Metro Vancouver, Canada: Implications for environmental health research

Katherine White[1], Kate Weinberger[1], Connor Wolff[2], Trevor Dummer[1], Lawrence Frank[1,3]
[1]School of Population and Public Health, University of British Columbia, Vancouver, Canada, [2]School of Community and Regional Planning, University of British Columbia, Vancouver, Canada, [3]Urban Studies and Planning, University of California San Diego, San Diego, USA

BACKGROUND AND AIM: Access and exposure to greenspace has been shown to promote mental and physical health; however, not all studies have found these benefits, with some studies reporting no association and others reporting associations with adverse health outcomes. It has been suggested that the use of diverse greenspace metrics, the varied quality of these metrics, and the specific methods used to quantify exposure or access, may contribute to these inconsistent findings. This project sought to compare the results of using different metrics in Metro Vancouver, Canada.

METHODS: Greenspace metrics were calculated from the centroid of each 6-digit postal code. Average buffer normalized differences vegetation index (NDVI), green landcover, tree canopy cover, and park count were calculated using circular and network buffers, at both 400m and 1000m. Pearson's correlation coefficients were calculated to compare the results for each metric and method.

RESULTS: The number of parks was only weakly positively correlated with each of the other three greenspace metrics for 1000m circular buffers (NDVI $r = 0.12$; green land cover $r = 0.07$; tree canopy $r = 0.14$, $p < .01$). for 1000m network buffers (NDVI $r = -0.34$; green landcover $r = -0.12$; tree canopy $r = 0.05$, $p < .01$) two of the correlations became negative. Circular and network buffer were most highly correlated for the tree canopy (1000m $r = 0.92$; 400m $r = 0.86$, $p < .01$), whereas park count had the weakest correlation (1000m $r = 0.66$; 400m $r = 0.66$, $p < .01$).

CONCLUSIONS: The associations between greenspace metrics vary. Selection of buffering method may be particularly influential when using park count data. These findings support the importance of intentional selection of greenspace metric and measurement method in environmental epidemiological research.

P-0311 Source tracking swine fecal waste on household surfaces proximal to swine concentrated animal feeding operations in southeastern North Carolina, USA

Kathleen Kurowski[1], Kristoffer Spicer[1], Carolyn Gigot[1], Nora Pisanic[1], Devon Hall[2], Devon Hall Jr[2], Margaret Carr[2], Arika Miller[2], Unique Hall[2], Ana M. Rule[1], Kate Kruczynski[1], Christopher D. Heaney[1]

[1]Johns Hopkins University, Department of Environmental Health and Engineering, Baltimore, USA, [2]Rural Empowerment Association for Community Help, Warsaw, USA

BACKGROUND AND AIM: In North Carolina, swine industrial livestock operations (ILOs) are located disproportionately in low-income and communities of color. Swine ILO neighbors have raised concerns about emissions from ILOs. We aim to compare the detection frequency and quantity of a swine-specific Bacteroides fecal microbial source-tracking marker (pig-2-bac DNA) contamination on outdoor and indoor household surfaces at ILO worker (ILO) compared to ILO neighbor (ILO-N) and metropolitan resident (metro) homes in North Carolina.

METHODS: at enrollment, ILO, ILO-N, and metro participants collected 2 outdoor and 2 indoor household surface settled dust samples wiping a Copan flocked swab across a 10 cm2 area. Using quantitative real-time PCR, pig-2-bac DNA copy number per area was estimated in household samples. We used logistic and linear regression to evaluate differences in pig-2-bac prevalence and quantity between the three household groups and on outdoor compared to indoor surfaces.

RESULTS: Ninety-one households (354 swabs) were sampled: 30 ILO (113 swabs), 31 ILO-N (119 swabs) and 30 metro (122 swabs). Prevalence of Pig-2-bac detection on >=1 household surface was 33%, 39%, and 0% among ILO, ILO-N, and metro households, respectively. Compared to metro households, higher log-10 pig-2-bac DNA copy number per 10 cm2 was observed at ILO (beta=0.5; 95% confidence interval [CI]=0.2, 0.7) and ILO-N households (beta=0.2; 95% CI=0.06, 0.4). Compared to indoor surfaces, higher log-10 copy number per 10 cm2S was observed on outdoor surfaces (beta = 0.181, 95% CI=0.02, 0.3).

CONCLUSIONS: Swine-specific fecal contamination was detected at a higher prevalence in ILO-N compared to ILO workers and metro resident homes. Both ILO and ILO-N groups had statistically significant increases in copy number compared to the metro group.

KEYWORDS: microbial contamination, pig-2-bac, industrial livestock operations, concentrated animal feeding operations

P-0312 Trends and Patterns in Industrial and Commercial Sources of Lead (Pb) in the US

Nichole Kulikowski[1], Stephanie DeFlorio-Barker[1], Rogelio Tornero-Velez[1], Archana Lamichhane[1]
[1]*US EPA, Durham, USA*

BACKGROUND AND AIM: Lead (Pb) exposures in the US have declined over the last 40 years due to phaseout of Pb in gasoline, residential paint, and plumbing. However, Pb still circulates in commerce (batteries, ammunition, glass, pigments, e-waste). While the Environmental Protection Agency (EPA) tracks large industrial movements of Pb (>25,000lbs), modest Pb movements are not identified and may translate to substantial cumulative exposure and public health significance due to proximity to residences, schools, or places of work. This research aims to identify and evaluate trends in commercial sources of Pb in the US.

METHODS: Peer-reviewed literature was used to identify relevant commercial sources of Pb and link to corresponding Standard Industrial Classification (SIC) codes. Counts of each SIC code were calculated per census tract, using geolocations from Dun and Bradstreet (D&B) from 1990-2018. Data capturing measurable Pb emissions (Toxics Release Inventory (TRI)) and area-level socioeconomic measures (CDC's Social Vulnerability Index) were further linked by census tract. Data were analyzed using R and ArcGIS.

RESULTS: A total of 31 unique SIC codes were identified, corresponding to >1,300 potential Pb-emitting businesses in 1,265 census tracts. The most common commercial businesses represented shooting ranges (n=838) and refuse systems (n=221). Preliminary analyses data indicate widespread current Pb-emitting industries are widespread but further socioeconomic and Pb-emission data will be analyzed. Preliminary data show a decline in some identified industries over time.

CONCLUSIONS: Preliminary results show the number of Pb-emitting industries has decreased over time in the US. However, certain geographic areas of the USA yield higher densities of Pb-emitting industries and commercial businesses, which could have a profound public health significance. The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.

KEYWORDS: Lead (Pb) exposure, environmental justice

P-0320 Case-cohort study of the association between PFAS and cancers of the kidney and bladder among participants in the American Cancer Society's Cancer Prevention II cohort

Andrea Winquist[1], James Hodge[2], W. Ryan Diver[2], Lauren Teras, Juan Rodriguez[1], Johnni Daniel[1]
[1]U.S. Centers for Disease Control and Prevention, Atlanta, USA, [2]American Cancer Society, Atlanta, USA

BACKGROUND AND AIM: Some per- and polyfluoroalkyl substances (PFAS), including perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS), have been associated with genitourinary system cancers in some, but not all previous studies. Many studies did not consider histology. We examined associations between PFAS exposure and risk of histologic subtypes of kidney and bladder cancer.

METHODS: We conducted a case-cohort study within the American Cancer Society's prospective Cancer Prevention Study II (CPS-II) LifeLink cohort for which serum specimens were collected during 1998-2001 (ages ≥54 years). This study included a subcohort (500 men, 499 women) randomly selected from cohort members without prior cancer diagnoses at serum collection, and all persons with incident (after serum collection) first cancers of the kidney (n=158, including 109 renal cell carcinoma/adenocarcinomas [RCC] and 47 transitional cell carcinomas [TCC]) and bladder (n=401, including 390 TCC). Concentrations of PFOA, PFOS, perfluorohexane sulfonic acid, perfluorononanoic acid, perfluorooctane sulfonamide and perfluoroheptanoic acid were measured in stored serum. Multivariable Cox proportional hazards regression was used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for associations between PFAS concentrations and risk of RCC and TCC. Models accounted for the study design and controlled for sex (using stratification), age and year at blood draw, education, race/ethnicity, smoking and alcohol use, and occupational exposures (coal dust/tar, dyes, and diesel/gasoline; TCC only).

RESULTS: Serum PFOA concentrations were positively associated with RCC among women [HRs (95% CIs) for PFOA quartiles 2-4, respectively, vs. quartile 1: 1.33 (0.42-4.19), 1.66 (0.54-5.13), 3.14 (1.02-9.65)] but not men. TCC (bladder or kidney) was not significantly associated with the measured PFAS, although PFOS-TCC HRs were elevated among men.

CONCLUSIONS: This study provides additional evidence for an association between PFOA and RCC. Consideration of histologic types might help clarify inconsistencies in the literature on PFAS exposure and cancer.

KEYWORDS: PFAS, cancer

P-0321 Biomonitoring Legacy and Emerging Contaminants and Local Fish Consumption in Susceptible Great Lakes Populations, 2010-2020

Zheng Li[1], Tara Serio[1], Susan Manente[2], Deanna Scher[3], Elizabeth Lewis-Michl[4], Jonanthan Meiman[5], Elizabeth Irvin[1], Angela Ragin-Wilson[1]

[1]Centers for Disease Control and Prevention/Agency for Toxic Substances and Disease Registry, Atlanta, USA, [2]Michigan Department of Health and Human Services, Lansing, USA, [3]Minnesota Department of Health, St. Paul, USA, [4]New York State Department of Health, Albany, USA, [5]Wisconsin Department of Health Services, Madison, USA

BACKGROUND AND AIM: Over the past century, the Great Lakes, the world's largest fresh surface water system, has been contaminated with numerous chemical pollutants. From 2010 to 2020, the Agency for Toxic Substances and Disease Registry conducted the Biomonitoring of Great Lakes Populations program to assess exposure to legacy and emerging contaminants in susceptible populations who consumed fish caught in contaminated waterbodies.

METHODS: The Program consists of a series of cross-sectional studies conducted collaboratively with health departments in Michigan, Minnesota, New York, and Wisconsin. The target populations–including various angler and refugee populations in different areas with known contamination–were sampled and recruited independently using sampling strategies that were tailored for the specific populations. Participants completed questionnaires focusing on fish consumption and provided biological samples. Selected blood metals and polychlorinated biphenyls (PCBs) were measured in all participants. Some chemicals of emerging concern, such as per- and polyfluoroalkyl substances (PFAS), were also measured in several studies.

RESULTS: Body burden levels of mercury, lead, and perfluorooctane sulfonic acid (PFOS) in most target populations were elevated compared to the U.S. population. Locally caught fish consumption was associated with blood mercury and serum PFOS in most cohorts. Serum PCB was elevated only in the Detroit shoreline angler cohort and was associated with eating locally caught fish.

CONCLUSIONS: Most target populations in this program had higher exposures to some metals and PFOS, and the exposures were generally associated with eating fish caught in local, contaminated waterbodies. The results generated from this program helped guide public health actions to reduce chemical exposures in vulnerable Great Lakes populations, including updated fish advisories and targeted education and outreach on risk and benefit of fish consumption.

KEYWORDS: Fish consumption, exposure, metals, PFAS, susceptible populations, Great Lakes

P-0326 Exposure to four metals and depressive symptom in adults: NHANES epidemiological study

Jiyoung Shin[1], Yuan Luo[1]
[1]*Dept. of Preventive Medicine, Feinberg School of Medicine, Northwestern University, Chicago, USA*

BACKGROUND AND AIM: Although some of the heavy metal are known to have an adverse effect on neurobehavioral symptoms, studies on the exposure to multiple metal and depression are limited. This study purposed to evaluate the association between individual and multiple heavy metal and depression in the adult population by using National Health and Nutrition Examination Survey (NHANES) dataset.

METHODS: This study used the data from the U.S. NHANES between 2007 to 2014 to examine cross-sectional relationships between metal exposure and depression in adult over 20 years. After applying exclusion criteria, 6021 subjects were included in the final analysis. We used four urinary metals including mercury, cadmium, lead, and arsenic as exposure variables. Patient Health Questionnaire (PHQ-9) was used to assess the depression symptom of the participants. Multivariate linear regression (MLR) for each heavy metal exposure and quantile g-computation model for multiple exposure to four heavy metals were applied. Stratification analysis according to the alcohol habit of the subjects was also performed.

RESULTS: MLR models indicated that urinary cadmium was positively associated with continuous depression score (β = 0.39, 95% confidence interval (CI): 0.24-0.53). Other urinary metals showed positive relationship with continuous depression score, but it was not significant. In the quantile g-computation model, statistically significant positive association were found between the mixture of urinary metals and depression score (Difference in PHQ-9 score increase: 0.32, 95% CI: 0.14-0.50). When stratified the model by alcohol consumption habit, a stronger association was found in a heavy alcohol consumption group.

CONCLUSIONS: When comparing the results from different models, not only individual urinary heavy metal was related to depression score, but also four heavy metals mixture was positively associated with a depression. Future cohort studies are needed to clarify the effect of metal mixture.

P-0330 Predicting Cumulative Lead (Pb) Exposure Using the Super Learner Algorithm

Xin Wang[1], Kelly Bakulski[1], Bhramar Mukherjee[1], Howard Hu[2], Sung Kyun Park[1]
[1]University of Michigan, Ann Arbor, USA, [2]University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Chronic lead (Pb) exposure causes long term health effects. While recent exposure can be assessed by measuring blood lead (half-life 30 days), chronic exposures can be assessed by measuring lead in bone (half-life of years to decades). Bone lead measurements, in turn, have been measured non-invasively in large population-based studies using x-ray fluorescence techniques, but the method remains limited due to technical availability, expense, and the need for licensing radioactive materials. Thus, we developed prediction models for bone lead concentrations using a flexible machine learning approach--Super Learner, which combines the predictions from a set of machine learning algorithms for better prediction performance.

METHODS: The study population included 695 men in the Normative Aging Study, aged 48 years and older, whose bone (patella and tibia) lead concentrations were directly measured using K-shell-X-ray fluorescence. Ten predictors (blood lead, age, education, job type, weight, height, body mass index, waist circumference, cumulative cigarette smoking (pack-year), and smoking status) were selected for patella lead and 11 (the same 10 predictors plus serum phosphorus) for tibia lead using the Boruta algorithm. We implemented Super Learner to predict bone lead concentrations by calculating a weighted combination of predictions from 8 algorithms based on selected predictors.

RESULTS: In the nested cross-validation, the correlation coefficients between measured and predicted bone lead concentrations were 0.58 for patella lead and 0.52 for tibia lead, which has improved the correlations obtained in previously-published linear regression-based prediction models. We evaluated the applicability of these prediction models to the National Health and Nutrition Examination Survey for the associations between predicted bone lead concentrations and blood pressure, and positive associations were observed.

CONCLUSIONS: These bone lead prediction models provide reasonable accuracy and can be used to evaluate health effects of cumulative lead exposure in studies where bone lead is not measured.

P-0331 Interactions between chemical mixtures and the overall antioxidant and inflammatory capacity of the diet in the association between dietary exposure to chemical mixtures and mortality risk in the E3N French prospective cohort

Chloé Marques[1], Pauline Frenoy[1], Thibault Fiolet[1], Gianluca Severi[1,2], Francesca Romana Mancini[1]
[1]Université Paris-Saclay, UVSQ, Inserm, Gustave Roussy, "Exposome and Heredity" team, CESP UMR1018, Villejuif, France, [2]Department of Statistics, Computer Science, Applications "G. Parenti", University of Florence, Florence, Italy

Since food is contaminated by many chemicals which may interact, resulting in additive, synergistic or antagonistic effects, it is necessary to study the exposure to chemical mixtures. These mixtures can interact with nutrients by targeting the same molecular signalling pathways and biological functions. Chemicals and nutrients may impact oxidative stress and chronic systemic inflammation, both associated with non-communicable diseases.
Our objective was to investigate the association between dietary exposure to chemical mixtures and mortality risk in the E3N (Etude Epidémiologique auprès de femmes de l'Education Nationale) prospective cohort, and to study the interactions between these mixtures and nutrients.
We considered 72585 women from the E3N cohort who completed a food frequency questionnaire in 1993. Using sparse non-negative matrix under-approximation, we identified the six main chemical mixtures to which these women were exposed through the diet. We analysed the association between dietary exposure to these mixtures and all-cause and cause-specific mortality with Cox proportional hazard models. We investigated the interactions between these exposures and the overall antioxidant and inflammatory capacity of the diet.
During the follow-up (1993-2014), 6441 deaths occurred. We observed statistically significant interactions between some chemical mixtures and the overall antioxidant and inflammatory capacity of the diet which modified the relationship between dietary exposure to the mixtures and mortality. for example, when considering a mixture characterised by the exposure to persistent organic pollutants, no association was highlighted with all-cause mortality for women with an anti-inflammatory diet (HR 1.02, CI 0.90-1.15), while a positive association was found for women with a pro-inflammatory diet (HR 1.16, CI 1.02-1.31).
This study highlighted for the first time the existence of interactions between chemical mixtures and the overall antioxidant and inflammatory capacity of the diet in a human-based study. More studies are needed to clarify the underlying biological mechanisms.

P-0333 Positive association between dietary exposure to polybrominated diphenyl ethers and breast cancer risk in the French E3N cohort: the role of vegetable oil consumption

Pauline Frenoy[1], Chloé Marques[1], Thibault Fiolet[1], German Cano-Sancho[2], Gianluca Severi[1,3], Francesca Romana Mancini[1]

[1]Paris Saclay University, Inserm CESP UMR1018, "Exposome and Heredity" team, Paris, France, [2]LABERCA, Oniris, INRAE, Nantes, France, [3]University of Florence, Department of Statistics, Computer Science, Applications "G. Parenti", Florence, Italy

BACKGROUND AND AIM: Exposure to endocrine-disrupting chemicals, like Polybrominated diphenyl ethers (PBDE), is suspected to play a role in the occurrence of breast cancer. Moreover, there is growing evidence that food chemical contaminants could interact with different components of the diet, especially lipophilic ones, such as PBDE. In an in-vitro study, vegetable oil has been shown to increase the bioaccessibility of PBDE. The objective of the present study was to assess the association between dietary intake of PBDE and breast cancer risk in the French E3N cohort study, and to investigate the potential modification of this association by vegetable oil consumption or lipid intake.

METHODS: The study included 67 879 women. Intake of individual PBDE were estimated using food consumption data from a validated semi-quantitative food frequency questionnaire. Hazard Ratios (HR) and 95% Confidence Intervals (CI) were estimated for the association between total PBDE dietary intake and breast cancer risk. Interaction measures for vegetable oil consumption were estimated on both additive and multiplicative scales.

RESULTS: The women were followed for a maximum of 21.4 years, and 5 686 developed an incident breast cancer. A positive linear trend was highlighted between dietary intake of PBDE in quintile groups and breast cancer risk, borderline with statistical significance (p-trend=0.06, HRQ5vsQ1 and 95%CI: 1.09 [0.99;1.20]). Interaction measures for vegetable oil consumption were significant both in additive and multiplicative scales. Higher effect sizes of the association were highlighted in high consumers of vegetable oil, i.e. ≥4.6 g/day (HRQ5vsQ1 and 95%CI: 1.23 [1.08; 1.40]), and almost no effect were found in low consumers (HRQ5vsQ1 and 95%CI: 0.97 [0.86; 1.10]).

CONCLUSIONS: Highlighting such interactions between nutrients and chemicals is crucial to develop efficient dietary recommendations to limit the negative health effects associated to exposure to food chemical contaminants.

KEYWORDS: Polybrominated diphenyl ethers; Breast cancer; Endocrine-disrupting chemicals; Interaction

P-0335 Ovarian volume mediates associations of phthalate metabolites with anti-Mullerian hormone in midlife women

Maria Kloboves[1,2,3], Diana Pacyga[1,3], Elnur Babayev[4], Francesca Duncan[4], Paige Williams[5,6], Jodi Flaws[7], Rita Strakovsky[1,3]

[1]Department of Food Science & Human Nutrition, Michigan State University, East Lansing, USA, [2]Department of Epidemiology & Biostatistics, Michigan State University, East Lansing, USA, [3]Institute for Integrative Toxicology, Michigan State University, East Lansing, USA, [4]Department of Obstetrics and Gynecology, Northwestern University, Chicago, USA, [5]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA, [6]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, USA, [7]Department of Comparative Biosciences, University of Illinois, Urbana-Champaign, USA

BACKGROUND AND AIM: We previously reported positive associations of phthalates with anti-Mullerian hormone (AMH), a biomarker of ovarian reserve, in midlife women. Growing follicles produce AMH, so we evaluated associations of phthalates with ovarian volume (indicating folliculogenesis), considering whether this relationship explained associations of phthalates with AMH.

METHODS: Midlife women had a transvaginal ultrasound of right and left ovaries to calculate ovarian volume. Women provided one blood sample for AMH quantification and up-to-four urine samples across one menstrual cycle, which we pooled to quantify nine phthalate metabolites. We assessed AMH as a binary variable (above/below the level of detection). Covariate-adjusted linear regression models were used to evaluate associations of phthalates with mean left/right ovarian volumes (both ln-transformed). Using a formal mediation analysis, we estimated the proportion of overall associations between phthalates and high AMH (total association) explained by relationships of phthalates and mean ovarian volume (indirect association).

RESULTS: In 666 midlife women, 65% were non-Hispanic White, 67% were premenopausal, and 33% perimenopausal. Only mono(3-carboxypropyl) phthalate (MCPP) and monobenzyl phthalate (MBzP) were positively associated with mean ovarian volume. In adjusted models, each two-fold increase in MCPP and MBzP was associated with 4.13% (95%CI: -0.75, 9.01) and 7.12% (95%CI: 0.83, 13.40) larger ovarian volume, respectively. These relationships partially explained associations of MCPP or MBzP with high AMH. The indirect association between MCPP and ovarian volume (β=0.03, 95%CI: 0.00, 0.07) explained 19% of the total association between MCPP and high AMH (OR=1.16; 95%CI: 0.96, 1.37). Similarly, the indirect association between MBzP and ovarian volume (β=0.06, 95%CI: 0.00, 0.13) explained 17% of the total association between MBzP and high AMH (OR=1.37; 95%CI: 1.05, 1.70).

CONCLUSIONS: Phthalates may induce folliculogenesis, with implications for midlife hormone production. Future prospective studies are needed and could consider mediation approaches using complex chemical mixtures.

KEYWORDS: phthalates, ovarian volume, AMH

P-0336 Urinary phthalate metabolites and melamine are linked to early renal injury in pregnant mothers in Taiwan

Chia-Fang Wu[1], Ming-Tsang Wu[2]
[1]International Master Program of Translational Medicine, National United University, Miaoli, Taiwan, [2]Research Center for Environmental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan

BACKGROUND: Pregnant women exposed to two regularly encountered toxicants, melamine and phthalate, could potentially be at risk of kidney damage.
AIM
This study investigated the effects of melamine and phthalates, specifically di-(2-ethylhexyl) phthalate (DEHP), alone and interactively, on early renal injury in a nationwide cohort of pregnant women during their third trimester, participants in Taiwan's Maternal and Infant Cohort Study (TMICS).

METHODS: Participants received questionnaires, physical examinations, and blood and one-spot overnight urine tests during regular routine checkups their third trimester between October, 2012 and May, 2015. The specimens were analyzed for melamine, eleven phthalate metabolites, microalbumin and N-acetyl-beta-D-glucosaminidas (NAG), two markers of renal injury. We calculated estimated daily DEHP intake using measurements of three urinary DEHP metabolites. If a participant was found to have urinary albumin/creatinine ratio (ACR) higher than 3.5 mg/mmol, she was defined as having microalbuminuria.

RESULTS: In total, we analyzed data collected from 1433 pregnant women, who were found to have a median urinary melamine value of 0.63 μg/mmol Cr and estimated DEHP intake of 1.84 μg/kg/day. Compared to those in the lowest quartile of estimated DEHP intake, those belonging in the highest quartile had significantly increased urinary ACR (β = 0.095, p = 0.043) and microalbuminuria (adjusted OR = 1.752, 95% confidence interval = 1.118–2.746). A significant interactive effect between urinary melamine and estimated DEHP intake on urinary ACR and NAG was also found.

CONCLUSIONS: There is a strong association between exposure to these two pervasive toxicants, both independently and interactively, and the urinary indicators of early kidney injury we measured in this nationwide birth cohort of pregnant women.

P-0340 Urinary biomonitoring of glyphosate exposure among male farmers and non-farmers in the Biomarkers of Exposure and Effect in Agriculture (BEEA) study

Vicky C. Chang[1], Maria Ospina[2], Shuai Xie[1], Gabriella Andreotti[1], Melissa C. Friesen[1], Danping Liu[3], Nathaniel Rothman[1], Debra T. Silverman[1], Laura E. Beane Freeman[1], Antonia M. Calafat[2], Jonathan N. Hofmann[1]

[1]Occupational and Environmental Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, USA, [2]National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA, [3]Biostatistics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, USA

BACKGROUND AND AIM: Glyphosate is the most widely applied herbicide worldwide. Despite potential health effects of glyphosate, biomonitoring data of glyphosate exposure in agriculture and other settings are limited. We measured urinary glyphosate concentrations and assessed their determinants among male farmers and non-farmers from Iowa and North Carolina in the BEEA study.

METHODS: Based on questionnaire-assessed pesticide exposure histories, we selected four groups of BEEA participants: recently exposed farmers with occupational glyphosate use in the last 7 days (n=98), farmers with high cumulative lifetime days of glyphosate use (>80th percentile) but no use in the last 7 days (n=70), farmers with minimal lifetime glyphosate use (n=100), and non-farmers with no occupational pesticide exposure (n=100). We quantified glyphosate in first-morning void urine samples using ion chromatography isotope-dilution tandem mass spectrometry. We estimated geometric mean urinary glyphosate concentrations across groups and evaluated associations with potential determinants using linear regression.

RESULTS: Glyphosate was detected in urine of most recently (91%), high-lifetime (93%), and low-lifetime (88%) exposed farmers, as well as non-farmers (81%); geometric mean concentrations were 0.86, 0.58, 0.44, and 0.37 µg/L, respectively. Compared to non-farmers, urinary glyphosate concentrations were significantly elevated among recently exposed farmers (P<0.0001), particularly those who used glyphosate within 1 day of urine collection [age- and creatinine-adjusted geometric mean ratio (GMR)=6.4, 95% confidence interval (CI)=4.3-9.3] and those not wearing gloves during glyphosate application (GMR=2.6, 95% CI=2.0-3.4).

CONCLUSIONS: Preliminary results suggest that a high proportion of both farming and non-farming populations may be exposed to glyphosate. Substantial exposure contrast between those with and without recent occupational glyphosate use was detectable in urine. Given the short elimination half-life of glyphosate, the exposure differences between groups may be even greater than those reflected by measured urine concentrations. Continued biomonitoring of glyphosate in various settings is warranted.

P-0346 Hazard and risk assessment for indoor air pollutants: dimethylsiloxanes, glycols, butanediol, hydrocarbons, trimethylbenzenes, benzene, naphthalene, and ethyltoluene

Kenichi Azuma[1], Hideto Jinno[2,4], Toshiko Tanaka-Kagawa[3,4], Shinobu Sakai[4]

[1]Kindai University Faculty of Medicine, Osakasayama, Japan, [2]Meijo University Faculty of Pharmacy, Nagoya, Japan, [3]Yokohama University of Pharmacy, Yokohama, Japan, [4]National Institute of Health Sciences, Kawasaki, Japan

Individuals living in an indoor environment are typically exposed to a greater variety of air pollutants than in an outdoor environment. Numerous sources of chemical emissions are found in the indoor environment, depending on the building materials as well as the lifestyle of the occupants. The quality of the indoor environment considerably impacts public health. Japan has established indoor air quality guidelines for 13 chemicals, including formaldehyde, acetaldehyde, xylene, ethylbenzene, styrene, 1,4-dichlorobenzene, and toluene. However, the types and concentrations of indoor pollutants have not been consistent over time due to alterations in lifestyle and development of novel household products and building materials. Therefore, a comprehensive approach and action plan for the overall reduction of health risks caused by indoor air pollutants are required for public health protection. To determine the high-risk indoor air pollutants that should be reduced, we conducted a preliminary risk assessment using data from nationwide exposure assessments and existing hazard data. In this assessment, identifications of the critical effects and the reference values obtained from reviewing the hazard or toxicological data are crucial. We identified indoor air pollutants that appeared with high frequency and high concentration in the nationwide exposure assessments. We previously reported the critical effects and reference values for acute and chronic effects of eight indoor air pollutants, including ethyl acetate, butyl acetate, propylene glycol monomethyl ether, 3-methoxy-3-methylbutanol, diethylene glycol methyl ether, diethylene glycol ethyl ether, propylene glycol monomethyl ether acetate, and methyl isobutyl ketone. In this study, the critical effects and the reference values of nine indoor air pollutants, including octamethyl cyclotetrasiloxan, decamethyl cyclopentasiloxan, propylene glycol, 1,3-butanediol, aliphatic saturated hydrocarbons (C8–C16), trimethylbenzenes, benzene, naphthalene, and ethyltoluene and the results of risk assessment are reported.

P-0348 Acetylcholinesterase activity and serum lead concentrations in pregnant women enrolled in the Rio Birth Cohort pilot Study, Brazil

Aline Santos[1], Liliane Silva[1], Isabella Giannini[1], Armando Meyer[1]
[1]*Federal University of Rio de Janeiro, Rio de Janeiro, Brazil*

BACKGROUND AND AIM: Lead (Pb) is considered one of the main chemicals of interest to public health, given its potential for neurotoxicity, especially in vulnerable populations such as pregnant women (WHO, 2020). One of the mechanisms proposed for Pb toxic effects on the nervous system is the acetylcholinesterase enzyme inhibition (AChE), considering that this metal mimics and inhibits the action of calcium in this enzyme (Breslller et al. 1991). Despite evidence from experimental studies, little is known about the effects of lead on AChE in humans (Nwobi et al. 2019). We evaluated the association between blood levels of Pb and erythrocyte AChE activity in pregnant women in an urban area of Rio de Janeiro.

METHODS: Cross-sectional study with 139 pregnant women enrolled in the Rio Birth Cohort Pilot Study in the third trimester of pregnancy. Socioeconomic and lifestyle data were obtained from a structured questionnaire. AChE activity was measured by the Ellman (1961) method modified by Oliveira-Silva (2000). Lead concentrations were measured in whole blood using inductively coupled plasma mass spectrometry (ICP-MS). Linear regression and Spearman correlation were used to assess the association between lead levels and erythrocyte AChE activity.

RESULTS: The median of lead concentrations in the whole blood of pregnant women was 3.9ug/dL (n=119). A weak negative correlation was observed between lead levels and AChE activity (rho= -0.289; p= 0.002). Elevated levels of lead seems to inhibit erythrocyte AChE activity (β= -0.30; 95%CI: -0.54, -0.06) in age-adjusted models.

CONCLUSIONS: Our results suggest that lead can inhibit erythrocyte AChE activity in pregnant women. This evidence reinforces the need to investigate a relationship little explored in the literature may indicate mechanisms of lead toxicity in humans.

P-0349 Persistent organic pollutant levels in maternal blood, umbilical cord blood, and breast milk: Results from the Rio Birth Cohort pilot Study, Brazil

Aline Santos[1], Josino Moreira[2], Antonio Azeredo[1], Ana Rosa[2], Volney Câmara[1], Carmen Asmus[3], Armando Meyer[1]
[1]Occupational and Environmental Health, Public Health Institute, Federal University of Rio de Janeiro., Rio de Janeiro, Brazil, [2]Center for Studies of Human Ecology and Worker's Health, National School of Public Health, Oswaldo Cruz Foundation., Rio de Janeiro, Brazil, [3]of Medicine, Maternity School Hospital, Federal University of Rio de Janeiro., Rio de Janeiro, Brazil

BACKGROUND AND AIM: Environmental exposure to 11 polychlorinated biphenyls (PCB) and 17 organochlorine pesticides (OCP) were evaluated in maternal blood, umbilical cord blood, and breast milk of women living in Rio de Janeiro, Brazil.

METHODS: The concentration of PCBs 28, 31, 52, 101, 105, 118, 128, 138, 153, 156, 180 and the OCPs DDT, chlordane, HCH, dicofol, dieldrin, endosulfan, metoxichlor, mirex, and pentacloroanisol, as well as some isomers and metabolites, were measured in 135 samples of maternal blood, 116 samples of umbilical cord blood, and 40, 47 and 45 breast milk samples during 1st, 3rd, and 6th follow-up months using gas chromatography triple quadrupole mass spectrometry (GC-MS/MS). Women were also asked to answer an enrollment questionnaire that included reproductive, lifestyle, residential, and sociodemographic questions.

RESULTS: The most commonly detected OCPs metabolites in the maternal blood were 4,4'-DDE (22.2%); β (8.9%); ɣ-HCH (7.4%); PCB 28 (4.4%); and PCB 153 (2.2%). In the umbilical cord blood, the most frequently found compounds were 4,4'-DDE (15.6%); 4,4'-DDT (10.4%); 4,4'-DDD (7.9%); β-HCH (11.2%), PCB 28 (4.3%); and PCB 153 (5.2%). In addition, p,p'-DDE was detected in 45, 47, and 13% of breast milk samples of the 1st, 3rd, and 6th follow-up months. Although not statistically significant, ∑DDT levels were higher among women with a pregestational BMI ≥30, non-white, and those older than >40 years. On the other hand, newborns with an Apgar score ≤8 at minute 5 of life showed significantly higher levels of ∑DDT in the umbilical cord blood.

CONCLUSIONS: Several persistent OCPs and PCBs were detected in the umbilical cord and maternal blood, and only p,p'-DDE was quantified during the three follow-ups. Although the concentrations of OCPs and PCBs were relatively low, they still pose a risk to the mothers' health, the pregnancy outcome, and the infants' post-natal development.

P-0350 The role of epidemiology studies in chemical risk assessment to inform risk characterization of vulnerable populations in Canada

Sareena McDonald[1]
[1]*Health Canada, Cornwall, Canada*

BACKGROUND AND AIM: The enhanced protection of vulnerable populations through the assessment of chemicals was a commitment made by the Government of Canada in 2018. Health Canada considers vulnerable populations in the assessment of existing chemical substances under the Canadian Environmental Protection Act (CEPA) (1999). Vulnerable populations include those in the general population with greater levels of exposure levels and/or increased biological susceptibility, resulting in the need for additional risk characterization. The populations considered in Screening Assessment Reports (SAR) may include infants and children, pregnant females, Indigenous communities and communities in close proximity to point source exposures, including commercial or industrial facilities. The aim of this abstract is to summarize and highlight the use of epidemiology data in risk characterization of chemical substances in vulnerable populations.

METHODS: An exploratory review of both draft and final SARs published by Health Canada and Environment and Climate Change Canada, as well as special publications was conducted. This review investigated the use of epidemiology data in chemical risk assessment, highlighting the use of epidemiology data in the assessment of vulnerable populations.

RESULTS: Several reports were identified that used observational data such as Zinc and Selenium. Observational data is used in numerous ways in these reports including characterizing exposure (concentrations of exposure, identification of exposure scenarios), informing the hazard of a substance (outcomes that cannot be assessed in animal models, populations with increased susceptibility), and characterizing risk (clarifying the mechanism of action, supporting the relevance of animal data to humans).
CONCLUSION: The consideration of epidemiological data in the risk assessment of chemical substances is an emerging area that requires further evaluation and research efforts to address the needs of vulnerable populations.

P-0353 Exposure to mercury and associated factors in Portuguese adolescents

Sónia Namorado[1,2,3], Diogo Gomes[4], Diogo Iria[4], Federico Cestelli[4], Afonso Mota[4], Bernardo Alves[4], João Leal[4], Andreia Luz[4], João Gomes[4], Rafael Barros[5,6], M. Ramiro Pastorinho[6,7,8], Ana C. Sousa[8,9]

[1]Department of Epidemiology, National Institute of Health Doutor Ricardo Jorge, Lisboa, Portugal, [2]NOVA National School of Public Health, Public Health Research Centre, Universidade NOVA de Lisboa, Lisbon, Portugal, [3]Comprehensive Health Research Center, Universidade NOVA de Lisboa, Lisbon, Portugal, [4]Colégio Valsassina, Lisbon, Portugal, [5]Health Sciences Research Centre (CICS), Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal, [6]NuESA - Health and Environment Study Unit, Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal, [7]Department of Medical and Health Sciences, School of Health and Human Development, University of Évora, Évora, Portugal, [8]Comprehensive Health Research Centre (CHRC), University of Évora, Évora, Portugal, [9]Department of Biology, School of Science and Technology, University of Évora, Évora, Portugal

Due to its well-known neurotoxicity and endocrine disrupting potential mercury has been recognized as a chemical of concern by governments and citizens alike, leading to the adoption of the Minamata Convention on Mercury in 2017 by 127 countries. This work aimed to evaluate exposure to mercury in Portuguese adolescents and simultaneously to increase their knowledge and awareness about the possible effects of mercury exposure and ways to reduce it. for that, the research team together with a group of teenagers from a school in Lisbon and their teachers developed and implemented a human biomonitoring survey.

Students from the 11th and 12th grades performed recruitment at the school under the supervision of their biology teachers and after having received training from researchers. Hair samples and data on possible mercury exposure sources (e.g. seafood consumption, dental amalgams) were collected. Atomic absorption spectrometry with thermal decomposition and gold amalgamation was used to analyse samples, alongside with human hair certified reference material. The study was approved by the school's Pedagogical Board and the National Data Protection Authority.

A total of 92 students were recruited. They were aged 12-18 years, 56.5% were females, most lived in urban areas (91.3%) and the majority (97.8%) didn't have dental amalgam fillings nor used hair dye. Participants' BMI ranged from 15.1 to 28.4 kg/m2, with a mean of 20.6 ± 2.6 kg/m2. Total mercury in hair ranged from 0.01 to 3.32 µg/g, with a mean of 1.09 ± 0.66 µg/g. Around 40% of the students had mercury levels higher than US-EPA reference limit (1 µg/g), while 9.8% exhibit levels higher than WHO reference dose (2 µg/g). Higher mercury levels were significantly associated with higher consumption of fish, namely seawater fish, and with having dental amalgam fillings, but not with shellfish or seaweed consumption.

P-0358 Low-level cadmium exposure and atherosclerosis in the carotid arteries: results from the Swedish population-based cohort SCAPIS

Florencia Harari[1], Lars Barregard[1], Gerd Sallsten[1], Niklas Forsgard[2], Margaretha Persson[3], Thomas Lundh[4], Björn Fagerberg[5], Gunnar Engström[3], Göran Bergström[6]

[1]Occupational and Environmental Medicine, University of Gothenburg and Sahlgrenska University Hospital, Gothenburg, Sweden, [2]Department of Clinical Chemistry, Sahlgrenska University Hospital, Sweden, [3]Department of Clinical Sciences in Malmö, CRC, Lund University and Skane University Hospital, Sweden, [4]Division of Occupational and Environmental Medicine, Department of Laboratory Medicine, Lund University and Skane University Hospital, Sweden, [5]Department of Molecular and Clinical Medicine, Wallenberg Laboratory for Cardiovascular and Metabolic Research, University of Gothenburg and Sahlgrenska University Hospital, Sweden, [6]Department of Molecular and Clinical Medicine, University of Gothenburg, and Department of Clinical Physiology, Sahlgrenska University Hospital, Sweden

BACKGROUND AND AIM: Cadmium exposure is associated with atherosclerosis and cardiovascular mortality. Few studies have, however, examined how cadmium affects the atherosclerotic burden. We investigated the association between cadmium exposure and atherosclerotic burden in a Swedish population-based cohort.

METHODS: We performed a cross-sectional study using data from the Swedish CardioPulmonary bioImage Study (SCAPIS), including 5622 middle-aged men and women, enrolled 2013-2018. Cadmium was measured in whole blood (B-Cd) using inductively coupled plasma mass spectrometry. Presence of atherosclerotic plaque (yes/no, uni-/bilateral), total plaque area (mm²) and presence of large plaques (>25 mm²), all measured in the carotid arteries by high-resolution ultrasonography, were used as outcomes. Associations between B-Cd (in quartiles, Q1-4) and the different outcomes were analyzed using Poisson (for dichotomized outcomes) and linear (for continuous outcomes) regression and adjusted for cardiovascular risk factors and confounders.

RESULTS: Atherosclerotic plaques were present in 57% of the individuals, for whom the median total plaque area was 16 mm² (range: 0.2-222). The median B-Cd concentration was 0.24 µg/L (range: 0.01-8.5). In multivariable-adjusted models, individuals in the fourth quartile of B-Cd (Q4) had a prevalence ratio (PR) for plaque of 1.10 (95%CI: 1.01, 1.19) when compared with the first quartile (Q1). Individuals in Q4 had on average 3.8 mm² larger plaques (95%CI 0.78, 6.7) and a 27% increased risk of having large plaques (95%CI 0.93, 1.74) compared with individuals in Q1. The PR for bilateral plaques for individuals in Q4 vs Q1 was larger than that for unilateral plaques [PR 1.21 (95%CI 1.06, 1.4) and PR 1.09 (95%CI: 0.96, 1.24), respectively]. Estimates were larger for men and for current smokers.

CONCLUSIONS: Our study shows that increasing cadmium exposure is associated with a larger atherosclerotic burden and reinforces the urgent need of public health measures to reduce cadmium exposure in the general population.

KEYWORDS: cadmium, atherosclerosis.

P-0359 Tattoos: a new ancient carcinogen?

Milena Foerster[1], Khaled Ezzedine[2], Céline Ribet[3], Marie Zins[3], Marcel Goldberg[3], Joachim Schüz[1]
[1]International Agency for Research on Cancer (IARC), Lyon, France, [2]Université Paris Est Créteil (UPEC), Paris, France, [3]French Institute of Health and Medical Research (INSERM), Paris, Lyon

Tattoo prevalence has been rising steeply during the last decades, a development seen worldwide mostly in the younger age groups. However, only few are aware that tattoo inks may contain harmful environmental and chemical contaminants classified as (probably) carcinogenic to humans. Amongst them are polycyclic aromatic hydrocarbons, primary aromatic amines and metals. However, as studies underlying this classification did not consider subcutaneous exposure, it remains to decipher whether tattoos might cause cancer in humans.
As it is known that the largest part of the nano- and microparticle sized injected tattoo pigments travels to the local lymph node and, from there, potentially to other organs, the systemic exposure is not restricted to the skin. Especially in young individuals exposure to tattoo ink is worrisome as they will have a long-term exposure to these substances. To understand the potential relationship of tattoos and certain kinds of cancer, epidemiological studies are needed, which are scarce worldwide. A sound study design needs to assure a long-term follow-up of (young) tattooed cohort participants, prospective and objective recruitment of medically confirmed cancer outcomes and the inclusion of major sociodemographic, medical and lifestyle confounders.
This in mind, the first longitudinal population based cohort study on tattoos and cancer is currently being set-up in the framework of the French national cohort “Constances”. The CRABAT (Cancer Risk Associated with the Body Art of Tattooing) study is led by the International Agency for Research on Cancer (IARC) and leverages the infrastructure of the French national cohort “Constances”. Here we present its conceptual framework, study design and exposure assessment.

P-0360 Detection of 4-hydroxychlorothalonil in human serum

Annette Krais[1], Emelie Rietz Liljedahl[1], Elin Wallstedt[1], Annelise Blomberg[1], Anna Rönnholm[1], Marie Bengtsson[1], Christel Nielsen[1], Christian Lindh[1]
[1]*Division of Occupational and Environmental Medicine, Lund University, Lund, Sweden*

BACKGROUND AND AIM: Chlorothalonil (CHT) is an organochlorine fungicide that has been widely used, e.g. in agriculture but also as wood protectant and paint additive. It has recently been banned in the European Union due to its potential impact on the environment and human health. The transformation product 4-hydroxychlorothalonil (4-OH-CHT) was recently identified using nontargeted analysis in human serum and breastmilk samples. Large knowledge gaps exist, but there are indications that 4-OH-CHT is more toxic and has a higher environmental persistency than CHT. Our aim was to investigate serum levels of 4-OH-CHT in a large human population.

METHODS: We developed a quantitative method for 4-OH-CHT analysis using liquid chromatography-triple quadrupole mass spectrometry (LC-MS/MS). We measured 4-OH-CHT in 1,815 serum samples collected from pregnant women between 1997-2015, which were originally stored in the Swedish Rubella Screening Program Biobank and analyzed as part of the NIH R01 funded Autism and Prenatal Endocrine Disruptors study. Linear regression models were used to assess time trends of 4-OH-CHT.

RESULTS: The validated analytical method performed well and the LOD was 0.1 ng/ml. 4-OH-CHT was detected in all serum samples with a median concentration of 4.1 ng/ml (range: 0.16-38 ng/ml). Concentrations showed clear seasonality, with higher concentrations in the first half of each year. A linear regression of log-transformed 4-OH-CHT by year showed no linear trend.

CONCLUSIONS: To the best of our knowledge, this is the first study to quantify a chlorothalonil metabolite in human serum. 4-OH-CHT does not seem to degrade after 25 years of storage. Concentrations of 4-OH-CHT were higher than expected and suggest a widespread and continuous chlorothalonil exposure in the general Swedish population. More research is needed to explore possible sources of exposure to CHT and 4-OH-CHT, as well as their persistency.

KEYWORDS: Chlorothalonil, emerging chemicals of concern, human biomonitoring

P-0362 The Use of Potentially Toxic Skin Bleaching Products Among Women In Urban and Rural Areas In Lagos State and Investigation of Active Chemicals In Selected Skin Lightening Products

Chidinma Gab-Okafor[1], Antoinette Ofili[2], Tanimola Akande[3], Kofoworola Odeyemi[4], Babatunde Salako[5]
[1]Department of Biochemistry and Nutrition, National Institute of Medical Research, Yaba, Nigeria, [2]Department of Community Health, University of Benin, Benin, Nigeria, [3]Department of Epidemiology and Community Health, University of Ilorin, Ilorin, Nigeria, [4]Department of Community Health and Primary Care, College of Health Sciences, University of Lagos, Idi-Araba, Surulere, Nigeria, [5]Clinical Sciences Department, National Institute of M edical Research, Yaba, Nigeria

BACKGROUND AND AIM: The prevalence of skin lightening SL is higher in African nations especially Nigeria and it cuts across all socio-demographic and geographical characteristics. Studies have reported various regulatory failures that remains unabated. This study was aimed at determining the use of SL products among women in urban and rural areas in Lagos state of Nigeria and assessment of SL compounds in selected SL products.
Methodology:
A comparative cross-sectional study carried out in Lagos State, among 1100 women within the age range 18-65 years who resided in rural and urban areas . Respondents were selected using a multi-stage sampling technique and data was collected using exploratory parallel mixed method. The study also involved laboratory analysis of SL compounds in SL products.

RESULTS: Knowledge of SL was significantly higher among rural (83.1%) than urban (87.9%) women ($p<0.05$). Conversely, about half of the respondents in the urban area (45.8%) had positive attitude to SL than rural respondents (36.2%; $p<0.05$). The reported prevalence (82.9%) was significantly higher in rural area than the urban area.
There were very elevated levels of the SL compounds in all categories of SL products. About 90% of the SL chemical compounds analysed were not declared on the ingredient list of the SL products. Similarly, 75% of the SL products had SL chemicals greater than the permissible limits on laboratory analysis.

CONCLUSIONS: There is outstanding gap in the knowledge and attitude to SL in both rural and urban areas of Lagos though there is a shift in the demography of users of SL products. The reported prevalence however is still higher among the rural women. The study highlights huge regulatory failure in cosmetic products. Advocacy, health information literacy and regulatory reinforcement can contribute to the control of SL in Nigeria.

P-0368 Per- and polyfluoroalkyl substances (PFAS) exposure and sleep health in U.S. adults, NHANES 2005-2014

Zhihao Jin[1], Pengfei Guo[1,2], Jiajun Luo[1,2], Kosuke Inoue[3], Krystal G. Pollitt[1,2], Nicole C. Deziel[1,2], Zeyan Liew[1,2]
[1]Department of Environmental Health Sciences, Yale School of Public Health, New Haven, USA, [2]Yale Center for Perinatal, Pediatric, and Environmental Epidemiology, Yale School of Public Health, New Haven, USA, [3]Department of Social Epidemiology, Graduate School of Medicine, Kyoto University, Kyoto, Japan

BACKGROUND AND AIM Per- and polyfluoroalkyl substances (PFAS) are synthetic chemicals that may induce oxidative inflammatory responses and disrupt the endocrine and the central nervous systems, all of which can influence sleep. This study aims to investigate the association between PFAS exposure and sleep health in adults using the U.S. National Health and Nutrition Examination Survey (NHANES).

METHODS: We analyzed serum concentrations of four PFAS [perfluorooctane sulfonic acid (PFOS), perfluorooctanoic acid (PFOA), perfluorohexane sulfonic acid (PFHxS), and perfluorononanoic acid (PFNA)] in 8,015 adults enrolled in five waves of NHANES between 2005 and 2014. Self-reported outcomes include diagnosis of sleep disorder (e.g., apnea, insomnia), insufficient sleep (<6 hours/day), and excessive sleep (>9 hours/day). Weighted multivariate logistic regression was utilized to estimate the association between the sleep outcomes and PFAS (individual compounds and mixtures) modeled continuously (log2) or in exposure tertiles, adjusting for potential confounders. A quantile g-computation was used to estimate the joint effects of PFAS mixtures on the sleep outcomes.

RESULTS: Overall, 8.4% (N=674) of participants had sleep disorder diagnosis, and 14.7% (N=1,177) and 2.8% (N=227) were classified as insufficient or excessive sleep, respectively. A doubling of serum-PFOS concentrations (ng/ml) was associated with lower odds of having diagnosed sleep disorder (OR=0.87, 95%CI: 0.81, 0.93) and experiencing insufficient sleep (OR=0.92, 95%CI: 0.85, 0.99). These inverse associations were also observed for PFAS mixtures, but only among male adults aged 60 and above. Adults with higher exposure tertiles of PFOS, PFOA, and PFNA were associated with higher odds of excessive sleep compared to those in the lowest tertiles.

CONCLUSIONS:PFAS exposure was linked to sleep outcomes in NHANES, but the effect direction varied by the chemical and outcome assessed. Potential influence from reverse causation and selection bias due to pre-existing sleep conditions needs to be considered.

KEYWORDS: Sleep; Chemical Mixtures; Endocrine Disruptors; Exposome

P-0369 Association between lead and cadmium exposure and kidney function and mediation effects of atherosclerosis

Carl Guldbrand[1], Huiqi Li[2], Niklas Forsgard[3], Florencia Harari[1]
[1]Occupational and Environmental Medicine, Department of Public Health and Community Medicine, University of Gothenburg and Sahlgrenska University Hospital, Gothenburg, Sweden, [2]School of Public Health and Community Medicine, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, [3]Department of Clinical Chemistry, Sahlgrenska University Hospital, Gothenburg, Sweden

BACKGROUND AND AIM: Environmental lead and cadmium exposure has been associated with reduced kidney function and chronic kidney disease as well as with a higher risk of atherosclerosis. The role of atherosclerosis in the associations between these metals and kidney function has not been studied before. The aim of this study is therefore to assess the associations between lead and cadmium exposure and kidney function and the role of atherosclerosis as a mediating factor.

METHODS: This cross-sectional study used data from the population-based Swedish CArdioPulmonary bioImage Study (SCAPIS) and involved 4804 men and women (50-65 years old), recruited in 2013-2017. Blood cadmium (B-Cd) and lead (B-Pb) concentrations, analyzed using inductively coupled plasma mass spectrometry, were used as exposure biomarkers. Estimated glomerular filtration rate (eGFR) based on serum creatinine and Cystatin C was used as marker of kidney function. Associations between B-Cd and B-Pb (in quartiles, Q1-4) and eGFR was assessed using linear regression models adjusted for known risk factors of renal disease and confounders. Mediation analysis was conducted to evaluate the indirect effect (via atherosclerosis) of lead and cadmium on kidney function.

RESULTS: The median B-Pb and B-Cd was 14µg/L (range: 0.75-178) and 0.24 µg/L (range: 0.0098-8.5), respectively. The median eGFR was 88 ml/min/1.73m2 (range: 17-122). In multivariable-adjusted models, individuals in Q4 of B-Pb had a -1.26 ml/min lower eGFR (95%CI: -2.24, -0.28) compared to those in Q1. This estimate remained unchanged after adjustment for cadmium. In stratified analyses, the effect size was similar for both never and current smokers. The mediation analyses showed that the effect of lead on eGFR is not mediated by atherosclerosis. There were no associations between eGFR and B-Cd.

CONCLUSIONS: Increased lead exposure was associated with a reduced eGFR. This association does not seem to be mediated by atherosclerosis.

KEYWORDS: heavy metals, kidney function, atherosclerosis

P-0370 The association of urinary nickel concentrations with type 2 diabetes and fasting blood glucose levels: A cross-sectional study from the China National Human Biomonitoring

Yingli Qu[1]
[1]*National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND AND AIM: Epidemiological studies on the effect of nickel exposure on the prevalence of type 2 diabetes (T2D) in the general population are scarce and remain controversial. We aimed to assess the association of nickel exposure with the odds of T2D and fasting blood glucose (FBG).

METHODS: The study included a total of 10,890 adults aged 18 years or older from the China National Human Biomonitoring conducted in 2017-2018. The urinary nickel concentrations and FBG were measured and lifestyle and demographic data were collected. Weighted multiple regression analyses were used to estimate the associations of urinary nickel concentrations with the odds of T2D and increased FBG.

RESULTS: The weighted median concentration (interquartile range) of urinary nickel was 1.74 μg/L (0.85-3.37 μg/L). After adjusting for potential confounding factors, the urinary nickel concentrations were correlated positively with the prevalence of T2D, and the odd ratios of T2D associated with the highest quartile of nickel concentrations were 1.84 (95% confidence interval (CI), 1.33-2.54) when compared to the lowest quartile. Elevated urinary nickels were associated with higher FBG, each one-unit increase in log10-transformed urinary nickel concentration was associated with a 0.39 (95%CI: 0.20-0.58) mmol/L elevation in FBG in the most adjusted categorical model. In addition, restricted cubic spline analysis showed a significant linear association between nickel exposure and the odds of T2D and FBG levels.

CONCLUSIONS: Our findings suggested that elevated urinary nickel levels may be related to an increase in FBG levels and T2D prevalence in Chinese adults.

P-0377 Exposure to perfluoroalkyl substances, incident Type 2 Diabetes risk and associated metabolic pathway dysregulation in a multiethnic population

Vishal Midya[1], Elena Colicino[1], Dinesh Barupal[1], Chris Gennings[1], Ruth J. F. Loos[2,3], Ryan W. Walker[1], Douglas I. Walker[1], Damaskini Valvi[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]The Charles Bronfman Institutes for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Novo Nordisk Foundation Center for Basic Metabolic Research, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark

BACKGROUND AND AIM: Growing experimental and epidemiology evidence suggests that exposure to perfluoroalkyl substances (PFAS) increase type 2 diabetes (T2D) risk; however, effects of PFAS-mixtures and underlying mechanisms are unclear. We examined associations of exposure to PFAS-mixture with incident T2D-risk and underlying plasma metabolic-pathways using untargeted metabolomics.

METHODS: We conducted a nested case–control study within BioMe, an electronic health record-linked biobank of >60,000 patients seeking primary care at Mount Sinai Hospital, New York, since 2007. A total of 180 incident T2D cases (33% African Americans, 33% Hispanics, 33% Whites) were matched to 180 controls by age, sex and ancestry. We used liquid-chromatography with high-resolution mass spectrometry, to quantify seven PFAS (PFOS, PFOA, PFHxS, PFHpA, PFDA, PFHpS and PFNA) and measured untargeted metabolomic profiles in prediagnostic plasma. Cases had an average of ~6 years between blood draw and T2D diagnosis. We used (1)Weighted Quantile Sum(WQS) regression to evaluate the PFAS-mixture association with incident T2D risk; (2)performed metabolome-wide association analysis using Hierarchical-Bayesian WQS and logistic regression to separately analyze PFAS-mixture and T2D associations with 656 annotated metabolites, adjusting for confounders. Pathway enrichment analyses were performed using Mummichog. We used inverse probability weighting to account for nested case-control design in PFAS-metabolites analysis. Multiple comparisons were accounted by calculating q-values.

RESULTS: Each tertile increase in PFAS-mixture(ng/mL) was associated with increased odds of incident T2D (OR[95%CI]=1.45[1.01, 2.09]) with PFOS and PFHpA having highest contributions to PFAS-mixture. T2D risk and PFAS-mixture associated top metabolites were aminoadipic acid, cortisol, gamma-glutamylglytamine, sulfolithocholylglycine, n-acetylaspartic acid and top pathways were alanine and aspartate metabolism, C21-steroid hormone biosynthesis and metabolism, androgen and estrogen biosynthesis and metabolism(p-value<0.05;q-value >0.2).

CONCLUSIONS: Exposure to PFAS mixtures may dysregulate pathways of amino acid metabolism and steroid-hormone biosynthesis and metabolism, increasing risk of T2D diagnosis in multiethnic populations.

P-0379 The Breast Milk Perfluorome is Associated with Infant Growth in the First Year of Life

Tanya Alderete[1], Jesse Goodrich[2], Hongxu Wang[2], Elizabeth Holzhausen[1], Maximilian Bailey[1], Xiangping Lin[3], Zoe Coates Fuentes[3], Douglas Walker[3], David Conti[2], Leda Chatzi[2], Michael Goran[4]
[1]University of Colorado Boulder, USA, [2]University of Southern California, USA, [3]Icahn School of Medicine at Mount Sinai, USA, [4]Children's Hospital of Los Angeles, USA

BACKGROUND AND AIM: Early life exposure to poly- and perfluoroalkyl substances (PFAS) has significant obesogenic effects that are manifested in early life. However, PFAS examined do not include the wide range of PFAS used in commercial applications.

METHODS: This pilot included 56 Hispanic mother-child pairs from Southern California. Maternal and infant characteristics were assessed, including infant weight, length, and fat mass. All mothers were breastfeeding, and breast milk was collected at 1-month postpartum. The perfluorome was characterized using untargeted high-resolution mass spectrometry. Organofluorine compounds were identified using the EPA CompTox Dashboard. Multivariable linear and logistic regression analyses were used to examine associations between PFAS with growth measures (12-months, change in first year, rapid growth) after adjusting for infant age, sex, pre-pregnancy BMI, gestational age, and formula feedings. Results are reported for associations with $p<0.05$ and were considered statistically significant using a false discovery rate (FDR) of 20%.

RESULTS: 484 suspect PFAS compounds were detected in ≥75% of samples. PFAS were associated with 12-month weight [n(%): 10(2.1%) positive, 12(2.5%) negative], change in weight [10(2.1%) positive, 22(4.5%) negative], 12-month length [21(4.3%) positive, 17(3.5%) negative] change in length [22(4.5%) positive, 25(5.2%) negative], 12-month fat mass [9(1.9%) positive, 12(2.5%) negative], and change in fat mass [18(3.7%) positive, 21(4.3%) negative]. Additionally, 12(2.5%) and 13(2.7%) of PFAS compounds were associated with an increased (OR=2.0-3.8) and decreased odds (OR=0.28-0.47) of rapid growth in the first, respectively. After FDR, three compounds, each detected in >98% of samples, were associated with change in length (q=0.01; n=2 positive, n=1 negative). Tentative annotations of these compounds identified novel PFAS, including methyl 4,4,5,5,5-pentafluoropent-2-ynoate3,4,4,5,5-Pentafluoro-2-methoxycyclopent-2-en-1-one, ethyl [5-(heptafluoropropyl)-1-methyl-1H-pyrazol-3-yl]acetate, and ethyl 2-acetyl-4,4,5,5,5-pentafluoro-3-oxopentanoate.

CONCLUSIONS: Results from this pilot suggest that a wide range of PFAS are present in human breast milk, which may impact infant growth in the first year of life.

KEYWORDS: breast milk, PFAS, infants

P-0380 Lindane use and the incidence of thyroid cancer in the USA; an ecological study

Mathilda Alsen[1], Vikram Vasan[1], Catherine Sinclair[1], Maaike Van Gerwen
[1]*Icahn School of Medicine at Mount Sinai, New York, USA*

INTRODUCTION: The increased thyroid cancer incidence rate may potentially be partially attributable to exposure to chemicals with endocrine disruptive properties. Lindane is an organochlorine pesticide with endocrine disruptive properties that has been classified as carcinogenic to humans. The aim of this ecological study was to evaluate potential correlation between Lindane exposure and thyroid cancer incidence in the USA (US).

METHODS: Data on age-adjusted thyroid cancer incidence rate (per 100,000 people) was obtained from the Centers for Disease Control and Prevention for all US states for 2018. Lindane use was obtained from the US Geological Survey and presented in quintiles for the years 1992 and 2007 to consider latency period. Trend of Lindane use between 1992 and 2007 was calculated using Mann Kendall correlation test. Lindane use estimates per cropland (kg/acres cropland) were overlaid on the map of age-adjusted thyroid cancer incidence rate using ArcGIS. Correlation between statewide Lindane use and age-adjusted thyroid cancer incidence rates was calculated using Spearman correlation.

RESULTS: Overall Lindane use decreased significantly between 1992 and 2007 ($T = -0.617$; $p < 0.001$). Statewide differences in the patterns of Lindane use as well as thyroid cancer were found, with high rates of thyroid cancer and Lindane use reported in several states including Delaware and Georgia. There was no statistically significant correlation between thyroid cancer incidence rates in 2018 and Lindane use in 1992 ($r=0.075$; $p=0.689$) nor Lindane use in 2007 ($r=0.01$; $p=0.935$), among males and females combined.

CONCLUSIONS: Restrictions clearly seem to be effective in reducing Lindane use. While, overall, there was no evidence of a correlation between thyroid cancer and Lindane use, more research is needed to explore this further specifically in highly exposed populations (e.g. rural areas) with longitudinal studies that assess the effects of long-term exposure to Lindane and other organochlorine pesticides.

P-0385 Exposure of adults aged 18 to 44 years to personal care products (PCPs) in Beijing, China: urinary levels, exposure patterns and risk evaluation.

Linxue Han[1], Xiao Lin[1], Xu Zhang[1], Ying Zhu[1]
[1]*China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND AND AIM: PCPs, including parabens, benzophenones and antimicrobials, are a group of typical EDCs that widely applied in various consumer products and industrial applications. Concern for adverse effects on human health arises from results of in vitro and in vivo experiments. The purpose of this study was to assess the characteristics of exposure to PCPs and to provide a preliminary assessment of exposure levels and health risks within typical PCPs in the target population in combination with estimated daily intake (EDI) and risk entropy (HQ).

METHODS: 15 PCPs were measured in 127 spot urine samples collected from Beijing residents aged 18 to 44 years from November 2021 to January 2022. Individual specific gravity (SG) was used to correct for urinary dilution. Since distributions of PCPs concentration were right skewed, non-parametric statistics were used. The relationships between different parabens and benzophenones were determined using the Spearman correlation coefficient. The difference of PCPs concentration in various demographic characteristics, such as gender and age, were compared by Mann-Whiney test.

RESULTS: We found that PCPs were ubiquitous in all urine samples, with methyl paraben(MP), ethyl paraben(EP) and propyl paraben(PP) being the main compounds with median concentrations of 27.08 μg/L, 0.76 μg/L and 1.16 μg/L, respectively. Non-parametric tests showed statistically significant differences in gender for 8 PCPs. There was a significant positive correlation between MP and PP concentrations, Benzophenone-1、Benzophenone-3 and Benzophenone-4 concentrations. The median EDI-urine values of PCPs varied in the range of 20.01~88,295 ng/kg-bw/day. More than 5% of the target population exhibited greater HQs > 1 for individual PCPs.

CONCLUSIONS: The high correlation between the different PCPs suggests that they may have the same and/or similar original sources. Exposure to PCPs might be a critical factor contributing to adverse health effects in Beijing residents.

KEYWORDS: PCPs, EDI, risk assessment

P-0386 Persistent Organic Pollutants and Dysregulation of microRNAs Expression in Humans and Animals - A Systematic Literature Review

Yijie Li[1], Brittney O. Baumert[1], Elizabeth Costello[1], Sarah Rock[1], Nikos Stratakis[2], Jesse Goodrich[1], Yinqi Zhao[1], Sandrah P. Eckel[1], Douglas I. Walker[3], Damaskini Valvi[3], Michele A. La Merrill[4], Rob McConnell[1], Victoria K. Cortessis[1], Max Aung[1], Haotian Wu[5], Andrea Baccarelli[5], David Conti[1], Lida Chatzi[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, USA, [2]Barcelona Institute for Global Health, ISGlobal, Barcelona, Spain, [3]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [4]Department of Environmental Toxicology, University of California, Davis, USA, [5]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA

BACKGROUND: MicroRNAs (miRNAs) are key regulators in many physiological processes. Evidence suggests that exposure to persistent organic pollutants (POPs) is associated with miRNA dysregulation. Exposure to POPs is ubiquitous and these chemicals are characterized by their environmental persistence. It is therefore of public health concern to understand the relationship between POPs and miRNA as it relates to health outcomes.
OBJECTIVES: The objective of this systematic review is to evaluate the relationship between exposure to POPs including per- and polyfluoroalkyl substances (PFAS), polychlorinated biphenyls (PCBs), dichloro-diphenyl-trichloroethane (DDT), hexachlorobenzene (HCB), and polybrominated diphenyl ethers (PBDEs), with miRNA expression in both human and animal studies.

METHODS: The systematic search of the literature was conducted in PubMed and Embase. Search results of human and animal studies were included if they included at least one POP of interest in relation to at least one miRNA. Data were synthesized to determine the direction and statistical significance of associations between POPs and miRNA. Finally, a review of disease pathways was conducted for miRNAs that were consistently associated with POPs.

RESULTS: Our search identified 35 studies, 8 of humans and 27 of model organisms. PFAS were associated with decreased expression of miR-144, miR-19 and miR-193, and increased expression of miR-26b, miR-199a-3p, miR-122 and miR-128 across studies. PCBs were associated with increased expression of miR-15a, miR-21, miR-1537 and decreased let-7b in both humans and animals. Pathway review suggested that PFAS-associated miRNAs are all involved in prostate cancer, hepatocellular carcinoma and nonalcoholic fatty liver disease, while PCB-associated miRNA are associated with gastric cancer.

CONCLUSIONS: This is the first systematic review of the association of POPs with miRNAs in humans and model organisms. Large-scale prospective human studies are now warranted to examine the role of miRNAs as mediators between POPs and health outcomes.

KEYWORDS: persistent organic pollutants, miRNAs, systematic review

P-0388 Associations of blood lead and cadmium co-exposure and hepatic dysfunction: A cross-sectional study among Chinese adults aged 18 and older

Xiao Lin[1], Linxue Han[1], Master Xu Zhang[1], Master Qi Sun[1], Master Tian Qiu[1], Ying Zhu[1], Yuebin Lv[1], Xiaoming Shi[1]
[1]*China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND AND AIM: Lead (Pb) and cadmium (Cd) were once toxic metals of occupational importance, but are now more harmful as environmental pollutants. Current evidence on the relationship between Pb and Cd co-exposure on liver function are still limited and findings remain conflicting. This study focused on studying the effects of Pb and Cd alone and co-exposure on liver function among Chinese adults aged 18 years and older.

METHODS: The study used data from the China National Human Biomonitoring (CNHBM) in 2017-2018. Pb and Cd levels were measured in whole blood. Alanine aminotransferase (ALT), Aspartate aminotransferase （AST） and γ-glutamyl transpeptidase （γ-GT） were selected as the hepatic function biomarkers. Combined effect of blood Pb and Cd were assessed using logistic regression.

RESULTS: The median of blood lead and blood cadmium in the population were 23.38 μg/L and 0.83 μg/L, respectively. In the joint association analyses of blood Pb and Cd, significant p-interaction values were found in all elevated hepatic biomarkers, indicating there was an interaction between these two metals. for biomarker ALT, in full adjusted model, the ORs of subjects with low Pb and high Cd, and high Pb/Cd were 1.37(1.03, 1.84) and 1.55 (1.16, 2.07), compared to those with low Pb/Cd, respectively. Similar results were exhibited in the biomarker AST. for biomarker γ-GT, the ORs of subjects with high Pb and low Cd, and high Pb/Cd, were 2.02(1.26, 3.23) and 1.97(1.27, 3.05) after adjusting for confounders.

CONCLUSIONS: Co-exposures of Pb and Cd were associated with hepatic dysfunction, efforts should be made to further reduce environmental Pb and Cd exposure in order to weaken the interaction effect.

KEYWORDS: lead, cadmium, co-exposure, liver, Chinese adults

P-0392 Relationships between urinary phthalate metabolites and lipidomic profile in a Taiwanese elderly population

Ming-Chieh Li[1], Chi-Hsien Chen[2,5], Ching-Yu Lin[3], Tzu-Chieh Chou[4], Yue Leon Guo[5,6,3]

[1]Department of Health Promotion and Health Education, College of Education, National Taiwan Normal University, Taipei City, Taiwan, [2]Department of Environmental and Occupational Medicine, National Taiwan University Hospital Hsin-Chu Branch, Hsinchu City, Taiwan, [3]Institute of Environmental and Occupational Health Sciences, College of Public Health, National Taiwan University, Taipei City, Taiwan, [4]Department of Public Health, College of Public Health, China Medical University, Taichung City, Taiwan, [5]Department of Environmental and Occupational Medicine, College of Medicine, National Taiwan University (NTU) and NTU Hospital, Taipei City, Taiwan, [6]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli County, Taiwan

BACKGROUND AND AIM: Phthalate exposure has been associated with circulating lipid composition. However, limited epidemiological study has been carried out in elderly people. Therefore, we conducted a cross-sectional study to examine the associations between urinary phthalate exposure and lipidomic profile in Taiwanese elderly people.

METHODS: A cross-sectional survey of the elderly (age >= 65 years) was conducted in Taipei city, New Taipei City, Hualien County, Chiayi County, and Kaohsiung City in Taiwan. A total of 11 urinary phthalates metabolites and 86 lipids (phosphatidylcholines (PCs) and sphingomyelins (SMs)) were assessed. Demographic information was obtained by a structured questionnaire. Serum lipidomic profile was identified using principal component analysis (PCA). A two-step analysis was performed. We first performed multiple linear regressions to evaluate whether urinary phthalate metabolites were related to the PCA-derived components of serum lipid concentrations. Then we performed multiple linear regressions to investigate each of the lipids that were suggestively correlated with some of the phthalates in PCA. Urinary concentrations of phthalate metabolites were log-transformed to normalize distributions.

RESULTS: A total of 886 participants (58.9% women) were included in the final analysis. There were ten components identified by PCA, which accounts for 63.2% of total variance. After adjusting for age, sex, body mass index, urinary creatinine, urinary phthalate metabolites were correlated with 6 components. Among them, component 7 was correlated with the most phthalates metabolites (Bonferroni corrected p-value < 0.007). Monomethyl phthalate (MMP) and monobutyl phthalate (MnBP) were negatively correlated with component 7, whereas monoisobutyl phthalate (MiBP), monobenzyl phthalate (MBzP), and monoisononyl phthalate (MiNP) were positively correlated with component 7. Among component 7, PC(16:0/16:0), PC(16:0/17:1), PC(16:0/18:1), PC(16:0/19:5), PC(16:0/20:5), PC(16:0/22:4), PC(38:0), PC(P-16:1/22:5), PC(P-40:4), and PC(P-40:5) were highly loaded.

CONCLUSIONS: Urinary phthalate metabolites were correlated with the lipidomic pattern. Most of them were diacyl-phosphatidylcholines, which might play a role in hepatic lipid metabolism.

P-0401 Exploratory Analysis of Relationship of Trihalomethane Levels in Water for Human Consumption and Health Profile in Municipalities of Sao Paulo State in Brazil

Marcio Ribeiro Barbosa[1], Telma de Cassia dos Santos Nery[2], Paulo Junior Paz de Lima[3]

[1]Universitary Hospital of University of São Paulo - USP - Department of Health of Government, São Paulo, Brazil, [2]Divisao de Pneumologia do INCOR HC FMUSP, Sao Paulo, Brazil, [3]Associacao Brasileira de Pesquisadores pela Justica Social, Sao Paulo, Brazil

Presence of chemicals, heavy metals (such as lead, arsenic) and agrochemicals in various regions are causing environmental and human health impacts. Water used for human consumption has been seen as a serious public health problem in Brazil, like in several countries. High levels of sanitary higienization products have been dumped into our effluents, with chlorine as the main halogen in its composition. The degradation of chlorine with the formation of trihalomethanes has been the object of study in several regions of Brazil, especially for its potential in carcinogenesis. The state of SP has a population of about 50 million people and has the best levels of sanitation in the country. Nevertheless, it does not analyze the relationships between levels of trihalomethanes and their impacts on public health. The objective of this study was to analyze the database referring to the presence of trihalomethanes in water for human consumption in 645 municipalities in the state of São Paulo in the last decade. The information was with exploratory analysis associated to the main pathologies responsible for the mortality profile in each municipality. The information banks of the national health system - DATASUS and the national water information system - SISAGUA were used. In the results we founded specific clusters of some specific groups of pathological, as compared to the international ICD 10 classification. Conclusion : In Brazil, the legislation is in a process of recent change with the confrontation of the current databases, contributing in the discussion on preventive measures in public health

P-0403 Astrocyte-derived extracellular vesicles: novel biomarkers of CNS metal exposure and elimination with applications in discerning the pathogenesis of neurodegenerative diseases

Roheeni Saxena[1], Tanya Butt[1], Mohammad Alayyoub[1], Cherine Jaafar[2], Lina Marcinczyk[1], Madeleine Strait[1], Nicole Comfort[1], Eva Tipps[1], Ronald Glabonjat[1], Kathrin Schilling[1], Diane Re[1]

[1]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA, [2]Paris Saclay University, Paris, France

BACKGROUND AND AIM: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative condition, and though environmental exposure to metals has been associated with ALS, there are no existing biomarkers for these potentially causal environmental exposures – a biomarker for toxicant load in the central nervous system is greatly needed. Upon exposure to toxic metals in vitro, central nervous system (CNS) astrocytes, critical in metallohomeostasis, were observed to produce extracellular vesicles loaded with metals, potentially as a cellular elimination pathway. Metals are known to bioaccumulate in the CNS; EVs originating from the CNS (CNS-EVs) are readily found in peripherally drawn blood and can be isolated using cell-specific surface proteins. This study examines whether blood-borne CNS-EV metal cargoes can serve as reliable biomarkers of CNS metal exposure and reveal a link between metal metabolism and neurodegenerative disease (i.e., ALS).

METHODS: Precautions were undertaken to ensure EV protocols were completed under metal-free conditions. CNS-EVs were isolated from human whole blood and plasma samples via direct immunoprecipitation using biotinylated antibodies for proteins expressed on astrocytes. Once EVs were isolated, ELISA analysis generated protein concentrations, ViewSizer Nanoparticle Tracking analysis quantified abundance, and Transmission Electron Microscopy visualized particles. EVs were analyzed for metal contents using a Perkin-Elmer NexION 350S via an ICP-MS/MS dynamic reaction cell method.

RESULTS: Results demonstrate that it is feasible to quantify the small quantities of metals within these CNS-derived EVs, particularly in terms of toxic metals known to be associated with neurodegenerative disorders, including copper, zinc, lead, aluminum, manganese, and iron.

CONCLUSIONS: CNS-derived EVs isolated from peripheral blood draws show promise as a potential biomarker of metal exposure and/or elimination in the brain and spinal cord, with promising applications in understanding the potential environmental pathogenesis of neurodegenerative disorders (i.e., ALS) among patients with relevant elevated CNS metal loads.

P-0404 Determinants of exposure to phenols, phthalates, parabens and triclosan in pregnant women, Colombia

CA Gómez-Mercado[1], Gregory Mejía- Sandoval[2], Albino Barraza-Villareal[3], Liliana Acevedo-Saenz[4], Damaskini Valvi[5], Cathrine Thomsen[6], CM Arango-Álzate[1], AK Sakhi[6], AM Segura-Cardona[1]

[1]CES University, Graduate School, Medellín, Colombia, [2]CES University, MVZ Faculty, Medellin, Colombia, [3]National Institute of Health of Mexico, Cuernavaca, Mexico, [4]CES University, Faculty of Nursing, Medellin, Colombia, [5]Icahn School of Medicine at Mount Sinai, Department of Environmental Medicine and Public Health, New York, EEUU, [6]Norwegian Institute of Public Health, Oslo, Norway

INTRODUCTION: Phenols, phthalates, parabens and triclosan are endocrine disruptors (1) and human beings are exposed daily through contact with skin, water, food and the air they breathe, these compounds are measured in urine (2).
OBJECTIVE: to determine the sources of exposure to phenols, phthalates, parabens and triclosan in pregnant women.

METHODS: study carried out in 400 women with ≤12 weeks of pregnancy from two institutions in Medellín. Demographic, nutritional and environmental exposure characteristics were investigated and 37 metabolites in urine were quantified at the Norwegian Institute of Public Health (NIPH), by means of ultra-high resolution liquid chromatography coupled to tandem mass spectrometry (UPLC-MS- MS) and dilution correction for specific gravity. Using t-student, differences were observed in the geometric measurements according to exposure determinants.

RESULTS: significant differences were found in the geometric means of Propyl Paraben (PRPA) according to the use of floor cleaners (yes: 7.94ng/mL 95% CI: 4.70-13.43; no: 18.76ng/mL 95% CI :9.21-38.21), Mono-iso-butyl phthalate(MiBP) given exposure to second-hand tobacco (yes:12.56ng/mL 95% CI:10.00-15.78; no:19, 94ng/mL 95% CI:14.86-26.76) and from exposure to the use of cosmetics, the GM of some phthalates were, Mono-4-methyl-7-oxooctyl phthalate(oxo-MiNP) [si:3, 03ng/mL 95% CI: 2.35-3.92; no:5.58ng/mL 95% IC:2.28-13.67], Mono-4-methyl-7-carboxyoctyl-phthalate(cx-MiNP) [yes:7.08ng/mL 95% IC:6.24- 805; no:11.28ng/mL 95% CI:5.57-23.26], 6-Hydroxy-Monopropylheptylphthalate(OH-MPHP) [yes:1.68 ng/mL 95% CI:1.51-1.86; no: 2.18ng/mL 95% CI: 1.39-3.41].

CONCLUSIONS: the determinants of exposure to phenols, phthalates, parabens and triclosan in pregnant women in the study were the use of floor cleaners, second-hand tobacco and the use of cosmetics.

KEYWORDS: phenols, parabens, triclosan, endocrine disruptors, urine

P-0405 Descriptive analysis of victims of poisoning, suicide attempts and deaths from pesticides in Brazil between 2010 and 2020

Paulo Junior Paz De Lima[1], Dra. Telma de Cassia dos Santos Nery[2]
[1]Brazilian Association of Researchers for Social Justice – ABRAPPS, Brazil, São Paulo, Brazil, [2]Divisao de Pneumologia do INCOR HCFMUSP, Sao Paulo, Brazil

Between 2010 and 2021, 3,474 new pesticides were registered and authorized in Brazil, of which 76.5% were only between 2016 and 2021. An increase of 540% in registrations of new pesticides when compared to 2010. As a result of this policy and with the approval in the first vote, in 2022, by the Brazilian Congress of the so-called poison package, this scenario could be even worse in the short and long term, with incalculable impacts on the health of the population and the environment. OBJECTIVES: To describe and analyze the profile of victims of pesticide poisoning, suicide attempts and deaths from agricultural, domestic, public health, rodenticide and veterinary pesticides between 2010 and 2020.

METHODS: Descriptive cross-sectional study. Data were collected from the Ministry of Health database – DATASUS.

RESULTS: There were 135,803 cases of intoxication, 73.2% of intoxications were not due to exposure at work; 71,009 suicide attempts and 3,944 deaths from poisoning, with 48.8% of the deaths being between black/brown and 36% white; 74.6% of intoxications were in urban residents and 21.9% in rural areas and 94.5% of deaths were not related to work. 712 of the victims of attempted suicides were younger than 1 year and 4 years old, 10,834 of the victims were between 10 and 14 years old.

CONCLUSIONS: The results point to higher rates of poisoning, suicide attempts and deaths from pesticide poisoning among black/brown children, with low schooling and, for the most part, living in urban areas and belonging to black/brown color/ethnicity. and no exposure to work.

KEYWORDS: Pesticides, intoxications, deaths, suicide, ethnicity.

P-0407 Mixture effects of gestational synthetic phenol and phthalate exposures on the neuro-behavior of children in the Healthy Start cohort

Dorothy Nakiwala[1], Wei Perng[1], Deborah Glueck[1], Dana Dabelea[1], Anne P. Starling[1,2]
[1]*Center for Lifecourse Epidemiology of Adiposity and Diabetes, University of Colorado, Anschutz Medical Campus, Aurora, USA,* [2]*Department of Epidemiology, University of North Carolina-Chapel Hill, Chapel Hill, USA*

BACKGROUND: Simultaneous exposure to multiple endocrine disruptors may be harmful even when individual exposures for which individual effects may be below observable levels. We sought to assess the effects of prenatal exposure to a mixture of phthalates and phenols on the neuro-behavior of preschool-aged children.
METHODOLOGY: In a sample of 293 mother-infant pairs from the Healthy Start pre-birth cohort, sixteen phthalate metabolites and phenols were assessed in maternal spot urine samples from mid-pregnancy. Behavioral outcomes in preschool children (4-5 years) were assessed using the child behavior check list (CBCL). We computed 3 composite scales for total behavioral, externalizing and internalizing problems. Covariate-adjusted weighted quantile sum (WQS) regression was used to estimate associations between the mixture of phenols and phthalates and the behavioral scales.

RESULTS: WQS regression indicated a positive trend with the externalizing scale. We observed a 0.15 points (95% CI: -0.02; 0.33, p-value = 0.09) increase in the externalizing problems' score for one tertile increase in the WQS index. The major contributors to this mixture effect were Di-isononyl phthalate (DiNP) (with a weight of 24%), Benzophenone-3 (22%), triclosan, methyl paraben (11%), MEP (7%) and bisphenol A (6%). No statistically significant (p-values > 0.1) associations were observed with the total (beta = 0.06(CI 95% -0.04; 0.16)) and internalizing (beta = -0.09(CI 95% -0.29; 0.11)) composite scores.

CONCLUSIONS: Exposure to mixtures of phenols and phthalates in utero may induce behavioral problems during early childhood. Future policy guidelines on exposure limits to these compounds should consider mixture effects as they are increasingly being reported in epidemiological studies.

P-0410 The effects of combined exposure of lead and stress during pregnancy on cognitive development in offspring

Xiangrong Guo[1,2], Shiwei Jiang[1], Jian Xu[2], Ying Tian[1], Fengxiu Ouyang[1], Xiaodan Yu[1], Chonghuai Yan[1], Junxia Liu[1], Jun Zhang[1]

[1]Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]The International Peace Maternity & Child Health Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

BACKGROUND AND AIM: To assess the current exposure levels of lead and stress during pregnancy, and compared the effects of prenatal combined exposure of lead and stress during different stages of pregnancy on the neurodevelopment of offspring.

METHODS: A total of 5270 mother-child pairs were assessed in the Shanghai Birth Cohort, maternal blood lead in early pregnancy and umbilical cord blood lead were measured. Assessments of prenatal maternal stress, the Center for Epidemiological Studies-Depression Scale and the Self-Rating Anxiety Scale during mid-pregnancy, postnatal maternal stress using the Edinburgh Postnatal Depression Scale were conducted, and groups of prenatal single exposure to lead/stress and combined exposure were therefore formed. The Ages-Stages-Questionnaires (at 6- and 12-months-of-age) and the Bayley-III (at 24-months-of-age) were performed to assess the offspring neurodevelopment.

RESULTS: The geometric means of maternal blood lead in early pregnancy and umbilical cord blood lead were 1.45 μg/dL and 1.53 μg/dL, respectively. A total of 1.86% and 0.18% of the mothers were screened positive for depression and anxiety. Adjusting for related confounders, the prenatal combined exposure in early pregnancy was associated with more deficits in infant communication skills and social-emotional skills, especially in social-emotional at 24-month-old (P=0.016); the prenatal combined exposure around birth was adversely associated with infant neurodevelopment levels in multiple domains.

CONCLUSIONS: The prenatal combined exposure to lead and stress may affect offspring neurodevelopment more profoundly (especially on social-emotional development), and the combined exposure in early pregnancy may induce more deficits in offspring social-emotional development than the combined exposure around birth.

P-0412 Early life organophosphate ester exposures and bone health at age 12 years: The Health Outcomes and Measures of the Environment (HOME) Study

Jordan Kuiper[1], Ann Vuong[2], Bruce Lanphear[3], Antonia Calafat[4], Maria Ospina[4], Kim Cecil[5], Yingying Xu[6], Kimberly Yolton[6], Heidi Kalkwarf[6], Joseph Braun[7], Aimin Chen[8], Jessie Buckley[1]

[1]Department of Environmental Health and Engineering, Johns Hopkins University Bloomberg School of Public Health, Baltimore, USA, [2]Department of Epidemiology and Biostatistics, School of Public Health, University of Nevada, Las Vegas, USA, [3]Faculty of Health Sciences, Simon Fraser University, Vancouver, Canada, [4]Division of Laboratory Sciences, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA, [5]Department of Radiology, Cincinnati Children's Hospital Medical Center, University of Cincinnati College of Medicine, Cincinnati, USA, [6]Department of Pediatrics, Cincinnati Children's Hospital Medical Center, University of Cincinnati College of Medicine, Cincinnati, USA, [7]Department of Epidemiology, Brown University, Providence, USA, [8]Department of Biostatistics, Epidemiology and Informatics, University of Pennsylvania Perelman School of Medicine, Philadelphia, USA

BACKGROUND AND AIM: No human studies have evaluated early life organophosphate ester (OPE) exposures with bone health outcomes, despite evidence of osteotoxicity. We assessed associations of urinary OPE metabolites measured across early life with bone mineral content (BMC) and areal bone mineral density (aBMD) at age 12 years.

METHODS: Among 223 mother-child dyads enrolled in the Health Outcomes and Measures of the Environment (HOME) Study, we quantified concentrations of bis-2-chloroethyl phosphate (BCEP), bis-(1,3-dichloro-2-propyl) (BDCIPP), di-n-butyl phosphate (DnBP), and diphenyl phosphate (DPHP) in urine collected from mothers during pregnancy and children at ages 1, 2, 3, 5, and 8 years. at age 12 years, we performed dual energy x-ray absorptiometry and calculated BMC and aBMD z-scores at six skeletal sites. Using a multiple informants framework, we estimated overall and sex-stratified BMC/BMD z-score differences per interquartile range (IQR) increase in OPE concentrations at multiple exposure timepoints: gestation (average) and 1–3 (average), 5, and 8 years.

RESULTS: In adjusted models, overall associations of BCEP and BDCIPP with total hip and 1/3rd distal radius aBMD varied significantly by exposure timepoint, as did BDCIPP with whole body aBMD. for example, differences (95% CI) in total hip aBMD z-score per IQR increase in BDCIPP were 0.33 (0.01, 0.65), -0.10 (-0.34, 0.14), -0.17 (-0.40, 0.05), and 0.14 (-0.09, 0.38) for concentrations during gestation and at 1–3, 5, and 8 years, respectively. Overall DnBP and DPHP associations were generally null at all timepoints. We observed sex-specific associations for some timepoints and skeletal sites. for example, an IQR increase in 8-year DPHP was associated with a 0.24 (0.08, 0.39) greater total hip aBMD z-score among females and a -0.15 (-0.39, 0.08) lower z-score among males.

CONCLUSIONS: Early life OPE exposures may be associated with sex- and exposure period-dependent alterations in early adolescent bone mineral accrual and strength.

P-0422 Prenatal exposure to emissions from a coalmine fire and childhood lung function

Emily Hemstock[1,2], Rachel Foong[3,4], Graham Hall[3,4], Amanda Wheeler[1,5], Shyamali Dharmage[6], Marita Dalton[1], Grant Williamson[1], Michael Abramson[7], Fay Johnston[1], Graeme Zosky[1,8]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]Centre for Air pollution, energy and health Research, NHMRC CRE, Glebe, Australia, [3]Children's Lung Health, Wal-yan Respiratory Research Centre, Telethon Kids Institute, Nedlands, Australia, [4]School of Allied Health, Curtin University, Bentley, Australia, [5]Mary McKillop Institute for Health Research, Australian Catholic University, Melbourne, Australia, [6]School of Population and Global Health, University of Melbourne, Melbourne, Australia, [7]School of Public Health & Preventive Medicine, Monash University, Melbourne, Australia, [8]Tasmanian School of Medicine, University of Tasmania, Hobart, Australia

BACKGROUND AND AIM: Studies linking early life exposure to air pollution and impaired lung health have focused on chronic, low-level exposure in urban settings. We have previously shown that early post-natal exposure to an acute, high-intensity air pollution episode was associated with mild impairments in peripheral lung mechanics. We aimed to determine whether in utero exposure to the same pollution event impaired lung function 7-years later.

METHODS: We conducted a prospective study in a cohort of children who lived in the vicinity of a coalmine fire that burned for 6 weeks in 2014. Individual exposure to $PM_{2.5}$ from the fire were estimated using dispersion and chemical transport modelling. Respiratory function was measured in children who were in utero during the fire, or conceived after the fire (unexposed), using the forced oscillation technique. Z-scores for resistance at 5Hz(R5), reactance at 5Hz(X5) and area under the reactance curve(AX) were calculated. Regression models were fitted to compare Z-scores of unexposed and in utero exposed children, and to examine the relationship between in utero $PM_{2.5}$ exposure and lung function.

RESULTS: of the 72 children, 22 who were unexposed and 50 exposed in utero, and had acceptable lung function measurements. Medians (interquartile ranges) for daily average and peak $PM_{2.5}$ for the children exposed in utero were 9.2(7.6–20.2) and 124(74–252) $\mu g/m^3$. There were no statistically significant differences between mean R5, X5 or AX Z-scores of unexposed and in utero exposed children. There were no associations between R5, X5 or AX Z-scores and in utero exposure to daily average or peak $PM_{2.5}$. This lack of association was maintained after inclusion of covariates in the models.

CONCLUSIONS: There was no detectable effect of in utero exposure to $PM_{2.5}$ from a local coalmine fire on post-natal lung function 7-years later.

P-0426 The impact of heat waves on children’s kidney health: Systematic review and meta-analysis

Youngrin Kwag[1], Eunhee Ha[1]
[1]*Ewha Women's University College of Medicine and Graduate School of Medicine, Seoul, Republic of Korea*

BACKGROUND: Children are known to be particularly sensitive to heat waves, but still there has been little research interest in this area . In particular, a systematic review and meta-analysis is needed to identify the relationship between climate change-related heatwaves and children's kidney health.
METHOD: Papers published between 2000 and 2022 was identified using keywords in PubMed. 320 of 2406 publications searched for "climate change", "heat wave", "children", "kidney" met the selection criteria.
RESULT: In our study we included kidney stones and urolithiasis as kidney disease. This study lists the consistent definitions of heatwaves in each literature from the perspective of children's health impact. Our study explores detailed outcome measures to quantify the effects of heatwaves on children's kidney health, and analyzes the literature to evaluate the effects of heatwaves

CONCLUSIONS: Through this study, the effect of heat wave on children's kidney health, with regards to age, gender and income, and vulnerability to heat wave between countries can be understood. In addition, it will be helpful in predicting the burden of children's kidney disease due to heat wave with respect to climate change, and developing effective heat wave damage mitigation and adaptation strategies.

P-0427 Comparative Analysis of Health Patterns and Gaps due to Environmental Influences in South Korea and North Korea, 2000-2017

Yoorim Bang[1], Jongmin Oh, Eun Mee Kim, Ji Hyen Lee, Minah Kang, Miju Kim, Seok Hyang Kim, Jae Jin Han, Hae Soon Kim, Oran Kwon, Hunjoo Ha, Harris Kim, Hye Won Chung, Eunshil Kim, Young Ju Kim, Yuri Kim, Younhee Kang, Eunhee Ha

[1]*Institute for Development and Human Security, Ewha Womans University, Seoul, Korea, Republic of Korea*

BACKGROUND AND AIM: Children's metabolism is immature and vulnerable to environmental stressors creating a larger burden of diseases. South Korea and North Korea have been isolated from each other and while sharing the same ethnicity and early history, this provides a rich ground for comparative research. The study aims to conduct a comparative study of children's health in South Korea versus North Korea with a focus on air pollution.

METHODS: The study used mortality rate, prevalence, and environmental indicators data from 2000 to 2017 from the World Bank and World Health Organizations. Comparative analysis and trend analysis of the two Koreas were conducted to evaluate changes in health status over time. Spearman's correlation analysis was used to find out the correlation between environmental indicators and children's health status.

RESULTS: The study found a distinct gap in children's health status. While North Korea reported a higher death rate of children than South Korea, it showed a decreasing trend and the gap in children's health status between them narrowed from 2000 to 2017. The prevalence of overweight and obesity increased and that of thinness decreased in both Koreas. Except for PM2.5 exposure, South Korea reported much higher figures in most indicators of air pollutant emissions (South Korea, mean (SD) = 28.3 (2.0); North Korea, mean (SD) = 36.5 (2.8), p-value=0.002).

CONCLUSIONS: The study empirically discovered the gaps and patterns of children's health between South Korea and North Korea. The findings imply epigenetic modification caused by environmental stressors affects children's health in the two Koreas despite sharing similar genetic characteristics. Considering the gaps in children's health between them, more attention and resources need to be directed towards North Korea because the necessary commodities and services to improve children's health are lacking in North Korea.

P-0428 Indoor coal ash and school and social competency among children aged 6-14 years old

Kristina M Zierold[1], John V Myers[2], Guy N Brock[2], Clara G Sears[3], Charlie H Zhang[4], Lonnie Sears[5]
[1]University of Alabama at Birmingham - Dept of Environmental Health Sciences, Birmingham, USA, [2]The Ohio State University - Center for Biostatistics, Columbus, USA, [3]University of Louisville - Dept of Environmental Medicine, Louisville, USA, [4]University of Louisville - Dept of Geographical and Environmental Sciences, Louisville, USA, [5]University of Louisville - Dept of Pediatrics, Louisville, USA

BACKGROUND AND AIM: Coal ash, a waste product generated when burning coal for energy, is comprised of small particles with neurotoxic heavy metal(loid)s found to be risk factors for learning and social problems in school. The purpose of this novel study was to assess the association of coal ash in children's homes with school and social competency.

METHODS: We recruited children aged 6-14 years old from communities located within 10 miles of two coal-burning power plants. In homes of the participants, coal ash was collected on polycarbonate filters using personal modular impactors. We measured school competency and social competency using the validated Child Behavioral Checklist. Using Tobit and linear regression we investigated the relationship of indoor coal ash with school and social competency.

RESULTS: Forty-three percent of children in the study had coal ash in their homes. In Tobit models that were adjusted for age, sex, self-reported race, mother's education, and traffic exposure, children with coal ash in their homes scored on average 2.5 (-4.9 to -0.1) points lower on the school competency scale than peers without ash in their homes (p=0.04). We did not observe that coal ash in homes was related with lower social competency.

CONCLUSIONS: Children with coal ash in their homes had poorer performance in the school setting, compared to peers without coal ash in homes. Coal ash consists of small particles, that contains neurotoxins and may be a contributing factor to poor school performance, which potentially impairs children's academic achievement. There are limited regulations on the storage of coal ash and this study provides impetus for more research.

KEYWORDS: coal ash, fly ash, school competency, social competency, school performance, environmental exposure

P-0441 Early life exposure to coal smoke and hospital visitation: findings from a data linkage cohort study

Myriam Ziou[1], Caroline Gao[2], Amanda Wheeler[1,3], Graeme Zosky[1,4], A/Prof Nicola Stephens[4], A/Prof Luke Knibbs[5], Shannon Melody[1], Alison Venn[1], Marita Dalton[1], Shyamali Dharmage[6], Fay Johnston[1]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia, [3]Mary MacKillop Institute for Health Research, Australian Catholic University, Melbourne, Australia, [4]Tasmanian School of Medicine, University of Tasmania, Hobart, Australia, [5]Sydney School of Public Health, The University of Sydney, Sydney, Australia, [6]Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia

BACKGROUND AND AIM: The extent to which air pollution exposure in early life could engender modifications of immune responses with long-term health consequences is still largely unknown. The aim of this study was to analyse emergency department (ED) visits and hospitalisations following prenatal and postnatal exposure to severe smoke from the Hazelwood coal mine fire (9 Feb-25 Mar 2014).

METHODS: The Victorian Emergency Minimum Dataset and the Victorian Admitted Episodes Dataset were linked to the Victorian Perinatal Data Collection to obtain ED visits and hospitalisations of children born in the Latrobe Valley, Australia from March 2012 to December 2015. Exposure to fire-related PM2.5 was assigned from gridded modelled estimates based on residential address at birth. Children exposed in utero and in infancy (<1 year old) were investigated separately. Associations between exposure to fire-related PM2.5 and ED presentations and hospitalisations for any cause, respiratory outcomes, respiratory-related infections, any infections, and allergies/skin rash in the first year of life (in utero) or in the year following the end of the fire (infant) were estimated with logistic regression models. Adjustment for potential confounders was performed through multiple regression in the dose-response analysis, and with propensity score weighting when comparing exposure groups.

RESULTS: A dose-response relationship was found between prenatal exposure to PM2.5 and ED presentations for allergies/skin rash (OR=1.14, 95%CI=1.01-1.27 per 100µg/m³) in the first year of life. A cumulative exposure >25 µg/m³ in infancy was associated with higher risks of presenting to the ED for respiratory causes (OR=1.39; 95%CI=1.06-1.81), respiratory-related infections (OR=1.41, 95%CI=1.07-1.86), and any infections (OR=1.21, 95%CI=0.98-1.49) in the year following the fire.

CONCLUSIONS: Exposure to large concentrations of smoke in early life could be associated with allergic and infectious conditions up to one year after return to normal levels of ambient air pollution.

KEYWORDS: Particulate matter; Long-term exposure; Infections; Allergies;

P-0442 Prenatal and early postnatal exposure to air pollution associations with primary care and prescription usage

Myriam Ziou[1], Caroline Gao[2], Amanda Wheeler[1,3], Graeme Zosky[1,4], A/Prof Nicola Stephens[4], A/Prof Luke Knibbs[5], Shannon Melody[1], Alison Venn[1], Marita Dalton[1], Shyamali Dharmage[6], Fay Johnston[1]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia, [3]Mary MacKillop Institute for Health Research, Australian Catholic University, Melbourne, Australia, [4]Tasmanian School of Medicine, University of Tasmania, Hobart, Australia, [5]Sydney School of Public Health, The University of Sydney, Sydney, Australia, [6]Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia

BACKGROUND AND AIM: Health consequences of air pollution in early life have been mostly studied in hospital settings, with less focus put on primary care and prescribed medications. The aim of this study was to investigate general practitioner (GP) consultations and prescriptions dispensed following exposure in utero and in the first year of life to the Hazelwood coal mine fire, a severe air pollution episode lasting six weeks.

METHODS: The Victorian Perinatal Data Collection was linked to the Medicare Benefits Schedule and the Pharmaceutical Benefits Scheme for a cohort of children born in the Latrobe Valley, Australia between March 2012 and December 2015. Modelled estimates of fire-related PM2.5 exposure were assigned at the residential address at birth. The total numbers of GP visits and of prescriptions of antibiotics, asthma inhalers and steroid skin creams dispensed in the first year of life or in the year following the fire were extracted for children exposed in utero and in infancy (<1 year old), respectively. Negative binomial regression models estimated associations between each outcome and exposure to fire-related PM2.5, with adjustment made for potential confounders.

RESULTS: Higher levels of PM2.5 in utero were associated with increased asthma inhalers dispensed (IRR=1.07, 95%CI=1.00-1.14 per 100µg/m³ of cumulative PM2.5; IRR=1.27, 95%CI=1.01-1.58 per 50µg/m3 of peak 24-h PM2.5) in infancy. Surprisingly, a cumulative exposure >25 µg/m³ in infancy was linked to fewer GP visits (IRR=0.83, 95%CI=0.68-0.99) in the year following the fire.

CONCLUSIONS: Our findings indicate that prenatal exposure to time-limited severe air pollution could be linked with increased need of asthma medications in infancy. They also suggest that such exposure in infancy could be associated with less GP consultations following extreme events, which could be due to increased needs of specialised and hospital care.

KEYWORDS: Particulate matter; Long-term exposure; Infections; Asthma;

P-0443 Associations of Prenatal First-Trimester Metal Mixtures and Childhood Adipokines in the Project Viva Cohort

Anna Rose Smith[1], Pi-I Debby Lin[2], Sheryl L. Rifas-Shiman[2], Robert O. Wright[3], Brent Coull[4], Marie-France Hivert[2,5], Emily Oken[2], Andres Cardenas[1]

[1]Division of Environmental Health Sciences, School of Public Health and Center for Computational Biology, University of California, Berkeley, Berkeley, USA, [2]Division of Chronic Disease Research Across the Lifecourse, Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, USA, [3]Department of Environmental Medicine and Institute for Exposomic Research, Icahn School of Medicine at Mount Sinai, New York City, USA, [4]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Harvard University, Boston, USA, [5]Diabetes Unit, Massachusetts General Hospital, Boston, USA

BACKGROUND AND AIM: The adipokines leptin and adiponectin, mainly produced in adipose tissue, are involved in energy homeostasis and insulin sensitivity. Lower adiponectin and higher leptin correlate with older childhood and adult adiposity, while the relationship in young children is less clear. Higher prenatal heavy metals and lower nonessential metals have been associated with childhood adiposity, but it is unclear if prenatal metals influence childhood adipokines.

METHODS: Six nonessential (As, Ba, Cd, Cs, Hg, Pb) and four essential (Mg, Mn, Se, Zn) metals were measured in first trimester red blood cells from pregnant participants in the Boston MA-area Project Viva cohort. Blood leptin and adiponectin were measured in early-childhood (N=527-526; mean 3.3 (SD 0.3) years), mid-childhood (N=426; 8.0 (0.8) years), and early-adolescence (N=477; 13.1 (0.9) years). Linear regression and quantile g-computation models estimated associations between individual and mixtures of metals and adipokines, adjusting for confounders.

RESULTS: Mean (SD) leptin was 1.9 (1.9) ng/ml in early-childhood, 5.6 (6.8) ng/ml in mid-childhood and 11.9 (14.7) ng/ml in early-adolescence. Mean (SD) adiponectin was 22.4 (5.5) µg/ml in early-childhood, 15.7 (8.5) µg/ml in mid-childhood and 6.4 (2.8) µg/ml in early-adolescence. A doubling in arsenic was associated with lower adiponectin at the early-childhood visit (β=-0.40 µg/ml, 95% CI: -0.73, -0.07), while cesium was associated with higher leptin at the early-adolescence visit (β=2.76 ng/mL, 95% CI: 0.22, 5.30). In mixture analyses, adjusting for metals not in the mixture, a quartile increase in nonessential metal mixture was associated with lower adiponectin (β=-0.18 µg/ml, 95% CI: -0.33, -0.03) at the mid-childhood visit.

CONCLUSIONS: Our findings suggest that certain prenatal metals are associated with adipokines in childhood, which might influence cardiometabolic risk. Future work will evaluate if adipokines mediate associations of prenatal metals with adiposity and cardiometabolic risk.

KEYWORDS: Heavy metals, Mixtures analysis, Children's environmental health

P-0444 Newborn Metabolomics linking prenatal air pollution exposure and autism spectrum disorder risk in children

Ni Kang[1], Lauren Petrick[2], Jiawen Liao[1], Md Mostafijur Rahman[1], Sarah Carter[4], Nathan Pavlovic[5], Frederick Lurmann[5], Ting Chow[4], Mayra Martinez[4], Xin Yu[3], Jane Lin[4], Sandrah Eckel[1], Joel Schwartz[6,7], Jiu-Chiuan Chen[1], Rob McConnell[1], Anny Xiang[4], Zhanghua Chen[1]

[1]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, USA, [2]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Spatial Science Institute, University of Southern California, Los Angeles, USA, [4]Department of Research & Evaluation, Kaiser Permanente Southern California, Pasadena, USA, [5]Sonoma Technology, Inc, Petaluma, USA, [6]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [7]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, USA

KEYWORDS: Metabolomics, Autism spectrum disorder, air pollution exposure, pregnancy, oxidative stress.

BACKGROUND: Prenatal PM2.5 and near-roadway air pollution (NRAP) exposures, particularly nonfreeway NRAP, have been associated with increased autism spectrum disorder (ASD) risk in children. However, the underlying biological mechanism is unclear.

Aim: To investigate neonatal metabolic pathways altered by prenatal PM2.5 and NRAP exposures that increase ASD risk.

METHOD: Using electronic medical records, 50 ASD cases diagnosed before age 5 and 50 controls matched on birth year, medical center, sex, and race/ethnicity were randomly selected from all children born at Kaiser Permanente Southern California between 2007-2009. Weekly PM2.5 and monthly nonfreeway NRAP exposures during pregnancy were estimated based on residential history using spatiotemporal prediction and California line-source dispersion models, respectively. Untargeted, high-resolution metabolomics was analyzed in archived newborn dry blood spots, resulting in 26,578 HILIC-positive and 27,614 C18-negative metabolomic features.

Conditional logistic regression was used to identify metabolomic features associated with ASD diagnosis. Linear regression was used to investigate associations between prenatal air pollution exposure and metabolomic features. Beyond matching factors, maternal age, education level and household income categories were adjusted in the analyses. Mummichog pathway analysis was performed to identify metabolic pathways associated with prenatal air pollution exposure and ASD.

RESULTS: Dysregulated aspartate and asparagine metabolism was associated with increased ASD risk($p=0.01$) and higher PM2.5 exposure during the 1st trimester and the entire pregnancy($p<0.001$). Glutamate metabolism was associated with PM2.5 during pregnancy($p=0.028$) and increased ASD risk($p=0.03$). Prenatal nonfreeway NRAP was associated with altered nitrogen ($p=0.027$) and sialic acid metabolism($p=0.038$), while nitrogen metabolism was also associated with increased ASD risk($p=0.02$).

CONCLUSIONS: Dysregulated metabolism reflected in aspartate, asparagine and glutamate was associated with both prenatal air pollution exposure, particularly PM2.5, and increased ASD risk, suggesting newborn oxidative stress and inflammation may be pathways of effects of prenatal air pollution exposure.

P-0445 Neonicotinoid, pyrethroid and organophosphate urinary metabolites in relation to neurobehavioral performance in Ecuadorian adolescents

Jessica Yen[1], Kun Yang[1], Ana Skomal[1], Xin Tu[1], Sheila Gahagan[1], Jose Suarez-Lopez[2]
[1]School of Medicine, University of California-San Diego, La Jolla, USA, [2]Herbert Wertheim School of Public Health, University of California-San Diego, La Jolla, USA

BACKGROUND AND AIM: Insecticides, including organophosphates and pyrethroids, have been found to affect the neurobehavioral development of children, but limited evidence exists among adolescents. These insecticides have been slowly replaced by neonicotinoids, but there is little epidemiological data regarding their effects on neurobehavior. We examined the associations between urinary insecticide concentrations and neurobehavioral performance amongst adolescents living in agricultural communities in Ecuador.

METHODS: This study included 522 participants aged 11-17 years who were examined in 2016. Urinary insecticide metabolites were measured using mass-spectrometry and neurobehavior was assessed using the NEPSY-II (domains: Attention/Inhibitory Control, Language, Memory/Learning, Visuospatial Processing, Social Perception). Associations were adjusted for creatinine and demographic, anthropometric, and socioeconomic characteristics. Multiple imputation was used for values below the level of detection.

RESULTS: The mean(SD) neurobehavior scores ranged from 7.03(2.04) to 8.69(2.28). Among organophosphate metabolites, 3,5,6-Trichloro-2-pyridinol (TCPy) was inversely associated with Language (score difference per 50% increase in metabolite concentration [β] = -0.11 [95%CI: -0.50, -0.02]) and para-Nitrophenol (PNP) was inversely associated with Social Perception (β = -0.26 [95%CI: -1.07, -0.20]). There was also evidence of a threshold: TCPy and PNP had significant inverse associations with Attention/Inhibitory Control only at concentrations above the 60th percentile (β = -0.22 [95%CI: -0.43, -0.00] and β = -0.29 [95%CI: -0.54, -0.04], respectively). The pyrethroid, 3-phenoxybenzoic acid (3-PBA), was inversely associated with Language (β = -0.11 [95%CI: -0.48, -0.05]) and had a negative quadratic association with Attention/Inhibitory Control ($p<0.01$). The neonicotinoid, 5-Hydroxy imidacloprid (OHIM), was positively associated with Memory/Learning (β = 0.21 [95%CI: 0.12, 0.93]). These associations did not differ by gender.

CONCLUSIONS: Organophosphate and pyrethroid metabolites were associated with lower performance on Language, Social Perception and Attention/Inhibitory Control, while neonicotinoids were associated with better Memory/Learning scores. These findings highlight the importance of limiting environmental insecticide exposures during developmental years.

KEYWORDS: Insecticides, adolescents, neurobehavior, pesticides

P-0448 Urinary metabolites of volatile organic compounds and polycyclic aromatic hydrocarbons increases the risk of nonalcoholic fatty liver disease in Korean adolescents: A Korean National Environmental Health Survey (KoNEHS) 2015-2017 analysis

Yun-Hee Choi[1,2], Yun-Hee Choi[1,2,3]

[1]*Department of Health and Safety Convergence Science, Korea University, Anam-ro 145, Seongbuk-gu, Seoul, Republic of Korea,*
[2]*BK21 FOUR R & E Center for Learning Health System, Korea University, Anam-ro 145, Seongbuk-gu, Seoul, Republic of Korea,*
[3]*Department of Health and Environmental Science, Korea University, Anam-ro 145, Seongbuk-gu, Seoul, Republic of Korea*

Non-alcoholic fatty liver disease (NAFLD) is one of the most common liver diseases in adolescents and is an urgent public health issue. Several animal studies have suggested that volatile organic compounds (VOCs) and polycyclic aromatic hydrocarbons (PAHs) led to NAFLD. However, few epidemiological studies have confirmed the associations of VOCs and PAHs with NAFLD in the general adolescent population. Therefore, we analyzed 798 adolescents from the Korean National Environmental Health Survey (KoNEHS) 2015-2017 to examine the associations of urinary metabolites for VOCs and PAHs with serum alanine aminotransferase (ALT) activity and NAFLD prevalence. We employed linear, logistic regression, and Bayesian kernel machine regression (BKMR) to evaluate the association of urinary VOCs and PAHs metabolites with ALT activity and NAFLD. After adjusting for all covariates, urinary benzylmercapturic acid level and 2-hydroxyfluorene level increased serum ALT activity and NAFLD prevalence. Additionally, the BKMR analyses showed a significantly positive overall effect on ALT activity and NAFLD prevalence with urinary concentrations of VOCs and PAHs metabolites, and 2-hydroxyfluorene contributed the most. Our study suggests that exposure to low-level VOCs and PAHs may have a detrimental effect on NAFLD risk in adolescents. Given the increasing prevalence of NAFLD in adolescents, future cohort studies are warranted to understand these chemicals' impact on NAFLD risk.

KEYWORDS: volatile organic compounds (VOCs), polycyclic aromatic hydrocarbons (PAHs), adolescents, Non-alcoholic fatty liver disease, Korean National Environmental Health Survey (KoNEHS)

P-0450 Effect of prenatal PM2.5 and its constituents exposure and fetal growth pattern on children's accelerated growth in the first three years

Shuang Zhou[1], MS. Tiantian Li[2], MS. Na Han[3], MS. Yi Zhang[2], Yuelong Ji[1], Qin Li[1], MS. Jue Liu[1], MS. Hui Wang[1], Jianlin Hu[4], MS. Ting Liu[4], Hai-Jun Wang[1]

[1]Department of Maternal and Child Health, School of Public Health, Peking University, Beijing, China, [2]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [3]Tongzhou Maternal and Child Health Care Hospital of Beijing, Beijing, China, [4]Jiangsu Key Laboratory of Atmospheric Environment Monitoring and Pollution Control, Collaborative Innovation Center of Atmospheric Environment and Equipment Technology, Nanjing University of Information Science & Technology, Nanjing, China

BACKGROUND: No study investigated the effect of prenatal exposure to PM2.5 and its constituents on accelerated childhood growth, with consideration of fetal growth pattern in utero. We aimed to examine the effect of prenatal PM2.5 and its constituents exposure, fetal growth pattern on children's accelerated growth in the first three years.

METHODS: The study was embedded in a population-based birth cohort in China, including 5,424 mother-child pairs. Prenatal PM2.5 and its constituents [organic carbon (OC), elemental carbon (EC), sulfate (SO42-), nitrate (NO3-), and ammonium (NH4+)] concentrations were estimated. Estimated fetal weight (EFW) Z-score by fetal ultrasound examination in second and third- trimester was calculated and then K-means algorithm was used to cluster the fetal growth pattern. Children's accelerated growth was defined as the change of BMI Z-score from birth to three years >0.67. Generalized logistic regression was used to analyze the effect of prenatal PM2.5 and its constituents exposure and fetal growth pattern on children's accelerated growth.

RESULTS: Compared with higher fetal growth, children with lower fetal growth had 1.706 (95%CI: 1.520, 1.915) times higher risk of children's accelerated growth from birth to three years old. An IQR increase in PM2.5, OC, NH4+, and SO42- was associated with 1.147 (95%CI:1.012, 1.300), 1.360 (95%CI:1.113, 1.662), 1.127 (95%CI:1.017, 1.248), and 1.257 (95%CI:1.012, 1.561) times higher risk of children's accelerated growth, respectively. Prenatal PM2.5 and its constituents exposure and fetal growth had joint effect on children's accelerated growth from birth to three years old, especially for OC (RERI:0.485, 95%CI: 0.018,0.952).

CONCLUSIONS: The study suggested that prenatal PM2.5 and its constituents exposure and fetal growth in utero had individual and joint effect on children's accelerated growth from birth to three years old.

KEYWORDS: PM2.5, constituents, accelerated childhood growth, fetal growth

P-0456 Systematic review in 2000-2020 on early childhood developmental conditions of environmental noise exposure

Elisa Herrera[1], Leticia Hernández[1], Ma Maricela Piña[1]
[1]*National Institute of Public Health, Cuernavaca, Mexico*

BACKGROUND AND AIM: Early childhood is a crucial stage of human development. Exposure to noise can alter their development and affect their health, reducing their quality of life. Information to facilitate decision making in this regard is still scarce in several countries, so the aim of this study was to characterize the developmental conditions in early childhood that have been related to environmental exposure to noise based on population-based studies.

METHODS: An exhaustive systematic review was carried out using Cochrane methodology during the period 2000-2020. Publications were included without restriction of language, country or publication type, with information on adverse developmental outcomes in early childhood (0-8 years of age) due to prenatal or concurrent exposure to environmental noise.

RESULTS: Thirty-four studies were selected that addressed early childhood with prenatal or postnatal exposure, grouping the effects into three groups: fetal period (malformations and miscarriage), neonatal period (premature birth, low birth weight, small for gestational age and physiological alterations) and childhood (physiological, constitutional, learning and behavioral alterations). Information sources for both, outcome and exposure events varied between direct and indirect measurements. Five articles address biological plausibility mechanisms. In Eight articles, no significant findings are reported, and in no study the impact on the quality of subsequent life stages was investigated.

CONCLUSIONS: Sufficient evidence was found to support the presence of conditions in early childhood due to prenatal and concurrent environmental exposure to environmental noise. The need to generate policies that allow routine monitoring of noise levels and their regulation to mitigate exposure and protect children's health is evident.

KEYWORDS: environmental noise, child development, early childhood, child developmental impairment, noise pollution.

P-0470 Multiple air pollutants and renal health in children and adolescents: An 18-year longitudinal study in Asia

Cui Guo[1], Xianglin Wei[1], Yiqian Zeng[1], Xiang Qian Lao[1]
[1]*The Chinese University of Hong Kong, Shatin, Hong Kong*

BACKGROUND AND AIM: Few studies have examined the effects of multi-pollutant air pollution on renal health, especially in children and adolescents. This study investigated the association between long-term ambient air pollution exposure and renal health in Asian children and adolescents.

METHODS: This study included 10,942 children and adolescents aged ≤ 25 years from Taiwan and Hong Kong from 2000 to 2017. PM2.5, NO2 and O3 concentrations were estimated using satellite-based spatiotemporal regression models. Two-year average concentrations, those of the year of visit and the preceding year, were used. Linear mixed models were used to examine the association between air pollution and yearly changes in estimated glomerular filtration rate (eGFR). Cox regression models with time-dependent covariates were used to examine the association between air pollution and the development of chronic kidney disease (CKD). Both single- and multi-pollutant models were used.

RESULTS: for the single-pollutant models, each 10μg/m3 increase in PM2.5 was associated with a 0.45μL/min/1.73 m2 [95% confidence interval (CI): 0.28−0.63] reduction in the yearly increase in eGFR and 53% [hazard ratio (HR): 1.53 (95%CI: 1.07–2.2)] greater risk of CKD. Each 10μg/m3 increase in NO2 was associated with a 7% [HR (95%CI): 1.07 (1.00–1.15)] higher risk of CKD, while an equivalent increase in O3 was associated with a 19% [HR (95%CI): 0.81 (0.67–0.98)] lower risk of CKD. for multi-pollutant models, the air pollution–CKD associations were slightly attenuated.

CONCLUSIONS: Long-term exposure to ambient PM2.5 and NO2 was associated with a slower growth of eGFR and a higher risk of CKD in children and adolescents. Our findings suggest that air pollution control in early life is imperative to improve lifelong renal health and alleviate the CKD burden.

P-0471 Prenatal air pollution exposure and infant weight trajectories from 3rd trimester to 2 years of age

NAN Ji[1], Mark Johnson[1], Sandrah Eckel[1], William Gauderman[1], Thomas Chavez[1], Dema Faham[1], Fred Lurmann[2], Nathan Pavlovic[2], Brendan Grubbs[1], Deborah Lerner[3], Rima Habre[1], Shohreh Farzan[1], Theresa Bastain[1], Carrie Breton[1]

[1]University of Southern California, Los Angeles, USA, [2]Sonoma Technology, Inc., Petaluma, USA, [3]Eisner Health, Los Angeles, USA

BACKGROUND AND AIM: Prenatal exposure to air pollution is increasingly viewed as harmful to fetal development and leads to childhood obesity. However, few studies have evaluated in utero growth measures and postnatal weight trajectories along a continuum in statistical models. This study aims to evaluate associations between prenatal air pollution and weight trajectories from the 3rd trimester through 2 years of life among infants in the Maternal and Development Risks from Environmental and Social Stressors (MADRES) pregnancy cohort, which comprises a low-income, primarily Hispanic population in Los Angeles, California.

METHODS: Fetal weights during the 3rd trimester were abstracted from maternal ultrasound records. Infant weight measures were abstracted from medical records and measured by staff at study visits. Ambient particulate matter ≤2.5 µm and ≤10 µm in diameter (PM2.5 and PM10) concentrations were assigned using spatial interpolation from the regulatory air monitoring stations. Piecewise linear spline models were used to assess non-linear associations between prenatal air pollution exposure and infant weight trajectories.

RESULTS: Weight increased most rapidly from 3 months prior to birth through 3 months of age, slowing thereafter. Pregnancy-averaged PM2.5 and PM10 were associated with a slower rate of growth from the 3rd trimester until age 2 years. A one IQR increase in PM2.5 (1.65 ug/m3) and PM10 (7.48 ug/m3) exposure were associated with a 0.28 kg and 0.38 kg lower weight at 2 years of age, respectively. In sex-stratified models, the effects of PM2.5 and PM10 were only significant in females.

CONCLUSIONS: Our findings suggest that prenatal exposure to PM2.5 and PM10 could impact infant weight gain trajectories and thus, impact childhood obesity, with potentially more pronounced impacts among females.

KEYWORDS: prenatal air pollution, growth trajectory

P-0480 The Season of Conception and Cerebral Palsy Risk in California

Haoran Zhuo[1,2], Beate Ritz[3,4], Zeyan Liew[1,2]

[1]Department of Environmental Health Sciences, Yale School of Public Health, New Haven, USA, [2]Yale Center for Perinatal, Pediatric and Environmental Epidemiology, Yale School of Public Health, New Haven, USA, [3]Department of Epidemiology, Fielding School of Public Health, University of California, Los Angeles, Los Angeles, USA, [4]Department of Neurology, School of Medicine, University of California, Los Angeles, Los Angeles, USA

BACKGROUND AND AIM: Cerebral palsy (CP) is the most prevalent, severe, costly neuro-motor disability in children, and it is permanent. The majority of CP cases have an unknown etiology. This is the first study to investigate whether season of conception is associated with CP in California.

METHODS: We analyzed a California birth cohort of 5,089,216 children born in 2005-2015. A total of 5,508 children diagnosed with CP were identified by linking their California birth records with the diagnostic records from the California Department of Developmental Services. We used multivariate logistic regression analyses to estimate the odds ratio (OR) and 95% confidence interval (CI) for CP according to the month and season of conception, controlling for maternal characteristics (age, race/ethnicity, education), child's sex, and the year of conception. Month of conception was estimated from the child's date of birth and length of gestation and was grouped into seasons (winter: Jan-March, spring: April-June, summer: July-Sept, fall: Oct-Dec). We performed stratified analyses by child's sex (females, males), disease subtypes (spastic, ataxic, hypotonic, other), limb involvement (unilateral, bilateral), and geographical locations of birth (Northern, Central, Southern) in California.

RESULTS: Having been conceived in winter and spring was associated with 9% higher odds of having CP (OR=1.09, 95% CI winter: 1.01-1.18, spring: 1.01-1.17) compared to summer conceptions. When considering months, consistent increases of CP with >10% higher odds were observed for each month from January to June compared to September, except for March. We observed no apparent differences in the stratified analyses.

CONCLUSIONS: This is the first study to show winter and spring conceptions to be associated with higher CP occurrence in the offspring. Environmental factors and/or infections that predominate in winter/spring in California may underly this increased CP risk and need to be further explored.

KEYWORDS: Cerebral Palsy, Seasonal Variation, Environment, Neurodevelopment, Birth cohort

P-0482 Congenital malformations of the male genital system and risk of attention deficit hyperactivity disorder

Ran Rotem[1,2], Gabriel Chodick[2], Marc Weisskopf[1]
[1]Harvard TH Chan School of Public Health, Boston, USA, [2]Maccabi Healthcare Services, Tel Aviv, Israel

BACKGROUND: Accumulating evidence suggests that gestational exposure to environmental anti-androgenic endocrine disrupting chemicals has important neurodevelopmental effects. Specifically, androgens have extensive influence on brain development in regions that are relevant for attention deficient hyperactivity disorder (ADHD), yet their specific involvement in the etiology of this common disorder remains unclear. Hypospadias (abnormal positioning of the urethral opening) and cryptorchidism (undescended testes) are two common male birth defects that are strongly associated with deficiencies in prenatal androgen exposure. Thus, having cryptorchidism or hypospadias is a proxy indicator of atypical gestational androgen exposure, yet the association between these disorders and ADHD has not been extensively studied.

METHODS: We analyzed singleton live births (boys=203,728; girls=199,065) born in 1999-2012 in a large Israeli healthcare organization. Boys with cryptorchidism (n=3,945) or hypospadias (n=2,860) were identified via a validated algorithm based on diagnosis and medical procedure records. ADHD cases (n=59,272) were identified through diagnosis records and verified through review of medication dispensing data. Analyses were conducted using Cox proportional hazard models with robust standard error to account for family clusters.

RESULTS: In multivariable-adjusted analyses, the hazard ratio (HR) for ADHD among boys with cryptorchidism was 1.10 (95% CI:1.02-1.18) and among boys with hypospadias was 1.16 (95% CI:1.07-1.25) compared with boys without these conditions. ADHD hazard was also higher among reproductive condition-free brothers of cryptorchidism cases (aHR=1.15, 95% CI:1.06-1.25) and sisters of hypospadias cases (aHR=1.14, 95% CI:0.99-1.30).

CONCLUSIONS: Boys with cryptorchidism or hypospadias had an elevated ADHD hazard compared with boys without these conditions. Results among unaffected siblings suggest that these associations were potentially partly driven by parental or environmental factors present outside of the pregnancy period. Understanding the links between these congenital malformations, androgen homeostasis, and ADHD could shed light on the etiology of the disorder and allow for early detection and intervention.

P-0490 Early-life exposure to phthalates among infants in Italy: characterization and time trends

Elena Righi[1], Lucia Palandri[1], Angela Ferrari[1], Riccardo Barbieri[1], Camilla Lugli[1], Viola Trevisani[2], Erica Passini[2], Fabio Facchinetti[2], Laura Lucaccioni[2]

[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, [2]Department of Medical and Surgical Sciences for Mothers, Children and Adults, University of Modena and Reggio Emilia, Modena, Italy

BACKGROUND AND AIM: Human exposure to phthalates, endocrine disruptors, and reproductive toxicants,is ubiquitous. Urine is the matrix of choice for biomonitoring and in utero exposure is well documented. Evidence of early life exposure to phthalates is scarce.
The aim of this study is to assess phthalate exposure and its changes over time in a cohort of healthy infants in the province of Modena, Italy.

METHODS: In this prospective birth-cohort study, we assessed phthalate exposure(8 metabolites of 6 phthalates)in urine samples collected from mothers just after delivery and in infants at birth, 3 and 6 months using phthalate-free bags. Mother-infant pairs were enrolled in a university hospital in Modena(Italy)between January 2019 and May 2020. After solid-phase extraction, samples were analyzed by triple Quad LC/MS Mass Spectrometry.

RESULTS: 188 mother-infant pairs were enrolled. MEP was always detectable and showed the highest levels, increasing over time. MMP and DEHP metabolites showed as well an increasing trend, however, they were detected at lower levels, while MnBP and MBzP showed intermediate concentrations and decreasing trends over time.
Significant associations between mother-infant pairs at birth were found only for a few metabolites(MMP, MEP, and MnBP). Infant levels at 3 and 6 months appeared more related, suggesting a continuative exposure to these chemicals inside the indoor environment.

CONCLUSIONS: Phthalate exposure appears wide and extended over time. Infants were exposed to several phthalates, including those more toxic and strictly regulated in infant toys, personal care products and food contact materials in the European Union. Their unregulated use in other consumers'products, building and decorating materials or home furniture may explain the potential exposure of at-risk groups, such as infants or pregnant women. To effectively protect the most vulnerable subjects, public health preventive and regulatory actions should address this specific issue as well.

KEYWORDS: Phthalates, Biomonitoring, Urine, Newborns, Postnatal Exposure.

P-0491 Prenatal exposure to poly- and perfluoroalkyl substances and serum concentrations of vaccine antibodies in early childhood

Lauren Zell-Baran[1,2], Jill M. Norris[1], Deborah H. Glueck[3,4], John Adgate[5], Jared Brown[6], Dana Dabelea[1,3,4], Kylie K. Harrall[1,3], Anne P. Starling

[1]Department of Epidemiology; Colorado School of Public Health; University of Colorado Anschutz Medical Campus, Aurora, USA, [2]Division of Environmental and Occupational Health Sciences; National Jewish Health, Denver, USA, [3]Lifecourse Epidemiology of Adiposity and Diabetes (LEAD) Center; Colorado School of Public Health; University of Colorado Anschutz Medical Campus, Aurora, USA, [4]Deparment of Pediatrics; University of Colorado Anschutz Medical Campus, Aurora, USA, [5]Department of Environmental and Occupational Health; Colorado School of Public Health; University of Colorado Anschutz Medical Campus, Aurora, USA, [6]Department of Pharmaceutical Sciences; University of Colorado Anschutz Medical Campus, Aurora, USA, [7]Department of Epidemiology; Gillings School of Global Public Health; University of North Carolina at Chapel Hill, Chapel Hill, USA

BACKGROUND AND AIM: Prenatal exposure to certain poly- and perfluoroalkyl substances (PFAS) have been associated with a reduced humoral response to tetanus and diphtheria vaccines. Whether this is observed for other childhood immunizations is unknown.

METHODS: In a sample of 120 children in the Healthy Start cohort, we measured semi-quantitative antibody titers to measles, mumps, rubella, and varicella in child serum at 4-6 years old. We employed separate Cox proportional hazards models to estimate associations between maternal serum concentrations of five PFAS and the risk of a non-protective antibody titer, based on time since most recent dose (stratified by number of doses received).

RESULTS: Maternal PFAS concentrations were generally at or below the US median. Most children had protective vaccine titers (rubella 100%, measles 98%, mumps 90%, varicella 80%). Unadjusted associations between individual PFAS and the hazard of non-protective antibody titers had wide confidence intervals including the null [e.g. after two doses, lnPFOA HR, 95% CI: mumps 1.09 (0.21, 5.54); varicella 1.09 (0.33, 3.61): lnPFOS mumps 1.87 (0.22, 16.12); varicella 2.12 (0.55, 8.23): lnPFNA mumps 1.63 (0.21, 12.64); varicella 1.68 (0.36, 7.79): lnPFHxS mumps 6.05 (0.86, 42.75); varicella 1.36 (0.59, 3.13): lnPFDA mumps 1.71 (0.27, 10.84); varicella 2.74 (0.83, 9.07)]. Sensitivity analyses adjusting for the potential confounders of child sex or age at collection did not meaningfully change the effect estimates. We were unable to estimate associations with measles and rubella antibodies due to the small number of children with non-protective titers.

CONCLUSIONS: In this cohort of young children with background levels of PFAS exposure, higher prenatal PFAS concentrations were not significantly associated with greater risk of non-protective mumps and varicella antibody titers. This study demonstrates the utility of time-to-event models for examining associations between environmental chemicals and loss of disease protection.

KEYWORDS: Per- and polyfluoroalkyl substances, vaccines, childhood, immune

P-0495 Air Pollution Exposures and Executive Function in Middle Childhood: A U.S. Multi-Cohort Study

Yu Ni[1], Alexis Sullivan[2], Adam Szpiro[1], Christine Loftus[1], Ruby Nguyen[3], Shanna Swan[4], Sheela Sathyanarayana[1,5], Emily Barrett[6], Nicole Bush[2], Catherine Karr[1], Kaja LeWinn[2]

[1]University of Washington, Seattle, USA, [2]University of California, San Francisco, San Francisco, USA, [3]University of Minnesota, Minneapolis, USA, [4]Icahn School of Medicine at Mount Sinai, New York, USA, [5]Seattle Children's Research Institute, Seattle, USA, [6]Rutgers University, Piscataway, USA

BACKGROUND AND AIM: Prior studies examining the association between spatiotemporally resolved air pollution and child executive function (working memory, inhibitory control, and cognitive flexibility) are limited. We aimed to fill this gap using data from the ECHO-PATHWAYS Consortium.

METHODS: We included 1,241 children from three U.S. pregnancy cohorts (CANDLE, TIDES, and GAPPS). Exposure to particulate matter ≤2.5μm in aerodynamic diameter ($PM_{2.5}$), nitrogen dioxide (NO_2), and ozone (O_3) at age 0-4 were derived from spatiotemporal models. at age 8-9, child working memory and inhibitory control were assessed using the Digit Span subtest from the Wechsler Intelligence Scale for Children, 5th Edition and the NIH Toolbox Flanker Inhibitory Control and Attention test, respectively. Cognitive flexibility was quantified by percent accuracy and mean latency of the Hearts and Flowers Task mixed block condition. We fitted linear regression models adjusted for sociodemographic, behavioral, and maternal psychological factors, and examined potential modification by child sex, maternal education, and neighborhood education quality.

RESULTS: Mean $PM_{2.5}$, NO_2, and O_3 were 8.9 (SD:1.7) μg/m³, 9.2 (SD:2.8) ppb, and 25.7 (SD:2.8) ppb, respectively. Overall, each 2-ppb increase of NO_2 was associated with a 1.1% lower percent accuracy in cognitive flexibility (95%CI: -1.8%, -0.3%), whereas other associations were all null. We found sex-specific inverse associations of NO_2 with working memory (Pinteraction: 0.019) and cognitive flexibility (Pinteraction: 0.017), and between $PM_{2.5}$ and inhibitory control (Pinteraction: 0.022), only in boys. The positive association between $PM_{2.5}$ and mean latency was stronger in children whose mothers completed high school or less (Pinteraction: 0.045). The protective association between $PM_{2.5}$ and cognitive flexibility was shown exclusively in children residing in neighborhoods with better education quality (Pinteraction: 0.004).

CONCLUSIONS: Our study contributes to a nascent literature on common air pollution exposures, notably NO_2, and child executive function.

P-0499 Residential green space as a positive influencer on early childhood bone mineral density

Hanne Sleurs[1], Ana Inês Silva[1], Esmée M. Bijnens[1,2], Yinthe Dockx[1], Leen Rasking[1], Tim S. Nawrot[1,3], Michelle Plusquin[1]

[1]Centre for Environmental Sciences, Hasselt University, Diepenbeek, Belgium, [2]Department of Human Structure and Repair, Ghent University Hospital, Ghent, Belgium, [3]Centre for Environment and Health, Department of Public Health, Leuven University, Leuven, Belgium

BACKGROUND AND AIM The most crucial contribution to lifelong bone health is attained during the first decades of life by achieving the highest possible peak bone mass. Besides a solid genetic impact, this process is sensitive to environmental and behavioral influences. We explored whether exposure to the surrounding residential green space is related to a change in bone density in young children.

METHODS Within the ongoing Belgian ENVIRONAGE (Environmental influence on Ageing in Early Life) birth cohort, we followed up 471 children aged 4-to-6-years and assessed their radial bone mineral density with ultrasonic speed of sound measurements. Green spaces surrounding their residence were calculated based on high-resolution land cover data within multiple radii (50m to 3000m). Multivariable linear regression modelling was used to explore the association between green space exposure and children's bone density adjusted for relevant confounders.

RESULTS Children's radial bone mineral density was on average (SD) 3682 (112.4) m/sec, and the mean total green space for a 50 to 3000m radius around the residence ranged from 46.20% to 60.02%, respectively. An interquartile range (IQR) increment in high growing (>3m) and total (sum of <3m and >3m) residential green space in a 500m radius was associated with a corresponding increase of 19 m/sec (95% C.I.: 4.3 – 33.0 m/sec) and 17 m/sec (95% C.I.: 3.0 – 31.9 m/sec) in bone density. Moreover, significant results were noted within extended radii with long-term exposure to the surrounding green space, viewed in a subgroup of children who did not relocate between birth and follow-up phase.

CONCLUSIONS We found a positive association between children's bone mineral density and the surrounding residential green space exposure. These results contribute to unravelling factors increasing peak bone mass in early life and improving lifelong bone health.

P-0502 Study on the concentration of polybrominated diphenyl ethers in serum of teenagers in Zibo, China

Yifu Lu[1], Mengmeng Wang[1], Linna Xie[1], Ying Zhu[1]
[1]*China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND: Polybrominated diphenyl ethers (PBDEs) can lead to thyroid dysfunction. Teenagers are in a critical period of growth and development. So we should pay more attention to the concentration of PBDEs in the serum of teenagers.
AIM: This study is to evaluate the distribution and concentration of PBDEs in the serum of teenagers and to gain a preliminary understanding of the exposure of PBDEs in teenagers.

METHODS: The 255 serum samples of teenagers (age=15 years) were collected from Zibo in 2018. The 14 PBDEs (including BDE17, 28, 47, 66, 71, 85, 99, 100, 138, 153, 154, 183,190,209) were analyzed with high resolution gas chromatography-high resolution mass spectrometry (HRGC-HRMS) based on CDC method.

RESULTS: The results showed that the PBDEs concentrations were higher in males than in females. The mass concentration of PBDEs in serum was in the range of 2.4-123.9 ng/g lipid, the median concentration of ∑PBDEs was 12.4 ng/g lipid and the geometric mean concentration was 19.2 ng/g lipid. BDE-47 was detected in the serum samples with a relatively high detection frequency, followed by BDE-28 and BDE-99. Although the BDE-209 detection rate was relatively low but contribute the most abundant to the total concentration of PBDEs. There is a correlation between ∑PBDEs and each component, as well as between the components of PBDEs. BDE-28 was correlated to BDE-99 (r=0.558), BDE-47 was correlated to BDE-99 (r=0.599), and BDE-28 was correlated to BDE-47 (r=0.477). ∑PBDEs was correlated to BDE-28, BDE-47, and BDE-99 (r=0.471, 0.423, and 0.484), respectively.

CONCLUSIONS: Compared with other studies, the serum ∑PBDEs levels were close to the level in South China, lower than in America, slightly higher than in Japan and Switzerland. The results imply that there had some PBDEs exposure to teenagers in this region.

KEYWORDS: polybrominated diphenyl ethers, serum, teenagers

P-0504 Launching of CHildren's Environmental health Clinic in Korea (CHECK) and Institute of Ewha-Seoul Clinical Laboratories for Environmental Health (IESEH): The first clinic to research model of pediatric environmental health in South Korea

Hanna Kim[1,2], Whanhee Lee[1,3], Yi-Jun Kim[1,3], Ji Hyen Lee[2,4], Jung Won Lee[2,4], Hae Soon Kim[2,4], Kyoung-Ryul Lee[5], SaeYun Baik[5], Eunhee Ha[1,3,6]

[1]Department of Environmental Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [2]CHildren's Environmental health Clinic in Korea (CHECK), College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [3]Institute of Ewha-SCL for Environmental Health (IESEH), College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [4]Department of Pediatrics, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [5]Department of Laboratory Medicine, Seoul Clinical Laboratories, Gyeonggi-do, Republic of Korea, [6]Graduate Program in System Health Science and Engineering, Ewha Womans University, Ewha Medical Research Institute, College of Medicine, Seoul, Republic of Korea

BACKGROUND: In recent years, environmental hazards affecting children's health have been a public health concern. Since the 1990s, the Pediatric Environmental Health Specialty Units (PEHSUs) in the USA have provided rigorous research, clinical care, and public health interventions; nevertheless, this systematic network is scarce globally, especially in Asia. Thus, we established South Korea's first integrated "clinic to research" network for protecting children's health.

METHOD

The first children's health and environmental clinic in South Korea, CHildren's Environmental health Clinic in Korea (CHECK), was established. CHECK aims to develop 1) a pediatric-environmental medical examination system with a biobank, 2) a consultation system by specialized pediatricians, 3) medical guidelines for pediatric-environmental diseases, and 4) clinic operation models in this field. Subsequently, we founded the Institute of Ewha-Seoul Clinical Laboratories for Environmental Health (IESEH) to perform multidisciplinary pediatric-environmental research in collaboration with CHECK and medical departments, including Pediatrics, Internal Medicine, Obstetrics and Gynecology, and Environmental Medicine.

RESULTS: CHECK promotes pediatric patients' health by providing medical examinations, laboratory tests (including heavy metals, volatile organic compounds, and endocrine-disrupting chemicals), and specialized counseling and education for patients and parents concerned about environmental risks. IESEH will build a big-data resource by integrating data systematically collected from CHECK, Korea's national health insurance, and the Korean CHildren's ENvironmental health Study (Ko-CHENS)—a nationwide birth cohort. Through this, IESEH undertakes divergent pediatric-environmental studies ranging from data science-based epidemiology to genetics and validation studies for clinical intervention.

CONCLUSION: CHECK is the first pediatric environmental health clinic in Korea. IESEH performs research on pediatric-environmental health in collaboration with multidisciplinary experts, utilizing integrative data from CHECK and national cohorts. CHECK and IESEH will provide a gold standard for pediatric environmental health clinics and laboratories as a standardized and specialized "clinic to research" model.

KEYWORDS: CHECK; IESEH; children; environmental health; clinic to research model.

P-0505 A joint analysis of school neighbourhoods' exposure to urban environment factors in Greater London

Niloofar Shoari[1], Sean Beevers, Michael Brauer, Marta Blangiardo
[1]*Imperial College London, London, UK*

BACKGROUND AND AIM: Schools and their immediate neighbourhoods are places where children spend the most time outside their homes. Depending on the school location, there are variations in exposure to multiple urban environment features that can create and widen health inequality among children. Our aim was to identify and characterize clusters of schools with similar exposure profiles within 400 m (5-10 minutes walking distance) of schools in Greater London. We then explored association between clusters characteristics, ethnicity, and socioeconomic status.

METHODS: We modelled joint exposure to air pollution (NO2 and PM2.5), access to public greenspace, food environment, and road safety for 2,929 schools, employing a Bayesian non-parametric approach based on the Dirichlet Process Mixture (DPM) modelling. We identified clusters with similar exposure profiles, computed the summary statistics for each cluster, and uncovered urban features that were dominant contributory factor to each cluster.

RESULTS: We identified 12 clusters of schools with similar exposure profiles and were able to make probabilistic statements on the magnitude of exposures. We found that schools with relatively high exposures to harmful factors and a low exposure to beneficial factors (greenspace) were located in the most deprived areas.

CONCLUSIONS: Schools have a crucial role in providing equitable and healthy environment for children. We provided a tool to help schools, public health officials, and policy-makers to understand schools joint exposure to specific urban environment features. Our study highlighted the presence of distinct subgroups of schools with respect to exposure. This helps prioritize interventions and design local policies, with the aim of targeting the schools most in need.

KEYWORDS: Air quality; greenspace; food environment; pedestrian child crash; school exposure; Bayesian nonparametrics

P-0506 The association between per-/polyfluoroalkyl substances in serum of teenagers and thyroid function parameters near a Chinese fluorochemical industrial plant: A cross-sectional study

Linna Xie[1], Xiaochen Wang[1], Shasha Hou[1], Zhenhuan Li[1], Ying Zhu[1]
[1]*China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

As the global pollutant, per-/polyfluoroalkyl substances (PFASs) are widely detected in population, inducing some adverse health effects, such as endocrine disruption. However, there are few studies on the exposure characteristics and health effects of PFASs on population with relatively high internal exposure of PFASs. In the current study, 906 teenagers (11-15 years old) living near an industrial plant were included, the concentrations of 18 PFASs had been determined, and the association between PFAS concentrations and thyroid function was explored. PFOA was found to be the predominant PFAS with a median concentration of 138 ng/mL, followed by PFOS (2.08 ng/mL), PFBA (1.12 ng/mL) and 6:2 Cl-PFESA (1.08 ng/mL). for the thyroid function parameters of participants, the abnormal rates of FT3 (29.7%) and FT4 (19.7%) were relatively high, but those of TSH (2.2%), TPO-Ab (2.1%) and TG-Ab (3.3%) were relatively low. Furthermore, logistic regression analysis showed that abnormal FT4 was significantly correlated with higher concentrations of PFOA. Results of multiple linear regression analysis showed that levels of FT4 were significantly and negatively correlated with concentrations of PFOA and PFHpA, and positively correlated with concentrations of PFHxA ($p < 0.05$) by adjusting gender, age, BMI, outdoor activity time and average sleep time. and there was a significantly positive correlation between FT3 levels and concentrations of PFHxA and PFHxS. for TSH, the levels of which were significantly and negatively correlated with PFOA concentrations, but positively correlated with PFHxS concentrations. In conclusion, PFOA may be the risk factor for decreased FT4 for the participants, but the evidence is not enough to demonstrate that other PFASs are the risk factor of thyroid function, local government should pay more attention to the above findings and take measures to reduce the PFASs external exposure of local residents. The present study is of great significance for the epidemiological findings.

P-0509 Clusters of small-scale sources of air carcinogens emissions increase the risks of acute lymphoblastic leukemia (ALL) in children and teenagers at a small area level in urban areas

Lizet Jarquin-Yanez[3], Luis E. Reyes-Arreguin[1], Monica Martinez-Acuna[3], Jaqueline Calderon, MSP Karla I. Lara-Rojas[1]

[1]UNIVERSIDAD AUTONOMA DE SAN LUIS POTOSI, San Luis Potosi, Mexico, [2]Boston College, Newton, USA, [3]Universidad Autonoma de Zacatecas, Zacatecas, Mexico

Vehicle exhaust emissions, small-scale commercial business (gasoline, paints, or pigments distributers), manufacturing of brick kilns, use of wood or coal for cooking, and hazardous waste management (incinerators, crematories), are some contributors to air carcinogens. Air exposure to benzene, polycyclic aromatic hydrocarbons (PAHs), fine respirable matter, and nitrogen dioxide have been associated with an increased risk of acute lymphoblastic leukemia (ALL) in children. The aim of this study was to identify clusters of ALL cases and examine possible relationships between clustered small-scale sources of carcinogens emissions in the metropolitan area of San Luis Potosi, Mexico.

METHODS: Hospital based-cancer registry (2010-2020) of ALL cases < 19 years old were geocoded. An inventory of fixed sources of air carcinogens emissions was created from governmental data sources. Also, information on air pollutants was taken from community air monitoring stations. ALL clusters' cases were identified through the Kernel density scan test. Multivariable spatial modeling assessed the effect of fixed urban sources and air pollutants controlling for socioeconomic status on ALL risk.

RESULTS: We identified five ALL clusters with excess risk (ranging from 1.1 to 2.3). The downtown area, brick kilns neighborhood, high-density vehicle areas, and vicinity to industrial sites. Clustered sources of brick kilns, crematories, incinerators, municipal landfills, and/or wood-coal commercial businesses were located close to ALL cases (less than 500 meters). Fine respirable matter (PM 2.5), nitrogen dioxide and wood use were contributing sources to the incidence of ALL cases.

CONCLUSIONS: Cumulative and aggregate environmental carcinogens from diverse sources increase the risk for ALL for the youth population. The gaps in our knowledge of the environmental ALL causes pose a major challenge for designing prevention strategies. Until now, pollution reduction has received scant attention in programs for cancer control and has been largely absent from prevention guidelines, which have focused almost exclusively on treatment.

P-0511 Prenatal exposure to Nitrogen Oxides and Waist-to-Height Ratio (WHtR) as a cardiovascular risk factor in school-aged children participants of the POSGRAD Cohort

Priscila Ceja Esparza[1]
[1]*The National Institute of Public Health of Mexico (INSP), Mexico City, Mexico*

BACKGROUND AND AIM: Prenatal exposure to NOx may increase the risk of obesity and cardiovascular risk factors in children. This study aims to evaluate the relationship between prenatal exposure to NOx and its effect on the behavior of the WHtR in school-aged children from the ages of 7 to 12 years old and to determine if the prenatal supplementation with docosahexaenoic acid (DHA) influences the outcome.

METHODS: We included 642 mother-child from the POSGRAD cohort. Land use regression models were performed to estimate exposure to NOx (NO, NO2 and NOx) using the results of passive outdoor monitoring from a representative sample of participant households. Child anthropometrics were taken yearly and WHtR was calculated. The association between prenatal exposure to NOx and WHtR was measured through a logistic random-effects model by tertiles of exposure and considering the prenatal supplementation status.

RESULTS: We found a significant difference in the risk of having a WHtR >= 0.5, on the second tertile of exposure for NOx between the supplemented (OR= 0.59, IC 95%: 0.10-3.49, p = 0.56) and placebo (OR=13.74, IC 95%: 1.94-97.24, p=0.01) groups when compared with the lowest tertile; in the third tertile the ORs were bigger for both groups, however, these were not significant.

CONCLUSIONS: Prenatal exposure to NOx can affect the WHtR outcome in children and prenatal supplementation with DHA can decrease this effect. The lack of protection of DHA at higher levels of exposure could suggest a need for higher doses of supplementation.

KEYWORDS: Prenatal, Waist-to-Height Ratio, Nitrogen Oxides, Cardiovascular Risk

P-0514 Nocturnal temperature range and in children asthma exacerbations in Lima, Peru, 2011-2016

Diego Fano-Sizgorich[1,2], Vilma Tapia[1], Gustavo F. Gonzales[1], William Checkley[3], Stella Hartinger[2]
[1]Laboratory of Endocrinology and Reproduction, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Centro Latinoamericano de Excelencia en Cambio Climático y Salud, Universidad Peruana Cayetano Heredia, Peru, [3]Johns Hopkins University, Baltimore, USA

BACKGROUND AND AIM: Asthma is the most common chronic disease in children <5-years-old, especially in LMIC's as Peru. Although the etiology of asthma is not known, environmental factors are considered one of its main triggers. Different studies have determined that temperature is associated with asthma exacerbations, but there is still low evidence about the effect of temperature variability. Thus, the aim of the study was to evaluate the association between nocturnal temperature range (NTR) and asthma in children <5 years-old in Lima, Peru, 2011-2016.

METHODS: Ecological study. Satellite mean (Tprom), minimum (Tmin) and maximum (Tmax) daily temperature and relative humidity (HR) for Lima were obtained from the NASA POWER platform; daily asthma exacerbation counts per district were obtained from Peru´s CDC; and daily district PM2.5 from WRF-Chem model. PM2.5 was grouped in quintiles, and present-day-Tprom in P5 (reference category), P95 and quartiles. NTR was calculated as present-day Tmin minus the previous day Tmax. The association was evaluated with negative binomial regression models clustered by districts, and adjusted for PM2.5, HR, and interaction terms between NTR and present-day-Tprom categories.

RESULTS: Nocturnal Temperature Range acted as a risk factor in the crude model (RR: 1.06, 95%CI 1.05-1.08, p<0.001). While in the adjusted model, there was a strong interaction effect of Tprom over NTR, in which for hotter days, NTR acted as an asthma risk factor in a semi-monotonic manner: RR 1.06 (95%CI 1.01-1.13) in present-day-Tprom Q1, 1.10 (95%CI 1.04-1.16) in Q2, 1.14 (95%CI 1.09-1.19) in Q3, 1.20 (95%CI 1.15-1.26) in Q4, and 1.09 (95%CI 1.01-1.18) in P95.

CONCLUSIONS: NTR acted as a risk factor for asthma exacerbation in children <5 year-old, with increasing risks for hotter days, since it could be related to airway inflammation thus leading to asthma.

P-0517 Combined exposures to air toxics in early-life and academic achievement in childhood

Jeanette Stingone[1]
[1]*Columbia University, Mailman School of Public Health, New York, USA*

BACKGROUND: Previous research has found associations between exposure to single air pollutants and children's cognitive health but has often lacked the ability to investigate combined impacts of pollutants. Characterizing the effects of combined exposures can provide a more realistic assessment of health effects for burdened communities, as well as identify interactions between pollutants. Identifying interpretable associations and interactions within the context of high-dimensional exposure data presents a computational challenge. Methods from domains such as data science can be incorporated into our analytic toolbox to address this challenge. Results from these data-driven approaches need to produce interpretable results that can be followed by targeted techniques. The objective of this research is to utilize tree-based methods, such as random forest, to develop an analytic pipeline to discover interpretable combinations of air toxics associated with children's academic outcomes.

METHODS: Residence at birth was used to link EPA data on estimated ambient concentrations of 40 air toxics to an administrative data linkage of public health and education registries for approximately 220,000 children born and raised in New York City. The random forest algorithm was applied to a 1/3 subset of the data to generate a collection of regression trees that identify the combinations of air toxics associated with 3rd grade standardized test scores in math and English language arts. Methods to account for confounding and validation of identified combinations were assessed and compared in a second 1/3 subset, with the remaining data held out for final analyses.

RESULTS: Our results suggest that early-life exposure to air toxics is associated with lower test scores but high correlation between pollutants and with social factors remains a challenge for interpretation.

CONCLUSIONS: Enhancements to the analytic pipeline, including incorporation of toxicological knowledge of pollutants, will be discussed.

KEYWORDS: mixtures, interactions, urban health

P-0518 Thyroid Nodules and Cancers in Fukushima: Analysis with Updated UNSCEAR Thyroid Dose Estimates

Yutaka Hamaoka[1]
[1]*Keio University, Minato-ku, Tokyo, Japan*

BACKGROUND AND AIM: After the Fukushima–Daiichi nuclear power plant (NPP) disaster, thyroid ultrasound examination (TUE) has been performed on subjects who were aged ≤18 years. In the 1st round of TUE (October 2011 to March 2014) and the 2nd round of TUE, 115 and 71 malignancies were detected, respectively. Following to previous study (Hamaoka 2021), I analyzed the same data with updated thyroid absorbed dose estimates (UNSCEAR 2022) that are about 1/8 lower than the previous estimates (UNSCEAR 2013).
DATA AND

METHODS: The relationship between radiation dose and the number of participants with thyroid nodule or malignancy was analyzed using publicly available municipality-level data without regional grouping (N=59). To analyze two-wave screening data, the multi-level random-effect Poisson regression model was applied. Interaction between dose and screening round dummy (0 for first and 1 for second screening) was also introduced to take into account latency.

RESULTS: UNSCEAR(2022) re-estimated thyroid dose to incorporate the latest information on ingestion of contaminated food, the flow of radiation plumes, and other factors. Although magnitudes were reduced, previous and re-estimated thyroid dose have a positive and significant correlation of 0.314. The number of participants with small nodules (≦5.0mm) was regressed on screening round dummy, estimated thyroid dose, and their interaction term. Although thyroid dose was insignificant (β=-0.017, z=-1.463), the interaction term was positive and significant (β= 0.033, z=4.42). Similar results were obtained for larger nodules (≧5.1mm) and malignancy.

CONCLUSIONS: These robust results are consistent with the conjecture: due to latency, the relationship between radiation exposure and impact on the thyroid will be observed in the later screening. Although this was an ecological study, health follow-up for children in Fukushima is urgent. Since the third screening, municipality-level data has been undisclosed because of privacy concerns. Data disclosure is necessary to understand the effect of the Fukushima disaster.

P-0521 Effect modification of greenspace on the associations between environmental exposures and childhood asthma: an intra-city study

Yabin Hu, Shenghui Li, Jianguo Tan, Yon Ying, Fan Jiang, Guangjun V, Chonghuai Yan, Shilu Tong
[1]*Shanghai Children's Medical Center, Shanghai, China*

BACKGROUND AND AIM: Greenspace may have a protective effect against the adverse health effects of non-optimal environmental exposures (EEs) such as temperature extremes and air pollution. However, inter-relations between these EEs and asthma haven't been quantified. This study aimed to examine if greenspace modifies the effects of EEs on childhood asthma.

METHODS: We conducted a population-based cross-sectional study among preschool and primary school children from 13 districts of Shanghai in 2019. The International Study of Asthma and Allergies in Childhood questionnaire was adopted to assess the childhood asthma. We collected the data on annually average climate conditions, air pollutants, and greenspace rate at different districts. Bayesian spatial models were used to evaluate the associations between environmental exposures and childhood asthma and the effect modification of greenspace.

RESULTS: There were 16,606 children aged 3-11 years in this study, including 8,709 (52.4%) boys. The prevalence of ever diagnosed asthma was 14.2%. An interquartile range (IQR) increase in mean temperature was associated with increased odds ratio (OR) of asthma (1.14, 95% confidence interval (CI): 1.04, 1.25). Greenspace rate was negatively associated with the OR of childhood asthma (0.244, 95% CI: 0.067, 0.887), and appeared to modify the associations between EEs and childhood asthma to various extents.

CONCLUSIONS: Non-optimal environmental exposures (e.g., temperature and NO2) could be the triggers of childhood asthma, and greenspace seemed to modify the adverse effects of EEs on childhood asthma.

P-0524 Prevalence of asthma and asthma symptoms among rural and urban pre-school children in Mpumalanga Province, South Africa

Joyce Shirinde[1], Rodney Mudau[1], Kuku Voyi[1]
[1]*University of Pretoria, Pretoria, South Africa*

BACKGROUND AND AIM: Asthma is the most common chronic illness in South African children and its prevalence is increasing in both urban and rural areas. Little is known about the prevalence of asthma amongst pre-school children living in Mpumalanga province, South Africa, which forms part of the Highveld region, a priority area in terms of air pollution. The area is known for poor air quality and elevated concentrations of criteria pollutants. The aim of the study was to investigate the prevalence of asthma and asthma symptoms among rural and urban pre-school children and the association with environmental risk factors.

METHODS: This analytical cross-sectional study that included 3145 pre-school children from Mpumalanga Province, South Africa. Parents of the children were requested to complete a modified ISAAC questionnaire. We analyzed the influence of potential risk factors on dependent variables using bivariate analysis. Significant risk factors identified in the bivariate analysis were included in a multiple logistic regression to develop a final model.

RESULTS: Self-reported prevalence of asthma was 2.3% (66/2810), with pre-school children in rural areas reporting a higher rate than pre-school children in urban areas (1.3% vs 1%), $\chi 2=10.86$, $P <0.001$). The prevalence of asthma symptoms was 15.1% (467/3084), with rural pre-school children reporting a higher prevalence of symptoms than urban pre-school children (10% vs 5%), $\chi 2 = 24.45$, $P < 0.001$). Risk factors for asthma and asthma symptoms were vigorous physical activity (odds ratio (OR) 2.31, 95% CI 1.14-4.66), home smoking exposure (OR 2.94, 95% CI 1.40-6.19) and male parent smoking (OR 1.46, 95% CI 1.01-2.12).

CONCLUSIONS: Pre-school children in rural areas reported a higher prevalence of asthma compared to pre-school children in urban areas. Risk factors for asthma included physical activity and smoking exposure in the home.

KEYWORDS: asthma, pre-school children, risk factors

P-0533 Early-life exposure to cadmium and onset of puberty in girls: a longitudinal mother-child cohort study in Bangladesh

Annachiara Malin Igra[1], Anisur Rahman[2], Anna L.V. Johansson[1], Jesmin Pervin[2], Pernilla Svefors[3], Shams El Arifeen[2], Marie Vahter[1], Lars-Åke Persson[3,4], Maria Kippler[1]
[1]Karolinska Institutet, Solna, Sweden, [2]icddr,b, Dhaka, Bangladesh, [3]Uppsala University, Uppsala, Sweden, [4]London School of Hygiene and Tropical Medicine, London, UK

BACKGROUND AND AIM: Cadmium is a toxic metal with endocrine disrupting properties, but there are few studies about its impact on puberty onset. We aimed to evaluate if early-life exposure to dietary cadmium is associated with the timing of female puberty.

METHODS: In a mother-child cohort in rural Bangladesh (n=935), we assessed the exposure to cadmium during pregnancy through concentrations in erythrocytes (half-life 3-4 months) and in the daughters at 5y and 10y through concentrations in urine, a marker of long-term exposure. Cadmium was measured with inductively coupled plasma mass spectrometry. Between the ages of 12 and 15 years, the girls were interviewed twice with a 6-month interval about their date of menarche, and they self-assessed their pubertal development according to Tanner stages. Associations with age at menarche were evaluated with Kaplan-Meier analysis and multivariable-adjusted Cox regression, and associations with pubertal stages with ordered logistic regression.

RESULTS: Median age at menarche was 13.0 years. We found no association between maternal exposure to cadmium during pregnancy and the daughters' age at menarche. Median urinary cadmium concentrations at 10y were 0.25 µg/L. Girls belonging to the highest quartile of urinary cadmium at 10y attained menarche 3.8 months later than girls in the lowest quartile. In multivariable-adjusted analysis, the corresponding hazard ratio of reaching menarche comparing girls in the highest and the lowest quartile of urinary cadmium was 0.77 (95% CI 0.60, 0.98). Similar associations were found for urinary cadmium at 5y. Urinary cadmium at 10y was also associated with delayed breast development; the odds ratio of reaching more advanced breast development stages comparing girls in the highest and the lowest quartile of urinary cadmium was 0.63 (0.40; 0.99).

CONCLUSIONS: Elevated childhood exposure to cadmium was associated with a pubertal delay in girls.

KEYWORDS: Cadmium, early-life, female puberty, menarche, longitudinal

P-0534 Nearby wildfire impacts, social vulnerability, and birthweight in a rural population

Cindy S. Leary[1], Jonathan M. Graham[1], Patrick Freeborn[2], Erin O. Semmens[1]
[1]Center for Population Health Research, University of Montana, Missoula, USA, [2]Rocky Mountain Research Station, Missoula Fire Sciences Laboratory, Missoula, USA

BACKGROUND AND AIM
Wildfires are increasing across the world and are associated with adverse impacts on vulnerable populations including pregnant people and young children. Wildfires may exert their harmful effects by elevating air pollutant exposure and may also fuel stress by disrupting daily activities and, if extreme, threatening or forcing evacuation. We aimed to estimate exposure disparities by social vulnerability and quantify the impact of nearby wildfires during pregnancy on birthweight.

METHODS: Our study population included 139,671 maternal-infant dyads from birth certificate records between 2008 and 2019 in Montana, USA. We classified pregnant people as "exposed" if they had an active, large (≥ 1000 acres) fire within 5 kilometers of their home detected by Moderate Resolution Imaging Spectroradiometer (MODIS) sensors. We characterized the population by neighborhood social vulnerability index (SVI), rurality, and race and estimated associations between nearby fires and birthweight in linear regression analyses adjusted for gestational and maternal age, education, race, parity, prenatal visits, and SVI.

RESULTS: Exposure to at least one large wildfire within 5 km of home occurred for 0.5% (n=712) of births in Montana between 2008 and 2019. Mean neighborhood SVI as well as rates of both rural residence and American Indian/Alaska Native maternal race were all significantly greater in "exposed" pregnancies. . Having at least one large nearby fire during pregnancy was associated non-significantly with a 21 gram (95% CI: -52.2, 10.2) lower birthweight in adjusted analyses.

CONCLUSIONS: Social vulnerability appears greater in those experiencing nearby wildfires during pregnancy. Although wildfire exposure within 5 km of home does not appear to influence birthweight, future work should evaluate whether the effects of nearby fires are felt more strongly in socially vulnerable populations.

KEYWORDS: wildfire, birthweight, social vulnerability, rurality

P-0536 Allergic rhinitis, rhinoconjunctivitis and hayfever symptoms among pre-school children are associated with school transport mode: an analytical cross sectional study

Joyce Shirinde[1], Rodney Mudau[1], Kuku Voyi[1]
[1]*University of Pretoria, Pretoria, South Africa*

BACKGROUND: Allergic rhinitis (AR) is a common condition affecting many people in the globally. In addition, the condition is mostly prevalent amongst children. The aim of the study was to investigate the association between the school transport mode and allergic rhinitis symptoms, rhinoconjunctivitis and hayfever among pre-school children living an in Mpumalanga Province, which in an area known for high levels of air pollution in South Africa.

METHODS: An analytical cross-sectional study consisting of 3145 participants was conducted in Mpumalanga South Africa. A modified ISAAC questionnaire was used to collect data. Bivariate analysis was performed between potential risk factors and dependent variables. Risk factors that showed association in the bivariate analysis were included in the multiple logistic regression to develop a final model.

RESULTS: The prevalence of self-reported rhinitis ever, current rhinitis rhinoconjunctivitis and hayfever was 21, 7, 8 and 4 % respectively. Rhinitis ever, current rhinitis, current rhinoconjunctivitis and hayfever were significantly associated with the frequent use of motorcar to school, (OR 1.45 95 % CI: 1.15 − 1.83), (OR 1.62 95 % CI: 1.27–2.08), (OR 1.64 95 % CI: 1.17–2.29) and (OR 3.36 95 % CI: 2.16–5.21) respectively. No associations were observed between trucks/buses/taxis traffic in resident area and allergic rhinitis symptoms in the multiple analyses.

CONCLUSIONS: The study shows a high prevalence of allergic rhinitis symptoms amongst Pre-schoolers. The results have shown that frequent use of motorcar pays a role in the prevalence of allergic rhinitis symptoms in preschool children.

Chan School of Public Health, Boston, USA, [9]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [10]Department of Psychiatry and Behavioral Sciences, Boston Children's Hospital, Boston, USA, [11]Department of Psychiatry, Harvard Medical School, Boston, USA

BACKGROUND AND AIM: Emerging studies investigated the adverse health effects of fine particulate matter (PM2.5) using data from multiple cohorts. However, associations often are not generalizable across cohorts. Our objective was to assess associations between prenatal PM2.5 and childhood cognition in two U.S. cohorts while accounting for between-site heterogeneity.

METHODS: We included 349 mother-child dyads enrolled from the dual-site (New York City and Boston) PRogramming of Intergenerational Stress Mechanisms (PRISM) study and the First Thousand Days of Life (FTDL) study participating in the Environmental influences on Child Health Outcomes (ECHO) consortium. Daily PM2.5 was estimated using satellite-based models linked to each woman's residential address during pregnancy. Children's cognition was assessed using the NIH Toolbox Cognition Battery between ages 3 and 8 years. We used a log-linear model applied to contingency tables formed by cross-classifying covariates by site to examine between-site heterogeneity. Multivariable linear regression was used to estimate the coefficients and 95% confidence intervals for the trimester-specific PM2.5 exposure and age-corrected standardized cognition scores (mean=100, SD=15), stratified by study site, child sex, and urbanicity.

RESULTS: The log-linear model indicated that inter-study associations were similar between PRISM-NYC and FTDL, which were different from those in PRISM-Boston. Accordingly, we combined the PRISM-NYC and FTDL cohorts. Findings showed that 1 μg/m³ increase of 3rd trimester PM2.5 was associated with -4.75 (95% CI= -11.86, -0.50) mean early childhood cognition scores in females in PRISM-Boston. We additionally observed a significant association between PM2.5 and picture vocabulary scores [-3.82, (-13.75, -0.01)] in males in NYC+FTDL non-urban areas.

CONCLUSIONS: We found associations between prenatal PM2.5 and impaired childhood cognition in this pooled analysis. Given that multi-site analyses are increasingly conducted, our findings suggest expanding the awareness of between-site heterogeneity, including site-specific confounders and effect modifiers.

KEYWORDS: air pollution, childhood cognition, log-linear model

P-0542 Air Pollution Mixture and Birth Outcomes: Modification of Placenta Leukocyte Telomere Length and Infant Sex

Xueying Zhang[1], Elena Colicino[1], Whitney Cowell[1], Allan Just[1,2], Itai Kloog[1,2,3], Brent Coull[4,5], Robert Wright[1,2], Rosalind Wright[1,2,6]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Institute of Exposomic Research, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Department of Geography and Environmental Development, Ben-Gurion University of the Negev, Beersheba, Israel, [4]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, USA, [5]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [6]Department of Pediatrics, Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: Multiple air pollutants such as fine particles matter (PM2.5), nitrogen dioxide (NO2), and ozone (O3) were associated with adverse birth outcomes, and their associations were potentially modified by the cellular aging of placenta and infant sex. But the joint association of those factors was less examined.
METHOD: This analysis included 310 mother-infant dyads (142 girls and 168 boys) enrolled in the PRogramming of Intergenerational Stress Mechanisms (PRISM) study. We applied Bayesian Kernel Machine Regression (BKMR) to examine the independent and mixed effects of prenatal PM2.5, NO2, O3, and placenta relative leukocyte telomere length (rLTL) on two birth outcomes (i.e., birth weight for gestational age z-score and preterm birth defined as less than 37 gestational weeks). The mixed effect was examined using an exposure index calculated as the summed multiplicities of the quintiles of pollutant and pollutant-specific weights estimated using Bayesian Weighted Quantile Sum (BWQS). The associations between exposure, outcome, and rLTL were examined for boys and girls separately.

RESULTS: NO2 drove the exposure effect on birth weight z-score in girls and on preterm birth in boys. Sex differences were observed. The estimated exposure index was negatively and positively associated with birth weight z-score and preterm birth in girls. These associations were inversed for boys. The observed modification effects of rLTL were varied by pollutant, outcome, and infant sex. for example, the results of the exposure index suggested stronger modification effects in boys, in which mothers with lower rLTL and higher exposure index jointly contribute to the higher birth weight z-scores and preterm birth.

CONCLUSIONS: Co-exposure to elevated air pollution and lower LTL during prenatal may contribute to adverse birth outcomes, especially among boys.

P-0548 Prenatal Ambient Air Pollutant Mixture Exposure and Neurodevelopment in Urban Children in the Northeastern USA

Yueh-Hsiu Mathilda Chiu[1], Brent A. Coull[2], Hsiao-Hsien Leon Hsu[1], Ander Wilson[3], Joel Schwartz[2], Robert O. Wright[1], Rosalind J. Wright[1]

[1]Icahn School of Medicine at Mount Sinai, New York, USA, [2]Harvard University, TH Chan School of Public Health, Boston, USA, [3]Colorado State University, Fort Collins, USA

BACKGROUND AND AIM: Prior studies of prenatal air pollution (AP) exposure on child neurodevelopment largely focus on a single pollutant. We leveraged daily exposure data and implemented novel data-driven statistical approaches to assess effects of prenatal exposure to a mixture of seven air pollutants on cognitive outcomes in children from an urban pregnancy cohort in the Northeastern USA.

METHODS: Analyses included 236 children born at ≥37 weeks gestation. Maternal prenatal daily exposure levels for nitrogen dioxide (NO_2), ozone (O_3), and constituents of fine particles [elemental carbon (EC), organic carbon (OC), nitrate (NO_3-), sulfate (SO_4^{2-}), ammonium (NH_4+)] were estimated based on residential addresses using validated satellite-based hybrid models or global 3-D chemical-transport models. Children completed the Wechsler Intelligence Scale for Children (WISC-IV), Wide Range Assessment of Memory & Learning (WRAML-2), and Conner's Continuous Performance Test (CPT-II) at 6.5±0.9 years of age. Time-weighted pollutant exposure levels were estimated using Bayesian Kernel Machine Regression Distributed Lag Models. Resulting weighted exposures were used in Weighted Quantile Sum regressions to examine AP mixture effects on cognitive outcomes, adjusted for sex, maternal age, education, and temperature. Sex-stratified models were explored.

RESULTS: Mothers were primarily ethnic minorities (81% Hispanic and/or black) reporting ≤12 years education (68%). Prenatal exposure to AP mixture (per decile increase) was associated with decreased WISC-IV IQ (β=-0.94, 95%CI=-1.69 to -0.19), decreased memory-related attention/concentration (β=-1.03, 95%CI=-1.78 to -0.27) and general memory (β=-0.64, 95%CI=-1.40 to 0.00) indices from WRAML-2, and increased CPT-II omission errors (β=1.55, 95%CI=0.34–2.77). When stratified by sex, associations with IQ and omission errors were significant in boys only, while associations with memory-related indices were significant in girls only. Sulfate, NO_2, and EC were major contributors.

CONCLUSIONS: Prenatal exposure to an AP mixture was associated with child cognitive outcomes in a sex- and domain-specific manner.

P-0549 Associations between Exposure to Prenatal Air Pollution Mixtures and Behavioral Problems in Urban Children

Hsiao-Hsien Hsu[1], Brent Coull[2], Ander Wilson[3], Yueh-Hsiu Mathilda Chiu[1], Joel Schwartz[2], Robert Wright[1], Rosalind Wright[1]

[1]Icahn School of Medicine at Mount Sinai, New York, USA, [2]Harvard School of Public Health, Boston, USA, [3]Colorado State University, Fort Collins, USA

BACKGROUND AND AIM: Previous studies investigating associations between prenatal air pollution and childhood behavior mainly focused on PM2.5, while little is known about the effect of air pollution mixtures and exposure timing throughout pregnancy. We used individual-level daily exposure data and implemented novel weighting approaches to assess effects of prenatal exposure to a mixture of seven air pollutants on behavioral outcomes in children from a Northeastern USA urban pregnancy cohort.

METHODS: Participants included 234 full-term
singleton children (≥37 weeks gestation). Children completed the Behavior Assessment System for Children 2nd Edition (BASC-2) at age 6.5±0.9 years. Daily exposure levels for nitrogen dioxide (NO_2), ozone (O_3), and constituents of fine particles [elemental carbon (EC), organic carbon (OC), nitrate (NO_3-), sulfate (SO_4^{2-}), ammonium (NH_4+)] were estimated based on residential addresses using satellite-hybrid models and 3D chemical-transport models. Time-weighted exposure levels of the seven air pollutants in the mixture were estimated using Bayesian Kernel Machine Regression Distributed Lag Models. We subsequently used in multivariable linear regressions including time-weighted exposures for all pollutants in the mixture., adjusted for sex, maternal age, education, and temperature. Effect modification by sex was also examined.

RESULTS: Participants were primarily Hispanic (59%) and Black (25%), with ≤12 years of education (68%). Time-weighted O_3 level (per one standard deviation increase) was associated with 4.77% increase in External Problems (95%CI= 0.7%–9%), 4.41% increase in Aggression (95%CI=0.9%–8.1%), 4.36% increase in Internal Problems (95%CI=0.5%–8.3%), and 4.18% increase in Anxiety (95%CI=0.1%–8.4%). When stratified by sex, these associations were only significant in boys. Time-weighted OC level was significantly associated with Internal Problems in girls only (4.6% increase, 95%CI=1.7%–7.7%).

CONCLUSIONS: In a prenatal air pollution mixture, ozone is associated with child behavioral problems, and the association is specific to sex and measured outcome scale.

P-0550 Proximity to coal flyash disposal site and infant neurodevelopment in Sri Lanka

Meghan Tipre[1], Amandhi Caldera[2], Ruwanthi Perera[2], Pavithra Godamune[2], Nalini Sathiakumar[1], Rajitha Wickremesinghe[2]

[1]University of Alabama at Birmingham, Birmingham, USA, [2]Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka

BACKGROUND: Fly ash from coal-fired power plants (CPP) often consist of trace heavy metals such as arsenic and lead which have been linked with deleterious health effects in exposed communities.
Objective. A cross-sectional study examined relationship between proximity to CPP, an indirect measure for environmental exposure to flyash, and neurodevelopment in infants 1- 3 years of age, measured using 'Bayley Scales of Infant and Toddler Development, third edition (BSID-III)'

METHODS: Set in Puttalam District in Sri Lanka, the study enrolled 208 children: 108 from the buffer zones around the CPP with radii of '<5kms' and 100 from '≥10kms', respectively. In a multivariable general linear regression, we analyzed the relationship between proximity to CPP and BSID-III cognitive, motor and language scores, adjusting for maternal age, ethnicity, wealth index, and child's age, sex and birthweight.

RESULTS: On average, children were 23.4 months (±6.4) old and 60.2% were female. Compared to children residing away from the CPP (≥10 kms), children residing in close proximity (<5 kms) had lower composite scores for BSID-III language (adj. means: 93.7 vs. 88.8, p= 0.0057), motor (88.0 vs. 86.0, p=0.2126) and cognitive (84.4 vs. 83.1, p= 0.4395) but only language was significant, after adjusting for covariates.
DISCUSSION. Our findings suggest lower developmental scores among children residing closer to CPP compared to those further away. Results of the study have scientific and policy implications for low- and middle-income countries as well as developed countries like US, where low-income, minority, rural and inner-city urban communities continue to disproportionately be exposed to higher levels of trace heavy metals released from industrial effluents, mining, fertilizers, and pharmaceuticals.

P-0551 The mortality burden of nervous system diseases attributed to ambient temperature: a multi-city study in China

Yonghong Li[1], Yibin Cheng, Xiaoyuan Yao
[1]*National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUNDS: Studies on the association between ambient temperature and human mortality have been widely reported, focusing on common diseases such as cardiopulmonary diseases. However, multi-city studies on the association between both high and low temperatures and mortality of nervous disorders were scarce, especially on the evidence of vulnerable populations.

METHODS: Weekly meteorological data, air pollution data and mortality data of nervous system were collected in 5 cities in China. A quasi-Poisson regression with distributed lag non-linear model was applied to quantify the association between extreme temperatures and mortality of nervous system diseases. Multivariate meta-analysis was applied to estimate the pooled effects at overall level. The attributable fractions (AFs) were calculated to assess the mortality burden attributable to both high and low temperatures. Stratified analyses were also performed by gender and age-groups through the above steps.

RESULTS: A total of 12,132 deaths of nervous system diseases were collected. The overall minimum mortality temperature was 23.9 ℃ (61.9th), the cumulative relative risks of extreme heat and cold for nervous system diseases were 1.33(95%CI: 1.10, 1.61) and 1.47(95%CI: 1.27, 1.71). The mortality burden attributed to non-optimal temperatures accounted for 29.54% (95%eCI: 13.45 %, 40.52%), of which the mortality burden caused by low temperature and high temperature accounted for 25.89% (95%eCI: 13.03%, 34.36%) and 3.65% (95%eCI: 0.42%, 6.17%), respectively. The mortality burden attributable to ambient temperature was higher in both males and the elderly (> 74 years old), with the AF of 31.85% (95%eCI: 20.68%, 39.88%) and 31.14% (95%eCI: -6.83%, 49.51%), respectively.

CONCLUSIONS: The non-optimal temperature can increase the mortality of nervous system diseases and the males and the elderly over 74 years have the highest attributable burden. The findings add the evidence of vulnerable populations of nervous system diseases against ambient temperatures.

KEYWORDS: temperature; nervous system diseases; mortality burden; vulnerable population

P-0557 Association of heat wave exposure with increased risk of hospitalization for dehydration or heat-related illness in young children in South Korea: A Time-series study

Jongmin Oh[1], Eunji Kim[1,2], Ji Hyen Lee[1], Youngrin Kwag[1], Hyungmi An[4], Eunhwa Kang[5], Hae Soon Kim[3], Yongho Jee[6], Eunhee Ha[1,2]

[1]Department of Environmental Medicine, School of Medicine, Ewha Womans University, Seoul, Republic of Korea, [2]Graduate Program in System Health Science and Engineering, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [3]Department of Pediatrics, Ewha Womans University College of Medicine, Seoul, Republic of Korea, [4] Institute of Convergence Medicine Ewha Womans University Mokdong Hospital, Seoul, Republic of Korea, [5]Ewha Womans University Seoul Hospital, Seoul, Republic of Korea, [6]Advanced Biomedical Research Institute Ewha Womans University Seoul Hospital, Seoul, Republic of Korea

BACKGROUNDS
Numerous studies have investigated the association between summer temperatures and increased heat related hospitalizations in the general population. However, little is known about the heat-related morbidity of heat waves in children. We aimed to evaluate the association between hospitalization for dehydration or heat-related illness in children and heat wave exposure in South Korea.

METHODS: We used the National Health Insurance Service (NHIS) database, which provides medical records from 2015 to 2019 in South Korea. We defined daily hospitalizations for dehydration or heat-related illness of children younger than five years of age during the summer period (June to August). A heat wave was defined using a total of six criteria from a maximum temperature 28°C or higher to 33°C or higher per day. A time-series analysis was used to investigate the association between the maximum temperature and a heat wave and hospitalization for dehydration or heat-related illness of children younger than five years of age. We used a two stage design involving a meta-analysis after modeling by each city.

RESULTS: We included 16,879 daily hospitalizations for dehydration or heat-related illness among children younger than five years of age during 2015 to 2019. The relative risk (RR) of hospitalization for dehydration or heat related illness was 1.023 [95% confidence interval (CI): 1.013, 1.034] per 1°C increase in the 3-day moving average maximum temperature during summer. The RR due to heat wave exposure (6 definitions: 28°C to 33°C) was ranged from 1.10 (95% CI: 1.06, 1.15) to 1.05 (95% CI: 0.98, 1.12). In the subgroup, we did not observe statistically significant gender differences.

CONCLUSIONS: Exposure to a heat wave during summer is associated with an increased risk of hospitalization for dehydration or heat-related illness among children younger than five years of age.

P-0559 Seasonal Temperature Variability and Mortality across the USA

James Patrick Healy[1], Mahdieh Danesh Yazdi[1], Yaguang Wei[1], Francesca Dominici[1], Liuhua Shi[2], Joel Schwartz[1]
[1]Harvard T. H. Chan School of Public Health, Boston, USA, [2]Emory Rollins School of Public Health, Atlanta, USA

BACKGROUND: Seasonal temperature variability remains understudied and is set to be modified by climate change. Most temperature studies consist of short-term exposures using time series data. These studies are limited by an inability to observe longer-term trends in temperature and mortality along with regional adaptation and short-term mortality displacement. Cohort studies can address these limitations, but no countrywide cohort study has been conducted to study these long-term temperature trends, especially in a cohort with differing climatic zones.
AIM:
We aimed to examine the association between seasonal temperature variability and mortality across the contiguous US with its five defined regional climate zones. Further, we aimed to investigate effect modification by race, poverty, population density, and green space.

METHODS: We carried out this analysis in the US Medicare cohort (age 65+) from 2000-2016 with 622,427,230 years of person time. Our exposure was seasonal temperature variability or the standard deviation of warm (April to September) and cold (October to March) season temperature.
We used adapted difference-in-difference, quasi-experimental methods to reduce unobserved confounding at the ZIP-code level. We employed a clustering approach based on climate zone and socioeconomic factors, combined with a meta-analysis.

RESULTS: We showed that for every 1 °C increase in warm and cold season temperature variability, the mortality rate increased by 1.54% and 0.69% in over 65s, respectively. Over 270 million Americans are exposed to at least one form of seasonal temperature variability. These effects were most pronounced in low-income individuals, low green space residents, and those in lower population density areas such as rural locations. Further, these effects were not modified by one's climate zone of residency.
CONCLUSION: Seasonal temperature variability was associated with an increased risk of mortality in over 65s across the US.

KEYWORDS: Mortality; Temperature Variability; Climate Change; Medicare Cohort; Race; Poverty; Green Space.

P-0564 Is short-term exposure to heat associated with mental health compared to other conditions?

Anne Weaver[1], Christine L. Gray[2], Erik Slawsky[3], Joshua Moyer[1], Cavin Ward-Caviness[1]
[1]US Environmental Protection Agency, Chapel Hill, USA, [2]Duke University Global Health Institute, Durham, USA, [3]Oak Ridge Associated Universities at US Environmental Protection Agency, Chapel Hill, USA

BACKGROUND AND AIM: Health impacts of heat exposure are increasingly important due to climate change. Anxiety and depression are common and understudied mental health conditions, possibly associated with heat exposure. We examined associations between short-term (5-day) apparent temperature and health visits for anxiety and/or depression in North Carolina.

METHODS: We linked electronic health records from a random sample of adults seen at University of North Carolina Healthcare System hospitals 2004-2018 in the EPA CARES resource with climate data from PRISM Climate Group. We examined 5-day mean apparent temperature (incorporating temperature and humidity) at the ZIP code level for patients diagnosed with anxiety and/or depression compared to first recorded visit for those with any other diagnosis. We used log binomial regression models adjusted for personal (age, sex, race, health insurance status), environmental (season, annual PM2.5 concentration, climate division) and neighborhood (median household income, percent Bachelor's degree or more, percent urban) covariates.

RESULTS: We included 17,145 patients, 2219 of whom were diagnosed with anxiety and/or depression. Those with anxiety and/or depression were, on average, younger (46.4 vs 48.0 years), more likely to be female (69.7% vs 59.7%), and White (74.7% vs 62.4%), compared to those with other diagnoses. Mean five-day apparent temperature was 17.6 degrees C (SD 10.4). The prevalence of having a diagnosis of anxiety and/or depression was 1% higher per degree increase in five-day mean apparent temperature (PR 1.01, 95% CI 1.00, 1.02) compared to other diagnoses. Results were similar when limiting to anxiety, depression, and geographic region.

CONCLUSIONS: We did not observe substantial associations between apparent temperature and anxiety or depression relative to other outcomes. Future studies should expand this work to larger areas with more temperature variability and consider mental health trends independent of other outcomes. This abstract does not reflect EPA policy.

KEYWORDS: climate, heat, mental health

P-0569 Temporal Variation in the Association between Temperature and Cardiovascular and Respiratory Mortality in 15 German cities

Masna Rai[1], Susanne Breitner, Siqi Zhang, Francesca de'Donato, Annette Peters, Alexandra Schneider
[1]*Helmholtz Center Munich, Neuherberg, Munich, Germany*

BACKGROUND AND AIM: There is limited evidence of temporal changes in the association between air temperature and the risk of cause-specific cardiovascular [CVD] and respiratory [RD] mortality. We explored temporal variations in the association between short-term exposures to air temperature and cause-specific CVD and RD mortality in the 15 largest German cities from 1993 to 2016.
METHOD: We applied time-stratified time-series analysis using city-specific confounder-adjusted Poisson models and estimated the temperature–mortality associations with distributed lag non-linear models with 14 lag days and then pooled by a multivariate meta-analytical model. We performed age- and sex-stratified analysis. A meta-regression with socioeconomic and demographic effect modifiers is currently being performed. Cold and heat effects are reported as relative risks [RR] at the 1st and the 99th temperature percentile, relative to the 25th and the 75th percentile, respectively.
RESULT: We analyzed a total of 1,003,305 CVD and 173,154 RD deaths. Cold-related RR for CVD mortality was seen to rise consistently over time from 0.98 (95% confidence interval [95% CI] 0.96, 1.01) in the period 1993-2004 to 1.10 (95% CI 1.08, 1.10) in the period 2005-2016. A similar increase in cold-related RR was also observed for RD mortality. The heat-related RR for RD mortality increased from 1.44 (95% CI 1.22, 1.70) to 1.83 (95% CI 1.66, 2.00). Males were particularly susceptible to cold for all causes of death and heat for total and RD mortality. The age group >64 years was susceptible to cold mainly for CVD mortality, whereas the younger age group (0-64 years) showed stronger effects of heat for RD mortality.

CONCLUSIONS: We found evidence of rising population susceptibility to both heat- and cold-related CVD and RD mortality. These findings may be useful to design targeted heat- and cold- adaptation plans in Germany.

BACKGROUND AND AIM: Limited knowledge is known about the impact of hydrometeorological conditions on dengue incidence in China, and the associated disease burden in the climate-changing future. This study projects the attributable excess risk of dengue in 365 cities across mainland China under climate change scenarios.

METHODS: The association between Palmer drought severity index (PDSI) and dengue in the historical period (2013-2019) was estimated with a spatiotemporal Bayesian model. We developed a dengue transmission biological model to project the potential risk area of dengue by 2100 under three representative concentration pathways (RCP 2.6, 4.5, and 8.5). The association combined with biological model was then used to project the annual excess risks of dengue related to PDSI by 2100. We further calculated attributable excess risk for dry and wet conditions.

RESULTS: A total of 93,101 dengue cases were reported between 2013-2019 in mainland China. Dry and wet conditions within three months lag were associated with increased risk of dengue. Locations with potential dengue risk in China will expand in the future. The hydrometeorological changes are projected to substantially affect the risk of dengue in regions with mid-low latitude, especially the coastal areas under high emission scenarios. By 2100, the annual average increased excess risk is expected to range from 7.49% (95% empirical CI: 4.55-16.64) in northwest to 71.89% (55.66-123.62) in south under RCP 8.5. Moderate dry is predicted to have the greatest impact on dengue risk across all regions.

CONCLUSIONS: Hydrometeorological conditions are predicted to increase the dengue risk in the future in the south, east, and central areas of mainland China in disproportional patterns. Our findings have implications for the preparation of public health interventions to minimize the health hazards of non-optimal hydrometeorological conditions under climate change context.

P-0571 The association between ambient temperature and cause-specific cardiovascular disease admissions in Japan: a nationwide study

Pan Rui[1], Okada Akira[2], Yamana Hayato[3], Yasunaga Hideo[4], Kumazawa Ryosuke[4], Matsui Hiroki[4], Fushimi Kiyohide[5], Kim Yoonhee[1]

[1]Department of Global Environmental Health, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, Tokyo, Japan, [2]Department of Prevention of Diabetes and Lifestyle-Related Diseases, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, Tokyo, Japan, [3]Department of Health Services Research, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, Tokyo, Japan, [4]Department of Clinical Epidemiology and Health Economics, The University of Tokyo, Tokyo, Japan, Tokyo, Japan, [5]Department of Health Policy and Informatics, Tokyo Medical and Dental University, Tokyo, Tokyo, Japan

BACKGROUND AND AIM: Substantial evidence suggests that non-optimal temperatures increase the risk of cardiovascular disease (CVD) mortality and morbidity. However, limited studies have reported inconsistent results for hospital admissions depending on study locations that also lack investigations on cause-specific CVDs at a national level. We aim to examine the short-term associations between temperature and acute CVD hospital admissions by specific categories [ischemic heart disease (IHD), heart failure (HF) and stroke] in 47 prefectures of Japan from 2011 to 2018.

METHODS: We performed a two-stage meta-regression analysis. First, we estimated prefecture-specific associations between temperature and CVD admissions using the time-stratified case-crossover design with a distributed lag nonlinear model over the lag of 21 days. Then we used a multivariate meta-regression model to obtain national average associations.

RESULTS: During the study period, a total of 2,416,707 CVD admissions were reported. We found significant cold risks on all CVD admissions and cause-specific categories. Compared with minimum hospitalization temperature (MHT) at 95th percentile of temperature, the cumulative relative risks (RRs) of cold (5th) and heat (99th) on all CVD were 1.222 [95% confidence interval (CI): 1.190, 1.255] and 1.003 (95% CI: 0.996, 1.011), respectively. The cold risk for HF [RR=1.566 (95% CI: 1.477, 1.660)] was higher than IHD [RR=1.136 (95% CI: 1.048, 1.231)] and stroke [RR=1.107 (95% CI: 1.057, 1.160)]. The MHTs varied by the specific causes. We also observed significant heat risk of temperature on HF with RR of 1.069 (95% CI: 1.030, 1.110). The subgroup analysis showed the ≥ 85-year age group was more vulnerable to the risk of temperature.

CONCLUSIONS: This study indicated that exposure to cold and heat could increase the risk of CVD hospital admissions, varying depending on the cause-specific, which may provide new evidence to reduce the burden of CVD.

P-0574 Childhood cognitive and behavioral effects of high summer temperatures

Scott Delaney[1], Keith Spangler[2], Michael Leung[1], Rachel Nethery[1], Henning Tiemeier[1], Marc Weisskopf[1]
[1]Harvard T.H. Chan School of Public Health, Boston, USA, [2]Boston University School of Public Health, Boston, USA

BACKGROUND AND AIM: As climate change accelerates, the frequency of high summer temperatures will increase, affecting nearly every domain of health, including behavioral health. Research suggests high temperatures increase aggressive behaviors and decrease cognitive performance in adults, but these effects in children remain poorly understood. Our work addresses this knowledge gap.

METHODS: We derived daily maximum heat indexes using meteorologic data from the PRISM Climate Group and linked them to cognitive and behavioral data from 4,387 children aged 9-10 who completed assessments from June-August in the Adolescent Brain Cognitive Development Study baseline wave, 2016-2018.
At 21 sites in the USA representing 5 climate types identified by the U.S. Department of Energy (Cold, Marine, Mixed-Humid, Hot-Dry, Hot-Humid), children completed NIH Toolbox neurocognitive assessments (age-normed total cognition score; mean=100.5; sd=17.9), and their caregivers completed the Achenbach Child Behavior Checklist (aggressive behavior subscale t-score; mean=52.2; sd=4.0).
We modeled site-specific 6-day lagged relationships using distributed lag nonlinear models adjusted for known confounders, then used meta-regression to estimate climate-specific associations.

RESULTS: for participants living in the Cold climate (n = 1886), the overall cumulative association for heat indexes in the 99th percentile (vs. the 90th percentile) of the site-specific summertime heat index distribution was a -11.5 (95% CI: -21.7, -1.2) unit lower cognition score and a 2.6 (95% CI: -1.0, 6.2) unit higher aggressive behavior score. Both point estimates are more than half a standard deviation from Cold climate means.
In other climate types, which included fewer participants (n = 288 to 1017), we found no consistent evidence of any association.
CONCLUSION: Hot summer temperatures were associated with decreased cognitive performance and increased aggressive behavior in children living in a Cold climate. These results suggest a novel mechanism by which climate change may impact childhood neurodevelopment.

P-0579 Impact of Wildfire Exposure on Preterm Births Identified in MarketScan Claims-Based Cohort, 2010-2015

Brooke Staley[1], Corinna Keeler[1], Cavin Ward-Caviness[2], Meghan E. Rebuli[3,4], Kristen Rappazzo[3,4], Ilona Jaspers[3,4], Linda Wei[2], Ana Rappold[2], Radhika Dhingra[5]

[1]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, USA, [2]USA Environmental Protection Agency, Center for Public Health and Environmental Assessment, Research Triangle Park, USA, [3]Department of Pediatrics, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, USA, [4]Center for Environmental Medicine, Asthma and Lung Biology, University of North Carolina at Chapel Hill, Chapel Hill, USA, [5]Department of Environmental Sciences and Engineering, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, USA

BACKGROUND AND AIM: Wildfire smoke is a growing contributor to ambient particulate matter and may lead to elevated risk of preterm birth. Studies that have investigated the effects of gestational wildfire smoke exposure (WSE) on preterm birth are inconsistent and inconclusive. This study aimed to estimate the effect of near-birth and trimester-based WSE on preterm births using a large-scale claims database.

METHODS: We linked IBM's MarketScan Commercial Claims and Encounters database with smoke plume data from NASA MODIS satellites using metropolitan statistical area (MSA) of residence at birth. Children born in an MSA in six Western states between 2010-2015, whose gestational age (GA) and birthdate were estimable from claims data were included (N=115,469); 759 births with <32 weeks gestation were excluded. MSA, GA, and birthdate were used to estimate average weekly days of WSE for each trimester and two near-birth periods (2 and 4 weeks pre-birth). Preterm birth was defined as live birth at GA between 32 and 37 weeks. Odds ratios were estimated using logistic regression models accounting for clustering by MSA and adjusted for maternal age (restricted cubic spline), birth season, and average temperature within each exposure period.

RESULTS: WSE in the first or second trimesters was associated with reduced likelihood of preterm birth (0.96 [95% CI: 0.91, 1.02] and 0.92 [95% CI: 0.87, 0.98], respectively), while WSE in the third trimester was associated with increased risk of preterm birth (1.05 [95% CI: 0.98, 1.12]). There was no evidence of association for the 2- and 4-week periods before birth. Sex-stratified analyses of near-birth and trimester exposures were not different from overall effect estimates.

CONCLUSIONS: We observed evidence of an association between WSE and pre-term birth that varied based on trimester of exposure, with increased risk seen for exposures during the third trimester.

P-0583 Comparison of heat-related mortality estimated using ambient temperature and wet-bulb globe temperature in Japan: Supporting evidence for heat health warning system

Hironobu Watanabe[1], Yasushi Honda[2,3,4], Kazutaka Oka[3], Masahiro Hashizume[4,5], Aurelio Tobias[4,6], Yoonhee Kim[1]
[1]Department of Global Environmental Health, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Faculty of Health and Sport Sciences, University of Tsukuba, Tsukuba, Japan, [3]Center for Climate Change Adaptation, National Institute for Environmental Studies, Tsukuba, Japan, [4]School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan, [5]Department of Global Health Policy, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [6]Institute of Environmental Assessment and Water Research (IDAEA), Spanish Council for Scientific Research (CSIC), Barcelona, Spain

BACKGROUND AND AIM: Wet-bulb globe temperature (WBGT) receives attention as a criterion in heatstroke alert system in Japan. However, epidemiological evidence related to its suitability as a heat indicator for all-cause mortality is insufficient. This study compares temperature and WBGT based on (1) their association with all-cause mortality (relative risk; RR) and (2) heat-related mortality burden (attributable fraction; AF) at high percentiles, such that a heat alert is issued. In addition, it evaluates if there are any regional tendency in the suitability of WBGT.

METHODS: A three-stage time-series analysis using data from 47 prefectures in Japan during the warm months (May-October) of 2010-2019 was conducted. First, we performed a time-series regression analysis for each prefecture to obtain prefecture-specific temperature- and WBGT-mortality associations. Second, we quantified prefecture-level RRs and AFs for the 90th percentiles of temperature and WBGT, respectively. Third, the prefecture-level RRs and AFs were pooled into region-level results, and a meta-regression analysis was conducted to compare the differences in prefecture-level RRs and AFs derived from temperature and WBGT.

RESULTS: The RRs for the 90th percentile of WBGT were 0.02% (95% confidence interval [CI]: -0.29%, 0.32%) higher than those for the 90th percentile of temperature. In addition, the AFs above the 90th percentile of WBGT were 0.16% (95% CI: -0.32%, 0.63%) lower than those above the 90th percentile of temperature. In Western Japan, temperature-related risk measures were higher than WBGT-related risk measures.

CONCLUSIONS: We found no evidence that which heat indicator shows higher risk measures for all-cause mortality. As a policy implication, it is advisable to consider practical aspects other than the magnitude of temperature- and WBGT-mortality association for the development of the heat health warning system that targets all-cause mortality.

P-0585 Meteorological Factors Associated with Visceral Leishmaniasis in São Paulo State, Brazil

Quinn Adams[1], Ian Sue Wing[2], Guilherme Werneck[3], Clarissa Valim[4], Gregory A. Wellenius[1]
[1]Boston University School of Public Health, Department of Environmental Health, Boston, USA, [2]Boston University, Earth and Environment, Boston, USA, [3]Instituto de Estudos em Saúde Coletiva, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [4]Boston University School of Public Health, Department of Global Health, Boston, USA

BACKGROUND AND AIM: Human visceral leishmaniasis (VL) is a vector-borne disease of significant public health concern in Brazil. Areas of high prevalence have shifted in recent decades due to rapid development, changing socioeconomic conditions, and climate change. Emerging evidence suggests that incidence is affected by regional weather patterns such as the El Niño-Southern Oscillation, which has profound impacts on local meteorological conditions in Brazil. However, understanding of the effects of short-term weather variability remains inadequate, particularly in the context of VL. Accordingly, we explored the relationship between local weather conditions and VL in São Paulo State, Brazil.

METHODS: We obtained monthly cases of VL in São Paulo State from the Ministry of Health Information System for Notifiable Diseases for each municipality from 2010-2020. We extracted monthly average temperature, precipitation, and specific humidity from ERA5. We used conditional quasi-Poisson regression models to assess the relationship between meteorological variables and VL, conditioning on municipality and adjusting for temporal trends. We assessed lagged effects of meteorological variables from 0 to 6 months, corresponding with the long incubation period for VL in humans.

RESULTS: There were 1,958 documented cases of VL from 2010-2020. We observed higher rates of VL associated with increased precipitation and humidity and decreased temperatures. Specifically, a 1˚C decrease in average monthly temperature was associated with a 4.6% (95% CI: 2.5%, 6.7%) increase in VL cases two months later. A 1 mm increase in precipitation and 1 g/kg increase in humidity led to a respective 2.5% (1.2%, 3.8%) and 3.3% (1.3%, 5.2%) increase in VL cases one month later.

CONCLUSIONS: Local weather patterns are associated with the incidence of human VL in São Paulo State. These results highlight the potential importance of continued climate change on the fluctuating distribution of VL.

P-0586 Climate change and migrant workers: Projections of temperatures and mortality in Kuwait

Barrak Alahmad[1], Ana Maria Vicedo-Cabrera[2], Kai Chen[3], Eric Garshick[4], Aaron Bernstein[5], Joel Schwartz[1], Petros Koutrakis[1]

[1]Harvard T H Chan School of Public Health, Boston, USA, [2]Oeschger Center for Climate Change Research, University of Bern, Bern, Switzerland, [3]Yale Center on Climate Change and Health, Yale School of Public Health, New Haven, USA, [4]Harvard Medical School, Boston, USA, [5]Center for Climate, Health and the Global Environment, Harvard T.H. Chan School of Public Health, Boston, USA

BACKGROUND–It is uncertain what climate change could bring to populations and countries in the hot desert environment of the Arabian Peninsula. Not only because they are already hot, countries in this region also have unique demographic profiles, with migrant populations potentially more vulnerable and constituting a large share of the population. In Kuwait, two-thirds of the population are migrant workers and record-high temperatures are already common.

AIM–We quantified the temperature-related mortality burdens in Kuwait in the mid- (2050-2059) and end-century (2090-2099) decades under moderate (SSP2-4.5) and extreme (SSP5-8.5) climate change scenarios.

METHODS–We fitted time series distributed lag non-linear models to estimate the baseline temperature-mortality relationship which was then applied to future daily mean temperatures from the latest available climate models to estimate decadal temperature-mortality burdens under the two scenarios.

RESULTS–By mid-century, the average temperature in Kuwait is predicted to increase by 1.80°C (SSP2-4.5) to 2.57°C (SSP5-8.5), compared to a 2000-2009 baseline. By the end of the century, we could see an increase of up to 5.54°C. In a moderate scenario, climate change would increase heat mortality by 5.1% (95% empirical confidence intervals [eCI]: 0.8, 9.3) by end-century, whereas an extreme scenario increases heat mortality by 11.7% (2.7, 19.0). Heat mortality for non-Kuwaiti migrant workers could increase by 15.1% (4.6, 22.8). for every 100 deaths in Kuwait, 13.6 (-3.6, 25.8) could be attributed to heat driven by climate change by the end of the century.

CONCLUSION–Climate change induced warming, even under more optimistic mitigation scenarios, may markedly increase heat related mortality in Kuwait. Migrant worker, who are already vulnerable, could borne a larger impact from climate change.

P-0592 Nonlinear Association between summer high Temperature and Mortality in people aged 65 or more: Past and Recent periods

Jonghyuk Choi[1], M.D. Hyungryul Lim[1], Ph.D. Sanghyuk Bae[2], Ph.D. Kyung-Hwa Choi[1], Ph.D. Xue Han[1], Ph.D. Mina Ha[1], Ph.D. Ho-Jang Kwon[1]

[1]Department of Preventive Medicine, College of Medicine, Dankook University, Cheonan, Republic of Korea, [2]Department of Preventive Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

BACKGROUND AND AIM: Climate change induces extreme weather including frequent heat waves in summer. We aimed to examine how the impact of high air temperature exposure to mortality of older people, a vulnerable group, has been changed from the past to recent periods.

METHODS: Temperature data from the Korea Meteorological Administration and mortality data from Statistics Korea were used. The time-series analysis was performed for the periods 1991–1995 and 2015–2019, in which included the recorded heat wave. We used the distributed lag non-linear models (DLNM) to estimate cumulative relative risks (CRRs) to see an association between daily temperature for July to August and mortality of people aged 65 or more. The CRR was estimated at each province and pooled the CRRs of all provinces using a random effect meta-analysis.

RESULTS: The CRRs on mortality of the daily mean temperature in summer for the population aged 65 or more for the whole 10-year period (1991-1995 and 2015-2019) were 1.098 (1.012, 1.192), 1.124 (1.027, 1.231), and 1.172 (0.986, 1.392) at 90%tile, 95%tile, and 99%tile, compared to 50%tile of the temperature. When the nonlinear associations between temperature and mortality were plotted in the past and recent periods separately, the CRR in the past increased substantially with temperature increases, while the increase of CRR in the recent appeared to be relatively small.

CONCLUSIONS: The effects of high temperatures in summer on mortality of people aged 65 or more have changed from the past to recent periods, and further studies are needed to explore factors potentially related with resilience of the society against climate change.

P-0607 Projections of temperature-attributable suicide under climate change scenarios in Japan

Ramita Thawonmas[1], Masahiro Hashizume[1], Yoonhee Kim[2]
[1]Department of Global Health Policy, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Japan, [2]Department of Global Environmental Health, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Japan

BACKGROUND AND AIM: Recent studies have projected all-cause mortality attributable to non-optimal temperature under climate change scenarios. However, the impact of climate change on mental health remains to be assessed. The short-term association between suicide and temperature has been reported, but there is a lack of future projections of temperature-attributable suicide. We projected the excess temperature-related suicide mortality in Japan under three climate change scenarios until the 2090s.

METHODS: Daily time series of mean temperature and the number of suicide deaths in 1973-2015 were collected for 47 prefectures in Japan. A two-stage time-stratified case-crossover analysis was used to estimate the temperature-suicide association. We obtained the modeled daily temperature series using five general circulation models (GCMs) under three climate change scenarios from the latest Coupled Model Intercomparison Project Phase 6 (CMIP6) Shared Socioeconomic Pathways scenarios (SSPs): SSP1-2.6, SSP2-4.5, and SSP5-8.5. We projected the excess temperature-related suicide mortality until 2099 for each scenario and evaluated the net relative changes compared with the 2010s.

RESULTS: During 1973-2015, there was a total of 1,049,592 suicides in Japan. Net increases in temperature-related excess suicide mortality were estimated under all scenarios, with the highest increase under the high-emission scenario (SSP5-8.5). The net change in 2090-99 compared with 2010-19 was 0.6% (95% empirical confidence interval [eCI]: 0.1, 1.6) for a low emission scenario (SSP1-2.6), 1.3% (95% eCI: 0.6, 2.4) for an intermediate scenario (SSP2-4.5), and 2.4% (95% eCI: 0.7, 3.9) for a high emission scenario (SSP5-8.5). The increases were greater the higher the emission scenarios were. The increase in excess temperature-related suicide mortality was minimized under the SSP1-2.6 scenario assuming mitigation strategies.

CONCLUSIONS: The comparison of projection results under different scenarios underscores the importance of mitigation, with the higher the emissions, the greater impact on the temperature-related suicide mortality.

KEYWORDS: Climate change, non-optimal temperature, mental health, projections, DLNM

P-0608 Prediction of the impact of climate change on the number of heatstroke patients in Tokyo, Japan with heat-adaptation effects

Kazutaka Oka[1], Yasushi Honda[1], Vera Ling Hui Phung[1], Yasuaki Hijioka[1]
[1]*National Institute for Environmental Studies, Tsukuba, Japan*

BACKGROUND AND AIM: Heatstroke has become a serious issue in Japan. To plan future adaptation measures, it is essential to understand to what extent the number of heatstroke patients will increase. Previous studies have predicted the number of heatstroke patients; however, they did not consider the effect of heat-adaptation. In this study, we conducted a future prediction study taking the effect of heat-adaptation into consideration.

METHODS: Japan, with its long north-south range, has a variety of climates, and it is necessary to explore its heat-adaptation effects. Our previous study showed that there was a positive correlation between the wet bulb globe temperature (WBGT) value at which heatstroke patients start to increase (WBGT threshold) and regional climate (average daily maximum WBGT between May and September: RCWBGT). Using the relationship, we translated this geographical effect of heat-adaptation to temporal adaptation by shifting the WBGT threshold to a higher side when the RCWBGT increases in the future owing to climate change. We focused on the age groups of 65+ yr, constituting the most vulnerable age group. Five future climate change scenarios and RCP8.5 scenario were adopted. All the data utilized in this study were public domain data and are available from the corresponding website.

RESULTS: In Tokyo, the number of heatstroke patients by mid-21st century will be 2.2 times as high as that of heatstroke patients at present and 6.9 times by the end of the century without heat-adaptation; however, the corresponding numbers will be 1.4 times and 2.5 times, respectively, with heat-adaptation.

CONCLUSIONS: The increase in the number of heatstroke patients was projected to substantially reduce owing to the effect of heat-adaptation.
Acknowledgement: This work was supported by the Climate Change Adaptation Research Program of the National Institute for Environmental Studies.

P-0609 Long-Term Exposure to Temperature, Residential Heating and Diabetes Incidence among the elderly population in China

Bo Yin[1], Keyi Lyu[1], Qian Di[1]
[1]*Tsinghua University, Beijing, China*

BACKGROUND: Mounting evidence has shown that short-term exposure to ambient temperature can increase mortality. However, the health effects associated with long-term temperature are less clear. Furthermore, more research has been focused on the mortality instead of prevalence of chronic diseases.

METHODS: We constructed two cohorts using China Family Panel Study (CFPS) and assigned annual means of wet bulb temperature and PM2.5 to study participants based on their ID code of residential. Cox proportional hazards models were used to examine the association between long-term exposure to ambient temperature, residential heating and diabetes incidence, adjusting for potential confounders.

RESULTS: We found a non-linear relationship between the long-term temperature and diabetes in multipollutant model, which is a U-shaped curve ($p<0.001$). The optimal temperature to lower diabetes risk was around 12°C. In addition, spring temperatures were negatively associated with diabetes risk, with warm temperature being protective of diabetes; while autumn temperatures were positively associated with diabetes incidences, with warm temperature being harmful. Apart from the long-term temperature, residential heating was also great threat to the diabetes incidence, with a HR = 1.18 (95% CI: 1.03, 1.36). Finally, we evaluated the extra diabetes cases in China if (1) central heating is installed in Southern China and (2) under different climate change scenarios.

CONCLUSIONS: Using two representative cohorts, we found that either higher or lower annual temperature deviating 12°C is harmful to the diabetes incidence. Therefore, the climate change will contribute different influence in Southern China and Northern China. To our surprise, residential heating is also bad for the diabetes incidence, which alert us that if it is necessary about the installing of residential heating in those areas without residential heating.

P-0616 Seasonal variation in the association between temperature variability and emergency department visits: a multi-site study in China

Yu Wang[1], Pro. Yibin Cheng[1], Pro. Dianxiu Ye[2], Pro. Xiaoyuan Yao[1], Pro. Yonghong Li[1]
[1]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]National Climate Center, China Meteorological Administration, Beijing, China

BACKGROUND AND AIM: Seasonal variation of temperature variability (TV) on emergency department visits (EDVs) remains unclear. We aimed to quantify the association between TV and cause-specific EDVs in China during 2014-2018, and explore seasonal variation, vulnerable populations, and sensitive diseases.

METHODS: We collected data on EDVs, weather, and air pollution from 20 sites in China. TV was calculated from the standard deviation of the minimum and maximum temperatures during exposure days. We applied a quasi–Poisson regression with a distributed lag nonlinear model to evaluate the TV-EDVs association. We used meta-analysis to pool site-specific estimates. We also conducted seasonal analysis and assessed the effects of modifiers.

RESULTS: A 1 ℃ increase in TV0-1 was associated with 0.36% [95% confidence intervals (CI): 0.24%, 0.48%)] increase in total EDVs. The effects became larger as exposure days increased and reached 0.59% (CI: 0.20%, 0.99%) for TV0-7. Male and people aged 0–17 were sensitive to TV with 0.40% (CI: 0.29%, 0.51%) and 0.58% (CI: 0.27%, 0.89%) increase per 1 ℃ increase in TV0-1. In seasonal analysis, effects of TV on total EDVs were lower in summer. People aged 60+ were vulnerable in winter. A 1 ℃ increase in TV0-1 corresponded to 1.84% (CI: 0.54%, 3.21%) increase of mental disease in spring, 0.43% (0.08%, 0.79%) increase of injury in autumn, and 0.63% (0.04% and 1.24%) increase of circulatory diseases in winter.

CONCLUSIONS: Exposure to TV was associated with increased risk of EDVs in China but varied in different seasons. Our results provided seasonal periods and vulnerable populations to conduct adaptive strategies and preventive measures.

P-0617 Effect modification of diabetes as a comorbidity on temperature variability and hospitalization for cardiovascular disease

Akira Okada[1], Hayato Yamana[2], Rui Pan[3], Ryosuke Kumazawa[4], Hiroki Matsui[4], Kiyohide Fushimi[5], Toshimasa Yamauchi[6], Masaomi Nangaku[7], Hideo Yasunaga[4], Takashi Kadowaki[8], Yoonhee Kim[3]

[1]Department of Prevention of Diabetes and Lifestyle-Related Diseases, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Department of Health Services Research, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [3] Department of Global Environmental Health, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [4]Department of Clinical Epidemiology and Health Economics, Tokyo, Japan, [5]Department of Health Policy and Informatics, Tokyo Medical and Dental University, Tokyo, Japan, [6]Department of Diabetes and Metabolism, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [7]Division of Nephrology and Endocrinology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [8]Toranomon Hospital, Tokyo, Japan

BACKGROUND AND AIM: Evidence has accumulated that large temperature variability (TV) is associated with an increased risk for hospitalization or death. However, no previous studies examined whether the association for TV is modified by diabetes comorbidity, which is particularly vulnerable to cardiovascular disease (CVD). We aimed to explore the short-term association between TV and CVD hospitalization, stratified by presence of diabetes as a comorbidity in 47 prefectures of Japan from 2011 to 2018.

METHODS: A two-stage meta-analysis was used. First, we used a time-stratified case-crossover design to estimate the association between TV and CVD admissions with and without diabetes comorbidity for each prefecture. We then pooled the estimates using a multivariate meta-regression model across the prefectures. The associations were also stratified by sex, age, smoking status, and season.

RESULTS: A total of 4,482,583 hospitalizations for CVD were included in this study. Each 1°C increase in 0–7 days TV exposure was associated with a 0.58% (95% confidence interval, CI= 0.20% to 0.96%) increase in risk for total CVD admission and a 2.07% (95% CI= 1.16% to 2.99%) increase in risk for heart failure admission in subjects with diabetes, while the respective increases in subjects without diabetes were 0.37% (95% CI= 0.12% to 0.63%) and 0.61% (95% CI= -0.02% to 1.23%). These patterns were broadly similar to those stratified by age, sex, and smoking status, while the association for TV was greater in spring in the season-stratified analysis.

CONCLUSIONS: Susceptibility to TV in relation to CVD onset may be stronger in subjects with diabetes than those without. Our findings may suggest that subjects with diabetes should be more cautious to sudden temperature changes.

P-0623 The association between ambient temperature and snakebites in Georgia, USA: a case-crossover study

Mariah Landry[1], Rohan D'Souza[1], Shannon Moss[1], Howard Chang[1], Stefanie Ebelt[1], Lawrence Wilson[2], Noah Scovronick[1]

[1]Rollins School of Public Health, Emory University, Atlanta, USA, [2]Emory University, Atlanta, USA

BACKGROUND AND AIM: The World Health Organization has identified snakebite as a highest priority neglected tropical disease, yet there is a dearth of epidemiologic research on environmental risk factors, including outdoor temperature. Temperature may affect snakebites through human behavior or snake behavior; snakes are ectotherms, meaning outdoor temperatures influence their internal body temperature and thus their behavior. Here we investigate the relationship between short-term temperature and snakebites in Georgia, one of the most biodiverse US states in terms of herpetofauna.

METHODS: We acquired emergency department visit data for Georgia between January 1, 2014 and December 31, 2018. Visits for venomous and non-venomous snakebites were identified using diagnosis codes. for comparison, we also considered visits for non-snake (e.g. insects, spiders, scorpions) envenomation. Daily meteorology from the Daymet 1km product was linked to patient residential ZIP codes. We applied a case-crossover design to estimate associations with maximum temperature.

RESULTS: During the five-year study period, there were 2,785 visits for venomous snakebites, 825 visits for non-venomous bites and 48,248 visits for non-snake envenomation. Across the entire period, a one-degree Celsius increase in same-day maximum temperature was associated with a 6.2% (95%CI: 4.0-8.5) increase in the odds of venomous snakebite and a 7.4% (95%CI: 3.5-11.4) increase in non-venomous snakebite. Associations were most robust in the spring and fall, particularly for venomous snakebites. We also observed a positive and significant association for non-snake envenomation, albeit slightly weaker and more consistent across seasons compared to those for snakebites.

CONCLUSIONS: Our study indicates an association between outdoor temperature and snakebites in Georgia. The results suggest that climate change could alter snakebite patterns in the future; however, impacts are likely to be dependent on the local climate and snake ecology (amongst other factors).

P-0624 Decrease and seasonal changes of suicides and suicide attempts in France over the last 10 years

Marine Ambar Akkaoui[1,2], Christine CHAN CHEE[3], Karine LAAIDI[3], Gregory FIFRE[4], Pierre Alexis GEOFFROY[1]
[1]Ghu Paris Psychiatrie & Neurosciences, Paris, France, [2]EPS Ville Evrard, psychiatric Emergency, Saint Denis, France, [3]Santé Publique France, France, [4]Météo France, France

INTRODUCTION: The objective of this study was to examine the evolution of suicides and suicide attempts over the last 10 years in France, according to the season.

METHODS: We analyzed the number of deaths by suicide and suicide attempts in metropolitan France (2009-2018) from French national databases, on a daily, weekly or monthly basis. Seasonal variation in suicide rates was modeled using a cosinor function. Based on this model, we determined the association of suicides and suicide attempts with geographic characteristics of the departments, age, gender, and psychiatric disorders. We also collected data on the means of suicide and suicide attempt.

RESULTS: The number of suicides and suicide attempts decreased over the last ten years in France (mean decrease of 14.49% and 11.69% per year). We observed a significant and recurrent seasonal pattern of suicides and suicide attempts in France, with a peak in spring. The suicide and suicide attempt rates were higher in the northern departments of France. Suicides are more common among men (75%) and middle-age individuals (45-54 years old), while suicide attempts affected more frequently women (62%) and young adults (15-19 and 40-49 years old). Nearly two-thirds of the patients who attempted suicide suffered from comorbid psychiatric disorder, with mood disorders being the most frequent psychiatric disorder. Voluntary drug intoxication was the most common means of suicide attempt (80%), while hanging was the most common means of suicide (54%).

CONCLUSIONS: The number of suicides and suicide attempts decreased in France over the last 10 years, with large seasonal variations. Further studies are warranted to better understand the underpinning physiological and meteorological factors that may influence these seasonal variations.

P-0625 Impact of meteorological factors and psychiatric disorders : a French exploratory study.

Marine Ambar Akkaoui[1], Damien Pires[1], Karine Laaidi[3], Christine Chan Chee[3], Gregory Fifre[4], Pierre Alexis Geoffroy[1]
[1]Ghu Paris Psychiatrie & Neurosciences, Paris, France, [2]EPS Ville Evrard, psychiatric Emergency, Saint Denis, France, [3]Santé Publique France, Paris, France, [4]Météo France, Paris, France

INTRODUCTION: The objective of our work was to study the link between meteorological factors (temperature, sunshine duration, rain, wind, humidity) and psychiatric disorders. for this purpose, we conducted two exploratory studies in France : the first one, studying the link between the weather and suicidal behaviors (suicides and suicide attempts); the other one between alcohol use disorders (AUD) and the weather.

METHODS: We analyzed the number of deaths by suicide and suicide attempts in metropolitan France (2009-2018) from French national hospitalization databases; patients who were admitted to an emergency department for an alcohol related condition were included using the Oscour database, and we used meteorological database from national weather services. Based on this model, we determined the association of suicides and suicide attempts with weather factors, and then between AUD and meteorological factors.

RESULTS: The number of suicides and suicide attempts decreased over the last ten years in France (mean decrease of 14.49% and 11.69% per year). We observed a significant and recurrent seasonal pattern of suicides and suicide attempts in France, with a peak in spring. The suicide and suicide attempt rates were higher in the northern departments of France. We found significant positive correlations between the number of alcohol-related ED visits and the mean temperature ($r = 0.55$; $p = 1.87e$) and the duration of sunlight ($r = 0.42$; $p = .0015$). Negative correlations were also found significant with rain ($r = −0.40$; $p = .0014$), humidity ($r = –0.41$; $p = .0023$) and wind speed ($r = −0.40$; $p = .0031$).

CONCLUSIONS: The number of suicides and suicide attempts decreased in France over the last 10 years, with large and recurrent seasonal variations. Emergency visits for AUD seem to increase with the temperature and duration of sunlight, and decrease with rain, humidity and wind speed.

P-0626 Long term associations of climatic factors on cognition in olderadults: Results from the Reasons for Geographic and Racial Differences in Stroke (REGARDS) Cohort

Peter Larson[1], Anam Khan[1], Robert Melendez[1], Philipa Clarke[1], Carina Gronlund[1]
[1]*University of Michigan, Ann Arbor, USA*

BACKGROUND: Evidence suggests that short term exposures to extreme heat and/or cold are associated with declines in cognition among older adults. However, the effect of long term exposures are not well understood.

METHODS: The Reasons for Geographic and Racial Differences in Stroke (REGARDS) study is a nationwide cohort study exploring regional and racial differences in stroke and cognitive function over time. ~30,000 people from all areas of the US were enrolled at age 45. Word List Learning (WLL) and Word List Delayed Recall (WLD) tests were administered on a yearly basis. Continuous cognition scores were produced using factor analysis based methods and applied to each measured time point for each individual. Associations of cognition with the number of extreme hot and cold days relative to region were tested using regression models of the continuous measure of cognition within a directed non linear Distributed Lag Non-linear Modelling framework.

RESULTS: Cognition data was available for 20,091 people with a mean age of 64.6 years over miltiple time points. of these, 39.2 percent were Black. On average, respondents experienced 25.4 and 14 extremely hot and cold days the year previous to the last date of survey. Cognition was significantly and negatively impacted by same year exposure to increased numbers of extreme heat days. No association of long term heat and/or cold exposure was found for exposure days greater than one year, or for exposure to cold or precipitation for all time periods tested.

CONCLUSIONS: Evidence suggests that the greatest impacts of temperature on cognition occurs within one year of exposure. Future work should explore the potential role of climate change in increasing incidence of cognitive decline in older adults.

P-0630 Heat Exposure and Emergency Department Visits for Sepsis in Phoenix, Arizona

Bailey Englund[1], Rohan D'Souza[1], Noah Scovronick[1], Jordan Kempker[1], Howard Chang[1], Stefanie Ebelt[1]
[1]*Emory University, Atlanta, USA*

BACKGROUND AND AIM: Climate change is increasing exposures to high temperatures, which can lead to death and illnesses requiring emergency care. Sepsis, the body's response to severe infection, is usually diagnosed in emergency departments (EDs). Little is known about outdoor temperatures as a risk factor for sepsis. Here, we assessed the association between temperature and sepsis-related ED visits in Phoenix, Arizona during 2016-2019.

METHODS: We acquired ED visit data for Arizona and selected visits among patients residing within the two-county Phoenix area with a diagnosis of sepsis present on arrival at the ED. We characterized the focus of infection (FOI, respiratory, urogenital, abdominal, bone and soft tissue, blood) for each sepsis visit through diagnosis codes. Using daily population-weighted average maximum temperature data from Daymet, we estimated associations with sepsis and FOI-specific sepsis ED visits via Poisson time-series regression.

RESULTS: During 2016-2019, there were 97 sepsis-related ED visits per day in Phoenix; the average daily maximum temperature was 30.5 degrees Celsius. Overall, we observed a positive association between same-day maximum temperature and sepsis-related ED visits (rate ratio: 1.014, 95% confidence interval: 1.000-1.028 for a 5 degree increase from 24 to 29 degrees Celsius). Associations were strongest in the warmer seasons of Spring, Summer, and Autumn. When stratifying by FOI, associations of same-day maximum temperature and ED visits for sepsis with infection of the urogenital area were positive; other FOIs showed null or negative (for blood) associations with temperature.

CONCLUSIONS: Results suggest that outdoor heat exposure may be an important risk factor for sepsis, in particular during the warm season and for urogenital-based infections. During times of high heat, exposure mitigation measures may reduce emergency care needs, and emergency department preparedness may be needed to ensure positive outcomes for patients.

KEYWORDS: Climate, Heat, Temperature, Sepsis, Morbidity

P-0632 Central heating in China and protection against cold temperature mortality: a longitudinal cohort study of older adults

Haofan Zhang[1], John Ji[2], Miaomiao Liu[1], Jun Bi[1], Yi Zeng[3]
[1]Nanjing University, Nanjing, China, [2]Tsinghua University, Beijing, China, [3]Duke University, Durham, USA

Central heating in northern China during the months is reliant on biomass combustion and causes air pollution. Prior studies using natural experiment design (north and south of Huai river) attribute higher pre-mature mortality due to central heating-related air pollution. However, the original intention of central heating is to protect against the cold. We used the 2000-2018 Chinese Longitudinal Healthy Longevity Survey (CLHLS), a nationwide cohort of older adults aged 65. We focused on five provinces that are between heating and non-heating areas. The heating status was measured according to the resided city. We obtained daily meteorological data from the closest national station and measured residential air pollution. Cox proportional hazards models were used to assess the effects of central heating and air pollution. We further compared the mortality risk of long-term and short-term cold temperatures for participants with and without central heating. Winter average temperature and temperature variability were used to measure the long-term cold temperature. for the acute exposure, we used a distributed lag non-linear model. We included 5,334 participants, totaling 34,608 person-years of follow-up. We recorded 6,667 deaths, and 2,051 occurred in winter. In the adjusted model, the mortality hazard ratio (HR) for central heating was 0.80 (95% CI 0.76, 0.85). In our subgroup analyses, the HR for each 1℃ increase in winter temperature variability was higher for participants without central heating than for participants with central heating (1.21 vs.1.08), but the HR for each 10 μg/m³ increase in PM2.5 was similar(1.13 vs. 1.14). Participants without central heating also had for higher mortality risk of extremely cold at the 5th percentile compared to the 60th percentile than participants with central heating (1.48 vs.1.14). Our results suggested that central heating significantly decreased winter mortality, which may partly be achieved by attenuating the mortality caused by cold temperatures.

P-0634 Allostatic load and climate change: analyzing epidemiological confounding variables, health effects and adaptative response in osteoporosis and kidney disease associated with NDVI greenness index

Fernando Gonzalez Botija[1], Pedro Diaz Peralta[2]
[1]Universidad Complutense de Madrid, Madrid, Spain, [2]Yale School of The Environment- Michelle L. Bell´s Research Group, New Haven, USA

BACKGROUND AND AIM: To explain individual response to stressors, research has brought attention to the common underlaying mechanisms for catecholamine- dependent adaptive response. Under this perspective, a trigger factors is the adaptation to extreme weather events linked to climate change (droughts, long warm summers, heat waves, etc) closely connected with the related concept of "allostasis" defined as “the physiological or behavioural changes required to stabilize the biological systems". As long as allostasis implies resilience (Karatsoreos, McEwen, 2011) it can be connected, conversely, with the negative effect of “allostatic load”. Nevertheless, its concurrence with confounding variables should be also evaluated: Allostasis can influence occurrence of osteoporosis-related fracture and changes on Bone mineral density (BMD) where researchers have found the apparently beneficial effect of greenness in relation to the positive impact of outdoor exercise as a stress reduction mechanism, also identified as a factor influencing BMD (Follis, Bea, Klimentidis et al. 2019)
Other example is the beneficial effect in kidney disease incidence and air pollution, where results shown that stricter air quality standards benefit kidney patients. (Lee, W, 2022)

METHODS: Systematic review on cases involving BMD and kidney disease and subsequent the catecholamine-dependent response following a two stage analysis. Residential proximity is defined as average of satellite-based Normalized Difference Vegetation Index (NDVI) in buffers of 50 m, 100 m and 250 m, 500 m

RESULTS: Evidence of beneficial effect of the greenness estimated from analysis of Normalized difference Vegetation Index- NDVI has

CONCLUSIONS: The influence of allostasis should be supported by clinical research evidence(Ramsay et al 2014). A number of studies estimating beneficial effects or greenness suggest that allostasis, as a measure of catecholamine-dependent response could be a valid approach for understanding the underlying mechanisms in environmental stressors

KEYWORDS: Allostasis, allostatic load, NDVI, greenness, behavioural changes

P-0638 Knowledge, Attitude and Practice of Health Workers and Shopping mall operators towards Decontamination during COVID -19 Pandemic in Ibadan

Taiwo Alawode[1]
[1]*University of Ibadan, Ibadan, Nigeria*

BACKGROUND AND AIM: Public facilities such as hospitals and shopping malls are a potential hotspot for transmission of infectious disease like COVID-19. Decontamination practice is therefore an essential infection prevention and control strategy used in preventing disease outbreaks. Information on knowledge, attitude, and practice of facilities workers towards decontamination are poorly investigated and documented in developing countries. This study, therefore, assessed the knowledge, determined the attitude and practice of hospital and shopping mall workers towards decontamination during the Covid-19 pandemic.

METHODS: The cross-sectional study utilized a comparative approach involving the use of Adeoyo hospital and a shopping mall in Ibadan, Nigeria. An interviewer-administered questionnaire was used to assess the knowledge, attitude, and practices of decontamination among 250 respondents. Data collected were analyzed using SPSS version 25, for mean, standard deviation, and T-test at 5% significance level.

RESULTS: Most (64%) of Adeoyo respondents and majority (89%) of Shopping mall respondents had a poor practice level towards decontamination at their workplaces, however, the majority (89.8%) and (81.1%) of the respondents in Adeoyo and shopping mall respectively had a good attitude towards decontamination. Although there was a significant association between knowledge ($p = 0.001$), practice ($p < 0.001$), and study location. A little more than half (56.1%) and some (21.2%) of respondents in Adeoyo and Shopping mall respectively had poor knowledge about decontamination. Among respondents from Adeoyo, level of education ($p = 0.006$) was significantly associated with level of practice on decontamination.

CONCLUSIONS: The study revealed that both study locations had poor decontamination practice and a large percentage had poor knowledge about decontamination, therefore Hospital and mall workers should be educated on the importance of decontamination. Necessary infrastructure should be put in place to ensure decontamination practice and ensure infection control.

KEYWORDS: Decontamination, Knowledge, attitude, practice, hospital, shopping mall

P-0645 Impact of air pollution on cardiovascular mortality during the COVID-19 pandemic in South Korea

Whanhee Lee[1,2], Lina Madaniyazi[3], Wook Bum Pyun[4], Chris Fook Sheng Ng, Jieun Min[6], Jongmin Oh[1], Ho Kim[6], Masahiro Hashizume[5], Eunhee Ha[1,2,7]

[1]Department of Environmental Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [2]Institute of Ewha-SCL for Environmental Health (IESEH), College of Medicine, Ewha Womans University, Seoul, Republic of Korea, [3]School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan, [4]Division of Cardiology, Department of Internal Medicine, Ewha Womans University Medical Center, Seoul, Republic of Korea, [5]Department of Global Health Policy, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [6]School of Public Health Science, Seoul National University, Seoul, Republic of Korea, [7]Department of Environmental Medicine, College of Medicine, Graduate Program in System Health Science and Engineering, Ewha Womans University, Seoul, Republic of Korea

BACKGROUND AND AIM Multiple studies have reported the impacts of the coronavirus-2019 pandemic on cardiovascular disease (CVD) and the concentration of air pollution, respectively. Although the association between air pollution and CVD outcomes has been widely identified, the changes in the association during the pandemic period have not been fully investigated. This study aimed to examine the nationwide changes in the short-term effect of fine particulate matter (PM2.5) on CVD deaths in South Korea.

METHODS: We performed an interrupted time-series analysis to estimate temporal changes in the association between PM2.5 and CVD-related deaths (total, ischemic health disease [IHD], cerebrovascular disease [CD], and hypertension) before (Jan 01, 2016 to Feb 17, 2020) and during the pandemic (Feb 18, 2020 to Dec 31, 2020), using daily data. Relative humidity, day-of-week, seasonality, and temporal trend were controlled. We conducted a two-stage analysis to estimate the risk of air pollution on CVD deaths for each of 16 regions and then generated an overall estimate.

RESULTS: The total number of CVD mortality was 53,552. The average annual concentration of PM2.5 changed before (23.8 μg/m3) and during the pandemic (17.1 μg/m3) in South Korea. for total CVD deaths, the changes in relative risks (RRs; for 10 μg/m3 increase in PM2.5) were not pronounced during the pandemic. Whereas, for ISH and CD, the RRs increased during the pandemic: (pre-pandemic to pandemic period) 1.00 (0.99, 1.01) to 1.02 (1.00, 1.04) for IHD and 1.00 (1.00, 1.01) to 1.02 (1.00, 1.04) for CD, although the changes were not statistically significant (p-values 0.08 and 0.24).

CONCLUSIONS:We found that the risks of short-term exposure to PM2.5 on mortality for IHD and CD increased in the first pandemic year in South Korea, compared to the pre-pandemic years.

KEYWORDS: COVID-19, Pandemic, PM2.5, Cardiovascular mortality.

P-0648 Higher incidence of novel coronavirus (COVID-19) cases in areas with combined sewer systems, heavy precipitation, and high percentages of impervious surfaces

Alisha Chan, Honghyok Kim, Michelle Bell
[1]*Yale University, Olney, USA*

Combined sewer systems (CSS) are water management systems that collect and transport stormwater and sewer water in the same pipes. During large storm events, stormwater runoff may exceed the capacity of the system and lead to combined sewer overflows (CSOs), where untreated sewer and stormwater are released into the environment. Previous studies identified SARS-CoV-2 in sewage, urine, feces, and municipal wastewater. As such, areas contaminated by CSOs may be a reservoir of SARS-CoV-2 and may result in illness after the ingestion and/or inhalation of contaminated splashes, droplets, or aerosols. We investigated the association between COVID-19 incidence and CSSs and whether this association differed by precipitation and percent impervious surfaces as a proxy for possible CSOs. We fitted a quasi-Poisson regression model to estimate the change in percentage of incidence rate of COVID-19 cases in counties with a CSS compared to those without, adjusting for potential confounders (i.e., state, population density, date of first documented COVID-19 case, social vulnerability, and percent vaccinated) and including interaction variables between CSS, precipitation, and impervious surfaces. Our findings suggest that heavy precipitation in combination with high percentages of imperviousness is associated with a higher incidence rate of COVID-19 cases in counties with a CSS compared to in counties without a CSS. We theorize that more COVID-19 cases may be seen in counties with a CSS, heavy precipitation, and high percentages of impervious surfaces because of the possible increase in frequency and severity of CSOs. The results suggest links between climate change, urbanization, and COVID-19.

P-0650 Using Google data and weather factors to predict COVID-19 transmission in Melbourne, Australia: A time-series predictive model

Hannah McClymont[1], Xiaohan Si[1], Wenbiao Hu[1]
[1]*Queensland University of Technology, Brisbane, Australia*

BACKGROUND AND AIM: We aimed to assess the effect of weather variability and Google data on COVID-19 transmission and develop multivariable time series AutoRegressive Integrated Moving Average (ARIMA) models for predicting COVID-19 transmission and outbreaks in Australia.

METHODS: Data including COVID-19 case notifications, meteorological factors and Google data were collected for the period of the Delta outbreak in Melbourne, Australia from the 1st of August to 15th November 2021. Time-series cross-correlation (TSCC) was used to evaluate the temporal correlation between weather factors, Google search trends, Google Mobility data and COVID-19 transmission. Time series ARIMA models with potential predictors were used to forecast COVID-19 incidence and Effective Reproductive Number (Reff) in the Greater Melbourne region. Five models were fitted to compare and validate predictive models using three-day ahead increments to test the predictive accuracy for both COVID-19 incidence and Reff. ARIMA models were fitted and validated using 70% training (75 days) and 30% validating (32 days) from 1st August 2021 to 15th November 2021 (107 days).

RESULTS: Maximum temperature (Tmax), absolute humidity, solar exposure, and transit station mobility (TSM) were significantly positively associated with COVID-19 incidence over time. Tmax and TSM were selected at a lag of 8 and 7 days respectively to develop multivariable ARIMA models. Multivariable ARIMA models including Tmax or TSM improved the predictive accuracy of COVID-19 cases slightly.

CONCLUSIONS: ARIMA modelling was useful for predicting epidemic growth, there is also a potential application for inclusion of weather and Google data in creating effective early warning systems for future outbreaks. Our results suggest that TSM and Tmax would be useful for further exploration and developing weather-informed early warning models for future potential COVID-19 outbreaks.

KEYWORDS: COVID-19, ARIMA, forecasting, weather, internet search queries, mobility

P-0652 Health impacts of a reduced aircraft noise exposure during the Covid-19-pandemic - A natural experiment in Stockholm, Sweden

Charlotta Eriksson[1,2], Andrei Pyko[1,2], Staffan Betnér[1,2], Caisa Laurell[1,2], André Lauber[1,2], Antonios Georgelis[1,2]
[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Center for Occupational and Environmental Medicine, Region Stockholm, Stockholm, Sweden

BACKGROUND AND AIM: The lock-downs during the Covid-19-pandemic induced significant changes in travel patterns. In Stockholm, Sweden, the aircraft traffic around Bromma airport reduced by 77 percent during the first wave of the pandemic, March 1 to June 15, 2020, resulting in a sharp decline in residential exposure to noise. Based on this "natural experiment", we aimed to assess the impact of the reduced aircraft noise exposure on population well-being and health.

METHODS: In September 2020, we invited 10 000 individuals residing in the vicinity of Stockholm Bromma airport (n=7 500) and in Nacka municipality (n=2 500), serving as a reference, to a web-based questionnaire survey. The questions related to a pre- and during the pandemic situation, respectively, and concerned individual and housing factors and various disturbances, e.g., noise annoyance, sleep impairment, and stress related symptoms. Residential exposure to aircraft noise was assessed for a pre-pandemic situation in 5 dB categories ranging from ≤45 to ≥55 dB Lden. Logistic general estimating equation models were used to assess Relative Risks (RR) and 95% Confidence Intervals (95% CI).

RESULTS: In total, 3 582 individuals responded to the survey (35,8%). In the pre-pandemic situation, statistically significant associations were found between aircraft noise and all investigated disturbances. During the pandemic, the associations reduced and approached unity. The RR for high noise annoyance dropped from 7.51 (95% CI 5.18-10.90) among those exposed ≥46 dB Lden compared to the reference before the pandemic, to 2.18 (95% CI 1.24-5.9) during the pandemic. Corresponding figures for high sleep disturbance were 7.64 (95% CI 3.90-15.0) and 1.57 (95% CI 1.62-1.02), respectively. Improvements were also seen for stress symptoms.

CONCLUSIONS: The reductions in aircraft noise exposure around Stockholm Bromma airport during the Covid-19-pandemic resulted in an overall improved health in the local population.

KEYWORDS: Aircraft noise, Covid-19-pandemic, annoyance, sleep, stress

P-0653 Environmental surveillance and clinical assessment of SARS-CoV-2 epidemiology and variant prevalence in an urban area in Spain

Veronica Chico[1], Judith Sanchez[2], Antonio Galiana[2], Antonio Martinez-Murcia[3], Maria del Mar Ortega-Villaizan[1], Belen Almendro[4], Jose Navarro-Pedreño[4], Luis Perez[1]

[1]Instituto de Investigación Desarrollo e Innovación en Biotecnología Sanitaria de Elche (IDiBE), Universidad Miguel Hernández (UMH), Elche, Spain, [2]Area de Microbiología, Hospital General Universitario de Elche, Elche, Spain, [3]Departamento de Producción Vegetal y Microbiología (UMH), Elche, Spain, [4]Departamento de Agroquímica y Medio Ambiente, (UMH), Elche, Spain

BACKGROUND AND AIM: Wastewater-based epidemiology (WBE) provides the means to monitor pathogens prevalence in the sewage system of a community. SARS-CoV-2, the virus responsible for the COVID-19 global pandemic, can be detected in the feces of infected individuals. Therefore, viral concentrations in wastewater can be taken as an indication of SARS-CoV-2 prevalence in the entire population. This work was aimed at the detection and sequence analysis of SARS-CoV-2 RNA in wastewater and its correlation with clinical data.

METHODS: Samples collected over a nine-month period (2020-21) at a wastewater treatment plant in Elche (Spain) were concentrated by ultrafiltration and analyzed for the presence of SARS-CoV-2 RNA by reverse transcriptase quantitative polymerase chain reaction (RT-qPCR). Sequences generated from cDNA samples with a MinION Nanopore device were compared to SARS-CoV-2 sequence databases.

RESULTS: The appearance of the first qPCR positive signals correlated with the increasing number of covid-19 cases in Elche at the onset of the second wave of COVID-19 (july 2020). Measurements of viral genomes in water samples in October-November 2020 reflected the higher number of clinical cases within that period. Nanopore sequencing assay allowed the detection of spike (S) protein mutations associated with circulating SARS-CoV-2 variants both in environmental as well as in clinical samples, reflecting the emergence of the B.1.1.7 variant in Elche in late 2020.

CONCLUSIONS: This study highligted the potential of wastewater-based epidemiology (WBE) in revealing the presence of pathogenic viruses in urban populations. By the use of the nanopore sequencing technology we were able to assess the changes in circulating SARS-CoV-2 variants in a whole population.

KEYWORDS: environmental epidemiology, SARS-CoV-2 variants, wastewater, nanopore sequencing

P-0670 COVID-19 in the Eastern Caribbean: Engaging the Root of Ill-Health and Unhappiness

Steve Whittaker[1], Samantha Bedford[1,2], Phibi Joseph[2], Alaynah Mitchell[2], Mx. Cyndi Joseph[1,2]
[1]Clarence Fitzroy Bryant College, Basseterre, Saint Kitts and Nevis, [2]Science, Technology, Research and Work Study (STRaWS),

BACKGROUND: The peripheral impacts of the global COVID-19 pandemic have had enduring effects on our everyday lives. Citizens of small island Caribbean states in particular faced increased frequencies and odds of morbidity beyond SARS-COV-19 infections.
AIM: Our pilot project sought to probe health-relevant outcomes among Eastern Caribbean residents.

METHODS: We surveyed residents of St. Kitts-Nevis, ages 17 to 55 and facilitated student focus groups (SFG) in 2021 and 2022. Analyses produced descriptive methods and odds ratios.

RESULTS: Among 81 respondents, 72.8% identified as female and 82.7% had been involved in academic training within a year of completing the questionnaire. Physical activity (50.6%) and mental health (69%) were at least moderately impacted due to the atmosphere of risk and restrictions. Male participants were less likely (OR: 0.32) to have friendships greatly impacted (95CI%: 0.11 - 0.86) while female participants were more likely (OR: 1.15) to report at least moderate declines in mental health (95CI%: 3.21 - 9.16). Students and teachers had a 3.92 higher odds (95CI%: 3.92 - 13.52) of experiencing mental health challenges relative to other occupations. Persons with moderate-to-severe feelings of negative mental health had increased odds (OR: 5.70; 95%CI: 2.05 - 17.83) of a moderate-to-severe comprise of diet relative to individuals feeling little to no changes in mental well-being. Informational sources such as TV as a source of COV-19 information was linked to greater mental health deficits (OR: 3.44; 95%CI; 1.31 - 9.45). SFG participants (n=8) qualified mental health challenges during the pandemic, highlighting lack of communication and clear instructions from their institutions, insufficient feedback and guidance from teachers, absenteeism due to parent(s) serving as essential worker(s) and isolation due to quarantine and/or lockdown.

CONCLUSIONS: Results reflect both unique and relatable ways in which Caribbean folks experience and reflect on health status throughout the unprecedented COV-19 pandemic.

P-0671 Long-term exposure to ambient air pollution and COVID-19 incidence in Italy

Andrea Ranzi[1], Massimo Stafoggia[2], Simone Giannini[1], Carla Ancona[2], Lisa Bauleo[2], Antonino Bella[3], Giorgio Cattani[4], Federica Nobile[2], Patrizio Pezzotti[3], Ivano Iavarone[3]

[1]Environmental Health Reference Centre, Regional Agency for Environmental Prevention of Emilia-Romagna, Modena, Italy, [2]Department of Epidemiology, Lazio Region Health Service / ASL Roma 1, Rome, italy, [3]Italian National Institute of Health (ISS), Rome, Italy, [4]Italian Institute for Environmental Protection and Research, ISPRA, Rome, Italy

BACKGROUND AND AIM: The SARS-CoV-2 pandemic gave rise to a large number of epidemiological studies linking ambient air pollution (AP) to COVID-19 incidence. However, to date, the role of chronic exposure to AP in explaining COVID-19 occurrence is still not clarified.

METHODS: Within a national study (EpiCovAir) promoted by National Institute of Health (ISS) and Italian Network of Environmental Protection (SNPA), we identified all COVID-19 cases in Italy from February 2020 to June 2021. Chronic exposure to particulate matter < 10 micron (PM10), < 2.5 micron (PM2.5) and nitrogen dioxide (NO2) were assigned at municipality level (n=7800) using a national satellite-based AP exposure model (1-km2 spatial resolution) for the period 2016-2019. We applied principal component analysis (PCA) and generalized propensity score (GPS) approaches to summarize information of about 50 area-level covariates to account for major determinants of the spatial distribution of COVID-19 cases (municipality characteristics, population density, mobility, population health, socio-economic status). Finally, we applied generalized negative-binomial regression models matched on GPS, age, sex, province and month to study the association between AP and COVID-19 incidence.

RESULTS: 3,995,202 COVID-19 cases occurred in Italy in the entire period (incidence rate=67x1000). Overall, incidence rates increase by 0.6% (95% CI: 0.5%, 0.7%), 0.5% (95% CI: 0.4%, 0.6%) and 0.9% (95% CI: 0.9%, 1.0%) per 1 □g/m3 increment in PM2.5, PM10 and NO2, respectively. Associations were consistent to different sensitivity analyses, particularly for NO2. Increments were higher among elderly subjects, and during the second pandemic waves (Sept. 2020-Dec. 2020). In two-pollutant models, NO2 estimates were robust to PM adjustment, while PM showed no associations after adjustment for NO2.

CONCLUSIONS: We found evidence of association between long-term exposure to ambient AP (particularly NO2) and the occurrence of 4 million COVID-19 cases in Italy, suggesting a role of AP in increasing the incidence of COVID-19 disease.

P-0674 Long-term Air Pollution Exposure on COVID-19 Risk and Severity

Saira Tasmin[1], Brisa Aschebrook-Kilfoy[1], Habibul Ahsan[1]
[1]*The University of Chicago, Chicago, USA*

Since the emergence of the COVID-19 pandemic, long-term exposure to air pollution has emerged as a possible risk factor for increased COVID-19 disease risk, severity, and mortality.
The objective of this study was to examine the association between COVID-19 and long-term exposure to air pollution.
This retrospective cohort study included patients who had a COVID-19 test at the University of Chicago Medicine Center from March 18, 2020, to March 30, 2021. Air pollution exposure was assessed using models developed for Chicago by the MESA Air Study and data from the Environmental Protection Agency's EJSCREEN. Air pollution exposure estimates were linked to the University of Chicago Medicine patients using residential addresses. Air pollution measurements included PM2.5 (MESA Air and EPA), NO2, diesel PM, the respiratory hazard index, traffic proximity, and ozone. The outcome was COVID-19 risk and severity (ICU admission). Mixed effect analyses were performed to test whether poor air quality status was associated with COVID-19 risk and severity, controlling for demographic, smoking, and comorbidity indicators collected from the medical records.
A total of 74,004 patients (mean [SD] age 44.0 [22.51] years; 42,979 [58.09%] women; and 32,870 [49.09%] African Americans) were linked to air quality exposure based on residence and other covariates using electronic medical record data in addition to COVID-19 test results. Overall, 8,463 participants (11.4%) tested positive for COVID-19. In the mixed effect analysis, long-term PM2.5 exposure was associated with increased risk of testing positive for COVID-19 (odds ratio [OR], 1.30; 95% CI, 1.23-1.38; P <0.01) and increased severity from COVID-19 (OR= 2.28; 95% CI, 2.00-2.60; P = <0.01).
The results of this retrospective cohort study provide some evidence of the effect of long-term air pollution exposure on COVID-19 risk and severity.

P-0678 Field measurements of indoor and community air quality in rural Beijing before, during, and after the COVID-19 lockdown

Xiaoying Li[1], Xiang Zhang[1], Talia Sternbach[1], Collin Brehmer[2], Jill Baumgartner[1], Christopher Barrington-Leigh[1], Sam Harper[1], Brian Robinson[1], Guofeng Shen[3], Shu Tao[3], Yuanxun Zhang[4], Ellison Carter[2]
[1]Mcgill University, Montreal, Canada, [2]Colorado State University, Fort Collins, USA, [3]Peking University, Beijing, China, [4]University of Chinese Academy of Sciences, Beijing, China

BACKGROUND AND AIM: The outbreak of the coronavirus (COVID-19) initiated a global prevention response to curb the spread of the virus, including a series of actions to reduce human mobility. Previous studies report reductions in outdoor $PM_{2.5}$ associated with COVID-19 lockdown in many countries and regions. Few studies assessed the impacts of COVID-19 on local air quality in environments with diverse socioeconomic and household energy use patterns. We evaluated whether indoor and community $PM_{2.5}$ in homes with different energy use patterns in rural Beijing, China differed before, during, and after the lockdown.

METHODS: We deployed low-cost $PM_{2.5}$ sensors (Plantower), calibrated with co-located filter-based $PM_{2.5}$, to measure indoor and community air quality in 147 homes from 30 villages in Beijing in January-April, 2022. We apply mixed-effects models to assess the impact of the COVID-19 lockdown on indoor $PM_{2.5}$ and used the random component superposition model (RCSM) to estimate the contributions of indoor and outdoor sources to indoor $PM_{2.5}$.

RESULTS: Community pollution was higher during the lockdown period (61 ± 47 μg/m³) compared with before (45 ± 35 μg/m³) and after (47 ± 37 μg/m³) the lockdown. However, we did not observe higher indoor $PM_{2.5}$ during the lockdown (during vs. before: 98 ± 86 vs. 96 ± 83 μg/m³). Indoor-generated $PM_{2.5}$ was lowest in homes using clean energy exclusively for heating and without smokers, and did not change significantly during the lockdown compared with homes using solid fuels.

CONCLUSIONS: Indoor air quality did not worsen during the COVID-19 lockdown in our rural Beijing sites, though community $PM_{2.5}$ was higher during the lockdown. Indoor-generated $PM_{2.5}$ in homes using clean energy exclusively for heating was low and stable, while decreased during the lockdown in homes using solid fuel, which may be due to less solid fuel burning for heating because outdoor temperatures warmed.

P-0680 How the COVID-19 infection and deaths are shaped by socioeconomic inequities and air pollution exposure in Mumbai, India?

Avik Kumar Sam[1], Siuli Mukhopadhyay[1], Harish C. Phuleria[1]
[1]*Indian Institute of Technology Bombay, Mumbai, India*

BACKGROUND: The COVID-19 pandemic caused a global health crisis and exposed the low socioeconomic groups to higher exposure and death due to the existing social inequalities. India witnessed three unprecedented waves of COVID infection and deaths. However, a systematic analysis of the impact of socioeconomic inequities and other environmental factors on COVID-19 infection and mortality are not well examined in India.
AIM:
The present study aims to understand the impact of socioeconomic inequities and air pollution on COVID-19 infection and deaths in Mumbai, India.

METHODS: Ward-level data on COVID-19 cases and deaths from 24 wards is obtained from the Municipal Corporation of Greater Mumbai. Socioeconomic data is acquired from the official Govt. of India 2011 census. Bivariate and multivariate regression is applied to examine the impact of various socioeconomic factors on COVID fatalities and infections.

RESULTS: Mumbai reported 1,032,563 positive cases with an overall mortality rate of 18.9. The maximum mortality (41.9) and recovery rate (991.4) were observed in wards B and A in south Mumbai. A significant negative correlation (r=-0.55) was observed between deaths and the total population, irrespective of gender. Education (defined by literacy rate) showed a positive association with the COVID cases for both genders, suggesting no significant disparity based on gender and education ($p<0.05$). The homeless population depicted a positive correlation with mortality rates and positive cases, indicating the role of economic inequities. The higher population density in the wards may have caused higher mortalities, as suggested by a significant positive association (r= 0.46).
CONCLUSION: Our initial analysis suggests the influence of healthcare and housing affordability on the mortality rates, whereas the total positive cases seem to be driven by the non-slum population. The effect of other socioeconomic variables and air pollution, and multivariate analysis is currently underway.

KEYWORDS: COVID-19, Socioeconomic inequity, Air Pollution, Healthcare, Mortality

P-0683 Environmental, health and economic benefits of Covid-19 lockdown in Morocco

Imane Sekmoudi[1], Kenza KHOMSI[2,3], Laila IDRISSI[1], Yassmine BELAMRI[4]

[1]Process and Environment Engineering Laboratory, Faculty of Sciences and Technologies, Mohammedia. Hassan II University, Casablanca, Morocco, Mohammedia, Morocco, [2]General Directorate of Meteorology, Casablanca, Morocco, [3]Laboratory of Chemistry-Biochemistry, Environment, Nutrition and Health, Faculty of Medicine and Pharmacy, Hassan II University, Ain Chock, Casablanca, P.O. Box 5696, Morocco, [4]Faculty of Sciences and Technologies, Mohammedia. Hassan II University, Casablanca, Morocco,

Several measures have been taken to mitigate the effects of the Covid-19 pandemic. In this context, almost all non-essential activities in Morocco have been halted since March 20, 2020. The main objectives of this work are firstly to study the effects of lockdown measures on air quality, by analyzing dust PM2.5, NO2 and O3. Secondly, to estimate the health and the total economic benefits caused by PM2.5 during the Covid19 scenario based on Environmental Benefits Mapping and Analysis Program (BenMAP). A review of the various health and economic studies of the impact of lockdown on air quality was conducted and taken into account. The dust PM2.5 analysis was carried out from 2016 to 2020. NO2 and O3 analysis was carried out in 2019 and 2020. This study, which is based on satellite data from TROPOMI Sentinel 5P and MERRA, has shown that Morocco has experienced an improvement in air quality during the lockdown. A significant reduction in surface dust PM2.5 and tropospheric NO2 was observed (-10%, -4%, respectively on average). The total column of ozone recorded a slight increase on average of around 1%. According to the results obtained, it is inferred that the reduction of PM2.5 concentration saved lives mainly from cardiovascular and respiratory diseases, with 291 and 137 avoided deaths respectively. According to the VSL method, the economic benefits of avoiding deaths from all causes due to a decrease in PM2.5 concentration of the order of 67 % in Morocco have been estimated at about 451 million USD. This hypothetical clean air scenario has shown us the significant health and economic benefits that could be achieved through transport, climate and environmental strategies and policies that at the same time support a robust economic recovery and reduced emissions.

KEYWORDS: Air quality, Covid-19, Morocco, health impacts, economic benefits.

P-0685 Race-ethnicity disparities in COVID-19 outcomes may be worsened by shorter- and long-term aerosol pollutants exposure

Arshad Arjunan Nair[1], Ian Ryan[1], Gan Luo[1], Xinlei Deng[1], Wangjian Zhang[1], Fangqun Yu[1], Shao Lin[1]
[1]*State University of New York at Albany, Albany, USA*

BACKGROUND AND AIM: The importance of ultrafine particles (UFP or $PM_{0.1}$) exposure to respiratory disease has been identified. However, its effect (and that of $PM_{2.5}$) on COVID-19 outcomes remain unknown. This study aims to identify and quantify shorter- and long-term aerosol impacts on COVID-19 in context of disparate outcomes observed for minority race-ethnicity groups in New York State (NYS).

METHODS: COVID-19 outcomes included infections, hospitalizations, ICU admissions, and deaths reported by the CDC COVID-19 Case Surveillance Restricted Access Detailed Data, 2020–2022. UFP and $PM_{2.5}$ data were simulated by a global three-dimensional model of chemical transport with state-of-the-science aerosol microphysical processes extensively validated with observations. for shorter-term (0–30 lag days) UFP and $PM_{2.5}$ exposure, Distributed Lag Non-linear Model (DLNM) were used to examine the association at county-level, adjusting for meteorological factors. Long-term (average level of 2013–2020) associations with COVID-19 were assessed by Negative Binomial Mixed Models adjusting for county-level confounders. County-level confounders from the Census Bureau, Behavioral Survey, and Homeland Infrastructure Data were used.

RESULTS: Compared to White, Hispanic/Black subgroups had greater excess risk of COVID-19 infection (+25%), hospitalization (+31%), ICU admission (+60%), and death (+5.5%). Excess risk per IQR increase for long-term UFP ($PM_{2.5}$) exposure was significant for COVID-19 hospitalization: +40%; 95%-CI=20.5–63.6% (+22%;18.8–25.5%), ICU admission: +44%;39.1–49.2% (+24%;18.6–30.5%), and death: +40%;38.0–42.4% (+19%;8.2–30.7%). for short-term exposures, risks for all COVID-19 outcomes were elevated (RRs range from 1.0–4.6, all $p < 0.05$) when UFP > 2000 #·cm−3 and $PM_{2.5}$ > 6.3 μg·m−3.

CONCLUSIONS: Both shorter- and long-term exposure to aerosols increased the risk of COVID-19 infection and subsequent outcomes, with ultrafine particles (UFP) exerting larger effects than $PM_{2.5}$, and with greater likelihood. The UFP and $PM_{2.5}$-associated risks were disproportionately higher for race-ethnicity minorities (particularly Hispanic and Black) and for their economically vulnerable subgroups.

P-0688 Maximum apparent temperature lowers birth weight and increase hazards of preterm birth in a constant high ambient temperature exposed population in Piura, Peru

Diego Fano-Sizgorich[1,2], Cinthya Vasquez-Velasquez[1,4], Vanessa Vasquez[1], Vilma Tapia[1], Jose Chauca[1], Victor Sernaque[3], Gustavo F. Gonzales[1,4]

[1]Laboratory of Endocrinology and Reproduction, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Centro Latinoamericano de Excelencia en Cambio Climático y Salud, Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Hospital Nacional Cayetano Heredia, Lima, Peru, [4]High Altitude Research Institute, Universidad Peruana Cayetano Heredia, Lima, Peru

BACKGROUND AND AIM: Exposure to high environmental temperature during pregnancy has been associated with lower birth weight and an increased risk of preterm birth (PTB). The province of Piura is a region with a higher environmental temperature than the rest of the country; however, it is unknown how temperature would be impacting reproductive health in populations exposed to high basal temperatures. The aim of the study is to determine the association between maximum apparent temperature (HImax) during pregnancy with birth weight and preterm birth in newborns in the province of Piura, 2011-2016.

METHOD: Semi-ecological study, where maternal-perinatal data from Santa Rosa Hospital (N=17,788); and maximum apparent temperature data were evaluated. Four exposure windows were analyzed: the entire pregnancy, and each gestational trimester, which were assigned according to date of birth and gestational age, categorized into quartiles. The association with birth weight was assessed by linear regression; and Cox regression for PTB.

RESULTS: A negative association was found between birth weight and HImax in all exposure windows, except for the first trimester, the effect being greater during the third trimester. As for preterm birth, higher HImax increased the hazard of PTB, with the highest effect seen in the P95 exposed group in every exposure window; nonetheless, the first and second trimester being the most temperature-sensitive exposure windows.

CONCLUSIONS: HImax during pregnancy is related to lower birth weight and higher PTB hazards, but with different susceptibility according to the stage of pregnancy.

P-0689 Residential exposure to Pesticides and Cleaning Detergents with increased risk of respiratory and allergic symptoms among farmworkers in Northern Tanzania

Joseph Bukalasa[1], Rose Owisso[2], Raphael Mwezi[1]
[1]Tropical Pesticides Research Institute, Arusha, Tanzania, United Republic of, [2]Arusha District Council, Department of Health and Sokoine University of Agriculture, College of Veterinary Medicine and Biomedical Sciences, Arusha, Tanzania, United Republic of, [3]Tropical Pesticides Research Institute, Arusha, Tanzania

BACKGROUND AND AIM: It has been suggested that environmental exposures to pesticides and cleaning detergents have an increased risk of respiratory and allergic symptoms in adults. However, the evidence of residential exposure to pesticides and cleaning detergents with increased risk of respiratory and allergic symptoms among farmworkers is limited. The aim was to investigate the association of environmental exposure to pesticides and cleaning detergents with increased risk of respiratory and allergic symptoms in farmworkers.

METHODS: In this cross-sectional analysis, we included farmworkers at the ages of 18 and 48 years from Kilimanjaro and Arusha region with information on residential exposure to pesticides, cleaning detergents, cough, rhinitis, wheeze, shortness of breath, cough with phlegm and itching skin collected in 2021 (N = 389) through administered questionnaires. Logistic regression analysis was used to estimate associations between exposure and outcomes, adjusting for potential confounders.

RESULTS: Cleaning detergents was associated with an increased risk of cough among farmworkers [adjusted odds ratios (95% CI) 3.90 (1.33, 11.38)]. However, there was a reduction of risk for itching when the farmworkers use cleaning agents [adjusted odds ratios (95% CI) 0.32 (0.16, 0.67)]. We found that there were risk reduction for cough, rhinitis, wheeze, shortness of breath, cough with up phlegm, difficulty in breathing and itching skin for farmworkers who had vegetable garden at their homes [adjusted odds ratios (95% CI) 0.31 (0.18, 0.54),0.48 (0.29, 0.78), 0.14 (0.05, 0.37), 0.35 (0.13, 0.96), 0.18 (0.07, 0.44), 0.20 (0.09, 0.47), 0.49 (0.25, 0.96)].

CONCLUSIONS: The findings of this study suggest that vegetable gardens at their homes had public health concerns as it reduced the risk of respiratory and allergic symptoms among our study participants. This is an important issue for future research.

KEYWORDS: Pesticides, Cleaning detergents, Respiratory, Allergic.

P-0696 Ambient air pollution and Carotid Intima-Media Thickness: a cross-sectional analysis from the Mexican Teachers' Cohort (MTC)

Karla Cervantes-Martínez[1], Dalia Stern[1], MSc. Rocío Torrico-Lavayen[1], Jorge Octavio Acosta-Montes[1]
[1]*World Health Organization, Cuernavaca, Mexico*

BACKGROUND AND AIM. Is well known that ambient air pollution increases the risk of cardiovascular health outcomes. Carotid Intima-Media Thickness (CIMT) is a marker of subclinical atherosclerosis and a strong predictor of both prevalent and incident cardiovascular morbidity and mortality, including coronary heart disease, myocardial infarction, and stroke. CIMT has been positively associated with air pollutants such as PM2.5 and NO2, nevertheless evidence from low- and middle-income countries is scarce. We evaluated the cross-sectional association between long-term exposure to air pollutants and mean (left and right) CIMT in a population of middle-aged women from the MTC.

METHODS: We analyzed a randomized selected clinical subsample of the MTC participants living in the Mexico City Metropolitan Area, who were measured the mean CIMT once in 2017, using a standardized protocol (n=265). Self-administered questionnaires collected information on health and sociodemographic characteristics. Ambient PM2.5 and NO2 annual averages were predicted at home and work addresses using high resolution Generalized Additive Models, which were validated using ground measurements. We fitted multiple linear regression models adjusting for potential confounders: age, diabetes, body mass index, cholesterol, triglycerides, smoking and socioeconomic status.

RESULTS: Mean CIMT among participants was 618.5 µm (±86.5 SD), while mean PM2.5 and NO2 exposure was 22.5 µg/m3 (±3.5 SD) and 22.5 ppb (±6.6 SD) respectively. After confounder adjustment, each 10-unit increment of PM2.5 and NO2 exposure was positively non-significant associated with a 12.97 µm (95% CI: -16.91, 42.86) and 12.26 µm (95% CI: -1.46, 29.97) higher CIMT, respectively. Sensitivity analyses evaluating CIMT sides shown larger effects on the left CIMT.

CONCLUSIONS: Although with limited precision, these results suggest that long-term PM2.5 and NO2 exposure is associated with subclinical atherosclerosis in an upper-middle income country women population. Small sample size may have limited the statistical power to detect the effect.

KEYWORDS: Air pollution, atherosclerosis, Carotid Intima-Media Thickness

P-0712 The association between urinary concentrations of organophosphate metabolites and asthma-related outcomes at 12-month follow-up among children from informal settlements in Western Cape, South Africa

Mohamed Aqiel Dalvie[1], Mashudu Mthethwa[1], Mohamed Jeebhay[1], Toyib Olaniyan[1]
[1]*University of Cape Town, Cape Town, South Africa*

BACKGROUND AND AIM: There is limited evidence on the relationship between pesticide exposure and child respiratory outcomes in non-agricultural settings. This study investigated the association between organophosphate pesticide (OP) exposure and child asthma-related outcomes among children from four informal settlements.

METHODS: This study was a longitudinal study of 590 schoolchildren, with a 12-month follow-up period. A standardised questionnaire adopted from the International Study of Asthma and Allergies in Childhood (ISAAC) was administered to caregivers on child's respiratory symptoms and household characteristics. Spirometry and fractional-exhaled nitric oxide (FeNO), including a phadiatop test (atopy status) and urinary concentrations of dialkyl phosphate (DAP) metabolites diethylphosphate (DEP), dimethylthiophosphate (DMTP)] were measured at baseline and follow-up. Dimethylphosphate (DMP) was measured only at baseline.

RESULTS: The mean age of schoolchildren were 9.9 ± 0.91 years and median sum DAP was 32.9 ng/ml (18.4 – 52.9 ng/ml) at baseline. Incidence proportions of new asthma outcome cases at 12-months were 2.2 % doctor diagnosed asthma, 17.8 % asthma-symptom score ≥ 2, 14.5 % forced expiratory volume 1< lower limit of normal, and 5.9 % airway inflammation across all areas. In the linear mixed and fixed effect model, no consistent patterns of increased risk of new asthma-associated outcomes at the 12-month was found. However, there was a significant increase in airway inflammation (β:2.99 (95% CI: 0.48 - 5.50) in the 3rd DEP quintile (1.9 – 3.0 ng/mL) compared to the reference quintile (1.10 ng/ml).

CONCLUSIONS: DAP concentrations were higher than those of children in other settings. However, the study did not find consistent associations between urinary concentrations of DAP metabolites and asthma related outcomes over a 12-month follow-up period among schoolchildren. Future studies with a longer follow-up period and repeated OP pesticide biomonitoring are recommended.

KEYWORDS: Pesticides, organophosphates, asthma, children, informal settlements, dialkyl phosphates, South Africa

P-0716 Epidemiological characteristics and spatio-temporal distribution patterns of human norovirus outbreaks in China, 2012-2018

Mengying Zhai[1], Jiao Wang[1]
[1]*China CDC, Beijing, China*

BACKGROUND AND AIM: Human norovirus are the leading cause of acute viral gastroenteritis worldwide. In China, the occurrence of norovirus outbreaks in different regions shows significant heterogeneity, while few study has focused on the spatial epidemiological characteristics of norovirus outbreaks. Thus, the aim of this study is to clarify the epidemiological characteristics and spatial distribution patterns of norovirus outbreaks.

METHODS: In China, according to the National Notifiable Disease Reporting System (NNDRS), 964 human norovirus outbreaks involving 50,548 cases in 26 provinces reported from 2012 to 2018 were analyzed in this study.

RESULTS: The outbreaks showed typical seasonality, with more outbreaks in winter and fewer in summer, and the total number of infected cases increased over time. The most common setting of norovirus outbreaks was school especially middle schools and primary schools with major transmission route of life-contact. More outbreaks occurred in southeast coastal areas of China and showed significant spatial aggregation. The highly clustered areas of norovirus outbreaks have expanded towards northeast over time.

CONCLUSIONS: By identifying the epidemiological characteristics and high-risk areas of norovirus outbreaks, this study provides important scientific support for the development of preventive and control measures of norovirus outbreaks, which is conducive to the administrative management of high risk settings and reduction of disease burden in susceptible areas.

KEYWORDS: norovirus outbreak; epidemiological characteristics; spatio-temporal heterogeneity; spatio-temporal aggregation

P-0718 The Risk of CVDs from Desalinated Seawater: A Nested Case-Control Study

Shaoxia Dong[1], Juexin Shi[1]
[1]*National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND AND AIM: Desalinated water has already been incorporated into municipal water supplies as the major source of water. The aim of this paper is to assess the association between desalinated seawater and cardiovascular diseases (CVDs).

METHODS: We conducted a nested case-control prospective study on a cohort of 7,806 subjects who live on an island of China that lacks fresh water. From this cohort, we identified 140 paired CVD cases and matched controls by sex and age during the same period. Questionnaires were used in order to investigate basic sociodemographic information and risk factors for CVDs, and urine samples were collected to measure calcium and magnesium levels. Using these data we developed and tested both univariate and multivariate logistic regression models.

RESULTS: We observed no significant differences in urinary calcium and magnesium levels between groups with and without directly desalinated seawater intake. From multivariate logistic regression, we found that obesity (OR= 5.38, 95% CI: 1.05 - 27.45), physical activity (OR= 0.35, 95% CI: 0.16 - 0.75), hypertension (OR= 3.61, 95% CI: 1.58 - 8.25), alcohol consumption (OR= 2.57, 95% CI: 1.02 - 6.47), and irritability (OR= 4.30, 95% CI: 1.93 - 9.60) were associated with an increased risk of CVD.

CONCLUSIONS: In this population, we found no association between desalinated seawater intake and CVDs; the incidence of CVDs was primarily related to lifestyle.

KEYWORDS: desalination, cardiovascular disease, incidence

P-0719 Socio-demographic heterogeneities govern the spatial dynamics of water and food-borne infections in the urban city of Ahmedabad, India

Ayushi Sharma[1], Bhavin Solanki[2], Veena Iyer[3], Ayushi Sharma[1]
[1]Chung Yuan Christian University, 200 Chung-Pei Road, 320, Zhongli, Taiwan, [2]Ahmedabad Municipal Corporation, Ahmedabad, India, [3]Indian Institute of Public Health Gandhinagar (IIPHG), Public Health Foundation of India (PHFI), Near Lekwada Bus Stop, Opp. Air force station, Gandhinagar, India

BACKGROUND AND AIM: Urban areas of low and middle-income countries (LMICs) are conducive to inequality, environmental hazards, and infectious diseases due to a confluence of unique and complex risk factors such as in-migration and informal settlements. Therefore, this study aims to evaluate socio-demographic heterogeneities as determinants of water and food-borne infections in an urban city of Ahmedabad, India.
METHOD: Spatial disease dynamics of viral hepatitis, typhoid, and diarrhea in Ahmedabad from 2010 to 2017 were analyzed with socio-demographic risk factors of age/gender, slum population density, and illiteracy rates. Additionally, the administrative units' geographical distance was also considered, i.e., wards vicinity from the river. The association was delineated by spatial regression models of Ordinary Least Square (OLS) and Spatial Lag Regression (SLR).

RESULTS: A total of 97,171 cases from 2010 to 2017 were reported of viral hepatitis, typhoid, and diarrhea. Temporal trend analysis identified a rising trend of cases over the study period. Further, spatial autocorrelation analysis revealed a significant positive correlation with Moran's I statistics ranging from 0.09 for typhoid to 0.21 for diarrhea, i.e., a similar prevalence in nearby wards. The multivariate regression model revealed slum population density as a significant risk factor for all three diseases. Illiteracy rate and vicinity to the river also significantly contribute to the prevalence of viral hepatitis. Finally, excess risk mapping of diseases identified central and southern zones of the city, to the east of river Sabarmati as hotspots wards.

CONCLUSIONS: This study identified spatial disease dynamics of water and food-borne infections in Ahmedabad with hotspot wards that can be relevant from a public health perspective. The study recommends advocating rehabilitation, capacity building, and health system strengthening at sub-ward/ward levels through micro-planning to reduce the risk of diseases arising from spatial heterogeneities.

P-0720 Factors underlying urinary arsenic levels in a population residing close to a coastal heavy-industrial area in southern Taiwan

Acharee Kaewlaoyoong[1], Shih-Ting Huang[1,2], Chao-Hung Kuo[3,4], Chih-Hsing Hung[1,5,6], Szu-Chia Chen[1,3,7], Assist. Chia-Fang Wu[1,8], Wen-Yi Lin[1,9], Ming-tsang Wu[1,2,10,11]

[1]Research Center for Environmental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, [2]Graduate Institute of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, [3]Department of Internal Medicine, Kaohsiung Municipal Siaogang Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [4]Faculty of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, [5]Department of Pediatrics, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [6]Department of Pediatrics, Kaohsiung Municipal Siaogang Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [7]Department of Internal Medicine, Division of Nephrology, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [8]International Master Program of Translational Medicine, National United University, Miaoli, Taiwan, [9]Health Management and Occupational Safety Health Center, Kaohsiung Municipal Siaogang Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [10]Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, [11]Department of Public Health, College of Health Sciences, Kaohsiung Medical University, Kaohsiung, Taiwan

The public in the southwestern Taiwan's Kaohsiung City expressed concern over risk of arsenic (As) to people living in six of that city's townships nearby a coastal area with heavy industry. To investigate, we first analyzed urinary total As levels in 539 subjects administered Taiwan's Nutrition and Health Survey, a nationwide survey of nutritional status 2005-2008 (NAHSIT 2005-8). We found the top three highest median urinary total As levels in residents from Penghu island (136.93 μg/L, n = 24), the upper northern region of Taiwan (78.54 μg/L, n = 69), and the southwestern region of Taiwan (71.87 μg/L, n = 36). We then measured total urinary As levels in 1,801 and 1,927 voluntary residents of the above-mentioned six townships in 2016 and 2018, respectively, and compared with those with people residing in the top three highest total As levels of NAHSIT 2005-8. Median urinary As levels were 84.6 μg/L in 2016 and 72.5 μg/L in 2018, similar to those in southwestern region of Taiwan, but far below those in Penghu island ($p < 0.05$). Finally, in 2020, we interviewed 116 healthy and voluntary residents from the same six townships and collected one-spot urine samples to analyze total inorganic-related As (TiAs), a summation of As3+, As5+, monomethylarsonic acid (MMA), and dimethylarsinic acid (DMA). Median urinary TiAs in participants consuming seafood two days before urine sampling (n=15) was 24.0 μg/L, significantly higher than those not consuming seafood then (median: 20.5 μg/L, n=101, $p=0.029$). The results remained significant after adjusting for other covariates ($p = 0.028$). These findings suggest that seafood consumption is probably the main source of urinary total As and TiAs in people residing close to that coastal heavy industrial area of southern Taiwan. A future intervention study (dietary control) could be conducted to re-confirm our findings.

P-0726 Determinants of carbon load in airway macrophages in pregnant women

Mohammad Miri[1], Lucia Alonso[2,3,4], Cathryn Tonne[2,3,4], Xavier Basagaña[2,3,4], Mark J. Nieuwenhuijsen[2,3,4], Jordi Sunyer[2,3,4], Tim S Nawrot[5,6], Payam Dadvand[2,3,4]

[1]Sabzevar University of Medical Sciences, Sabzevar, Islamic Republic of Iran, [2]ISGlobal, Barcelona, Spain, [3]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [4]CIBER Epidemiología y Salud Pública (CIBERESP), Spain, [5]Centre for Environmental Sciences, Hasselt University, Belgium, [6]Centre for Environmental Sciences, Hasselt University, Hasselt, Belgium

BACKGROUND AND AIM: The airway macrophages carbon loading (AMCL) has been suggested to be a biomarker of the long-term exposure to air pollution; however, to date no study has characterized AMCL for the pregnancy period. Therefore, this study aimed to assess the determinants of AMCL during pregnancy in Iran, a middle-income country.

METHODS: This study was based on a sample of 234 pregnant women with term and normal vaginal delivery who were residing in Sabzevar, Iran (2019). Image analysis was applied to calculate the carbon area (µm2) in airway macrophages as an indicator of AMCL. Measuring the AMCL was performed by two independent investigators and checked by third investigator to reduce the AMCL measurement bias. We characterized 35 potential determinants of personal exposure to air pollution for each participant, including six personal, nine indoor, and 20 home-outdoor factors. We applied Deletion/Substitution/Addition algorithm to identify the most relevant determinants that could predict AMCL levels.

RESULTS: The median (IQR) of AMCL level was 0.12 (0.30) µm2 with a successful sputum induction in 82.9% (194) of participants. Ambient residential PM2.5 levels were positively associated with higher AMCL levels. On the other hand, increased residential distance to the traffic lights, squares and ring-roads, the duration of opening window per day, and opening window during cooking were inversely associated with AMCL levels.

CONCLUSIONS: This study is the first to characterize AMCL during pregnancy. Moreover, this is one of the largest reported studies on characterization of AMCL levels. Furthermore, this is the first study to explore the personal, indoor and outdoor determinates of personal exposure to air pollution in pregnant women in an LMIC. Our findings provide novel insights on the different personal, indoor, and outdoor determinants of personal exposure to air pollution during pregnancy in a middle-income country.

KEYWORDS: Air pollution, Pregnancy, Biomarker, Lung

P-0727 Association of Traffic-Related Air Pollution with Newborn's Anthropometric Indexes at Birth

Mohammad Miri[1], Vahideh MoghaddamHosseini[1]
[1]*Sabzevar University of Medical Sciences, Sabzevar, Islamic Republic of Iran*

BACKGROUND AND AIM: The evidence suggested many adverse health effects due to exposure to traffic-related air pollution (TRAP). However, the evidence on neonatal anthropometric measurements (NAPM) in low and middle-income countries is very scarce yet. Therefore, we investigate the association of prenatal exposure to indicators of traffic and ambient particulate matter (PM) with NAPM.

METHODS: This cross-sectional study was based on hospital medical records of 4053 mother-neonate pairs (2016-2018). Pwere estimated at residential addresses based on validated spatiotemporal models. Moreover, total street length in 100, 300 and 500m buffers around the home, residential distance to the ring road, major roads, heavy-traffic lights, gas station, motorway junction, bank, square, bus terminal, public parking and industrial land-use were calculated as indicators of traffic. The head circumference (HC), birth weight (BW) and birth length (BL) of neonates were collected as NAPM. Multivariate regression models were applied to evaluate the relationship between PMs and indicators of traffic with NAPM, controlled for relevant covariates.

RESULTS: The adjusted models revealed that higher exposure to PM2.5 and PM10 was significantly related with lower BW and BL. Similarity results were observed for total street length in a 100 m buffer around maternal home with BW and BL. Moreover, higher distance to heavy traffic lights was significantly associated with higher BW and BL. An IQR increase in PM10 was significantly related to lower HC (95% CI: -0.11, -0.01, P-value = 0.03). An increase in distance from residential address to heavy traffic lights, ring roads, bus terminal, and transportation land-use was associated with higher HC.

CONCLUSIONS: This is the first study on the association of prenatal exposure to ambient PMs and different indicators of traffic with NAPM. Overall, our findings suggested that higher prenatal exposure to TRAP was related with lower BW, BL and HC.

KEYWORDS: Infant, Maternal, Neonates

P-0731 Physical Activity Profiles and Uptake of Fitness Tracking Technology among Caribbean Residents

Steve Whittaker[1,2], Samantha Bedford[1,2], Mx. Cyndi Joseph[1,2], Phibi Joseph[2], LaBiska Prince[3], Sherine Powerful
[1]Clarence Fitzroy Bryant College, Basseterre, Saint Kitts and Nevis, [2]Science, Technology, Research and Work Study (STRaWS), [3]Holistic Education, Research and Conservation (HERC), Saint Kitts and Nevis

BACKGROUND: Health is inextricably linked to, among various lifestyle factors, physical activity. However, countries in the Caribbean are understudied relative to other nations in North America, Europe and Asia regarding probes of potential associations between well-being and physical activity.
AIM: Our pilot study aimed to investigate physical activity in the Caribbean.

METHODS: We survey Caribbean ages 18 to 75 from 2016 to 2022. Analyses included descriptive statistics and logistic regression.

RESULTS: Among 272 survey respondents including a 10-member fitness tracker focus (FTF) group, approximately 53.0% reported not having diagnoses or symptoms of any illnesses. The most popular activities that persons engaged in were dancing (34.9%), football (27.6%), track and field (26.1%) and walking (38.2%). at least one hour was spent per week exercising (70.2%) and socializing (83%). The most popular recreational event types were related to carnival festivities (46.2%) and concerts (26.7%). Persons who participated in carnival were less likely to report recent maladies relative to non-participants (OR: 0.57; 95%CI: 0.35, 0.92). FTF group members report greater activity when supported by peers. FTF "revelers" (carnival participants) logged up to ten times more steps on carnival event days than non-event days. The top three barriers to being consistent in physical activity were lack of time (72.1%), lack of motivation (58.1%) and access to workout facilities (27.2%). While persons 30 and over were less likely than persons under 30 to be perceive facility access as an obstacle (OR: 0.45, 95%CI: 0.26, 0.78), persons under 30 were more likely to report insufficient time as a challenge to being more active relative to their older counterparts (OR: 1.84; 95%CI: 1.08, 3.17).

RESULTS: Findings proffer insight into the unique ways in which Caribbean peoples pursue and participate in various forms of physical activity with potential health benefits, partially mediated by peer support and fitness technology.

P-0732 NutriBodEC: A Cross-sectional Survey on Nutrition and Body Image in the Eastern Caribbean

Steve Whittaker[1,2], Mx. Cyndi Joseph[1,2], Phibi Joseph[2], LaBiska Prince[3]
[1]Clarence Fitzroy Bryant College, Basseterre, Saint Kitts and Nevis, [2]Science, Technology, Research and Work Study (STRaWs), [3]Holistic Education, Research and Conservation (HERC), Saint Kitts and Nevis

BACKGROUND: Body image dissatisfaction often driven by experiences as well as exposure to “unrealistic” body images through various visual media, has been linked to individual health.
AIM: Our pilot study intended to assess perceptions of body image and links to various lifestyle factors including diet.

METHODS: We surveyed 115 persons, ages 17 to 65, between 2018 and 2022 in the Eastern Caribbean country of St. Kitts and Nevis. Logistic analyses were applied.

RESULTS: Less than 20% of participants regarded their diet as "healthy". Neither food type nor portion sizes were significantly associated with weight, body types or perceptions of self. However, respondents with higher BMI (>25 kg/m2) were more likely (OR: 3.64; 95%CI: 1.63, 8.60) to eat larger portions of fish than those with lower BMI. The most desirable body types were (i) for women: hourglass (wide bust, narrow waist, with wide hips) and triangle (wide hips) and (ii) for men: inverted triangle (broad shoulders with small waist) and trapezium (broad shoulders with medium waist). Median complexions were higher ranked than extremes. While most respondents did not rate body types similar to their own as highly desirable, persons tended to rank complexion at least somewhat similar to their own more favorably. Male respondents were less likely to have negative thoughts about their appearance (OR: 0.41; 95%CI: 0.17, 0.94). Persons with BMI>25 kg/m2 were marginally more likely to be dissatisfied with taking selfies (OR: 2.84; 95%CI: 0.90, 10.91) than participants with lower BMI. Students, many of whom had to wear tailored uniforms to school, had a higher likelihood of anxiety (OR: 3.19; 95%CI: 1.10, 11.62) around their appearance relative to their non-academic counterparts.

CONCLUSIONS: Findings contribute to existing literature on perceptions of body image, while providing profiles of diet, body image satisfaction and health in an overlooked population

P-0744 Household fuel choices and the risks of cooking-related burns in Ghana

Courage` Gidglo, Ann Brettah Cudjoe, Reginald Quansah[1]
[1]*School of Public Health, University of Ghana, Accra, Ghana*

BACKGROUND AND AIM: Cooking-related burns are a major public health concern in developing countries. Women and children are extremely vulnerable to burns at home. This study aimed to assess the determinants of household fuel choices and the risk of cooking-related burns among two riparian peri-urban communities along the Lower River Volta of Ghana.

METHODS: This cross-sectional study was conducted as part of a baseline assessment of an ongoing Invasive Aquatic Weeds Biomass Briquette Production for use as a Cooking Fuel project (AQUAWEB). The AQUAWEB is a cluster randomized control trial involving 400 households in intervention and control riparian communities (1:1) along the Lower Volta Lake in Ghana. In-person interviews guided by structured questionnaires hosted on the REDCap application served as the primary data source for the study. Chi-square tests and Logistic Regression tests were employed to analyze the data.

RESULTS: The majority of the households depended largely on charcoal (64.99%) and less on wood fuel (15.12%) and LPG (19.89%) as their primary cooking fuel. of the LPG users, 53.7% used LPG exclusively, whereas 3.3% and 43.3% used wood fuel and charcoal as secondary fuels respectively. Among charcoal users, 57% used it exclusively but 11% and 31.8% used wood fuel and LPG as their secondary fuel respectively. Among the primary users of wood fuel, 75% used it exclusively. But 23.6% and 1.3% used charcoal and LPG as their secondary fuel respectively. 68.5% of the adult population in households suffered any household air pollution cooking-related burns. Charcoal (OR=2.15, p-value = 0.004) and wood fuel (OR=1.98, p-value = 0.038) were associated with cooking-related burns.

CONCLUSIONS: Charcoal is predominantly used in riparian communities as a primary fuel. Wood fuel and LPG were also used to support the primary fuel. Charcoal and wood fuel is associated with cooking-related burns.

P-0745 Urinary pesticide residual levels and acute respiratory infections in children under five years of age: Findings from the Offinso North Farm Health Study

Reginald Quansah[1]
[1]*School of Public Health, University of Ghana, Accra, Ghana*

BACKGROUND: Several environmental factors are associated with the risk of acute lower respiratory infections (ALRIs) and upper respiratory infections (URIs) in children under five years of age (YOA). Evidence implicating chemical pesticides remains equivocal. There are also no data on this subject in these children in Ghana. This study investigated the association between urinary pesticide residual levels and the risk of ALRIs/URIs in children under five YOA .

METHODS: The participants for this study were from the Offinso North Farm Health Study, a population-based cross-sectional study. 254 parents/guardians who had answered affirmatively to the question "Has your child ever accompanied you to the farm?" were interviewed on household socio-demographic and environmental factors, being breastfed, child education, age, gender, and respiratory infection. 150 children were randomly selected to provide the first void urine.

RESULTS: The proportion of children with ALRI was 22.1% and those with Upper Respiratory Infection (URI) were 35.8%. We observed a statistically significant exposure-response relation of p,p'-DDE (tertile) with ALRI [1.7-3.2 µg/L urine: prevalence ratio (PR)=1.22 (1.05-1.70), ≥ 3.2 µg/L urine: 1.50 (1.07-3.53) (p-for trend=0.0297)]. This observation was observed in children older than 2 YOA (p-for trend=0.0404). Delta-HCH and beta-HCH (2-levels) were significantly associated with ALRI but not URI. The risk of ALRI increased with deltamethrin levels in an exposure-response manner [2.5-9.5 µg/L urine: 2.10 (1.37-3.24), ≥ 9.5 µg/L urine: 4.38 (1.87-10.32) (p-for trend=0.0011) and this was also observed in older than 2 YOA. Similar observation was noted for URI. Bifenthrin (>0.5µg/L urine) was associated with ALRI and URI. But permethrin (≥1.2 µg/L urine) was associated with URI.

CONCLUSIONS: The present study reinforces the hypothesis that exposure to chemical pesticides is associated with respiratory infections in children under five YOA.

P-0746 Differential impact of environment on malaria due to control interventions in Uganda, 2010-2018

Margaux Sadoine[1,2], Dre Audrey Smargiassi[1,2], Dre Ying Liu[1,2], Philippe Gachon[3], Guillaume Dueymes[3], Jane Frances Namuganga[4], Grant Dorsey[5], Michel Fournier[6], Dre Bouchra Nasri[1,2], Dre Kate Zinszer[1,2]

[1]School of Public Health of Montreal University, Montréal, Canada, [2]Centre de recherche en santé publique (CReSP), Montréal, Canada, [3]Étude et Simulation du Climat à l'Échelle Régionale, Montréal, Canada, [4]Infectious Diseases Research Collaboration, Kampala, Uganda, [5]University of California San Francisco, San Fransisco, USA, [6]Montreal Regional Department of Public Health, Montréal, Canada

BACKGROUND AND AIM: Studies have estimated the impact of environment on malaria incidence although few have explored the differential impact due to vector control interventions. We aimed to evaluate the influence of temperature, rainfall, humidity, and vegetation, in presence or absence of long-lasting insecticide treated bednets (LLIN) and indoor residual spraying (IRS).

METHODS: This study used weekly malaria cases from 2010 to 2018 from six health facility-based malaria surveillance in Uganda. Environmental variables were extracted from remote sensing sources and include enhanced vegetation index (MODIS), cumulative rainfall (ARC2), minimum and maximum temperature (ERA5), specific humidity (ERA5), averaged over different time periods (one to four months). Non-linearity of environmental variables was investigated, and general linear models based on a negative binomial distribution was used to explore the influence of ITN and LLIN on the malaria-environment relationship.

RESULTS: A total of 204,252 malaria cases were laboratory confirmed and the median (range) weekly cases was 58.0 (0-597), rainfall 18.6 mm (0-129), minimum temperature 17.6˚C (12.3-24.2), maximum temperature 26.7˚C (20.1-34.8), and humidity 0.014 kg.kg (0.006-0.018). The best fit model was with the meteorological measures averaged over 3 months. All environmental variables showed a relatively linear pattern. Both IRS and LLIN were significantly associated with risk reduction (IRR: 0.39, 95% CI: 0.36–0.42 ; IRR: 0.71, 95% CI: 0.67–0.75, respectively). Marginal effects of environmental variables showed that joint effect of IRS and LLIN reduced the weekly predicted counts of malaria by 72.5% compared to no intervention.
CONCLUSION: LLIN and IRS both reduced the influence of environmental drivers of malaria and therefore morbidity in various transmission setting in Uganda. The benefits appeared to be greatest when the two interventions are used in combination.

P-0751 Personal exposure to heat amongst older adult women in Tamil Nadu, India

Aniruddha Deshpande[1], Noah Scovronick[2], Ajay Pillarisetti[3], Kalpana Balakrishnan[4], Vigneswari Aravinth[4], Thomas Clasen[2], Jennifer Peel[5]

[1]Department of Epidemiology, Emory University, Atlanta, USA, [2]Gangarosa Department of Environmental Health, Emory University, Atlanta, USA, [3]Department of Environmental Health Sciences, University of California, Berkeley, Berkeley, USA, [4]Department of Environmental Health Engineering, ICMR Center for Advanced Research on Air Quality, Climate and Health, Sri Ramachandra Institute for Higher Education and Research (Deemed University), Chennai, India, [5]Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, USA

BACKGROUND AND AIM: In 2019, 127,000 deaths were attributed to heat exposure globally, with over 40% in India, where a substantial portion of the population has limited access to cooling technologies. This substantial burden is expected to worsen with climate change, but little is known about personal exposure to outdoor temperatures in India We leverage data collected as part of the Household Air Pollution Intervention Network (HAPIN) randomized controlled trial to describe personal temperature exposure of older adult women in Tamil Nadu. We compare personal exposure to ambient monitoring stations and modelled temperature products.

METHODS: As part of HAPIN, older adult women in Tamil Nadu periodically wore instrumentation for a 24-hr period to measure air pollution; these instruments also measure temperature. We analyzed temperature measurements taken between 2018 and 2021 and compared them to the nearest identified ambient monitoring stations, and to the ERA5 and GLDAS meteorological products.

RESULTS: Personal measurements were recorded from 105 different participants for a total of 1.7 million datapoints. The mean temperature recorded was 28.6 °C with a standard deviation of 3.5 °C. Differences of ≥5 °C across individuals on the same day were not uncommon, nor were intra-individual exposures that varied by several degrees within an hour -- potentially a result of elevated heat while cooking. ERA5 estimates were more positively correlated with personal exposure than with GLDAS or ambient monitors. Correlations varied by season, with best performance across all products during the monsoon season.

CONCLUSIONS: Accurate exposure assessment is important for assessing health effects of heat – a growing problem. There is substantial variability in how well public datasets correlate with personal experience, not only by product type but also location and season. It is important to quantify these differences to appropriately estimate health effects.

KEYWORDS: Heat, India, Remote Sensing, Exposure Assessment

P-0762 Health outcomes in redlined versus non-redlined neighborhoods: A systematic review and meta-analysis

Eun Kyung Lee[1], Gwendonlyn Donley[2], Timothy Ciesielski[2], India Gill[2], Owusua Yamoah[2], Abigail Roche[2], Roberto Martinez[2], Darcy Freedman[2]
[1]Boston University School of Public Health, Boston, USA, [2]Case Western Reserve University, Cleveland, USA

BACKGROUND AND AIM: Redlining was a racialized zoning practice in the U.S. that blocked fair access to home loans during the 1930s, and recent research is illuminating health problems in the current residents of these historically redlined areas. However, this work has not yet been holistically summarized. Here, we present the first systematic review and meta-analysis comparing health outcomes in redlined versus non-redlined neighborhoods in U.S. cities.

METHODS: We extracted relevant articles in PubMed, Web of Science, Cochrane and Science Direct databases published from January 2010 to September 2021.

RESULTS: The search revealed 12 studies on preterm births (n=3), gunshot-related injuries (n=2), cancer (n=1), asthma (n=1), self-rated health (n=1), multiple health outcomes (n = 2), heat-related outcomes (n=1) and COVID-19 incidence and mortality (n=1). A meta-analysis of three studies found the odds of having preterm birth was significantly higher (OR=1.41, 95% CI: 1.05-1.88; p=0.02) among women living in redlined areas compared to those in non-redlined areas. Review of other outcomes revealed that gunshot-related injuries, asthma, heat-related outcomes, and multiple chronic conditions were worse in redlined areas, while associations with cancer varied by cancer type. In terms of cause-specific mortality, one study revealed no link between residential redlining and infant mortality rate, while one study on COVID-19 outcomes was inconclusive.

CONCLUSIONS: Overall, this review presents evidence that living in historically redlined areas is associated with increased risk of multiple serious adverse health outcomes. Further research on mechanisms, remediation, and neighborhood-level interventions is needed to strengthen the understanding of the impacts of redlining on health.

P-0764 Identifying susceptibility factors for methylmercury-induced developmental neurotoxicity

Bita Khoshhal[1,2], Leonid Kopylev[2], Alexandra Larsen[2], Rebecca Nachman[2], Onyemaechi Nweke[2], Elizabeth G. Radke[2], Deborah Segal[2]

[1]George Mason University, Fairfax, USA, [2]USA Environmental Protection Agency, Washington, USA

BACKGROUND AND AIM: Methylmercury (MeHg) exposures during pregnancy or childhood can cause developmental neurotoxicity (DNT), including cognitive, behavioral, and other effects. While many studies have reported on these effects, fewer have examined other factors that contribute to susceptibility to MeHg-induced DNT. The first objective of this project is to determine whether there are demographic, biological, psychosocial, societal, environmental, or other factors that may make developmentally exposed individuals more susceptible to these effects. A second objective is to develop a replicable approach for identifying susceptibility data in assessments of the health effects of chemicals.

METHODS: A systematic literature search for 2019-2021 aimed to identify all epidemiology studies that examined methylmercury exposure and DNT. Identified studies were then screened for susceptibility information at the title/abstract and full text levels by two reviewers. A search string was also developed and applied to title/abstracts to determine whether these studies could be identified without extensive screening. Susceptibility information was then summarized.

RESULTS: Data examining several potential susceptibility factors for MeHg were identified, including genetic polymorphisms, sex, maternal factors, nutritional status, and multi-chemical exposures.

CONCLUSIONS: This project identifies potential susceptibility factors associated with MeHg and DNT. The methods applied to MeHg may be adapted and utilized for identifying and interpreting the literature on susceptibility factors for adverse health effects from other chemical exposures.

KEYWORDS: methylmercury, developmental neurotoxicity, susceptibility, systematic review, environmental justice

P-0769 Association between historical redlining and preterm birth in North Carolina, 2003-2015

Adrien Wilkie[1], Monica Jimenez[1], Christine Grey[2], Wei-Lun Tsai[3], Alison Krajewski[3], Kristen Rappazzo[3], Thomas Luben[3]

[1]Oak Ridge Institute for Science and Education (ORISE) Postdoctoral Fellow at US EPA, Research Triangle Park, USA, [2]Duke Global Health Institute, Duke University, Durham, USA, [3]US Environmental Protection Agency, Center for Public Health and Environmental Assessment, Research Triangle Park, USA

BACKGROUND AND AIM: Starting mid-1930s, the Home Owners' Loan Corporation (HOLC) ranked urban neighborhoods as least to most desirable in terms of perceived mortgage stability. This racist practice, redlining, likely led to disparities in proximity to environmental pollutants in these areas. Recent research suggests associations between historical redlining and adverse birth outcomes today. We investigated the association between historical redlining and preterm birth (PTB, <37 weeks gestation) in North Carolina (NC) and evaluated modification of that association by gestational parent (GP) race/ethnicity.

METHODS: We assembled a retrospective, administrative cohort of singleton births in NC from 2003-2015, linking geocoded residences at time of delivery to Mapping Inequality's HOLC polygons. Eligible births were assigned HOLC grade A (Best), B (Still desirable), C (Declining), or D (Hazardous). We estimated odds ratios (OR (95%CI)) using logistic regression adjusting for GP age at delivery and smoking during gestation, and applying generalized estimating equations to account for clustering by city.

RESULTS: Our analysis included 36,571 births within historically redlined cities in NC (Asheville, Charlotte, Durham, Greensboro, Winston-Salem). for births within the historically defined HOLC grades B, C, and D, respectively, the odds of PTB were 1.43 (95%CI: 1.10, 1.86), 1.77 (1.50, 2.09), and 2.10 (1.79, 2.48) compared to HOLC grade A. In stratified analyses, ORs were null and imprecise for all HOLC grades compared to HOLC grade A among non-Hispanic Black individuals (e.g. D vs A: 1.01 (0.60, 1.72)). ORs were positive but similarly imprecise among Hispanic and non-Hispanic white individuals with ORs that ranged from 1.61 (0.57, 4.54) to 1.70 (0.74, 3.93) and 1.20 (0.96, 1.50) to 1.27 (0.97, 1.67), respectively.

CONCLUSIONS: These preliminary results suggest that historical redlining is associated with poorer PTB outcomes decades later, providing additional evidence that historically racist practices continue to have lasting negative environmental burdens and health impacts on communities today.

P-0772 Quantifying sociodemographic inequities in exposure to point source carcinogenic industrial pollution emissions across the USA

Jessica Madrigal[1], Abigail Flory[2], Jared Fisher[1], Danielle Duarte[1], Mary Ward[1], Rena Jones[1]
[1]Occupational and Environmental Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, USA, [2]Westat, Inc., Rockville, USA

BACKGROUND AND AIM: Few studies have investigated how carcinogenic environmental exposures are distributed among the general population. We described recent cross-sectional relationships between carcinogenic industrial emissions and sociodemographic characteristics across the USA (US).

METHODS: We linked US Environmental Protection Agency's 2018 Toxics Release Inventory to sociodemographic characteristics in 2010 Census tracts. Using chemical abstract service registry numbers, we identified onsite emissions (e.g., air, landfill, surface) of known and probable carcinogens as classified by the International Agency for Research on Cancer. Tract characteristics included total population, median household income, Yost neighborhood deprivation index, poverty, and percentages of Black, Hispanic, and white populations. We used linear regression to investigate the relation between quintiles of emissions in each census tract and distributions of these characteristics.

RESULTS: 5,209 (7%) tracts with an estimated 23.2 million population contained 7,028 facilities emitting known (n=22) or probable (n=33) carcinogens, including 1 billion pounds of these emissions in total (median: 226; IQR 7-5970 pounds/tract). Compared to tracts without emissions (all p-values <0.01), those with the highest quintile of emissions had higher proportions of rural (44% vs. 19%) and white (71% vs. 62%) populations, lower median household income ($45,000 vs. $55,000), and a higher deprivation score (62 vs. 49). Tracts with the highest emissions had a higher proportion of population with a high school education or less (53% vs. 44%). Overall, the proportions of families below the poverty level did not differ; however, greater numbers of black and white families below poverty lived in the tracts with the highest emissions. We observed similar demographic patterns in analyses restricted to air emissions.

CONCLUSIONS: Our novel assessment demonstrates that carcinogenic emissions are not homogeneously distributed among the US population. It may be important to consider joint distributions of sociodemographic characteristics when describing environmental exposures and associated health disparities.

KEYWORDS: carcinogens, health disparities

P-0786 Quantification of green and walkable neighbourhoods across the distribution of social and material deprivation in Metro Vancouver, Canada

Katherine White[1], Kate Weinberger[1], Connor Wolff[2], Trevor Dummer[1], Lawrence Frank[3]
[1]School of Population and Public Health, University of British Columbia, Vancouver, Canada, [2]School of Community and Regional Planning, University of British Columbia, Vancouver, Canada, [3]Urban Studies and Planning, University of California San Diego, San Diego, USA

BACKGROUND AND AIM: Along with other environmental exposures, both neighbourhood walkability, and greenspace exposure and access have been linked to many diverse health benefits. Previous work has examined the spatial relationship of built and natural environments according to levels of neighbourhood deprivation; however, less is known about how these relationships may vary when different greenspace metrics are used. This work examines how normalized differences vegetation index (NDVI), tree canopy cover, green land cover, and park count metrics relate to walkability, and how these neighbourhood characteristics associate with both social and material deprivation.

METHODS: Greenspace exposure was measured using NDVI, tree canopy cover, and green land cover, while park access was quantified by the number of designated public parks within 1000m and 400m network buffers for each six-digit postal-code centroid in Metro Vancouver, Canada. Local area deprivation was measured using the 2016 Material and Social Deprivation Index (MSDI). Pearson's correlation coefficients were calculated to compare these neighbourhood characteristics.

RESULTS: Walkability was positively associated with social deprivation (1000m $r = 0.48$; 400m $r = 0.48$, $p < .01$), while walkability has a weak inverse relationship with material deprivation (1000m $r = -0.21$, $p < .01$). Tree canopy was negatively related to both social (1000m $r = -0.23$, 400m $r = -0.23$, $p < .01$) and material deprivation (1000m $r = -0.24$, 400m $r = -0.23$, $p < .01$). In contrast, the relationship between park count and both deprivation measures was weak.

CONCLUSIONS: In this study, areas with greater social and material deprivation tend to have less greenspace, but not necessarily less park access. The identification of neighbourhoods with higher material deprivation, low walkability, and low greenspace, may be prioritized by urban planners and decision makers as possible locations for additional greenspace allocation.

KEYWORDS: greenspace, walkability, social deprivation, material deprivation

P-0794 Disparities in adverse birth outcomes attributable to elevated ambient air pollution in the U.S.

Laura Gladson[1,2], Julia Gohlke[3], Kevin Cromar[1,2]
[1]Marron Institute of Urban Management, New York University, Brooklyn, USA, [2]New York University Grossman School of Medicine, New York, USA, [3]Environmental Defense Fund, Washingon, USA

BACKGROUND AND AIM: Preterm birth and low birth weight are global health challenges that increase a child's lifelong risk for chronic disease. These adverse birth outcomes (ABO) are associated with ambient air pollution with differential risks across socioeconomic groups, yet are not presently accounted for in environmental policy assessments. This study estimates annual counts of ABO associated with $PM_{2.5}$ exceeding American Thoracic Society (ATS) recommended standards and investigates relevant disparities by race and income.

METHODS: Pollution increments of annual $PM_{2.5}$ were calculated for all monitored U.S. counties by comparing 2018-2020 EPA design values to counterfactuals meeting ATS recommended levels (8 μg/m³ for annual and 25 μg/m³ for 24-hour $PM_{2.5}$). Increments were coupled with current concentration-response functions and CDC baseline incidence data to determine county-level annual numbers of ABO associated with $PM_{2.5}$ above counterfactual levels. Sub-group analyses by mother's race and source of delivery payment were conducted to determine exposure differentials.

RESULTS: Across monitored U.S. counties, approximately 7,300 (95% CI: 3,700–11,500) preterm and 5,200 (95% CI: 3,300–7,500) low weight births are associated with $PM_{2.5}$ levels above ATS recommendations. $PM_{2.5}$-related ABO rates were higher among Black vs. White mothers, driven by higher baseline incidence rates experienced by Black mothers. $PM_{2.5}$-related ABO rates were higher among Medicaid vs. non-Medicaid payees, a result of both higher $PM_{2.5}$ increments and higher baseline incidence among Medicaid payees.

CONCLUSIONS: Approximately 12,500 annual U.S. ABO can be linked to $PM_{2.5}$ above ATS recommended levels, with trends towards greater air pollution-related ABO for both Black mothers and Medicaid recipients. The magnitude of this effect, combined with lifelong health impacts attributable to these birth outcomes, provides a compelling argument that ABO should be factored into future environmental policy assessments.

P-0806 Use of gradient boosting machine for exposome-wide analyses: application for pharmaceutical risk factors for amyotrophic lateral sclerosis

Ran Rotem[1,2], Andrea Bellavia[1], Gabriel Chodick[2], Marc Weisskopf[1]
[1]Harvard TH Chan School of Public Health, Boston, USA, [2]Maccabi Healthcare Services, Tel Aviv, USA

BACKGROUND
Accumulating evidence suggests that human health is affected by a complex set of exposures, including to environmental toxicants, dietary constituents, psychosocial stressors, and physical factors. Capturing the complexity of the whole exposome is pivotal for advancing etiological knowledge, yet standard statistical methods, as well as recent developments for mixtures analysis, are limited to considering only a modest number of exposures and interactions while often also making the implicit assumption that the exposures are continuous. Machine learning approaches could offer benefits in these very high-dimensional settings.
METHOD
Using gradient boosted decision trees coupled with Bayesian model optimization and a nested cross-validation design, we describe an approach for outcome prediction based on a mixture of exposures, and for identification of specific culprit factors within the mixture that consistently drive the association while allowing for synergistic or antagonistic interactions between the predictors. While this flexible approach is applicable to many settings, we used it to evaluate the association between patients' history of medication use and risk of amyotrophic lateral sclerosis (ALS), as a steppingstone for integrating additional exposures and in a setting that largely avoids exposure measurement errors that further complicate many toxicant mixtures.

RESULTS: of nearly 800 binary predictors, we identified 7 medication classes that were consistently associated with ALS risk across independently trained models. Interactions between medication groups did not substantially affect the risk. Prediction accuracy was consistent, but low due to the lack of information on other etiological risk factors for ALS.
SUMMARY
The described methodology allows to predict the overall effect of a mixture and to identify specific culprit factors in very high dimensional settings and when both continuous and categorical exposures are of interest. While causal interpretation of purely predictive models should generally be avoided, the repeated sampling of the dataset has interesting causal inference implications.

P-0808 World Trade Center Exposome: A novel, data-driven approach to modeling risk and protective factors for adverse mental and physical health outcomes among WTC Responders

Elza Rechtman[1], Elena Colicino[1], Christopher R. Dasaro[2], Christopher J. Hahn[2], Azzurra Invernizzi[1], Susan L. Teitelbaum[1], Andrew C. Todd[1], Megan K. Horton[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]World Trade Center Health Program General Responder Data Center, Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: Responders involved in rescue and recovery efforts following the 9/11 World Trade Center (WTC) attacks were exposed to hazardous working conditions and toxic agents. Previous studies associating WTC exposure with adverse health outcomes focus on a small number of risk factors selected a priori. We proposed a data-driven, exposomic approach to investigate the mixture of risk and protective factors experienced by WTC responders (i.e., a 'WTC exposome') and its relation to responder health.

METHODS: We included 34,096 responders from the WTC Health Program (WTC-HP) with a physical and mental health evaluation and exposure assessment at first (post 9/11/01) visit. We used generalized weighted quantile sum (gWQS) regression to examine positive (i.e., risk) and negative (i.e., protective) associations between the "WTC Exposome" index containing 84 factors (i.e., dust and traumatic exposures, baseline health information, social support) and five WTC-related health outcomes as dichotomous (ever/never): post-traumatic stress disorder (PTSD), gastroesophageal reflux disease (GERD), respiratory problems, diabetes, and headaches. All models were adjusted for age, race, ethnicity, and gender.

RESULTS: The WTC exposome was associated with all five health outcomes (PTSD β_{risk} = 6.4, $\beta_{protective}$ = 0.1; GERD β_{risk} = 4.4, $\beta_{protective}$= 0.5; respiratory problems β_{risk} = 3.9, $\beta_{protective}$ = 0.6; diabetes β_{risk} = 1.6, $\beta_{protective}$ = 0.7; headaches β_{risk} = 5.6, $\beta_{protective}$ = 0.3; $p<0.0001$ for all models). The WTC exposomic profile (i.e., the mix of risk and protective factors) differed by health outcome. for example, working in an enclosed area contaminated with dust contributed most to PTSD risk while full-time employment post 9/11 appeared protective against PTSD.

CONCLUSIONS: Understanding WTC-related risk and protective factors enable us to better identify responders vulnerable to adverse outcomes and identify factors that may protect against the development or progression of disease. This approach has potential for future disaster response studies.

P-0815 Sex-specific associations between prenatal exposure to phthalates and neurocognitive development in Taiwanese children: Application of environmental mixture methods to small study sample

Juwel Rana[1,2,3], Stefano Renzetti[4], Shu-Li (Julie) Wang[5], Alexander Keil[6], Youssef Oulhote[7]
[1]North South University, Dhaka, Bangladesh, [2]McGill University, Montreal, Canada, [3]South Asian Institute for Social Transformation (SAIST), Dhaka, Bangladesh, [4]Università degli Studi di Brescia, Brescia, Italy, [5]National Institute of Environmental Health Sciences, Taipei, Taiwan, [6]National Cancer Institute, Bethesda, USA, [7]University of Massachusetts Amherst, Amherst, USA

BACKGROUND AND AIM: Few studies have examined the sex-specific effect of phthalates as a mixture by applying multiple mixture methods to a small study sample. This study, therefore, examined sex-specific associations of prenatal exposure to urinary phthalates with neurocognitive development in Taiwanese children aged two to three years old.

METHODS: The study included 127 children who were followed up at the ages two-three years in the Taiwanese Maternal and Infant Cohort Study. The Mental Development Index (MDI) and Psychomotor Development Index (MDI) were measured in children using the Bayley Scales of Infant Development-II (BSID-II). The monomethyl phthalate, monoethyl phthalate, mono-butyl phthalate (MBP), mono-benzyl phthalate, mono-2-ethylhexyl phthalate (MEHP), mono(2-ethyl-5-hydroxyhexyl) phthalate, mono (2-ethyl-5-oxohexyl) phthalate (MEOHP) were measured in urine samples collected from mothers during pregnancy. Multivariable linear regression (MLR), Weighted Quantile Sum (WQS) regression, quantile g-computation (qgcom), Bayesian Kernel Machine Regression (BKMR), the Super Learner with g-computation were applied and compared to examine the sex-specific effects of the phthalate mixture on MDI and PDI.

RESULTS: The mediation MDI and PDI were 94.0 and 99.0, respectively. The spearman correlation ranged between -0.01 and 0.74. None of these methods could detect any sex-specific associations between phthalates and MDI. Results suggest that WQS and qgcomp were able to detect inverse associations between phthalates and PDI with a stronger effect in boys. BKMR and Super Learner with g-computation were unable to detect any precise associations of phthalates with PDI. However, mixture methods detected mixtures' negative directionality and linear dose-response effects on neurocognitive development. MBP, MEHP, and MEOHP dominated these associations with PDI.

CONCLUSIONS: Mixture methods outperformed MLR. However, flexible approaches like BKMR and Super Learner with g-computation may perform better with larger samples. Therefore, the study recommends using multiple mixtures methods for getting comprehensive results from mixture studies.

KEYWORDS: Mixture; Neurodevelopment; WQS; BKMR; G-computation

P-0820 Residential greenness, air pollution, and incident ischemic heart disease: A prospective cohort study in China

Tiezheng Li[1], Zhebin Yu[1], Lisha Xu[1], Yonghao Wu[1], Luhua Yu[1], Zongming Yang[1], Menglin Tang[1], Minjuan Jin[1], Kun Chen[1], Jianbin Wang[1]
[1]*Zhejiang University, Hangzhou, China*

BACKGROUND AND AIM: Green living environments are associated with beneficial health outcomes, whereas higher air pollution exposure might increase the risk of chronic diseases. Moreover, few studies have explored the interaction between residential greenness and air pollution on the risk of ischemic heart disease (IHD). Therefore we aimed to estimate the associations of residential greenness and air pollution with IHD and their interaction.

METHODS: We performed a prospective cohort study that included 29,141 adult participants recruited from Yinzhou District, Ningbo, China. Normalized Difference Vegetation Index (NDVI) around each participant's residence was calculated to measure residential greenness exposure. Land-use regression models were conducted to estimate long-term individual exposure to air pollutants, including nitrogen dioxide (NO2) and particulate matter with aerodynamic diameters ≤ 2.5 μm (PM2.5) and ≤10 μm (PM10). Cox proportional hazard models were used to calculate the hazard ratios (HRs) and 95% confidence intervals (95% CIs) for the association of residential greenness and air pollutants with the risk of incident IHD.

RESULTS: During 101,172.5 person-years of follow-up, 1,392 incident IHD cases were reported in the study population. Residential greenness, expressed as an interquartile range (IQR) increase in NDVI within 300m, was inversely associated with incident IHD. However, long-term air pollution exposures were associated with higher IHD incidence. Mediation analyses suggested that the beneficial effect of residential greenness on incident IHD could be partly mediated by reducing the exposure to PM2.5.

CONCLUSIONS: Higher greenness was associated with decreased risk of IHD, while air pollutants were positively associated with incident IHD. Meanwhile, residential greenness may decrease the risk of IHD by reducing PM2.5 exposure.

KEYWORDS: Residential greenness; Air pollution; Ischemic heart disease; Cohort study; Effect mediation

P-0827 Solar and Geomagnetic Activity Reduces Pulmonary Function and Enhances Particulate Pollution Effects

Kritika Anand[1], Carolina L.Z. Vieira[1], Eric Garshick[2,3], Veronica Wang[1], Annelise Bloomberg[1,5], Diane R Gold[1,3], Joel Schwartz[1,3], Pantel Vokonas[4], Petros Koutrakis[1]

[1]Department of Environmental Health, Harvard T.h. Chan School of Public Health, Boston, USA, [2]Pulmonary, Allergy, Sleep, and Critical Care Medicine Section, VA Boston Healthcare System, Boston, USA, [3]Channing Division of Network Medicine, Brigham and Women's Hospital, and Harvard Medical School, Boston, USA, [4]VA Normative Aging Study, Veterans Affairs Boston Healthcare System and the Department of Medicine, Boston University School of Medicine, Boston, USA, [5]Division of Occupational and Environmental Medicine, Lund University, Lund, Sweden

BACKGROUND: Increased solar and geomagnetic activity (SGA) may alter sympathetic nervous system activity, reduce antioxidant activity, and modulate physiochemical processes that contribute to atmospheric aerosols, all which may reduce pulmonary function.
Aim: Investigate associations between forced expiratory volume at 1 second (FEV1) and forced vital capacity (FVC) with SGA, and assess whether SGA enhances adverse effects of black carbon (BC) and particulate matter ≤2.5 μm in diameter (PM2.5).

METHODS: We conducted a repeated measures analysis in 726 Normative Aging Study participants (Boston, USA) between 2000 and 2017, using interplanetary magnetic field (IMF), planetary K index (Kp), and sunspot number (SSN) as SGA measures. Linear mixed effects models were used to assess exposure moving averages up to 28 days for both SGA and pollution.

RESULTS: Increases in IMF, Kp Index and SSN from the day of the pulmonary function test averaged through day 28 of were associated with a significant decrement in FEV1 and FVC, after adjusting for potential confounders. There were greater effects for longer moving averages and enhanced effects of PM2·5 and BC on FEV1 and FVC with increased SGA. for example, for each inter-quartile increase (4.55 μg/m3) in average PM2·5 28 days before testing, low IMF (10th percentile: 3.2 nT) was associated with a -21.4 ml (95% CI:-60.8, 18.1) and -7.1 ml (95% CI:-37.7, 23·4) decrease in FVC and FEV1, respectively; high IMF (90th percentile: 9.0 nT) was associated with a -120.7 ml (95% CI:-166.5, -74.9) and -78.6 ml (95% CI: -114.3, -42·8) decrease in FVC and FEV1, respectively.

CONCLUSIONS: Increased periods of SGA may directly contribute to impaired lung function and enhance effects of PM2.5 and BC. Since exposure to solar activity is ubiquitous, stricter measures in reducing air pollution exposures are warranted, particularly in elderly populations.

P-0841 The urban vegetation and allergic rhinitis in Montreal, Canada

Alexandre Barris[1], Sophie Goudreau[2], Ying Liu[1,3], Naizhuo Zhao[4,5], M.D. David Kaiser[2,6,7], Audrey Smargiassi[1,3]
[1]Department of Environmental and Occupational Health, School of Public Health, University of Montreal, Montreal, Canada, [2]Montreal Department of Public Health, Montreal, Canada, [3]Centre of Public Health Research, University of Montreal and CIUSSS du Centre-Sud-de-l'Île-de-Montréal, Montreal, Canada, [4]Centre d'étude de la forêt, Département des Sciences Biologiques, Université du Québec à Montréal, Montreal, Canada, [5]Division of Clinical Epidemiology, McGill University Health Centre, Montreal, Canada, [6]Department of Epidemiology, Biostatistics and Occupational Health, Faculty of Medicine and Health Sciences, McGill University, Montreal, Canada, [7]Department of Social and Preventive Medicine, School of Public Health, University of Montreal, Montreal, Canada

BACKGROUND: Urban vegetation offers many benefits to population health and wellbeing. In addition to these benefits, trees also emit pollen that can cause allergies.
Objective: This study aimed to assess the association between urban vegetation and allergic rhinitis in the Montreal area.

METHODS: Data on spring symptoms (April, May, June) of allergic rhinitis were retrieved from the 2008 and 2014-2015 Quebec Population Health Surveys (EQSP) and population-weighted. 2015 Landsat-8 satellite images and LiDAR (Light Detection and ranging) point cloud were used to calculate, respectively, the Normalized Difference Vegetation Index (NDVI) and the average crown volume of trees. The values of these indices were classified into population quintiles. Associations between vegetation parameters and the prevalence of symptoms of allergic rhinitis were assessed with logistic regression models within buffer zones of 100, 250, 500, and 1000 meters around the respondent's six-digit residential postal codes, adjusting for sex, age and categories of income.

RESULTS: The combined sample of the two surveys totaled 6,901 respondents. The estimated prevalence of spring symptoms of allergic rhinitis in the population was 11.3% (CI95%: 10.4 – 12.2). The NDVI and average crown volume were not associated with symptoms of allergic rhinitis for any of the buffer zones. for a buffer zone of 250 meters, the adjusted odds ratio for an increase from the lowest to the highest NDVI value (Q1 and Q5) was 1.029 (CI95%: 0.764 – 1.385). The adjusted odds ratio for an increase from the lowest to the highest average crown volume value was 1.167 (CI95%: 0.878 - 1.552).

CONCLUSIONS: The results suggest that vegetation density does not have an impact on the prevalence of spring symptoms of allergic rhinitis in residents of the Montreal urban area. More detailed assessments on the associations with vegetation types are needed.

KEYWORDS: Urban vegetation, allergic rhinitis, Remote Sensing, NDVI

P-0843 Spatiotemporal exposure modeling of environmental circadian misalignment

Mimi Ton[1,2], Matthew D. Weaver[3,4], Trang VoPham[1,5]
[1]Department of Epidemiology, University of Washington, Seattle, USA, [2]Cancer Prevention Program, Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, USA, [3]Division of Sleep and Circadian Disorders, Departments of Medicine and Neurology, Brigham and Women's Hospital, Boston, USA, [4]Division of Sleep Medicine, Harvard Medical School, Boston, USA, [5]Epidemiology Program, Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, USA

BACKGROUND AND AIM: Light exposure is the most powerful resetting signal for circadian rhythms. Environmental circadian misalignment (ECM) occurs from geographic variation in light exposure due to location within a time zone (delayed circadian phase from less morning and greater evening light exposure moving west in a time zone). The aim of this study was to develop and validate the first-ever nationwide spatiotemporal exposure model of ECM in the US.

METHODS: for all US census tracts, the ECM exposure model incorporated elevation (in meters) and the average difference (in minutes) in sunrise time and sunset time between the census tract center of population and the eastern-most time zone boundary. Higher ECM exposure values indicate higher circadian misalignment due to higher elevation (fewer obstructions/extended field of view) and larger differences in sunrise and sunset times. Spearman correlation coefficients and multivariable linear regression adjusting for age, sex, race, ethnicity, median household income, and population density were used to validate the ECM exposure model with census tract-level prevalence of obesity (2016-2019) (known outcome associated with circadian misalignment).

RESULTS: Among the 60,943 census tracts included in this study, obesity prevalence was 32.62%. ECM exposure was positively correlated with obesity prevalence, with the strongest correlation in the Eastern time zone (r_s=0.44, $p<0.01$). The highest vs. lowest ECM quintile was associated with higher obesity prevalence in the Eastern (adjusted β=6.00, 95% CI 6.68, 7.11) and Central time zones (adjusted β=2.85, 95% CI 2.62, 3.09), which are the US time zones characterized by the largest east-to-west distance (i.e., opportunity for ECM).

CONCLUSIONS: We developed and validated a US nationwide spatiotemporal ECM exposure model, which can be used for exposure assessment in epidemiologic studies to enable comprehensive characterization of geographic variation in light exposure potentially impacting circadian phase.

P-0846 Phenols, parabens and triclosan in maternal urine, Medellín-Colombia

Carlos Alberto Gómez-Mercado[1], Gregory Mejía- Sandoval[2], Albino Barraza-Villareal[3], Catalina Arango-Álzate[1], Angela Maria Segura-Cardona[1], Liliana Acevedo-Saenz[4], Damaskini Valvi[5], Amrit Kaur Sakhi[6], Cathrine Thomsen[6]
[1]CES University, Medellín, Colombia, [2]CES University, Medellín, Colombia, [3]National Institute of Health of Mexico, Cuernavaca, México, [4]CES University, Medellín, Colombia, [5]Icahn School of Medicine at Mount Sinai, New York, EEUU, [6]Norwegian Institute of Public Health, Oslo, Norway

INTRODUCTION: Phenols, phthalates, parabens and triclosan are endocrine disruptors and are suspected of generating epigenetic damage during prenatal life (1). The biological matrix most used to measure them is urine (2). Objective: to quantify the concentrations of phenols, parabens and triclosan) in pregnant women in two health institutions in Medellín.

METHODS: 400 pregnant women were recruited and of these it was possible to analyze 38 pools of urine (20 punctual samples) to quantify the metabolites of phenols, parabens and triclosan, the analysis was carried out at the Norwegian Institute of Public Health (NIPH), by ultra-high resolution liquid chromatography coupled to tandem mass spectrometry (UPLC-MS-MS) (2), the analyzes were corrected by specific gravity.

RESULTS: the geometric means according to the metabolites were Bisphenol A (BPA: 1.78 ng/mL), Methyl paraben (MEPA: 88.91 ng/mL), Ethyl paraben (ETPA: 2.95 ng/mL), Propyl paraben (PRPA: 10.32 ng/mL), Oxybenzone (OXBE: 27.94 ng/mL) and Triclosan (TRCS: 36.74 ng/mL).

CONCLUSIONS: This is the first study in Colombia that quantifies concentrations of phenols, phthalates, parabens and triclosan in pregnant women from Medellin. The geometric means of the metabolites BPA and parabens are in the middle when comparing with studies, but TRCS is above other studies in the world.

KEYWORDS: phenols, parabens, triclosan, endocrine disruptors; urine

P-0849 Personal exposure to radiofrequency electromagnetic fields in various occupations in Spain

Maxime Turuban[1,2], Hans Kromhout[4], Javier Vila[5], Ghislaine Bouvier[6], Michelle Turner[1,3]
[1]Isglobal, Barcelona Institute for Global Health, Barcelona, Spain, [2]Universitat Pompeu Fabra, Barcelona, Spain, [3]CIBER Epidemiología y Salud Pública, Madrid, Spain, [4]Institute for Risk Assessment Sciences (IRAS), Division of Environmental Epidemiology, Utrecht University, Utrecht, Netherlands, [5]Environmental Protection Agency (EPA), Office of Radiation Protection and Environmental Monitoring, Wexford, Ireland, [6]Inserm UMR 1219 EPICENE Team, Bordeaux Population Health Research Center, Bordeaux, France

BACKGROUND: A Job-Exposure Matrix (JEM) for radiofrequency electromagnetic fields (RF-EMF) was previously created based on measurements collected from the literature and individualized EMF source-based information. In the context of an international study aimed at enhancing this preliminary JEM, personal measurements of occupational exposure to RF-EMF were conducted among various occupations in Spain.

METHODS: Identification and prioritization of occupations to be measured were based on the levels and prevalence of exposure to RF fields in the preliminary RF-JEM and expert judgements. A screening questionnaire developed within our project was used to identify potential participants, based on job titles, tasks, and reported sources of RF exposure. Personal full-shift measurements were conducted using 10 Narda RadMan 2XT personal measurement devices.

RESULTS: Personal full-shift measurements were collected for 285 workers of various occupations in Spain. Exposures to electric (E) and magnetic (H) fields were low (99.74% of (E-fields) measurements <1% ICNIRP standards). Results exceeded the ICNIRP limits for only 3% of the workers, though these exceedances lasted a few seconds. Overall, almost 50% of workers had values above 1% of the ICNIRP standards (exposure duration between 1 second and 27.13 minutes). Electric and magnetic fields peaks exceeding 100% of the standards were observed among 8% of the physiotherapists (N=59) and 7% of the nursing auxiliaries (N=28), with exposure durations ranging from 1 to 13 seconds (E-fields) and 2 to 36 seconds (H-fields) of exposure above the limits, respectively.

CONCLUSIONS: We performed the first phase of data collection of personal RF-EMF measurements among various occupations in Spain in the framework of an international study. The initial results in Spain showed low prevalence and low overall levels of exposure to RF fields, despite some short-term peaks. Additional measurements will be conducted in France and the Netherlands.

P-0857 Assessing environmental exposure and socioeconomic history prior to cancer diagnosis

Bian Liu[1,2], Furrina Lee[3], Li Niu[2], Francis Boscoe[3,4]

[1]Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [3]Bureau of Cancer Epidemiology, Division of Chronic Disease Prevention, New York State Department of Health, Menands, USA, [4]Pumphandle, LLC, Portland, USA

BACKGROUND AND AIM Exposure assessment solely based on the address at cancer diagnosis assumes fixed exposure over time, while ignoring exposures from other addresses prior to cancer diagnosis. We aim to examine excess exposure risks of non-asbestos air toxics and socioeconomic status (SES) estimated over available residential history for mesothelioma patients.

METHODS: Patients' residential histories were obtained by linking mesothelioma cases (n=1,015) diagnosed during 2011-2015 from the New York State Cancer Registry to LexisNexis administrative data and inpatient claims data. Percentile ranking of lifetime cancer risk from inhalation of non-asbestos air toxics was based on the National Air Toxic Assessment. SES was measured by Yost index, which is a percentile ranking derived from U.S. Census data. Excess exposure risk was calculated by dividing exposures at individual census tracts by the state-level average and subtracting one. We used a generalized linear regression model with the generalized estimating equation to compare the excess exposure risk in years prior to and at cancer diagnosis.

RESULTS: Approximately 43% of the study sample had a residential history prior to the cancer diagnosis for up to 30 years, and 94% up to 5 years. The excess exposure risks at the cancer-diagnosis tracts were below the state average, with means ranging from -0.22 to -0.11 for air toxics, and from -0.23 to -0.18 for SES. Excess exposure risks for both air toxics and SES tended to be higher in earlier addresses than addresses at cancer diagnosis, though the effect size was relatively small (1%-6.2%).

CONCLUSIONS:We demonstrated the feasibility of including residential history in cancer research and revealed differences between multiple approaches of estimating residence-related exposure risks over time. As the findings may be unique to the mesothelioma patients studied, future examinations using different exposure indicators and among different patient populations and other cancer types are needed.

P-0864 Influence of Environmental and Dietary Exposures on Trace Metals and Organochlorine Pollutants Accumulation Among the Residents of a Major Industrial Harbour (Fos-sur-Mer, France)

Maxime Jeanjean[1], Sylvaine Goix[1], Marine Periot[1], Julien Dron[1], Marie−Pierre Etienne[2], Renaud Persoons[3], Philippe Marchand[4], Annabelle Austruy[1], Gautier Revenko[1], Philippe Chamarret[1]

[1]Institut Écocitoyen Pour la Connaissance Des Pollutions, Fos-sur-mer, France, [2]University of Rennes, Agrocampus Ouest, CNRS, UMR 6625 IRMAR, Rennes, France, [3]University of Grenoble Alpes, CNRS, Grenoble INP, CHU Grenoble Alpes, TIMC, Grenoble, France, [4]LABERCA, Oniris, INRAE, Nantes, France

BACKGROUND AND AIM. – We investigated whether residents who lived closer to the core of one of the largest industrial zone in Europe (Fos-sur-Mer, France) had higher serum or urine levels of trace metals (Antimony, Arsenic, Cadmium, Chromium, Cobalt, Mercury, Nickel, Lead and Vanadium) and organochlorine indicators (NDL-PCBs, DL-PCBs and PCDD/Fs) than people who lived out of the industrial core zone (Saint-Martin-de-Crau, France).

METHODS: –The INDEX cross-sectional study was conducted from September to November 2016. We collected blood samples from 138 people (80 in the exposed area and 58 in the control area), which were included using a stratified random sampling method and selected with strict criteria (e.g., 30–65 years old, living in the area for at least 3 years, not working in the industrial sector, non-smoker). Biomonitoring indicators were calculated using single-pollutant multivariate linear regression models (using substitution when censored data were under 15% and Tobit models alternatively), adjusting for personal physiological, social, dietary, housing characteristics and leisure activities. We also measured these pollutants in samples of lichens (Xanthoria parietina) and atmospheric particles (PM2.5).

RESULTS: – Living close to the core industrial zone was significantly associated with an increase in blood levels of lead (adjusted geometric mean = 17.2 [15.8-18.7] vs 15.1 [13.7–16.7] µg.g-1 creatinine, $p<0.05$). We reported that behaviours that involved environmental exposures (i.e., gardening, dietary history of consumption of vegetables, eggs, poultry, and local seafood) were significantly associated with an increase in some organochlorine and trace metals urine/serum levels amongst residents of the industrial port zone compared to the residents of the control area.

CONCLUSIONS: - These results brought interesting clues, in complement to national programs, regarding the exposure to trace metals of residents living in a major industrial european harbor.

KEYWORDS: - Industrial pollution - Biomonitoring - Heavy metals - PCBs – Dioxines - Dietary habits

P-0867 Urinary Creatinine Concentrations and Its Explanatory Variables in General Chinese Population: Implications for Creatinine Limits and Creatinine Adjustment

Miss. Saisai Ji[1], Yuebin Lv[1], Yingli Qu[1], Xiaojian Hu[1], Yifu Lu[1], Junfang Cai[1], Shixun Song[1], Xu Zhang[1], Yingchun Liu[1], Yanwei Yang[1], Wenli Zhang[1], Yawei Li[1], Miss. Mingyuan Zhang[2], Chen Chen[1], Chengcheng Li[1], Zheng Li[1], Heng Gu[1], Ling Liu[1], Jiayi Cai[1], Miss. Tian Qiu[1], Hui Fu[1], John Ji[3], Feng Zhao[1], Ying Zhu[1], Zhaojin Cao[1], Saisai Ji[1]

[1]National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]School of Public Health, Jilin University, Jilin, China, [3]Vanke School of Public Health, Tsinghua University, Beijing, China

BACKGROUND AND AIM Urinary creatinine (Ucr) is commonly used to determine the acceptability of spot urines and to adjust for dilution variation of spot urine specimens. However, some controversy exists over the creatinine limits (0.3–3.0 g/L) recommend by WHO. Ucr concentrations variy across individuals and are affected by numerous factors, which may complicate epidemiologic associations related to chemical-to-creatinine ratios. An improved understanding of the variation and predictors of Ucr concentrations is necessary. The study aimed to analyze the applicability of the WHO's exclusionary guidelines in the general Chinese population, and to identify Ucr related factors.

METHODS: The cross-sectional study included 21,167 participants aged 3 to 79 years from the initial cycle of the China National Human Biomonitoring Program. We used mixed linear models and restricted cubic splines (RCS) to analyze associations between explanatory variables with Ucr.

RESULTS: In general Chinese population, the geometric mean and median concentrations of Ucr were 0.90 g/L and 1.01 g/L, respectively. 9.36% samples were outside 0.3-3.0 g/L, including 7.83% below the lower limit and 1.53% above the upper limit. Middle age, male, obesity, smoking, higher frequency of red meat consumption and chronic kidney disease were significantly associated with higher concentrations of Ucr. Results of RCS showed Ucr was inversely and linearly associated with BMI, systolic blood pressure, diastolic blood pressure, triglycerides and glomerular filtration rate, and were non-linearly associated with triiodothyronine.

CONCLUSIONS:The age- and sex-specific cut off values of Ucr determining the validity of urine samples in general Chinese population were recommended. To avoid introducing bias into epidemiologic associations, potential predictors of Ucr observed in the present study should be considered when choosing correction methods.

[1]Health public and Medecine,Official University of Mbujimayi and Regional Research and Medical Benefit, Mbujimayi, Congo-Kinshasa (The Democratic Republic of the Congo), [2]Toxicology and Environment Unit, Department of Public Health, Faculty of Medicine, University of Lubumbashi, Lubumbashi, DR Congo, Lubumbashi, Congo-Kinshasa (The Democratic Republic of the Congo), [3]Higher Institute of Medical Techniques Lubumbashi (ISTM), Lubumbashi, Congo-Kinshasa (The Democratic Republic of the Congo), [4]Department of Public Health and Primary Care, Leuven, KU Leuven, Leuven, Belgium, [5]Catholic University of Leuven, Brussels Leuven, Leuven, Belgium

BACKGROUND: In July2021, the Tshikapa river became heavily polluted by mining wastes from a diamond mine in neighboring Angola, leading to massive killing of fish, disease and even deaths among residents living along the Tshikapa and Kasai rivers. The exact nature of the pollutants was unknown.

METHODS: In a cross-sectional study, conducted in the city of Tshikapa in August 2021, we enrolled by opportunistic sampling 65 residents (11 children <16y) living alongside the polluted rivers, and 65 control residents (5 children) living alongside the Kasai river upstream from the Tshikapa-Kasai confluence. We administered a questionnaire and obtained river water and spot urine samples for measuring thiocyanate (a metabolite of cyanide) and 26 trace metals (by ICP-MS).

RESULTS: Participants from both groups consumed river water. In the area affected by the pollution, most participants had eaten dead fish. Prevalences of reported health symptoms were higher in the exposed group than among controls: skin rashes (52% vs 0%), diarrhea (40% vs 8%), abdominal pain (8% vs 3%), nausea (3% vs 0%). In polluted water, concentrations [median (range)] were only higher for nickel [(2.2(1.4–3.5)µg/L] and uranium [78(71–91)ng/L] than in non-polluted water [0.8(0.6–1.9)µg/L; 9(7–19)ng/L]. In urine, concentrations [µg/g creatinine, median(IQR)] were significantly higher in the exposed group than in controls for lithium [19.5(12.4–27.3) vs 6.9(5.9–12.1)], thallium [0.41(0.31–0.57) vs 0.19(0.16–0.39)], and uranium [0.026(0.013–0.037)] vs 0.012(0.006–0.024)]. Urinary thiocyanate concentrations did not differ.

CONCLUSION. This study after an ecological disaster in DR Congo has documented contamination of river water by nickel and uranium, and high urinary levels of some trace metals among affected riverine populations. However, the exact cause of the massive fish kill and disease among residents remains elusive. The capacity to rapidly investigate toxic pollution events must be increased in the area.

P-0874 An ecological analysis of the association between industrial air pollution and asthma onset in children of Quebec, Canada

Ying Liu[1], Marianne Hatzopoulou[2], Jad Zalzal[2], Sham Gamage[2], Shoma Yamanouchi[2], Sara Torbatian[2], Ling Liu[3], Michel Fournier[4], Elhadji Anassour Laouan Sidi[5], Stéphane Buteau[6], Audrey Smargiassi[1]

[1]Department of Environmental and Occupational Health, School of Public Health, University of Montreal, Montreal, Canada, [2]Department of Civil & Mineral Engineering, University of Toronto, Toronto, Canada, [3]Environmental Health Science and Research Bureau, Health Canada, Ottawa, Canada, [4]Montreal Department of Public Health, Montreal, Canada, [5]Institut National de Santé Uublique du Québec, Quebec City, Canada, [6]Institut National de Sante Publique du Quebec, Montreal, Canada

BACKGROUND AND AIM: Asthma is the most prevalent respiratory disease in children worldwide. During the past decades, industrial emissions decreased dramatically in Canada. However, whether these decreases contributed to the decrease in asthma cases is still unclear. The aim of this study was to assess the associations between the changes in concentrations of industrial PM2.5, NO2, and SO2 emissions and the changes in asthma onset in children (<12 years) in Quebec, Canada with an ecological longitudinal design.

METHODS: Within 1310 small geographic sectors of Québec, yearly new cases of asthma in children were compiled from linked medico-administrative databases. The annual ambient concentrations of PM2.5, NO2, and SO2 related to industrial emissions from overall sectors for 2002 to 2015 were estimated by the POLAIR3D chemical transport model. Fixed-effects regression models were used to assess the associations between the time trend of industrial air pollution levels and the time trend of rates of asthma onset within the small areas, adjusting for median annual household income. Environmental tobacco smoke was additionally adjusted in sensitivity analyses.

RESULTS: The pollutant levels from industrial emissions per small area ranged from 0 to 12.91 µg/m3 for PM2.5, 0 to 28.63 ppb for NO2, and 0 to 494.34 ppb for SO2, respectively. The adjusted incidence rate ratios per 1 µg/m3 increase in PM2.5 and per 1 ppb increase in NO2 and SO2, were 1.045 (95% CI: 1.016 - 1.075), 1.045 (1.032 - 1.060), and 1.006 (1.004 - 1.07), respectively.

CONCLUSIONS: Industrial emission-related air pollutions were significantly associated with childhood asthma onset in Quebec. Since significant reductions in industrial emissions of air pollutants and asthma incidence have been observed in Quebec over the past two decades, our results suggest that the reduced industrial emissions may have contributed to the decreased asthma onset rate.

P-0877 Predicting Monthly Community-level Radon Concentrations with Spatiotemporal Random Forest METHOD: a Study in Northeastern and Midwestern USA

Longxiang Li[1], Petros Koutrakis[1]
[1]*Department of Environmental Health, Harvard T.H Chan School of Public Health, Boston, USA*

BACKGROUND AND AIM: Exposure to radon gas is the lead cause of lung cancers in never-smokers in the USA. Studies associating radon to other health outcomes have reported conflicted results, likely due to the inaccurate exposure assessments. Most previous radon-related epidemiological studies relied on an out-of-date county-level exposure model without temporal variation, which introduced misclassifications. Tens of millions of radon measurements have been conducted in the U.S, therefore enabling us to estimate radon concentrations at higher resolutions with better accuracy.

METHODS: We obtained over four million radon measurements from Spruce Environmental Technologies, Inc, a leading radon detector manufacturer. Community-level monthly radon concentrations were predicted based on geological, architectural, meteorological, and socioeconomic factors. Our innovative spatiotemporal random forest method extended the original one by allowing the relation between radon and its predictors to vary across space and time. Specifically, we fitted an independent model for each ZCTA and month based on the nearby radon measurements that are defined by the spatiotemporal proximity. The abundance of measurements enabled us to predict concentrations in the basement and upstairs respectively.

RESULTS: In Northeastern and Midwestern U.S, the average radon concentrations are 81.8 Bq/m3 in the basement and 50.7 Bq/m3 in the upstairs. The correlation (R2) between the predicted and observed geometric mean of radon concentrations is 0.77 in the basement and 0.57 in the upstairs if there are over 10 radon measurements in the same ZCTA and month. The mean absolute error (MAE) and mean relative error (MRE) are 19.7 Bq/m3 and 14.3% without obvious spatial trends.

CONCLUSIONS: Our predicted radon concentrations are highly correlated with the observed levels, therefore can be used in epidemiological studies to reduce misclassifications. The temporal variation characterized in our model will facilitate studies regarding the acute effects of radon.

P-0879 A National Comparison Between Short- and Long-term Radon Measurements in the USA

Longxiang Li[1], Brent Coull[1,2], Petros Koutrakis[1]
[1]Department of Environmental Health, Harvard T H Chan School of Public Health, Boston, USA, [2]Biostatistics Department, Harvard T H Chan School of Public Health, Boston, USA

BACKGROUND AND AIM: Understanding the spatiotemporal distribution of radon is essential to assess residential radon exposure. Long-term radon measurements that last over 90 days are considered gold standard to assess residential exposure but were conducted in a limited quantity due to the long duration. Tens of millions of short-term radon measurements, which normally last 2 to 4 days, have been conducted in the past decades because radon disclosures are required during property transaction in 35 out of 48 contiguous states. However, the application of these massive short-term measurements is limited likely because of the unknown real-life uncertainty.

METHODS: We therefore collected 2,450 pairs of collocated short- and long-term measurements, evaluated the pairwise correlation between them, and investigated the factors that determine the correlation between them via stratified linear regression and bootstrapping resampling.

RESULTS: We found that the pairwise correlation between the short- and long-term radon measurements is a joint function of two factors: the temporal difference between two measurements and the measuring length of the following long-term measurements. The correlation was as high as 0.76 (0.95 Confidence Interval [CI]: 0.70 to 0.84) when the temporal difference was shorter than two weeks and the length of long-term measurement was shorter than 100 days. Meanwhile, the correlation can be as low as 0.13 (0.95 CI: 0.09 to 0.32) when the temporal difference was over two months, and the length was close to a calendar year.

CONCLUSIONS: The high correlations indicates that short-term measurements can be used as a reliable proxy to a long-term measurement under specific conditions after adjusting for inherent differences. Our conclusion will facilitate the usage of this abundant data source, which has been obtained but was underutilized, thus likely enhancing our knowledge regarding other health effects associated with radon.

P-0883 Case-crossover study between PM2.5 and hospital admissions for respiratory diseases in Pretoria

Chantelle Howlett-Downing[1], Joyce Shirinde[1], Janine Wichmannn[1]
[1]*University of Pretoria, Pretoria, South Africa*

BACKGROUND: Particulate matter air pollution has been associated with adverse health effects. Air pollution epidemiology traditionally focuses on the relationship between individual air pollutants and health outcomes (e.g., mortality). To account for potential co-pollutant confounding, individual pollutant associations are often estimated by adjusting or controlling for other pollutants in the mixture. The objective of the study is control for components within the mixture which are highly correlated.
METHOD: An overall study is performed where PM2.5, BC, UV-PM and trace elements were controlled for Tapp and public holidays, stratified for age and sex. A second model, where PM2.5 is also controlled, was performed.

RESULTS: In total, there were 15 155 reported hospitalisations for respiratory diseases (J00-J99) over the 34-month period. The increase in respiratory hospital admissions was significantly increased by an increase in total PM2.5 of 2.7% (95% CI: 0.6, 4.9) per 10 µg/m3 increase. respiratory hospital admissions significantly increased for Ca by 4.0 % (95% CI: 1.4% - 6.8%), Cl by 0.7 % (95% CI: 0.0% - 1.4%), Fe by 3.3 % (95% CI: 0.5% - 6.1%), K by 1.8% (95% CI: 0.2 – 3.5) and Si by 1.3 % (95% CI: 0.1% - 2.5%). When controlling for PM2.5, respiratory hospital admissions increased significantly for total Ca by 3.2 % (95% CI: 0.3, 6.1) and for the 0 – 14 age group by 5.2 % (95% CI: 1.5, 9.1). Hospital admissions was positive and significantly increased with an increase in resuspended dust matrix by 2.9 % (95% CI: 0.1% - 5.7%) and for biofuel burning by 1.6 % (95% CI: 0.1% - 3.2%) sources.

CONCLUSIONS: Controlling for a co-pollutant which is highly correlated with PM2.5 does reduce overestimation, but further studies should include deposition rates and parallel sampling analysis.

P-0896 Intrauterine exposure to phthalates in pregnant women, Colombia

Carlos Alberto Gómez-Mercado[1], AK Sakhi[2], Thomsen Cathrine[2], Valvi Damaskini[3], CM Arango-Álzate[1], AM Segura-Cardona[1], A Barraza-Villareal[4], L Acevedo-Saenz[5], G Mejía- Sandoval[6]
[1]CES University, Graduate School, Medellín, Colombia, [2]Norwegian Institute of Public Health, Oslo, Norway, [3]Icahn School of Medicine at Mount Sinai, New York, EEUU, [4]National Institute of Health of Mexico, Cuernavaca, Mexico, [5]CES University, Faculty of Nursing, Medellin, Colombia, [6]CES University, MVZ Faculty, Medellin, Colombia

INTRODUCTION: Phthalates are endocrine disruptors used in the manufacture of multiple industrial products, mainly plastics. Intrauterine life represents the main window of vulnerability and exposure to phthalates in this stage of life generates adverse fetal and postnatal effects (1). The most reliable biomarker for phthalate measurement is urine.
OBJECTIVE: To characterize the different sources of exposure to endocrine disruptors and to quantify the urinary concentration of phthalates in pregnant women.

METHODS: 400 women ≤12 weeks pregnant were included at baseline, and of these 38 pools of urine (20 spot samples) were analyzed for phthalate metabolites, analysis was performed at the Norwegian Institute of Public Health (NIPH) (2), analyzes were corrected for specific gravity and descriptive statistics are presented.

RESULTS: The geometric means of phthalate Di(2-ethylhexyl)phthalate(DEHP), Mono-n-butyl phthalate(MnBP), Mono-2-ethyl-5-hydroxyhexyl phthalate(MEHHP), and Mono-2-ethyl-5- oxohexyl phthalate(MEOHP) were 162.72 µg/L, 58.50 µg/L, 33.93 µg/L and 31.63 µg/L, respectively.

CONCLUSIONS: it is the first study that quantifies phthalate metabolites in Colombia. Concentrations of MnBP, MEHHP, and MEOHP in urine are higher than those found in pregnant women around the world.

P-0898 Occupational Exposure to Diesel Exhaust in Bus Drivers in the New York Metropolitan Area

Hsiao-Hsien Hsu[1], MPH Demetrios Papazaharias[1], JD, MA, SM Lynn Onyebeke[1], MSPH CIH Alice Freund[1], MS Norman Zuckerman[1], BA Mathew Pendo[2], Luz Claudio[1], Roberto Lucchini[2], Yueh-Hsiu Mathilda Chiu[1]
[1]Icahn School of Medicine at Mount Sinai, New York, USA, [2]Florida International University, Miami, USA

BACKGROUND AND AIM: Exposure to diesel exhaust (DE) has been associated with adverse respiratory health outcomes and bus drivers could be at significant risk. We leveraged exposure data collected from real-time personal monitoring and geospatial location information to identify the factors influencing DE exposure in New York bus drivers.

METHODS: DE exposure was estimated via black carbon (BC; a component of DE) measurements recorded using a micro-Aethalometer (microAeth®Model-AE51) every minute over six 24-hour periods in four bus drivers during September-October 2014. Driving routes originated from two Westchester bus depots and traversed lower Westchester. Each driver's location was continuously recorded every minute using a global positioning system (GPS) device. Information on fuel type, smoking status, worker activities, and meteorological variables were collected. Road density indices were calculated based on an 100-meter buffer. We performed multivariable-adjusted regression models to assess the factors associated with BC levels.

RESULTS: BC data were collected for a total of 2682 working minutes and 4328 non-working minutes. Overall median BC level was 578 ng/m3 (IQR: 189-1487 ng/m3) [working hours: 1166 (612-2168) ng/m3; non-working hours: 351 (132-860) ng/m3]. Multivariable-adjusted models predicted that compared to times working in office, workers were on average exposed to an additional 1403.5 ng/m3 and 2150.4 ng/m3 of BC when they were in the depot yard and driving the bus, respectively. Driving a diesel-powered vehicle was associated with 2.7-fold increase in BC levels compared to gasoline-powered. for every 10% increase in the sum of road length index, BC level increased by 19% (95%CI=15-24%). Further, for every 10% increase in average speed, BC level increased by 20% (95%CI=17-23%).

CONCLUSIONS: Driving a diesel-powered vehicle presented significantly more BC exposure comparing to gasoline-powered vehicle. Roadway density and driving speed contributed to elevated BC levels.

P-0912 Health Benefit of PM2.5 Control Legislations in Korea

Eunjin Oh[1], Soontae Kim[2], Ho-Jang Kwon[3], Sanghyuk Bae[4]
[1]The Catholic University, Seoul, Republic of Korea, [2]The Ajou University, Suwon, Republic of Korea, [3]The Dankook University, Cheonan, Republic of Korea, [4]The Catholic University, Seoul, Republic of Korea

BACKGROUND AND AIM: Exposure to PM2.5 has been associated with increased mortality. The aim of the present study was to evaluate the health benefit of policies to reduce air pollution.

METHODS: We selected three air pollution control policies that were implemented between 2006 and 2018 in Seoul and Incheon, Korea. We estimated three types of impacts to evaluate the benefit of each policy. These impacts are benefit from reduced PM2.5 concentration (Impact 1), benefit from reduced magnitude of association (Impact 2) and reduced both concentration and magnitude of association (Impact 3). We conducted interrupted time series analyses to examine changes in PM2.5 concentration and magnitude of association with mortality after the implementation of the policies. We calculated the health benefit accounting for reduced daily PM2.5 concentration and its association with mortality.

RESULTS: We observed a decrease of PM2.5 concentrations after interventions in Seoul and Incheon. The effect of policy on associations between PM2.5 and mortality were different from intervention to intervention, but the magnitude of association in Seoul continued to decline. The numbers of prevented deaths in Seoul in one year after the implementation of each policy were 252 (95% CI: 221, 293), 365 (95% CI: 24, 432) and 120 (95% CI: 0, 262), respectively. In Incheon, the numbers of prevented deaths were 68 (95% CI: 0, 197), 167 (95% CI: 0, 184) and 149 (95% CI: 0, 298), respectively.

CONCLUSIONS: The present results suggests that air pollution control policies in Seoul and Incheon were effective in terms of preventing mortality.

KEYWORDS: mortality, health impact assessment, policy, particulate matter, attributable deaths

P-0913 Association of sound pressure levels and frequency components of road traffic noise with prevalent depression in Taichung, Taiwan

Jia Yi Lin[1], Wan Ju Cheng[2], Chang Fu Wu[3], Jia-Yi Lin[4]

[1]China Medical University, Taichung City, Taiwan, [2]China Medical University Hospital, Taichung City, Taiwan, [3]National Taiwan University, Taipei City, Taiwan, [4]China Medical University, Taichung City, Taiwan

The World Health Organization has reported that the prevalence of mental illness is 4% in the global population. Epidemiological studies have reported a relationship between road traffic noise exposure and depression, but the association between noise frequency components and depression remains unclear. This cross-sectional study investigated the associations between road traffic noise exposure and its frequency components with prevalent depression. A total of 3,200 residents living in Taichung who participated in the Taiwan Biobank between 2010 and 2017, were included as study participants. We used land-use regression models to evaluate individual annual average values of A-weighted equivalent sound level over 24 h (Leq,24h) and particulate matter with an aerodynamic diameter less than 2.5 μm (PM2.5) using the geographic information system. Multiple logistic regression was applied to estimate the odds ratios (ORs) for depression after adjusting for potential risk factors and PM2.5. An interquartile range increase in Leq,24h at full frequency (4.7 dBA), 1000 Hz (5.2 dB), and 2000 Hz (4.8 dB) was significantly associated with an elevated risk for depression with ORs of 1.62 (95% confidence interval [CI]: 1.03, 2.55), 1.58 (95% CI: 1.05, 2.37), and 1.58 (95% CI:1.03, 2.43), respectively, by controlling for PM2.5. The high-exposure group (≥ the median of noise levels) at full frequency, 500 Hz, and 2000 Hz had an increased risk for depression with ORs of 1.87 (95% CI: 1.03, 3.39), 1.94 (95% CI: 1.03, 3.65), and 1.86 (95% CI: 1.03, 3.37), respectively, compared with the low-exposure group (< the median of noise levels) after adjustment for PM2.5. Road traffic noise exposure may be associated with an increased prevalence of depression, particularly at 500 to 2000 Hz.

P-0917 Multiple xenoestrogen air pollutants and breast cancer risk: statistical approaches to investigate the combined exposures effect

Amina Amadou[1,2], Fabiola Ngaleu[1,2], Delphine Praud[1,2], Thomas Coudon[1,2], Camille Giampiccolo[1,6,7,8], Lény Grassot[1,2], Elodie Faure[3], Florian Couvidat[4], Julien Caudeville[4], Gianluca Severi[3,5], Francesca Romana Mancini[3], Pr Pascal Roy[6,7,8], Pr Béatrice Fervers[1,2]

[1]Department of Prevention Cancer Environment, Centre Léon Bérard, Lyon, France, [2]Inserm U1296 Unit, «Radiation: Defense, Health and Environment», Lyon, France, [3]Université Paris-Saclay, UVSQ, Inserm U1018, CESP, "Exposome Heredity, Cancer and Health", Gustave Roussy, Villejuif, France, [4]National Institute for industrial Environment and Risks (INERIS), Verneuil-en-Halatte, France, [5]Department of Statistics, Computer Science and Applications (DISIA), University of Florence, Florence, Italy, [6]Service de Biostatistique–Bioinformatique, Pole Sante Publique, Hospices Civils de Lyon, Lyon, France, [7]Laboratoire de Biometrie Et Biologie Evolutive, CNRS UMR 5558, Villeurbanne, France, [8]Université Claude Bernard Lyon 1, Lyon, France

BACKGROUND AND AIM: Despite that the population is exposed to a mixture of multiple air pollutants, the joint effect of these pollutants on breast cancer (BC) has never been investigated. We applied two new statistical approaches to assess the complex effect of exposure to a mixture of four xenoestrogen air pollutants (Benzo-[a]-pyrene (BaP), cadmium, dioxins, Polychlorinated Biphenyl 153(PCB153)) on the risk of BC.

METHODS: The study was conducted on 5,222 cases and 5,222 matched controls nested within the French national E3N cohort. Annual estimates of exposures to pollutants at participants' addresses for each year from recruitment 1990 through 2011, were assessed using a chemistry transport model. Mean annual concentrations for each pollutant was then estimated from inclusion in the study to the index date. We fitted the bayesian kernel machine regression (BKMR) and the weighted quantile sum (WQS) regression models to estimate the risk of BC associated with the joint effect of co-exposure of four xenoestrogens air pollutants.

RESULTS: In BKMR, despite the no statistically significant association, there was an increasing trend between the joint effect and the risk of BC, when fixing other chemicals at their median concentrations. BaP, cadmium and PCB153 showed positive trends in the multi-pollutant mixture, while dioxin showed a modest inverse trend. In WQS, there was a borderline positive association between the WQS index of the joint effect and the risk of BC (odds ratio (OR)=1.06, 95% confidence intervals (CI):0.99-1.10). By menopausal status, there was a differential joint effect, with a significant positive association observed only in women who underwent menopausal transition (OR=1.09, 95% CI:1.02-1.14)

CONCLUSIONS: Overall, although no clear association was observed with BKMR model, there was a tendency of an increased risk of BC associated with co-exposure to long-term xenoestrogens air pollutants using both approaches. Further studies are needed to confirm these findings.

P-0921 Estimating attributable deaths from short-term pollution effects: Differential air pollution impact on cause-specific mortality

Ariel Spira-Cohen[1], Rebecca Goldberg[1], Sarah Johnson[1], Masha Pitiranggon[1], Kazuhiki Ito[1]
[1]*New York City Dept. of Health and Mental Hygiene, New York, USA*

BACKGROUND AND AIM: Health impact assessment (HIA) is a common policy tool that quantifies health burden from air pollution under different policy scenarios. Most HIAs consider all-natural-cause deaths from single-pollutant models, leaving uncertainty about varying impacts on cause-specific mortality from multiple air pollutants.

METHODS: Daily city-wide average air pollution concentrations were collected from the Environmental Protection Agency's Air Quality System and mortality records (2005-2019) from New York City (NYC) Vital Statistics. Total cumulative pollution attributable fractions (AFs) and annual average attributable counts (ACs) of mortality were estimated from single- and co-pollutant quasi-Poisson distributed lag time-series models at one lag day. Three mortality outcomes were evaluated: all-natural-cause, cardiovascular (CVD), and respiratory. Full year and seasonal models, adjusting for temperature and seasonal trends, were fit for sulfur dioxide (SO_2), nitrogen dioxide (NO_2), ozone, fine particulate matter ($PM_{2.5}$), and carbon monoxide (CO).

RESULTS: Across all pollutants, outcomes, and seasons, single-pollutant models showed positive associations, although cold-season models generally had lower AFs and larger confidence bands. for all-natural-cause mortality, NO_2 AF from the full-year, single-pollutant model was 1.4% (95% CI: 0.6%, 2.3%) representing the largest pollution AC, about 660 deaths annually, which did not change when additional pollutants were added to the model. CVD full-year model of $PM_{2.5}$ was robust to addition of NO_2, contributing about 250 deaths annually: 1.2% AF (0.5%, 1.9%). for respiratory mortality, warm-season NO_2 AF was 4% (-0.4%, 7.9%) and robust in co-pollutant models with $PM_{2.5}$ and NO_2, but not ozone. Warm-season ozone AF was 8.1% (2.9%, 13%), representing about 125 respiratory deaths annually.

CONCLUSIONS: Concentration-response functions used to quantify health burden based on air pollution attributable all-natural-cause deaths must consider short-term NO_2 associations in NYC. Cause-specific associations differ from those for all-natural-cause deaths, with $PM_{2.5}$ more important for CVD deaths and ozone for respiratory deaths.

P-0922 Chronic exposure to ambient air pollution and the risk of non-alcoholic fatty liver disease: A cross-sectional study in Asia

Yacong Bo[1], Changqing Lin[2], Cui Guo[3], Bo Huang[4], Martin Wong[3], Alexis Lau[2], Yu Huang[5], Xiang Qian Lao[3]
[1]School of Public Health, Zhengzhou University, Zhengzhou, China, [2]The Hong Kong University of Science and Technology, Hong Kong, Hong Kong, [3]School of Public Health, The Chinese University of Hong Kong, Hong Kong, China, [4]Department of Geography and Resource Management, The Chinese University of Hong Kong, Hong Kong, China, [5]City University of Hong Kong, Hong Kong, China

BACKGROUND AND AIM: Information on the relation between air pollution and non-alcoholic fatty liver disease (NAFLD) is scarce. We conducted a population-based cross-sectional study to evaluate the relationship between air pollution and NAFLD.

METHODS: We recruited 329,048 adults (mean age: 41.0 years) without other liver disease (hepatitis and cirrhosis) or excessive alcohol consumption in Taiwan and Hong Kong from 2001 to 2018. The levels of PM2.5 were estimated using a satellite-based spatio-temporal model, and the concentrations of NO2 and O3 were measured using a space–time regression model. NAFLD was determined using the hepatic steatosis index (HSI) or the fatty liver index (FLI). NAFLD-related advanced fibrosis was determined using fibrosis-4 (FIB-4) or the BARD score. A logistic regression model was used for data analysis.

RESULTS: We found positive relationships between PM2.5 and the odds of NAFLD and NAFLD-related advanced fibrosis, with a 10% (95% confidence interval [CI]: 9%–11%) increase in the prevalence of NAFLD and an 8% (95% CI: 7%–9%) increase in the prevalence of advanced fibrosis for every standard deviation (SD, 7.5 μg/m3) increase in PM2.5 exposure. Similarly, every SD (18.9 μg/m3) increase in NO2 concentration was associated with 8% (95% CI: 7%–9%) and 7% (95% CI: 6%–8%) increases in the prevalence of NAFLD and NAFLD-related advanced fibrosis, respectively. In addition, every SD (9.9 μg/m3) increase in O3 concentration was associated with 12% (95% CI: 11%–13%) and 11% (95% CI: 9%–12%) decreases in the prevalence of NAFLD and advanced fibrosis, respectively.

CONCLUSIONS: Long-term exposure to PM2.5 and NO2 is associated with higher odds of NAFLD and NAFLD-related fibrosis. Our findings indicate that reducing PM2.5 and NO2 concentrations may be an important strategy for preventing NAFLD. Further investigations on O3 are warranted.

KEYWORDS: PM2.5; NO2; ozone; non-alcoholic fatty liver disease; advanced fibrosis

P-0933 Interdisciplinary Community-based Participatory Health Research across a Major Industrial Harbour (Fos-sur-Mer, France)

Maxime Jeanjean[1], Johanna Lees[2], Barbara L. Allen[3], Alison K. Cohen[4]
[1]Institut Écocitoyen Pour la Connaissance Des Pollutions, Fos-sur-mer, France, [2]Centre Norbert Elias (UMR 8562), Laboratoire de sciences sociales appliquees, Marseille, France, [3]Department of Science, Technology and Society, Virginia Tech University, Falls church, USA, [4]University of California San Francisco, Department of Epidemiology & Biostatistics, San Francisco, USA

BACKGROUND AND AIM. – We conducted a community-based participatory environmental health study in three towns: two in the heart of Marseille's (France) industrial zone (Fos-sur-Mer and Port-Saint-Louis-du-Rhône) and one on the periphery located about 30 km away (Saint-Martin-de-Crau).

METHODS: – We first conducted a cross-sectional survey of a random sample of residents in each of the three towns. We asked study participants to self-report a wide variety of health issues (Port-Saint-Louis: n = 272, Fos-sur-Mer: n = 543, Saint-Martin-de-Crau: n = 439). We then conducted focus groups with residents and other stakeholders to share preliminary data in order to propose areas of reflection and collaboratively produce contextually-situated knowledge of their health and environment. We directly standardized the prevalences (by age and gender) to the French metropolitan population to make our results more comparable.

RESULTS: – Study participants who lived closer to the core industrial zone (residents of Fos-sur-Mer and Port-Saint-Louis-du-Rhone) had significant higher prevalences of eye irritation, nose and throat problems, chronic skin problems and headaches than people who lived further away (residents of Saint-Martin-de-Crau). Residents also offered diverse qualitative insights about their environment and health experiences, strengthening an understanding of their own empirical observations which helps to produce knowledge about health in an industrial context. The results of the workshops show an important benefit from the co-production of local knowledge.

CONCLUSIONS: – We encourage future researchers to do in-depth, community-based research to comprehensively describe the health of residents in other heavily polluted zones, product local knowledge and to help identify policy solutions, engender trust among the local people, and identify opportunities for intervention.

P-0934 Association between polycyclic aromatic hydrocarbon exposure and esophageal cancer risk in typical areas of China

Yifu Lu[1], Xiaoyan Dong[1], Jiayi Cai[1], Wenli Zhang[1]
[1]*China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China*

BACKGROUND: Studies of people show that individuals exposed by breathing, skin contact, or diet for long periods to polycyclic aromatic hydrocarbon (PAHs) can develop cancer, such as lung, skin, and bladder cancer. However, their effects on esophageal cancer have not been well examined.
AIM: This study is to compare the concentration of PAHs metabolite(OH-PAHs) in the urine of patients in the early stages of esophageal cancer and healthy people, and to evaluate the association between PAHs exposure and esophageal cancer risk.

METHODS: The 211 urine samples were collected from 105 esophageal cancer patients in the early stages and 106 healthy people in three high Incidence districts of esophageal cancer from November 2019 to June 2020. The 10 OH-PAHs (including 1-NAP, 2-NAP, 2-FLU,3-FLU,9-FLU,1-PHE,2-PHE, 3-PHE, 4-PHE,1-PYR) were analyzed with isotope dilution gas chromatography/tandem mass spectrometry (GC-MS/MS) based on CDC method.

RESULTS: The 10 OH-PAHs detection rate were relatively high more than 90%. 1-NAP and 2-NAP were the most abundant contributor to the total concentration of OH-PAHs.The mass concentration of OH-PAHs in the urine of healthy people was in the range of 1.5-44.6 μg/g, the median concentration of ∑OH-PAHs was 6.1 μg/g and the geometric mean concentration was 6.8 μg/g. ∑OH-PAHs concentration in the urine of esophageal cancer patients in the early stages was in the range of 3.6-104.2 μg/g, the median concentration of ∑OH-PAHs was 9.8 μg/g and the geometric mean concentration was 10.2 μg/g.

CONCLUSIONS: The results showed ∑OH-PAHs concentrations in urine from esophageal cancer patients in the early stages were higher than healthy people. The different habits and way of life, such as smoking and fried food, were increasing the PAHs exposure causing esophageal cancer risk.

P-0938 Cluster analysis of premature deaths attributable to PM2.5 in aging population, South Korea

Cham Nguyen Thi[1]

[1]*National Cancer Center, Graduate School of Cancer Science & Policy, Korea, Goyang, Republic of Korea*

BACKGROUND AND AIM: Health impact analysis for PM2.5 can display spatial heterogeneity of premature deaths attributable to PM2.5 and stands out as one of the best effective tools to present scientific evidence to guide policy actions. Subsequent spatial cluster analysis allows us to detect the areas with large burden and guide intervention programs to target such areas. We aimed to estimate the number of attributable deaths associated with PM2.5 exposure and identify the clustered areas with large attributable deaths compared to other areas in Korean aging population.

METHODS: We computed district-specific attributable deaths for lung cancer, chronic obstructive pneumonia disease, ischemic heart disease, and stroke each year for 2016 – 2019 using district averages of PM2.5 obtained from a previously-validated prediction model, district-level population aged 65 years and over, provincial-level mortality rate, and relative risks of cause-specific deaths for PM2.5. Then, we aggregated to total attributable deaths including all four causes in each of the 250 districts over four years. Finally, we applied spatial scan statistic with optimal size of elliptic shape window and identified the most significant cluster of high premature deaths.

RESULTS: Over four years, the total number of deaths attributable to PM2.5 was 49,449 out of 35,368,100 old adults in South Korea. The premature deaths attributable to PM2.5 were higher in the Northwest and Southeastern districts where population is relatively old. The cluster analysis showed the Southeastern districts as the significantly high mortality burden cluster attributed to PM2.5.

CONCLUSIONS: This study suggests that the cluster analysis can increase the benefit of the health impact analysis.

KEYWORDS: health impact assessments, cluster analysis, ambient air pollution, premature death

P-0939 NATURGREEN: Health impact assessment of greening Denver through native plants

Michael Garber[1], Michael Guidi[1], Jennifer Bousselot[1], Tarik Benmarhnia[2], David Rojas-Rueda[1]
[1]Colorado State University, Fort Collins, USA, [2]University of California San Diego, San Diego, USA

BACKGROUND: Cities often use exotic plants (e.g., turf grass and non-native trees) to expand green space to reduce micro-heat islands or promote physical activity. Native plants, however, may require less water, be more drought-tolerant, and have co-benefits for local biodiversity (e.g., pollinators). Epidemiologic studies suggest urban green space can improve human health and prevent premature mortality, but the benefits associated with this specific type of vegetation has received little attention.
AIM: We aim to estimate premature deaths that would be prevented by the implementation of native-plants policy scenarios in the City of Denver, Colorado, USA.

METHODS: To develop realistic native-plants policy scenarios, we conducted interviews with local stakeholders engaged in green-space advocacy, research, and policy in Denver. We build four scenarios: 1) greening a 20% of all city census-block groups to the greenness level of native plants, 2) adding 200-foot native-plants buffers around riparian areas, 3) constructing additional large water retention ponds landscaped with native plants, and 4) greening parking lots. We measured existing green space with satellite imagery and linked with census and land-use data. Using a health-impact assessment approach, we estimated premature mortality averted under each scenario.

RESULTS: In the most ambitious scenario, we estimated that 45 (95% confidence interval (CI): 42, 49) annual premature deaths would be prevented by greening 20% of all city census block groups with native plants. We estimated that greening 20% of parking-lot surface with native plants would prevent 8 annual deaths (95% CI: 7, 9), adding the native buffers around riparian areas would prevent 8 annual deaths (95% CI: 6, 9), and adding the planned native-landscaped stormwater retention ponds would prevent 1 annual death (95% CI: 1, 1).

CONCLUSIONS: Using native plants to increase green spaces has the potential to prevent substantial premature deaths in the City of Denver.

P-0941 Health risk assessment of PM2.5 and PM2.5-bound trace elements in Pretoria, South Africa

Chantelle Howlett-Downing[1], Joyce Shirinde[1], Janine Wichmannn[1]
[1]*University of Pretoria, Pretoria, South Africa*

BACKGROUND: The objective of the present study was to assess the human health risks associated with fine particulate matter (<PM2.5) and trace elemental constituents in Pretoria, South Africa.
METHOD: Outdoor ambient PM2.5 was sampled at the School of Health Systems and Public Health from 18 April 2017 to 28 February 2020. The health risk assessment method followed the USA Environmental Protection Agency's (US EPA) health risk assessment method. Reference doses for PM2.5 were taken from the World Health Organization (WHO) guidelines and the South African National Ambient Air Quality Standards (NAAQS).

RESULTS: The average yearly concentration for PM2.5 was 23.2 µg/m3 (N = 350) for the 34-month sampling campaign. This is above the yearly WHO guidelines (5 µg/m3) and the South African NAAQS (20 µg/m3). The monthly PM2.5 concentration is seasonal as is the concomitant Health Quotient (HQ). The calculated HQ for Adults, Children and Infants was above 1 when utilising both the WHO guidelines and the SA standard for ambient PM2.5. Children and Infants were three times higher at risk than adults throughout the year for summer and in winter for K and Si. Particle-bound Ni presented a cancer risk (CR) throughout the year.

CONCLUSIONS: It can be concluded that PM2.5 poses health risks in central Pretoria.

KEYWORDS: Air pollution, PM2.5, Seasons, Health Risk Assessment, South Africa, Trace elements

P-0943 Effects of hourly levels of ambient air pollution and the emergency department visits for asthma in Taiwan

Mu-Jean Chen[1], Pau Chung Chen[1], Yu Cheng Chen[1]
[1]*National Health Research Institutes, Miaoli County, Taiwan*

BACKGROUND AND AIM: Daily exposure to O_3, NO_2, and $PM_{2.5}$ is associated with asthma attacks. However, peak exposure (hourly) of such air pollution exacerbating asthma symptoms remains unknown.

METHODS: Daily emergency department visits (EDVs) of asthma from the National Health Insurance Research Database and hourly concentrations of O_3, $PM_{2.5}$, and NO_2 recorded at fixed-site monitoring stations in Taiwan from 2006 to 2016 were used. Excess risks (ERs) of asthma EDVs (ICD-10-CM: J45) at 0–2 lag days associated with daily maximum rolling 1-, 3-, 8-, and 24-hour concentrations of air pollutants were evaluated using the quasi-Poisson generalized additive models (GAMs). Models were stratified by warm and cold season and adjusted for townships, days of the week, and the smoothing splines as the year, temperature, and relative humidity at the same hours.

RESULTS: A total of 369,256 asthma EDVs in 50 townships of Taiwan from 2006 to 2016 were observed. The cold period (110 ± 125) had a higher average count of daily asthma EDV than the warm period (70 ± 90). Among air pollutants, there were positive associations between concentrations of all hourly pollutants and asthma EDVs, even in 1-hour exposure. Every a 10-unit increase in 1-hour exposure to $PM_{2.5}$ in warm (lag2) and O_3 in cold (lag2) increases the risks of daily asthma EDVs by 1.74% (95% CI, 1.43–2.04%) and 1.13% (95% CI, 0.83–1.44%), respectively. Exposure to 1-hour NO_2- in warm had the most significant effect (ER = 2.91%, 95% CI: 2.36–3.46%) on daily asthma EDVs. Then, all pollutants indicated that the 24-hour exposure was much more severe than 1-hour.

CONCLUSIONS: Short-term (1-hour) exposure to air pollutants is significantly associated with daily asthma EDVs. Hourly standard of air quality is suggested.

P-0946 The effectiveness of a text messaging intervention trial to reduce mercury contaminants and conserve healthy fish consumption in reproductive age Chicago Asian women

Mariam Oladosu[1], Susan Buchanan[2], Jing Zhang[2], Noel Chavez[3], Sally Freels[1], Kyeezu Kim[1], Mary Turyk[1]
[1]University of Illinois at Chicago, Division of Epidemiology and Biostatistics, Chicago, USA, [2]University of Illinois at Chicago, Division of Environmental and Occupational Health Sciences, Chicago, USA, [3]University of Illinois at Chicago, Division of Community Health Sciences, Chicago, USA

BACKGROUND AND AIM: Hg exposure during pregnancy can impact cognition, memory, attention, language, fine motor skills, and visual spatial skills in offspring. There is a high prevalence of elevated mercury (Hg) levels among Asian communities, attributable to frequent fish consumption. A controlled, cluster-randomized, 6-month intervention trial was conducted to decrease consumption of fish with moderate to high mercury levels and/or very frequent fish consumption and to reduce hair Hg levels.

METHODS: Reproductive age Asian women were recruited with the help of community organizations serving the Chinese, Vietnamese, and Korean communities in Chicago. The control group (n = 131) received general nutrition text messages, while the intervention group (n = 154) received text messages on risks and benefits of fish consumption, with advice tailored to the Chicago Asian communities based on a prior community assessment. Outcomes were hair Hg measurements and rates of fish consumption. Non-parametric tests compared treatment groups at baseline and six months and the effect of the intervention on outcomes was tested using longitudinal linear models with random effects for cluster.

RESULTS: Geometric mean hair mercury decreased 16% in the intervention group and increased 2% in the control group (p=0.04, Figure). In Chinese women, hair Hg decreased 9% in intervention and control groups, while in Korean women hair Hg decreased 27% in the intervention and increased 10% in the control group (p=0.04). The rate of ingestion of moderate and high mercury fish (g/day) decreased 50% in the intervention and 35% in the control group (p = 0.15).

CONCLUSIONS: Our findings suggest that in reproductive age Asian American women, a text messaging intervention providing information on healthy fish consumption and health risks of contaminated fish consumption decreased hair mercury levels, but efficacy differed by Asian ethnicity.

P-0952 The Association of Air Pollution and Serum Biomarker Abnormalities in Individuals with Hemodialysis-Dependent Kidney Failure

Yuzhi Xi[1,2,3], David Richardson[3], Abhijit Kshirsagar[4,5], Jennifer Flythe[4,5], Eric Whitsel[3,5], Timothy Wade[6], Ana Rappold[6]
[1]Emory University, Atlanta, USA, [2]Oak Ridge Institute for Science and Education at the USA Environmental Protection Agency, National Health and Environmental Effects Research Laboratory, Environmental Public Health Division, Research Triangle Park, USA, [3]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, USA, [4]University of North Carolina Kidney Center, Division of Nephrology and Hypertension, Department of Medicine, UNC School of Medicine, Chapel Hill, USA, [5]Department of Medicine, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, USA, [6]USA Environmental Protection Agency, Center for Public Health and Environmental Assessment, Public Health and Integrated Toxicology Division, Research Triangle Park, USA

BACKGROUND AND AIM: Ambient PM2.5 is a ubiquitous air pollutant with established adverse health consequences. While postulated to promote a systemic inflammatory response, few studies have demonstrated changes in serum biomarkers related to PM2.5 exposure. To examine associations between short-term PM2.5 exposure and commonly measured biomarkers known to be affected by inflammation among patients receiving maintenance in-center hemodialysis.

METHODS: We conducted a retrospective open cohort study from 1/1/2008 to 12/31/2014 among 173,697 cohort patients identified from the USA Renal Data System and linked at the patient level to laboratory data from a large dialysis organization. Daily ambient PM2.5 was estimated on a 1 km grid for the entire contiguous US and assigned to cohort patients based on the ZIP code of their dialysis clinics. Serum albumin, serum ferritin, transferrin saturation (TSAT), and serum hemoglobin were ascertained from the dialysis provider organization database. Mixed-effect models were used to assess the changes in biomarker concentrations associated with PM2.5 exposure.

RESULTS: Among study cohort, 50.3% patients were older than 65 years at the initiation of hemodialysis, 44% were female, and 62.8% were of white race. Overall, the daily ZIP-level ambient PM2.5 averages were 8.4 to 8.5 µg/m3, and the inter-quartile ranges (IQRs) were 5.9 to 6.0 µg/m3 for dates when biomarkers were measured. A 10 µg/m3 increase in same-day ambient PM2.5 exposure was associated with higher relative risks of low albumin (RR: 1.01, 95% CI: 1.01, 1.02) and low hemoglobin (RR: 1.02, 95%CI: 1.01, 1.03). Associations of same-day ambient PM2.5 exposure and high ferritin and low TSAT did not reach statistical significance.

CONCLUSIONS: Short-term PM2.5 exposure was associated with low serum hemoglobin and albumin. The findings among patients receiving in-center hemodialysis lend support for the potential of inflammation-driven changes after PM2.5 exposure.

P-0953 Diesel exhaust particles affected heart rate variability but not endothelial function – results from a controlled chamber study

Leo Stockfelt[1], Yiyi Xu[1], Anders Gudmundsson[2], Jenny Rissler[2,3], Christina Isaxon[2], Jonas Brunskog[4], Joakim Pagels[2], Patrik Nilsson[2], Margareta Berglund[5], Lars Barregard[1], Mats Bohgard[2], Maria Albin[6,7], Inger Hagerman[5], Aneta Wierzbicka[2]

[1]Gothenburg University/Sahlgrenska University Hospital, Gothenburg, Sweden, [2]Ergonomics and Aerosol Technology, Department of Design Sciences, Lund University, Sweden, Lund, Sweden, [3]Bioeconomy and Health, RISE Research Institutes of Sweden, Lund, Sweden, Lund, Sweden, [4]Department of Electrical Engineering, Technical University of Denmark, Denmark, [5]Department of Cardiology, Karolinska Institute, Karolinska University Hospital, Huddinge, Sweden, Stockholm, Sweden, [6]Division of Occupational and Environmental Medicine, Lund University, Sweden, Umeå, Sweden, [7]Unit of Occupational Medicine, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden

BACKGROUND: Adverse cardiovascular effects have been associated with exposure to both diesel exhaust and road traffic noise. Effects of these highly correlated exposures are hard to disentangle in epidemiological studies, but effects on intermediary outcomes and mechanisms can be studied experimentally. Heart rate variability (HRV) and peripheral arterial tonometry (PAT), a measure of endothelial function, are noninvasive methods to study mechanisms related to the autonomic nervous system associated with cardiovascular risk. The aim of this study was to evaluate the impact of diesel exhaust particles and traffic noise on HRV and PAT, and possible synergistic effect of combined exposure.

METHODS: Eighteen healthy adults were in a controlled chamber exposed to four exposure scenarios in a randomized cross-over fashion. Each scenario consisted of either filtered (clean) air or diesel engine exhaust (PM concentrations around 300 µg/m3), and low (46 dB(A)) or high (75 dB(A)) traffic noise for three hours at rest. ECG was recorded for 10-minute periods before and during each scenario, and frequency-domain heart rate variability (HRV) computed. Endothelial function and arterial stiffness were assessed after each exposure using EndoPAT 2000.

RESULTS: Compared to the control scenario, HRV in the high frequency band decreased during exposure to diesel exhaust, both alone and combined with noise, but not during exposure to noise only. The differences were stronger in women. There were no synergistic effects of combined exposure, no significant differences between exposure scenarios for other HRV indices, and no effect on endothelial function or arterial stiffness after exposure.

CONCLUSION: Three-hour exposure to diesel exhaust, but not noise, was associated with decreased HRV in the high frequency band. This indicates activation of irritant receptor-mediated autonomic reflexes, and increased cardiovascular risk during chronic diesel exposure.

P-0954 Placental Cellular Composition and Umbilical Cord Metal Concentrations: A Descriptive Molecular Epidemiology Study Leveraging DNA Methylation

Catherine Bulka[1], Lauren A. Eaves[1], Amaree J. Gardner[1], Patrick J. Parsons[2,3], Aubrey L. Galusha[2,3], T. Michael O'Shea[4], Rebecca C. Fry[1,5,6]

[1]Department of Environmental Sciences & Engineering, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA, [2]Division of Environmental Health Sciences, Wadsworth Center, New York State Department of Health, Albany, USA, [3]Department of Environmental Health Sciences, School of Public Health, University at Albany, Rensselaer, USA, [4]Department of Pediatrics, School of Medicine, University of North Carolina, Chapel Hill, USA, [5]Institute for Environmental Health Solutions, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA, [6]Curriculum in Toxicology, University of North Carolina, Chapel Hill, USA

BACKGROUND AND AIM: During pregnancy, potentially toxic metals and metalloids can cross the placenta with varying degrees of efficiency. We hypothesized metal toxicokinetics may be regulated by placental cellular composition. Until recently, disentangling complex placental tissue at the population level has been challenging. Here, we leveraged DNA methylation profiles to characterize major placental cell types and described relationships with umbilical cord metal concentrations in an extremely preterm birth cohort.

METHODS: Among 145 infants born before 28 weeks' gestation enrolled in the US-based ELGAN cohort (2002-2004), we quantified concentrations of 7 non-essential metals/metalloids in cord tissue, representing passage through the placental barrier. Placental DNA methylation profiles were measured by the Illumina EPIC BeadChip and deconvoluted using a novel reference-based approach (planet) to estimate proportions of six constituent cell types. To satisfy the sum-to-one constraint of proportions, we transformed the data into pivot coordinates (a special case of isometric log-ratios) before fitting linear regression models with cord tissue metal concentrations.

RESULTS: Arsenic, lead, strontium, and barium were detected in all umbilical cord tissue samples; cadmium and mercury were detected in 97.9% and antimony in 93.7%. The most relatively abundant cell type in placental tissue was syncytiotrophoblast (31.7%), followed by nucleated red blood (27.3%), endothelial (19.4%), Hofbauer (9.6%), stromal (8.8%), and trophoblast cells (3.2%). As syncytiotrophoblasts increase, arsenic levels in cord tissue decrease (Coefficient = -0.6 ng per 1-percentage point, p-value = 0.03) whereas as Hofbauer cells increase, cadmium levels increase (Coefficient = 0.3 ng per 1-percentage point, p-value = 0.03). Null associations were observed for the other metals/metalloids.

CONCLUSIONS: The findings suggest the cellular composition of the placenta may influence the transport of environmental metals to the fetus. Future studies examining prenatal environmental exposures should consider methylation-based deconvolution as a powerful tool for investigating placental biology.

P-0965 Impact of urban exposures during pregnancy on placental small non-coding RNAs

Marta Cosin-Tomas[1,2,3], Sofia Aguilar-Lacasaña[1,2,3], Ramil Nurtdinov[7], Ioar Rivas[1,2,3], Maria Foraster[1,2,3,8], MDolores Gomez-Roig[4], Elisa Llurba-Olivé[5,6], Payam Dadvand[1,2,3], Mariona Bustamante[1,2,3], Jordi Sunyer[1,2,3]

[1]ISGlobal, Barcelona, Spain, [2]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [3]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [4]BCNatal – Barcelona Center for Maternal Fetal and Neonatal Medicine (Hospital Sant Joan de Déu and Hospital Clínic), University of Barcelona, Barcelona, Spain, [5]Maternal and Fetal Medicine Unit, Obstetrics and Gynecology Department, Sant Pau University Hospital, Barcelona, Spain, [6]Development Network (SAMID), RD16/0022/0015, Instituto de Salud Carlos III, Madrid, Spain, [7]Centre for Genomic Regulation (CRG), The Barcelona Institute of Science and Technology, Barcelona, Spain, [8]PHAGEX Research Group, Blanquerna School of Health Science, Universitat Ramon Llull (URL), Barcelona, Spain

BACKGROUND AND AIM: Epidemiological studies show that urban exposures (e.g., air pollution, built and natural environment, and noise) during pregnancy could adversely influence the developing foetus. Although the underlying mechanisms are unclear, recent findings suggest that placental transcriptome can be a proxy of placental function during pregnancy and a plausible mediator of the association between intrauterine environmental exposures and foetal growth and development, and childhood and adult health trajectories. In particular, there is an increasing interest in small non-coding(nc)RNAs, including microRNAs (miRNAs), which are regulatory RNAs critical for placenta function and foetal development. Our main aim is to assess the association of several urban exposures during pregnancy with placental small ncRNA profiles in the Barcelona Life Study cohort (BiSC).

METHODS: BiSC is a population-based birth cohort of 1,086 mother-child pairs from the Barcelona metropolitan area (2018 onwards). We will characterize exposure to air pollution, noise, green space, and built environment as indicators of the urban exposome. Placental RNA was obtained from 450 placental foetal villi biopsies. Small ncRNA profiles were measured by RNA-sequencing (library insert of 17-52 nucleotides length, 50 nucleotides sequencing length, and 5M reads/sample). Quality control, processing of RNA-sequencing data, and small ncRNAs annotation and quantification will be done with the SeqCluster/SeqBuster bioinformatic tool.

RESULTS: A pilot study of 8 samples identified a total of 550 small ncRNAs, 44% being miRNAs. MiRNAs of the placental specific C19MC cluster were found among the most abundant. In the ISEE Conference we will present the placental small ncRNA profiles and their association with urban-related exposures.

CONCLUSIONS: Studying the impact of pregnancy exposures on the foetus and its biological intermediates is crucial to prevent their harmful effects and to develop biomarkers that allow early monitoring and treatment.

P-0968 Epigenome-Wide Association of Neonatal Methylation and Prenatal PM2.5 Exposure Suggests Timing-Specific Effects

Milan Parikh[1], Cole Brokamp[1,2], Erika Rasnick[1], Lili Ding[1,2], Tesfaye Mersha[2,3], Katherine Bowers[1,2], Alonzo Folger[1,2]
[1]Division of Biostatistics and Epidemiology, Cincinnati Children's Hospital Medical Center, Cincinnati, USA, [2]Department of Pediatrics, University of Cincinnati College of Medicine, Cincinnati, USA, [3]Division of Asthma Research, Cincinnati Children's Hospital Medical Center, Cincinnati, USA

BACKGROUND AND AIM: Exposure to particulate matter with an aerodynamic diameter smaller than 2.5 microns (PM2.5) can affect birth outcomes through physiological pathways such as inflammation. One potential way PM2.5 affects physiology could be through altering DNA methylation (DNAm). Considering that exposures during specific windows of gestation may have unique effects on DNAm, we hypothesized a timing-specific association between PM2.5 exposure during pregnancy and DNAm in the neonatal epithelial-cell epigenome.

METHODS: After collecting salivary samples from a cohort of 91 neonates, DNAm was assessed using the MethylationEPIC array (EPIC) which covers over 850,000 CpG methylation sites (850K) on the epigenome. Daily ambient PM2.5 concentrations were estimated based on the mother's address of primary residence during pregnancy. PM2.5 was then averaged over the first two trimesters, separately and combined, and tested for association with DNAm through an epigenome-wide association (EWA) analysis. for each EWA, FDR-corrected $p < 0.05$ constituted a significant finding, and every CpG site with uncorrected $p < 0.0001$ was selected to undergo pathway and network analysis to identify molecular functions enriched by them.

RESULTS: Our analysis showed that cg18705808 was associated with the combined average of PM2.5. Pathway and network analysis revealed little similarity between the first two trimesters. Previous studies reported that TMEM184A, the gene regulated by cg18705808, has a putative role in inflammatory pathways.

CONCLUSIONS: The differences in pathway and network analyses could potentially indicate trimester-specific effects of PM2.5 on DNAm. Further analysis with greater temporal resolution would be valuable to fully characterize the effect of PM2.5 on DNAm and child development.

P-0972 Exposure to Metals and the microRNA Profile of Participants in the Normative Aging Study

Mahdieh Danesh Yazdi[1], Cuicui Wang[1], Anna Kosheleva[1], Nicole Comfort[2], Haotian Wu[2], Andrea Baccarelli[2]
[1]Harvard TH Chan School of Public Health, Boston, USA, [2]Columbia Mailman School of Public Health, New York City, USA

BACKGROUND AND AIM: Metals have previously been associated with adverse effects in multiple organ systems. However, the molecular mechanisms by which they cause these effects are not fully elucidated. MicroRNAs are short non-coding RNA sequences that play an important role in the regulation of gene expression and may be a mechanism by which metals influence health.

METHODS: The study population consisted of496 persons (with 694 samples) enrolled in the Normative Aging Study (NAS). This cohort began recruiting male veteran who lived in the New England area in 1963 and has followed up with them every three to five years ever since. Our study period includes visits from 1999 to 2014. Extracellular microRNAs were sequenced from participants' plasma, and toenail samples were used to measure levels of metals, namely: arsenic (As), cadmium (Cd), lead (Pb), manganese (Mn), and mercury (Hg). We used canonical correlation analysis (CCA) to find whether metal levels correspond with microRNA levels. We further assessed the relationship between metals and microRNA using Bayesian kernel machine regression (BKMR).

RESULTS: Our preliminary CCA results showed very strong correlations between the first five canonical variables of the metals and those of the microRNA, with correlation values of 0.937, 0.923, 0.903, 0.894, 0.886, respectively. However, only the correlation between the first canonical variables was statistically significant. Pb and Cd showed the strongest association with the first canonical variable of the metals dataset. The strongest associations between the first canonical variable in the microRNA set were with the following microRNAs: miR-182-5p, miR-183-5p, miR-516b-5p, and miR-26a-5p.

CONCLUSIONS: There was a strong correlation between the first canonical variables of the metals and the microRNA, indicating a potential association between them. Future analyses will use BKMR to assess the joint effect of metals on the microRNA profile.

KEYWORDS: Metals, microRNA, Epigenetics, Mixtures Analysis

P-0975 Exposure to persistent organic pollutants and biomarkers of oxidative stress - A scoping review

Jiawen Chen[1], Brittney Baumert[1], Shante Robinson[2], Yiping Li[1], Yijie Li[1], Elizabeth Costello[1], Sarah Rock[1], Jesse Goodrich[1], Yinqi Zhao[1], Sandrah Eckel[1], Max Aung[1], Rob McConnell[1], David Conti[1], Lida Chatzi[1]
[1]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, USA, [2]University of Southern California, Los Angeles, USA

BACKGROUND AND AIM: Oxidative stress is a known mediator in pathways related to environmental exposures and numerous diseases. However, epidemiological studies investigating the association of persistent organic pollutants (POPs) and oxidative stress are limited and revealed inconsistent results. This scoping review evaluates the effect of POPs, including per- and polyfluoroalkyl substances (PFAS), polychlorinated biphenyls (PCBs), organochlorine pesticides, and polybrominated diphenyl ethers (PBDEs), on oxidative stress biomarkers in epidemiological studies.

METHODS: A search was conducted in PubMed and Embase through September 7, 2021, to identify all published studies related to POPs and oxidative stress. Search results were uploaded into Covidence systematic review management tool for de-duplication and for double independent abstract and full-text screening. We included human observational studies reporting at least one exposure and oxidative stress biomarker of interest for data extraction. The Office of Health Assessment and Translation risk of bias assessment tool was implemented for quality assessment.

RESULTS: Thirteen epidemiological studies met inclusion criteria – 7 for organochlorine pesticides, 5 for PFAS, 3 for PCBs, and 1 for PBDEs. Ten studies have overall low risk of bias. We found consistent positive associations of organochlorine pesticides and PFAS with several oxidative stress biomarkers, eg, of organochlorine pesticides with protein carbonyls, nitric oxide, and malondialdehyde, and of PFAS with 8-hydroxyguanosine and malondialdehyde. Additionally, we found consistent negative associations of organochlorine pesticides with several antioxidants, such as with acetylcholine esterase and paraoxonase-1, but associations of organochlorine pesticides, PCBs, and superoxide dismutase were inconsistent.

CONCLUSIONS: This is the first review of association of POPs and oxidative stress biomarkers in humans. Lack of prospective studies and some inconsistent results pose challenges to draw causal inference. Further evidence is needed to better elucidate the relationship of POPs and oxidative stress.

KEYWORDS: persistent organic pollutants, oxidative stress, biomarkers, review

P-0979 Use of high-resolution metabolomics to assess the biological perturbations associated with maternal exposure to Bisphenol A and Bisphenol F among pregnant African American women

Youran Tan[1], Rachel Tchen[1], Dana Barr[1], P. Barry Ryan[1], Tran ViLinh[2], Zhenjiang Li[1], Yi-Juan Hu[3], Alicia K. Smith[5], Dean P. Jones[4], Anne L. Dunlop[5], Donghai Liang[1]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Clinical Biomarkers Laboratory, Division of Pulmonary, Allergy and Critical Care Medicine, School of Medicine, Emory University, Atlanta, USA, [3]Department of Biostatistics and Bioinformatics, Emory University, Atlanta, USA, [4]Department of Medicine, School of Medicine, Emory University, Atlanta, USA, [5]Department of Gynecology and Obstetrics, School of Medicine, Emory University, Atlanta, USA

BACKGROUND: Human and animal exposure to bisphenol A (BPA) is strongly associated with adverse developmental and reproductive effects. The molecular mechanisms by which BPA exposure exerts its effects are not well-understood, even less known about its analogues bisphenol F (BPF). To address these knowledge gaps, we conducted an untargeted metabolome-wide association study (MWAS) to identify metabolic perturbations associated with BPA/BPF exposures in a pregnant African American cohort.

METHODS: From a subset (N=230) of study participants enrolled in the Atlanta African American Maternal-Child cohort, we collected both urine samples, for targeted exposure assessment of BPA and BPF, and serum samples, for high-resolution metabolomics (HRM) profiling, during early pregnancy (8-14 weeks' gestation). Using an established untargeted HRM workflow consisting of MWAS modeling, pathway enrichment analysis, and chemical annotation and confirmation, we investigated the potential metabolic pathways and features associated with BPA/BPF exposures.

RESULTS: The geometric mean creatinine-adjusted concentrations of urinary BPA and BPF were 0.85±2.58 and 0.70±4.71 μg/g creatinine, respectively. After false positive discovery rate correction at 20 % level, 264 and 733 unique metabolic features were significantly associated with urinary BPA and BPF concentrations, representing 10 and 12 metabolic pathways, respectively. Three metabolic pathways, including steroid hormones biosynthesis, lysine and lipoate metabolism, were significantly associated with both BPA and BPF exposure. We confirmed the chemical identity of 16 of the metabolites significantly associated with BPA or BPF exposure with Level One evidence using reference standard.

CONCLUSIONS: Our findings support that exposure to BPA and BPF in pregnant women is associated with the perturbation of aromatic amino acid metabolism, xenobiotics metabolism, steroid biosynthesis, and other amino acid metabolism closely linked to stress responses, inflammation, neural development, reproduction, and weight regulation.

P-0982 Short-term PM2.5 exposure and executive function: association and neurophysiological mechanisms

Limei Ke[1], Yao Zhang[1], Qian Di[1]
[1]*Tsinghua University, Beijing, China*

INTRODUCTION: Although converging evidence has shown that exposure to PM2.5 caused adverse effects on brain structure and cognitive function, the association between the short-term exposure to PM2.5 and cognition dysfunction remain underexplored, especially possible neurophysiological mechanisms.

METHODS: We conducted a longitudinal observational study with four repeated measurement sessions among 90 young adults from September 2020 to June 2021. During each measurement session, we measured participants' personal level air pollution exposure for one week with portable monitors, followed by executive function assessment and electrophysiological signals recordings at the assessment center. Standard Stroop color-word test was used accompanied with electrophysiological recordings to assess performance on executive function.

RESULTS: Adjusted mixed-effect models demonstrated that elevated PM2.5 exposure three days prior to cognitive assessment (lag 3) was associated with (1) declined performance in both congruent and incongruent tasks in Stroop tests, (2) reduced lower alpha event-related desynchronization (ERD) during 500-1000 ms after stimuli, both indicating impaired executive control. No associations were found between short-term PM2.5 exposure and aperiodic exponents both in tonic and phasic state, residual periodic alpha oscillation in tonic state.

CONCLUSIONS: Our results provided evidence that short-term PM2.5 exposure was associated with brain executive dysfunction. Reduced alpha ERD was likely to be the underlying pathway through which PM2.5 induced adverse effects on neuron activities during cognitive tasks. This study implies that transcranial electric stimulation and transcranial magnetic stimulation could be applied to access cortical neuron excitability to compensate for the cognitive impairment caused by PM2.5 exposure.

P-0983 Persistent organic pollutant exposure contributes to Black/White differences in leukocyte telomere length: Evidence from NHANES 1999-2002

Emily Roberts[1], Jonathan Boss[1], Stephen Salerno[1], Bhramar Mukherjee[1], Ami Zota[2], Belinda Needham[1]
[1]University of Michigan, Ann Arbor, USA, [2]Columbia University, New York, USA

BACKGROUND AND AIM: Despite racial disparities in diseases of aging and premature mortality, non-Hispanic Black Americans tend to have longer leukocyte telomere length (LTL), a biomarker of cellular aging, than non-Hispanic White Americans. Previous findings suggest that exposures to certain persistent organic pollutants (POPs) are both racially-patterned and associated with longer LTL. We examine whether Black/White differences in LTL are explained by differences in exposure to 15 POPs by estimating the indirect effect (IE) of race on LTL that is mediated through polychlorinated biphenyls (PCBs), furans, and dioxins, as well as their mixtures.

METHODS: Our study includes 1,251 adults from the 1999-2000 and 2001–2002 cycles of the National Health and Nutrition Examination Survey (NHANES). We characterized single-pollutant mediation effects by constructing survey-weighted linear regression models and implemented various approaches to quantify a global mediation effect of POPs, including unpenalized linear regression, ridge regression, and three summary exposure scores (derived from principal components analysis [PCA], principal direction of mediation, and the Toxic Equivalency Quotient [TEQ] score) using survey weights when possible.

RESULTS: We found support for the hypothesis that exposure to PCBs partially mediates Black/While differences in LTL. In single-pollutant models, there were significant IEs of race on LTL through PCBs 118, 138, 153, 170, 180, and 187 (percent mediated ranging 18.4-43.4%) after correction for multiple testing. Ridge regression and models examining summative exposure scores with linear combinations derived from PCA and TEQ scores showed significant IE when incorporating survey weights (percent mediated 26.0-34.8%), which also supports our hypothesis based on the IE attributable to exposure mixtures.

CONCLUSIONS: Exposures to individual POPs and their mixtures, which may arise from residential and occupational segregation, may help explain why Black Americans have longer LTL than their White counterparts, challenging genetic explanations for counterintuitive race differences in cellular aging.

P-0984 Effects of prenatal exposure to air pollution on placental molecular hallmarks and black carbon load

Laura-Concepció Gómez Herrera[1,2,5], Dries S Martens[2], Marta Cosin-Tomas[1], Eva Bongaerts[2], Sofia Aguilar-Lacasaña[1,5], Yumjirmaa Mandakh[7], Ioar Rivas[1], Maria Foraster[1,3,4], Maria Dolores Gomez-Roig[6], Payam Dadvand[1,3,4], Tim S Nawrot[2], Mariona Bustamante[1,3,4], Jordi Sunyer[1,3,4]

[1]ISGlobal, Barcelona, Spain, [2]Centre for Environmental Sciences, Hasselt University, Hasselt, Belgium, [3]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [4]CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [5]Universitat de Barcelona (UB), Barcelona, Spain, [6]BCNatal | Barcelona Center for Maternal Fetal and Neonatal Medicine, Hospital Sant Joan de Déu, Barcelona, Spain, [7]Environment, Society and Health, Division of Occupational and Environmental Medicine, Department of Laboratory Medicine, Lund University, Lund, Sweden

BACKGROUND AND AIM: There is a rising social concern regarding the effects of air pollution on fetal development, as increasing epidemiological evidence shows an association with several adverse birth outcomes. However, the specific mechanisms that drive these outcomes are still not comprehensively elucidated. To better understand the pathophysiology of prenatal exposure to air pollution through the placenta is precisely one of the aims of the Barcelona Life Study Cohort (BiSC).

METHODS: BiSC is a birth cohort of 1086 mother-child pairs residing in the Barcelona metropolitan area (Spain) that includes a comprehensive follow-up, both environmental (personal exposure to noise and air pollution) and clinical (3rd trimester comprehensive sonography and reproductive outcomes). Further post-natal follow-up is focused on neurocognitive development and includes a Bayley's test (BSID-III) at 6 months.
A specific work package in BiSC is focused on how the placenta responds to prenatal exposure to air pollution, as an intermediate organ between the environment and its effects on early-life development. Specific sections include:
1. To precisely evaluate the personal exposure to air pollution during pregnancy and quantify the translocation of air pollution particles (black carbon) to placental tissue through advanced microscopy.
2. To evaluate placental function measuring maternal-fetal circulation through Doppler sonography, as well as molecular biomarkers (telomere length and mitochondrial DNA content through qPCR) to define both the degree of tissue aging and metabolic capacity.

RESULTS: Black carbon particle detection, telomere length and mitochondrial DNA content measures are currently being performed in placental samples from the BiSC cohort. Dose response associations between air pollution exposure, placental carbon load and markers of placental function (maternal-fetal circulation, placental telomere length and mitochondrial DNA content) will be investigated.

CONCLUSIONS: This study will help to understand underlying mechanisms of air pollution effects on early life.

KEYWORDS: Air pollution, DOHaD, placental function, fetal development

P-0990 Phthalates and Adipokines in Midlife Women: A Cross-sectional Study in the Study of Women's Health Across the Nation (SWAN)

Mia Peng[1], Carrie Karvonen-Gutierrez[1], William Herman[1,2], Bhramar Mukherjee[1,3], Sung Kyun Park[1,4]
[1]Department of Epidemiology, University of Michigan School of Public Health, Ann Arbor, USA, [2]Department of Internal Medicine, School of Medicine, University of Michigan, Ann Arbor, USA, [3]Department of Biostatistics, University of Michigan School of Public Health, Ann Arbor, USA, [4]Department of Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, USA

BACKGROUND AND AIM: Phthalates are associated with obesity and its metabolic complications, but the mechanisms are not well-understood. We examined if phthalate exposure was associated with adverse adipokine profiles, a potential mechanism of metabolic disturbance.

METHODS: In 1250 midlife women in the Study of Women's Health Across the Nation (SWAN), we measured 11 phthalate metabolites in spot urine samples and leptin and high-molecular-weight (HMW) adiponectin in fasting blood samples from 2002/2003. We used linear regression to examine the association between each hydration-adjusted metabolite and log-transformed leptin, HMW adiponectin, and the leptin:HMW adiponectin ratio, adjusting for demographic, lifestyle, and menopause-related factors. Additionally, we used Bayesian kernel machine regression (BKMR) to examine the joint associations between the phthalate metabolite mixture and adipokines.

RESULTS: In single-pollutant models adjusted for all covariates except body mass index (BMI), most phthalate metabolites were positively associated with leptin. Mono(2-ethylhexyl) phthalate (MEHP) was positively associated with HMW adiponectin and inversely associated with the leptin:HMW adiponectin ratio. Adjustment for BMI attenuated all associations with leptin, but MEHP remained robustly associated with higher HMW adiponectin and a lower leptin:HMW adiponectin ratio. Compared to the 1st quartile, the 2nd to 4th quartiles of MEHP were associated with -16.9% (95% confidence interval (CI): -29.1, -2.6), -24.0% (-35.2, -10.8), and -17.7% (-30.2, -3.1) lower leptin:HMW adiponectin ratio. BKMR revealed a statistically significant, positive association between the phthalate metabolite mixture and HMW adiponectin and identified MEHP as the most important metabolite.

CONCLUSIONS: Phthalates were not associated with leptin concentrations independent of BMI. MEHP was associated with higher HMW adiponectin and a lower leptin:HMW adiponectin ratio, suggesting a more beneficial adipokine profile. The apparent difference between these findings and phthalates' associations with metabolic diseases calls for further investigations on phthalates' potential metabolism-disrupting mechanisms.

P-0992 Periconceptional and Prenatal Metals Exposure and Extracellular Vesicle miRNA in Breast Milk: A Pilot Study

Caitlin Howe[1], David Armstrong[2], Meghan Muse[1], Diane Gilbert-Diamond[1], Jiang Gui[1], Anne Hoen[1], Thomas Palys[1], Brock Christensen[1], Margaret Karagas[1]
[1]Dartmouth College, Lebanon, USA, [2]White River Junction VA Medical Center, White River Junction, USA

BACKGROUND AND AIM: Breast milk is a rich source of extracellular vesicle (EV) miRNA, which are hypothesized to contribute to maternal-offspring communication during the postnatal period and child development. Impacts of environmental contaminants on EV miRNA in breast milk are largely unknown. Our pilot study examined the relationships of metal exposures during the periconceptional and prenatal periods with breast milk-derived EV miRNA.

METHODS: EV miRNA were extracted from breast milk samples collected approximately 6 weeks postpartum from participants (N=54) in the New Hampshire Birth Cohort Study. 799 miRNA were profiled using the NanoString nCounter platform; 200 miRNA were widely detectable and retained for downstream analyses. Exposure to five metals (arsenic, manganese, mercury, lead, and selenium) during the periconceptional and prenatal periods was measured in maternal toenail clippings collected at two time points. Metal-miRNA associations were evaluated using covariate-adjusted robust linear regression models.

RESULTS: In this preliminary analysis, we found 12 miRNA to be inversely associated with As exposure in the periconceptional period and 42 miRNA to be inversely associated with As exposure in the prenatal period. Four miRNA were inversely associated with As exposure at both time points (miR-106b-5p, miR-152-3p, miR-429, miR-1234-3p). Associations for other metals showed potential trends which motivate further investigation in a larger study.

CONCLUSIONS: In a pilot study of participants in northern New England, we identified four miRNA that were inversely associated with both periconceptional and prenatal As exposure and an additional set of miRNA that were inversely associated with As exposure in a time-dependent manner. In future studies, we plan to expand the number of participants with these measures to investigate multiple metal exposures simultaneously using environmental mixture modeling approaches, examine possible downstream consequences for children's health, and conduct validation studies in other cohorts.

P-1004 Hair cortisol as a biomarker of chronic stress: influence of school context and bullying

Izaro Babarro[1,2], Ainara Andiarena[1,2], Elvar Theodorsson[3], Eduardo Fano[1,2], Andrea Lebeña[3], Monica Guxens[4,5,6,7], Jordi Sunyer[4,5,8], Jesus Ibarluzea[1,2,4,9]

[1]University of the Basque Country (UPV/EHU), Donostia/San Sebastian, Spain, [2]Biodonostia Health Research Institute, Donostia/San Sebastian, Spain, [3]University of Linköping, Linköping, Sweden, [4]Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Madrid, Spain, [5]Institute for Global Health (ISGlobal), Barcelona, Spain, [6]University of Pompeu Fabra (UPF), Barcelona, Spain, [7]Erasmus University Medical Centre-Sophia Children´s Hospital, Roterdam, The Netherlands, [8]Municipal Institute of Medical Research (IMIM-Hospital del Mar), Barcelona, Spain, [9]Health Department of Basque Government, Donostia/San Sebastian, Spain

BACKGROUND: Bullying has been identified as the most common form of aggression and the main source of stress during childhood and adolescence. The study aimed to analyze the effects of school context and bullying (victim, bully and bully/victim roles) as chronic stressors, using hair cortisol as a biomarker. Moreover, executive function was examined for its relationship with cortisol as well as its influence on bullying and academic skills.
METHOD: The study included 659 eleven-year-old preadolescents from the INMA cohorts of Gipuzkoa and Sabadell. Bullying (Olweus Bully Victim Questionnaire) and variables related to the school context were used as stressors: perception of the school environment (Kidscreen-27 questionnaire), problems with peers (SDQ: strength and difficulties questionnaire) and academic skills (ad hoc questionnaire). Hair samples were used to measure cortisol levels. Additionally, executive function was evaluated using the Cups Task neuropsychological test. To test our hypothesis, structural equation modeling was conducted.

RESULTS: In this study, it was found that being a bully/victim in bullying situations is associated with higher hair cortisol concentrations (b=0.075; p=0.056). Additionally, higher hair cortisol concentrations were associated with worse executive functions across all models (victims: b=0.113; p=0.004; bullies: b=0.112; p=0.004; bullies/victims: b=0.112; p=0.004). Finally, having a poorer relationship with peers, a poorer perception of a school environment or lower academic skills did not affect hair cortisol levels (p>0.05).

CONCLUSIONS: The present study examines the relationship between school context in general and bullying in particular with hair cortisol concentrations as an indicator of chronic stress for the first time. Despite concluding that the role of bully/victim appears to be related to hair cortisol concentrations, more research is needed to study this relationship.

P-1006 The Association between Exposure to Metals and Phthalates during Pregnancy and Children's DSM-oriented Problems at Age Four Years

Tsung-Lin Tsai[1], Chia-Jung Hsieh[2], Ming-Tsang Wu[3], Mei-Lien Chen[4], Po-Hsiu Kuo[5], Chien-Wen Sun[1], Shih-Fen Tsai[1], Huei-Ju Liu[1], Shu-Li Wang[1]

[1]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli, Taiwan, [2]Department of Public Health, Tzu Chi University, Hualien, Taiwan, [3]Research Center for Environmental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, [4]Institute of Environmental and Occupational Health Sciences, College of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan, [5]Department of Public Health, Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan

BACKGROUND AND AIM: About 10%–20% of children and adolescents suffer from mental problems worldwide, and it may increase the global burden of disease. Neurotoxic metals are associated with inflammation or cytotoxicity in the brain. Prenatal phthalates (PAEs) exposure is associated with cognitive function deficits. However, the effect of co-exposure to metals, PAEs, and the association with child behaviors are less well studied. We aimed to investigate prenatal co-exposure to metals and PAEs and the consequent behavioral outcomes in early childhood.

METHODS: Participants from the central, southern, and eastern areas of the Taiwan Maternal and Infant Cohort Study were followed up during 2015–2017. We quantified the maternal urinary concentration of metals and metabolites of PAEs as prenatal exposure. Child mental disorders at age four years were according to caregiver-reported scales of the Child Behavior Checklist to define DSM (The Diagnostic and Statistical Manual of Mental Disorders)-oriented problems. Finally, there were 408 children included in further statistical analysis.

RESULTS: Maternal urinary copper was significantly associated with depressive (OR=2.30), attention-deficit/hyperactive (OR=2.31), and oppositional defiant (OR=1.98) in children. Increased concentration of cadmium and lead was significantly associated with attention-deficit/hyperactive (OR=2.55), and oppositional defiant (OR=1.70) problems, respectively. Maternal urinary concentration of mono-isobutyl phthalate was also significantly associated with depressive problems (OR=1.72) in children. In the further analysis that considering prenatal co-exposure to metals and PAEs, co-exposure to these materials was significantly associated with autism spectrum problems in children (OR=5.15).

CONCLUSIONS: We observed that prenatal exposure to copper, cadmium, lead, and dibutyl phthalate was associated with some DSM-oriented problems in children at age four. Also, prenatal co-exposure to metals and PAEs may play a certain role in children's mental health. Reduction of exposure to metals and PAEs in pregnancy is suggested to prevent increased mental problems in childhood.

KEYWORDS: birth cohort, metal, phthalate, mental disorder

P-1007 Pesticide exposure and development in children living in low- and middle-income countries: a systematic review

Lilia Bliznashka[1], Aditi Roy[2], Lindsay Jaacks[1]
[1]Global Academy of Agriculture and Food Systems, University of Edinburgh, Midlothian, UK, [2]Public Health Foundation of India, New Delhi, India

BACKGROUND AND AIM
Pesticides are widely used in residential and agricultural settings in low- and middle-income countries (LMICs). Evidence from high-income settings shows that pesticide exposure in pregnancy and childhood is associated with poor child development. Our aim was to systematically review evidence on the associations between pesticides and development in children <18 years in LMICs.

METHODS: We searched 10 electronic databases through November 2021 with no language restriction. We included prospective cohort and cross-sectional studies investigating associations between self-reported or measured pesticide exposure in children and development. Two independent researchers screened studies and extracted data. Results were summarised narratively.

RESULTS: of 3372 records retrieved, 31 articles from 12 countries met the inclusion criteria. All articles assessed associations cross-sectionally; sample sizes ranged from 35 to 1762 (n=9083 total participants). Twenty-one articles assessed urine or blood biomarkers, five assessed self-reported exposure, and five used community of residence as a proxy for exposure. Two articles assessed organochlorines, 26 organophosphates, 11 carbamates, and eight pyrethroids.
In the three articles assessing children <2 years, pesticides were negatively associated with motor and social development (n=2), but not with language or adaptive development (n=2). In the 12 articles assessing pre-schoolers (2-5 years), pesticides were negatively associated with motor (n=4), language (n=3), and social (n=3) development, and with attention, memory, and processing speed (n=2). Two studies found no associations between organophosphates and these outcomes. In the 21 articles assessing school-aged children (6-18 years), pesticides were negatively associated with motor development (n=4), memory (n=6), attention (n=4), processing speed (n=4), and IQ (n=2). Five studies found no associations between pesticides and these outcomes.

CONCLUSIONS: Pesticides may be associated with deficits in multiple child development domains. However, evidence in LMICs remains inconclusive due to the small number of studies and variable methodologies used.

KEYWORDS: pesticides, child development, developing countries

P-1009 Associations of gestational phenol exposure with cognition in 7.5-month-old infants

Jenna Sprowles[1], Megan Woodbury[2], Elizabeth Enright[3], Andrea Aguiar[1], Antonia Calafat[4], Susan Schantz[1]
[1]Beckman Institute for Advanced Science and Technology, University of Illinois, Urbana-Champaign, Urbana, USA, [2]College of Engineering, Northeastern University, Boston, USA, [3]Department of Psychology, St. Mary's College of Maryland, St. Mary's City, USA, [4]Division of Laboratory Sciences, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA

BACKGROUND AND AIM: Triclosan and benzophenone-3 are ubiquitous phenolic endocrine disrupting chemicals. Similar chemicals are associated with adverse neurodevelopmental outcomes, but little is known about the effects of triclosan and benzophenone-3 on neurodevelopment. We investigated associations of gestational triclosan or benzophenone-3 exposure with infant cognitive outcomes.

METHODS: A visual recognition memory task assessed 312 7.5-month-old infants (151 males; 161 females) from a prospective birth cohort study. Triclosan and benzophenone-3 concentrations were quantified in maternal urines pooled from five timepoints across pregnancy. Infrared eye-tracking recorded infants' looking as they observed identical black-and-white photographs of human faces side-by-side (familiarization) and then the familiar next to a novel face (test trials). All infants saw the same face pairs. However, half the infants saw one set of faces as familiar (stimulus set 1), and half saw the other set as familiar (stimulus set 2). Multivariable generalized linear models (adjusted for income, parity, gestational age, testing age, child sex, stimulus set) assessed associations of triclosan or benzophenone-3 with time to familiarization (time to accrue 20s of looking during familiarization; attention measure), average run duration (time looking at stimuli before looking away; information-processing speed measure), and novelty preference (proportion of time looking at novel faces; recognition-memory measure).

RESULTS: Mothers were mostly white and college-educated with household income >$50,000/yr. Urinary concentrations (mean ± SD μg/L) of triclosan (68.8 ± 43.5) and benzophenone-3 (339.2 ± 638.5) were higher than those in reproductive-age females in the general U.S. population. Sex- and set-specific estimates demonstrated associations only in males who saw set 2: triclosan with longer time to familiarization (β=0.076; 95%CI: 0.04,0.112; p<0.0001) and benzophenone-3 with longer run duration (β=0.001; 95%CI: -0.0001,0.002; p=0.067).

CONCLUSIONS: In male infants, gestational exposure to triclosan and benzophenone-3 may be associated with poorer attention and slower information processing, respectively. (ES007326;ES022848;RD83543401;OD023272)

P-1011 The effect of Bisphenol A exposure on Attention Deficit Hyperactivity Disorder

I-Jen Wang[1]

[1]*Department of Pediatrics, Taipei Hospital, Ministry of Health and Welfare; School of Medicine, National Yang-Ming University; China Medical University, Taiwan,*

BACKGROUND The effect of Bisphenol A (BPA) on attention deficit/hyperactivity disorder (ADHD) is not fully understood. This study investigated the associations (i) between postnatal BPA exposure and ADHD in children; and (ii) between BPA and IgE levels for the possible disease pathogenesis.

METHOD A total of 453 children from Childhood Environment and Allergic Diseases Study cohort with urine samples were recruited in Taiwan. Urinary BPA glucoronide (BPAG) levels were measured by UPLC-MS/MS. The associations between BPAG levels and IgE levels and the risk of ADHD were evaluated by multivariate linear regression and logistic regression.

RESULT The geometric mean (SD) of BPAG concentrations was 8.84(±2.57) ng/ml at age 6. Urinary BPAG levels were positively associated with the risk of ADHD at age 6 (β=3.21 KU/l per ln-unit increase BPAG level; 95% CI, 0.99- 10.51 KU/l), after adjusting for potential confounders . There was no significant gender difference. The BPAG levels were positively associated with IgE levels at age 6 (β=64.85 KU/l per ln-unit increase BPAG level; 95% CI, 14.59- 115.11 KU/l).

CONCLUSION BPA exposures were positively associated with the risk of ADHD in children. The BPAG levels were positively associated with IgE levels.

P-1019 Early-life critical windows of metal exposure associated with internalizing symptoms in young adolescents

Elza Rechtman[1], Christine Austin[1], Paul Curtin[1], Esmeralda Navarro[1], Demetrios M. Papazaharias[1], Libni A. Torres-Olascoaga[2], Luis Bautista[2], Sandra Martínez-Medina[3], Rafael Lara-Estrada[4], Erika Proal[2], Viviana Villicana[2], Cheuk Y. Tang[5], Martha M Téllez-Rojo[3], Robert O. Wright[1], Megan K. Horton[1], Manish Arora[1]

[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Center for Nutrition and Health Research, National Institute of Public Health, Mexico, [3]National Institute of Perinatology, Mexico, [4]National Research Laboratory in Imaging and Medical Instrumentation, Universidad Autónoma Metropolitana, México, [5]Department of Diagnostic, Molecular, and Interventional Radiology, Icahn School of Medicine at Mount Sinai, New York, USA

Introduction and Aim: Internalizing disorders, such as anxiety and depression, affect 10 – 20% of children and increase the risk for later-life psychopathology. The neural circuitry subserving internalizing phenotypes begins developing in utero and is vulnerable to early-life environmental exposures. Although early-life exposure to metals can adversely impact children's neurodevelopment and have lifelong impacts on mental health, little is known about critical windows to metal exposures and adolescent internalizing disorders. In this study, we hypothesized that early-life exposure to a mixture of metals is associated with increased internalizing problems in early adolescence.

METHODS: Among 431 (8-12 years; 216 females) pre-adolescents enrolled in the Programming Research in Obesity, Growth, Environment and Social Stressors (PROGRESS) longitudinal birth cohort study in Mexico City, we estimated weekly concentrations of 15 metals in naturally shed deciduous teeth using laser ablation-inductively coupled plasma-mass spectrometry (i.e., Ba, Bi, Cd, Co, Cr, Cu, Li, Mg, Mn, Mo, Ni, Pb, Sn, Sr, and Zn) from the 14th gestation week through one year of age). Internalizing problems were assessed using the Behavior Assessment System for Children, 2nd edition (BASC-2). We used lagged weighted quantile sum (lWQS) regression to estimate a time-varying mixture effect of multiple metals on internalizing problems. Models were adjusted for age and sex.

RESULTS: A higher metal mixture index in the 22nd-43rd postnatal weeks was associated with increased internalizing problems (maximum $\beta = 0.37$ [95% CI 0.06, 0.69]), driven mainly by Mg, As, Sn, and Bi.

CONCLUSIONS: This study supports the hypothesis that mixed metal exposure during specific critical windows in early life may associate with mental health disorders in childhood and adolescence. Our lWQS modeling approach and results may inform the role of exposure timing in driving neurodevelopmental outcomes, thereby pointing to future optimal, efficient, and properly timed public health interventions.

P-1022 Associations of Prenatal Metal Exposure and Non-nutritive Suck Among Infants from the Puerto Rico Testsite for Exploring Contamination Threats (PROTECT) Birth Cohort Study

Christine Kim[1], Deborah Watkins[1], Emily Zimmerman[2], Bhramar Mukherjee[1], Zaira Rosario-Pabon[3], Carmen Velez-Vega[3], Akram Alshawabkeh[2], Jose Cordero[4], John Meeker[1]

[1]University of Michigan, Ann Arbor, USA, [2]Northeastern University, Boston, USA, [3]University of Puerto Rico, San Juan, Puerto Rico, [4]University of Georgia, Athens, USA

BACKGROUND AND AIM: Infant non-nutritive sucking (NNS) has been used as an early marker of neonatal brain function. Although there is an established relationship between metal exposure and brain development, the association between prenatal metal exposure and NNS has yet to be explored. To have a better understanding of the relationship, in this study, we explored associations between maternal urinary metal concentrations and NNS measurements among 116 infants from the Puerto Rico PROTECT birth cohort.

METHODS: We measured urinary concentrations for seven metals collected between 16-20 weeks and 24-28 weeks gestation. Linear mixed effects models (LMEs) were used to regress NNS on metals, adjusting for specific gravity, maternal age, birth weight, and fetal sex. Fetal sex effects were estimated using interaction terms between metal exposure variables and fetal sex indicators.

RESULTS: We observed significant positive associations between mercury and manganese with NNS duration (mercury: Δ= 1.08, 95% CI: 0.42, 1.74; manganese: Δ= 0.67, 95% CI: 0.15, 1.20) and NNS cycles/min (mercury: Δ= 1.85, 95% CI: 0.58, 3.11; manganese: (Δ= 1.37, 95% CI: 0.40, 2.34). Furthermore, the association between NNS cycles/burst and manganese (Δ= 4.44, 95% CI: 1.40, 7.47) were in the opposite direction from its association with zinc (Δ= -9.30, 95% CI: -14.71, -3.89), as well as with copper (Δ= -6.58, 95% CI: -12.06, -1.10). We also observed differences in metal-NNS associations by fetal sex.

CONCLUSIONS: We observed significant associations between prenatal metal exposure and child neurodevelopment, using NNS measurements, among infants from the ongoing Puerto Rico PROTECT cohort. We believe this study will inform future efforts aimed at reducing health risks related to early life metal exposures, such as developing early identification of metal-induced adverse outcomes in child neurodevelopment.

P-1029 Early-life exposure to a mixture of phthalates and phenols and child social behavior in a new type of mother-child cohort relying on within-subject pools of repeated urine biospecimens

Vicente Mustieles[1], Matthieu Rolland[1], Isabelle Pin[1], Cathrine Thomsen[2], Amrit Sakhi[2], Azemira Sabaredzovic[2], Karine Guichardet[1], Rémy Slama[1], Claire Philippat[1], SEPAGES Study Group[1]

[1]University Grenoble Alpes, INSERM, CNRS, Team of Environmental Epidemiology applied to Reproduction and Respiratory Health, Institute for Advanced Biosciences (IAB), Grenoble, France, Grenoble, France, [2]Norwegian Institute of Public Health (NIPH), Oslo, Norway

BACKGROUND AND AIM: Previous cohorts characterized exposure to phenols and phthalates using few spot urine samples, incurring in exposure misclassification. Early infancy exposure remains understudied. We relied on a cohort with improved exposure assessment to examine associations of phthalates and phenols with child autistic traits.

METHODS: This analysis included 406 mother-child pairs from the French SEPAGES cohort. 25 phenols/phthalate metabolites were measured in within-subject pools of repeated urine samples collected at second and third pregnancy trimesters (median= 21 samples/trimester), and at 2 and 12 months of age (median= 7 samples/period). Autistic traits were parent-reported at 3 years using the Social Responsiveness Scale (SRS). Adjusted differences in SRS raw scores were estimated per doubling in each biomarker concentration using linear regression. A literature review was performed to prioritize the measured phthalates/phenols based on their likelihood to affect social behavior. The mixture effect was estimated for the prioritized compounds (bisphenol A, triclosan, DEHP, MEP, MnBP and MBzP) using Bayesian Weighted Quantile Sum (BWQS) regression.

RESULTS: Most associations were observed in the 12-months exposure window. Among the prioritized compounds, triclosan (β= 0.79; 95%CI: 0.01, 1.56) and MEP (β= 0.92; 95%CI: -0.11, 1.95) were associated with worse total SRS scores, while MnBP and ∑DEHP were associated with worse social awareness (β= 0.25; 95%CI: 0.01, 0.50), and social communication (β= 0.43; 95%CI: -0.02, 0.88) scores, respectively. The mixture of prioritized compounds was associated with worse total SRS scores (Beta1= 1.40; 95%CrI: -0.22, 2.99), driven by the social awareness (Beta1= 0.36; 95%CrI: 0.03, 0.70) and social communication (Beta1= 0.87; 95%CrI: 0.31, 1.51) subscales.

CONCLUSIONS: The literature search allowed to prioritize the compounds with a higher weight of evidence. Our results suggest that early infancy is a critical window for the effects of phenols and phthalates on child social development.

KEYWORDS: phthalates, bisphenol, neurodevelopment, social behavior, autism

P-1034 Associations between phthalates and sleep quality in pregnant women with repeated assessment of exposure

Archana Lamichhane[1], Myung-Sook Park[2], Hwan-Cheol Kim[1]
[1]Department of Occupational and Environmental Medicine, Inha University School of Medicine, Incheon, Republic of Korea, Incheon, Republic of Korea, [2]Institute of Environmental Medicine, Seoul National University Medical Research Center, Seoul, Republic of Korea, Seoul, Republic of Korea

BACKGROUND AND AIM: Phthalates are associated with sleep disorders in midlife women. However, this relationship among pregnant women remains unknown. This study investigated associations of repeated measures of urinary phthalates in early and late pregnancy with sleep quality in pregnant women.

METHODS: This study analyzed eight urinary phthalates in pregnant women from the Korean Children's Environmental Health Study (n = 2,324). Multiple informant models were fit using generalized estimating equations to examine the association between phthalate metabolites measured in early and late pregnancy and sleep quality. Summary measures of phthalate mixtures, including the phthalates from plastic sources (∑Plastic), anti-androgenic phthalates (∑AA), di-(2-ethyhexyl) phthalate (∑DEHP), and all phthalate metabolites measured (∑All), were calculated from urinary phthalate metabolites. The sleep quality was assessed by the Pittsburgh Sleep Quality Index (PSQI) global and subscale scores.

RESULTS: Compared to the lowest quartile, ∑Plastic (adjusted odds ratio [OR] = 1.36; 95% confidence interval [CI]: 1.02, 1.81), ∑AA (OR = 1.60; 95% CI: 1.20, 2.12), ∑DEHP (OR = 1.37; 95% CI: 1.03, 1.82), and ∑All (OR = 1.66; 95% CI: 1.25, 2.20) in the highest quartile were significantly associated with increased odds of low sleep efficiency (85% or less). The highest quartile of ∑All had 1.40 times (95% CI: 1.02, 1.94) the odds of short sleep duration (7 hour or less). In linear models, there was a trend with any of the summary phthalate measures and sleep efficiency: each log-unit increase in concentration was associated with 1.20 to 1.24 times the odds of low sleep efficiency. Summary phthalate measures showed a nonlinear association with sleep efficiency and sleep duration (p for nonlinearity < 0.05) in the restricted cubic spline regression.

CONCLUSIONS: Our findings suggest that phthalate exposure is associated with poor sleep quality in pregnant women.

KEYWORDS: Phthalates, Pittsburgh Sleep Quality Index, sleep efficiency, pregnant women

P-1038 Wildfire Smoke and Symptoms Affecting Mental Health among Adults in Oregon

Maria Mirabelli[1], Ambarish Vaidyanathan[2], Audrey Pennington[1], Dongni Ye[1,3], Carol Trenga[4]
[1]Asthma and Community Health Branch, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA, [2]Climate and Health Program, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, USA, [3]Oak Ridge Institute for Science and Education, Oak Ridge, USA, [4]Public Health Division, Oregon Health Authority, Portland, USA

BACKGROUND AND AIM: The impact on mental health status of experiencing a wildfire is believed to be substantial; however, few data are available to describe symptoms affecting mental health among people affected by wildfires. We assessed associations between exposure to wildfire smoke and self-reported symptoms affecting mental health among adults living in Oregon, a geographic area of the USA regularly affected by wildfires.

METHODS: We analyzed data from 5,807 adults in Oregon who responded to the 2018 Behavioral Risk Factor Surveillance System's depression and anxiety module. We linked by interview date and county of residence each adult's responses about the symptoms affecting their mental health status with smoke plume density, a proxy for wildfires and wildfire smoke exposure. Associations between days in the past year with light, medium, and heavy smoke plume densities and symptoms affecting mental health during the two weeks before the interview date were estimated using predicted marginal probabilities from logistic regression models.

RESULTS: In the year before completing the interview, 100% of respondents experienced ≥14 days of medium or heavy smoke plumes, with an average exposure duration of 32 days. Nearly 10% reported being unable to stop or control their worrying more than half the time over the past two weeks. Medium or heavy smoke for 42–74 days in the past year, compared to ≤27 days in the past year, was associated with a 30% higher prevalence of being unable to stop or control worrying more than half the time during the past two weeks (prevalence ratio: 1.30, 95% confidence interval: 1.03, 1.65).

CONCLUSIONS: Among adults in Oregon, selected symptoms affecting mental health were associated with extended durations of medium and heavy smoke. These findings highlight the burden of symptoms affecting mental health among adults living in communities affected by wildfires and wildfire smoke.

P-1050 Effect of Cadmium on the Association between Blood Pressures and Telomere Length: A Population-based Cross-sectional Study in Japan

Kyi Mar Wai[1], Masahiro Umezaki, Yuki Mizuno, Kaori Sawada, Okuyama Shinya, Shigeyuki Nakaji, Kazushige Ihara
[1]*Department of Social Medicine, Hirosaki University, Hirosaki, Japan*

BACKGROUND AND AIM: Telomeres (TL) are repeated oligomers in the end of chromosome. TL shortening is associated with many pathophysiological outcomes, later in life such as cardiometabolic diseases and malignancy. However, not much is known regarding the role of heavy metals in TL shortening in association with increased blood pressure (BP). The objective of this study is to determine whether the association between high BP and TL shortening could be modified by the environmental cadmium (Cd) exposure.

METHODS: This study was a community-based cross-sectional study with 1047 individuals of age more than 19 years of 2019 Iwaki Health Promotion Project, Japan. A questionnaire survey, blood pressure measurement and blood sampling were performed by the trained research teams. Spot urine sample was also collected, and urinary Cd concentrations was measured, while Leucocyte TL was assessed by G-tail telomere hybridization protection assay. Regarding the statistical analysis, first, descriptive analysis was done using means, frequency, and percentage. Later, multivariate linear regression analysis was performed to evaluate the associations between urinary Cd concentration, BP/hypertension, and TL in relevance.

RESULTS: In high Cd concentration group, systolic blood pressure (SBP), diastolic blood pressure (DBP) and pulse pressure were significantly higher while TL was significantly shorter. By stratified multivariate regression models, telomere G-tail shortening was significantly associated with higher SBP (beta= -27.31; 95% CI: -50.71, -3.91, p=0.022) and DBP (beta= -49.33; 95% CI: -87.25, -11.42, p=0.011), only in high Cd concentration group. Similarly, TL was shorter among the hypertensive individuals (beta= -978.79; 95% CI: -1920.09, -37.51, p=0.042).

CONCLUSIONS: This study firstly identified that the negative associations of BP and TL were observed only in high Cd concentration group. These findings indicate that the associations of BP and TL could be mediated by environment Cd exposure.

KEYWORDS: Blood Pressure; Hypertension; Telomere; Cadmium; Japan

P-1054 The Effects of Minimally Processed and Ultra-Processed Food Intake on Cardiovascular Health based on the Korea National Health and Nutrition Examination Survey (KNHANES), 2013-2015

Lita Kim[1,2], Yun-Hee Choi[1,2], Da-An Huh[3], Kyong Whan Moon[1,2,4]

[1]Department of Health and Safety Convergence Science, Korea University, Seoul, Republic of Korea, [2]BK21 FOUR R&E Center for Learning Health System, Korea University, Seoul, Republic of Korea, [3]Institute of Health Sciences, Korea University, Seoul, Republic of Korea, [4]Department of Health and Environmental Science, Korea University, Seoul, Republic of Korea

Cardiovascular disease (CVD) is the leading cause of death worldwide. CVD risk factors are usually chronic, and a diet and lifestyle can be important determinants of cardiovascular health (CVH). Recently, the importance of dietary patterns rather than single nutrients has been emphasized for CVH. Consumption of processed food is increasing due to socio-economic changes in Korea. Although harmful substances may be added or created during the processing and packaging of foods, few studies evaluated the CVH effects of processed foods in Koreans. This study investigated the effect of minimally processed food (MPF) and ultra-processed food (UPF) intake on CVH. We used the data of 6,945 adults from the Korea National Health and Nutrition Examination Survey 2013–2015. Based on the CVH metrics (Life's simple 7), the CVH indicator was estimated as the sum (0–12) of the six (blood pressure, fasting plasma glucose, total cholesterol, body mass index, smoking status, physical activity) scores, and categorized as Inadequate (0–4), Average (5–8), and Optimum (9–12). MPF and UPF intake were estimated as the distribution of total energy intake using NOVA food classification. The mean (standard deviation) of MPF and UPF intake was 61.28(0.28) and 20.27(0.24) %kcal/day, respectively. After adjusting for all covariates, we found significant positive associations between MPF intake and CVH ($p<0.001$), while associations between UPF intake and CVH were significantly negative ($p<0.001$). Comparing the highest quartiles with the lowest of MPF intake, the adjusted odds ratio (OR) (95% Confidence interval) for Inadequate (compared with Optimum) was 0.36 (0.22–0.58), while UPF intake, adjusted OR was 2.63 (1.52–4.55). This study suggests that processed food intake was significantly associated with CVH in Korean adults. Public health policies are needed to promote choosing less processed foods to prevent CVD.

KEYWORDS: Cardiovascular Health, Minimally Processed Food, Ultra-Processed Food, Dietary, NOVA food classification

P-1055 Association of perfluoroalkyl substances (PFAS) with lipid trajectories in midlife women: the Study of Women's Health Across the Nation

Habyeong Kang[1], Ning Ding[1], Carrie Karvonen-Gutierrez[1], Bhramar Mukherjee[2], Sung Kyun Park[1,3]
[1]Department of Epidemiology, University of Michigan School of Public Health, Ann Arbor, USA, [2]Department of Biostatistics, University of Michigan School of Public Health, Ann Arbor, USA, [3]3Department of Environmental Health Sciences, University of Michigan School of Public, Ann Arbor, USA

BACKGROUND AND AIM: Despite lipid-lowering effects of perfluoroalkyl substances (PFAS) observed in rodent models, PFAS have been associated with unfavorable blood lipid profiles in human populations. However, evidence from longitudinal studies in the general population is limited. We examined the association of serum concentrations of PFAS with longitudinal trajectories of blood lipids in the Study of Women's Health Across the Nation.

METHODS: We included 1143 women aged 45-56 years in 1999-2000. Concentrations of PFAS including linear and branched perfluorooctane sulfonic acid (n-PFOS and Sm-PFOS), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), and perfluorohexane sulfonic acid (PFHxS) were measured in serum collected at baseline. Total, low-density lipoprotein (LDL), and high-density lipoprotein (HDL) cholesterol, and triglycerides were measured in blood annually or biannually during follow-up through 2016. Using latent class growth models (LCGMs), trajectories of each lipid were estimated based on the population data. The associations between PFAS and lipid trajectory classes were evaluated by multinomial log-linear models with latent class membership as outcomes and log-transformed PFAS as exposure.

RESULTS: Three distinct lipid trajectories (low, medium, and high trajectories) were identified. After adjustment for covariates, n-PFOS and Sm-PFOS were positively associated with higher LDL cholesterol [ORs (95% CI) for high vs. low trajectory per doubling of each PFAS: 1.28 (1.04, 1.56) and 1.24 (1.04, 1.48), respectively]. N-PFOS, n-PFOA, PFNA, and PFHxS were inversely associated with higher triglycerides [ORs (95% CIs) for high vs. low trajectory per doubling of each PFAS: 0.72 (0.55, 0.94), 0.65 (0.50, 0.84), 0.78 (0.62, 1.00), and 0.76 (0.62, 0.93), respectively]. The associations of PFAS with total or HDL cholesterol were insignificant.

CONCLUSIONS: Higher serum concentrations of selected PFAS were associated with a higher trajectory of LDL cholesterol and a lower trajectory of triglycerides. Further studies on the underlying mechanisms of the findings are warranted.

KEYWORDS: PFAS, dyslipidemia, midlife women

P-1056 Frequent Cannabis Smoking and Association with Prediabetes and Diabetes in Early Adulthood

Janet Gukasyan[1], Jesse Goodrich[1], Sarah Rock[1], Liz Costello, Arlette Lopez[1], Katerina Margetaki[1], Tanya Alderete[2], Zhanghua Chen[1], Frank Gilliland[1], David Conti[1], Lida Chatzi[1]

[1]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, USA, [2]Department of Integrative Physiology, University of Colorado Boulder, Boulder, USA

BACKGROUND: Cannabis use in young adulthood has been linked with increased risk of prediabetes later in life. However, many previous studies have only used fasting blood samples to determine risk for type 2 diabetes (T2D), which may not detect early changes in glucose homeostasis. The objective of this study was to determine the association between cannabis use and risk for prediabetes and T2D in young adults using several measures of glucose homeostasis, including an oral glucose tolerance test (OGTT).

METHODS: The Meta-CHEM study is a subset (N=84) of overweight and obese young adults aged 22–25 years from the Children's Health Study (CHS). Participants underwent a single clinical visit which included a 2-hour OGTT and questionnaire about cannabis smoking habits in the past year. Participants were classified as non-smokers, light cannabis smokers (smoke <once a week), and heavy cannabis smokers (smoke >once a week). Those smoking more than one cigarette in the past week were excluded from the study. Participants were classified as having prediabetes or T2D if they had a HbA1c >5.6%, fasting glucose >99 mg/dL, and/or 2-hour OGTT glucose >139 mg/dL. Logistic regression was used to assess the associations between cannabis smoking habits and metabolic outcomes after adjusting for age, sex, education, body mass index, Hispanic ethnicity, physical activity, and alcohol consumption.

RESULTS: 52 (62%) participants were non-diabetic, 28 (33%) had pre-diabetes, and 4 (0.05%) had T2D. 25 (30%) participants were nonsmokers, 47 (56%) were light cannabis smokers, and 12 (14%) were heavy cannabis smokers. The odds of having prediabetes or T2D was 7.3 times higher among heavy smokers (95% CI: 0.94, 7.7), and 1.5 times higher among light smokers (CI: 0.43, 6.0) than nonsmokers (P-value for trend = 0.03).

CONCLUSIONS: Cannabis use in overweight and obese young adults was significantly associated with risk of having prediabetes or T2D.

P-1062 Seasonal variations of hospitalizations for chronic rhinosinusitis by different endotypes

Lan Jin[1], Satish Govindaraj[2], Zongzhi Liu[1], Lei Ai[1], Mitchell Higashi[1], Tomi Jun[1], Kyeryoung Lee[1], Kalpana Raja[1], Xingmin Zhang[1], Minghao Li[1], Ediz Calay[1], Radoslav Savic[1], Krish Ghosh[1], Andrew Kasarskis[1], Qi Pan[1], William Oh[1,2], Gustavo Stolovitzky[1], Eric Schadt[1,2], Xiaoyan Wang[1]
[1]Sema4, Stamford, USA, [2]Icahn School of Medicine at Mount Sinai, New York, USA

BACKGROUND AND AIM: chronic rhinosinusitis (CRS) affects ~12% of the population and costs ~$30 billion each year in the US. A recent study reported winter and spring exacerbations of sinonasal symptoms among CRS patients; however, little is known about seasonal exacerbations by endotypes. This study aims to investigate seasonal variations of CRS hospitalizations among different inflammatory endotypes.

METHODS: CRS patients with different endotypes were identified in Mount Sinai electronic health records using a multi-layer CRS phenotyping algorithm integrating features such as encounter frequencies, surgeries, provider specialties and biomarkers, which was previously evaluated with high prediction performance (PPV=0.91). The patients with hospitalizations from 2003-2019 were included while patients with comorbidities of asthma or allergic rhinitis were excluded. Quasi-Poisson regression models were used to evaluate the associations between seasons and daily counts of CRS hospitalizations, adjusting for long-term temporal trend, day-of-the-week, daily temperature and PM2.5.

RESULTS: The counts of CRS hospitalizations were 32,194 in spring, 31,993 in summer, 32,077 in fall, and 30,584 in winter. for all CRS patients, no significant differences by season were detected. Among patients with nasal polyps (1615/7604), the highest risk of hospitalization was seen in spring (RR: 1.11; 95% CI: 1.06-1.17), followed by fall (RR: 1.06; 95% CI: 1.01-1.12), compared to winter. Similar patterns were observed in patients with blood eosinophil count > 300 cells/mcL (596/7604): increased risks of hospitalization were observed in spring (RR: 1.10; 95% CI: 1.04-1.16) and fall (RR: 1.08; 95% CI: 1.01, 1.14). In contrast, no differences by season were found for CRS patients without nasal polyps or with low eosinophil count.

CONCLUSIONS: Elevated risks of hospitalizations in spring and fall were only observed in CRS patients with endotypes related to eosinophilic type 2 inflammation. The high recurrence and refractory nature of these endotypes might be attributable to seasonal environmental factors.

KEYWORDS: rhinosinusitis, seasonal exacerbations

P-1066 Long-term air pollution, cardiometabolic multimorbidity, and genetic susceptibility: a prospective study in UK biobank cohort

Meijie Jiang[1], Xu Gao[1]
[1]*Peking University, Beijing, China*

BACKGROUND AND AIM: Air pollution has been associated with individual cardiometabolic diseases (CMDs) including type II diabetes (T2D), ischemic heart disease (IHD), and stroke. However, little is known about their relationship with the risk of cardiometabolic multimorbidity (CMM) with at least two of the CMDs. Therefore, we aimed to explore whether the long-term exposure to PM2.5, PM10, PM2.5–10, NO2, and NOx were associated with the progression of CMM.

METHODS: We used data from 415,855 adults of UK Biobank that were free of any of the three CMDs at baseline enrollment with a median follow-up of 8.93 years. The Land Use Regression model was used to estimate the annual average ambient concentrations of PM2.5, PM10, PM2.5–10, NO2, and NOx. We employed a multi-state model to assess associations of five pollutants with different transitions of the CMM trajectory.

RESULTS: A total of 33,375 participants developed one CMD, 3,257 of which subsequently developed another one or two. We found that PM2.5, PM10, NO2, and NOx levels were associated with the transition from healthy to having the first cardiometabolic disease (FCMD), and then to CMM with relatively higher risks. for instance, per 5-μg/m¬3 increasing in PM2.5 levels, the FCMD risk increased 27% (95% CI: 1.20-1.34) and the subsequent CMM risk raised to 41% (95% CI: 1.18-1.68). Robust associations of a weighted air pollution index with the CMM trajectory were also observed. Participants with IHD first were more likely to develop CMM than those with T2D or stroke. Additionally, the observed relationship between air pollution and CMM could be enhanced by the genetic susceptibility of CMDs.

CONCLUSIONS: Air pollution is not only associated with the individual CMDs but also could expedite the progression of CMM, which could be modified by genetic predisposition.

KEYWORDS: air pollution, PM2.5, cardiometabolic multimorbidity, multi-state model, genetic susceptibility

P-1069 Lung Cancer Mortality Risks of Long-term Exposure to Particulate Matter in South Korean Adults Including and Excluding Lung Cancer Patients

Miyoun Shin[1], Sun-Young Kim[1]
[1]*National Cancer Center Graduate School of Cancer Science and Policy, Goyang, Republic of Korea*

BACKGROUND AND AIM: Lung cancer is a major burden of disease worldwide. Many epidemiological studies suggested particulate matter(PM) as a prominent risk factor of lung cancer mortality. The risk also could differ depending on the cancer status related to susceptibility, but few studies focused on this difference. This study aims to compare the associations of PM2.5 and lung cancer mortality by including and excluding lung cancer patients in the Seoul Metropolitan Areas using a population-based nationwide cohort.

METHODS: From the National Health Insurance Services-National Sample cohort for 2002-2015, we selected the study population who carried out national screening during 2005-2007, aged over 30, were non-severely disabled, and had full address information every year. for our comparison, we created two sub-populations excluding and including those who had been diagnosed with lung cancer until the baseline in 2007. Lung cancer deaths were identified for 2007-2015, while individual-level long-term exposures to PM2.5 were assessed as 5-year average concentrations estimated from a previously-validated prediction model. We performed time-dependent Cox proportional hazards model to estimate hazard ratios (HRs) and 95% confidence intervals (95% CIs) per 10ug/m3 increase in PM2.5 adjusting for individual characteristics.

RESULTS: of 87,608 and 86,739 people including and excluding 867 lung cancer patients, 367 (0.42%) and 53 (0.06%) people died with lung cancer, respectively. Although all effect estimates were statistically non-significant, both groups showed positive effect estimates with similar magnitudes. (HR=1.60 [95% CI=0.24-10.76] and 1.55 [0.73-3.26] for the populations excluding and including lung cancer patients, respectively).

CONCLUSIONS: Our finding of positive risk estimates, although non-significant, between two populations including and excluding lung cancer patients suggest a possibility of consistent risks of dying with lung cancer attributed to PM2.5 regardless of susceptibility derived by cancer status. Further studies need to confirm our findings using extended populations.

P-1073 Prenatal Maternal and Paternal Household Pesticide Exposure and Childhood Acute Lymphoblastic Leukemia (ALL): Does Exposure Comparison Modeling Influence Risk Estimates?

Alexandra Ruth[1], Umer Rehman[1], Patricia Stewart[2], Lee Moore[3], Recai Yucel[1], Robin Taylor Wilson[1]
[1]Temple University College of Public Health, Department of Epidemiology and Biostatistics, Philadelphia, USA, [2]Stewart Exposure Assessments, LLC, Arlington, USA, [3]National Cancer Institute, Division of Cancer Epidemiology and Genetics (ret.), Bethesda, USA

BACKGROUND AND AIM: Household pesticide exposure is associated with increased risk of childhood acute lymphoblastic leukemia (ALL). We sought to investigate whether ALL risk estimates for pest-specific use categories (PSUC) change when using an analysis method (AM) versus a design method (DM) of multiple-PSUC confounding adjustment.

METHODS: Cases (N=1810) ages ≤15 were identified through Children's Cancer Group institutions between 1989-1993 and age-/sex-matched to community controls (N=1951). Household pesticide use during pregnancy (including the month prior) was collected via telephone interview. We used unconditional logistic regression to estimate ALL odds ratios (OR) for parental (mother/father/both) exposure to ten household PSUC (ant-cockroach-fly-bees, moths, spiders-mites, rodents, fleas-ticks, termites, slugs-snails, weeds, plants, or commercial exterminator). for AM, we assessed risk by including all PSUC covariates. for DM, each PSUC was assessed as a contrast with a zero-use comparison group (all ten-categories=zero) in adjusted models. All models were adjusted for known ALL risk factors which remained significant in final models (income, maternal age, and prenatal-vitamin use).

RESULTS: Pesticide use during pregnancy was prevalent (54% reported exposure to 2+ PSUC). PSUC bivariate correlations were all less than 0.25. Using AM, elevated ORAM (range: 1.41-1.55) were observed in three maternal and one paternal PSUC ($p<0.05$). All ORs increased when using DM (mother's range: 22.84%-62.50%; father's range: 22.34-60.50%). Risks were highest for termite (ORDM=3.98, 95% CI: 1.24-12.75, mothers) and spider-mite pesticides (ORDM=2.72, 95% CI: 1.29-5.75, fathers).

CONCLUSIONS: ALL risk estimates for exposure to ten pesticide use categories increased among both mothers and fathers when restricting exposure contrasts to a zero-use comparison group. These results are consistent with other studies reporting highest risks for termite pesticide exposure. This may reflect either a true risk difference or other characteristics among zero-use households which reduce risk. Investigation of potential mediation among pesticide classes appears warranted.

KEYWORDS: Acute Lymphoblastic Leukemia; childhood; pesticides; prenatal; case-control

P-1076 Dietary intakes of dioxins and polychlorinated biphenyls (PCBs) and breast cancer risk in 9 European countries

Thibault Fiolet[1], Corinne Casagrande[2], Geneviève Nicolas[2], Zsuzsanna Horvath[3], Pauline Frenoy[1], Manon Cairat[2], Marina Kvaskoff[1], Inge Huybrechts[2], Francesca Romana-Mancini[1], EPIC On Behalf of the EPIC Network[4]
[1]University of Paris-saclay, Cachan, France, [2]International Agency for Research on Cancer, Lyon, France, [3]European Food Safety Authority, Parma, Italy, [4]EPIC Network, Europe, Europe

BACKGROUND AND AIM: Dioxins and polychlorinated biphenyls (PCBs) are known to be mobile and highly persistent in the environment leading to a ubiquitous pollution. These chemicals are carcinogenic. Due to bioaccumulation along the food chain, the main route of exposure in general population is through diet. However, evidence in general population is lacking. The aim of the present study was 1) to estimate dietary intakes for 17 dioxins and 35 PCBs in the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort 2) to investigate the association with breast cancer risk

METHODS: EPIC is a prospective cohort that has enrolled 520,000 adults recruited across 10 European countries. Dietary and lifestyle data have been collected at baseline through validated questionnaires. Dietary intake for 17 dioxins and 35 polychlorobiphenyls were assessed through a combination of EPIC food consumption data and food contaminant levels from the European Food Safety Authority monitoring programs. Association between intakes of dioxins and PCBs and breast cancer risk were estimated using multivariate Cox regression. Analyses included 318,607 women with 13,241 incident breast cancers (median follow-up: 14.9 years).
RESULTS
Exposure to dioxins, Dioxin-Like-PCBs (DL-PCBs), and Non-Dioxin-Like-PCBs (NDL-PCBs) estimated from reported dietary intakes were not associated with breast cancer incidence, with the following hazard ratios (HRs) and 95% confidence intervals for an increment of 1 SD: HRdioxins = 1.00 (0.98 to 1.02), HRDL-PCB = 1.01 (0.98 to 1.03), and HRNDL-PCB = 1.01 (0.99 to 1.03), respectively. Results remained unchanged when analyzing intakes as quintile groups, as well as when analyses were run separately per country, or separating breast cancer cases based on estrogen receptor status

CONCLUSIONS: This large European prospective study does not support the hypothesis of an association between dietary intake of dioxins and PCBs and breast cancer risk.

KEYWORDS: Breast cancer, dioxins, PCBs

P-1077 Dietary intakes of Dioxins and polychlorobiphenyls (PCBs) and mortality: EPIC cohort study in 9 European countries

BACKGROUND AND AIM: Dioxins and polychlorinated biphenyls (PCBs) are persistent organic pollutants which are carcinogenic. The main route of exposure in general population is through diet. Cohort studies have reported inconsistent associations between these chemicals and mortality. The aim of the present study was 1) to estimate dietary intakes for 17 dioxins and 35 PCBs in the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort 2) to investigate the impact on mortality.

METHODS: EPIC is a prospective cohort that has enrolled 520,000 adults recruited across 10 European countries. Dietary intake of dioxins and PCBs was assessed combining EPIC food consumption data with European food contamination data provided by the European Food Safety Authority. Association between intakes of dioxins and PCBs and breast cancer risk and mortality were estimated using multivariate Cox regression. Analyses included 451,390 adults with 46,627 deaths (median follow-up: 17.4 years).
RESULTS
A U-shaped non-linear association with all-cause mortality for dietary intake of dioxins (Pnon-linearity<0.0001), DL-PCB (Pnon-linearity=0.0001), and NDL-PCBs (Pnon-linearity<0.01) was observed. for example, the hazard ratios (95%Confidance interval) for all-cause mortality obtained with the spline model was equal to 1.03 (1.02-1.05) for low intake of dioxins (7 pg TEQ/day), 0.93 (0.90-0.96) for moderate intake (25pg TEQ/day), while for high intake of dioxins (55pg TEQ /day) it was 1.03 (0.97-1.09). There was no association between intakes of dioxins and cancer mortality, but a U-shaped association was observed for intake of DL-PCBs and intake of NDL-PCBs and cancer mortality. Intakes of dioxins, DL-PCBs and NDL-PCBs was not associated with cardiovascular mortality.

CONCLUSIONS: This large European prospective study does support the hypothesis of a non-linear association between dietary intake of dioxins and PCBs and mortality which might be explained by endocrine disrupting properties

KEYWORDS: mortality, dioxins, PCBs

P-1079 Long-term atmospheric exposure to PM2.5 and PM10 and breast cancer risk in a case-control study nested in the French E3N cohort from 1990 to 2011

Delphine Praud[1], Maryline Bouilly[1], Amina Amadou[1], Thomas Coudon[1], Lény Grassot[1], Margaux Duboeuf[1], Elodie Faure[2], Pr Béatrice Fervers[1]

[1]Department Prevention Cancer Environment, Centre Léon Bérard, Lyon, France, [2]Gustave Roussy Institute, Villejuif, France

BACKGROUND AND AIM: Breast cancer is one of the most prevalent cancers in women and its incidence increased in France during the past thirty years. Known risk factors include ageing, genetic, reproductive, anthropometric, and lifestyle factors. Since they fail to totally explain the observed risk increase, it has been hypothesized that some of this increase could be related to environmental exposure to endocrine disrupting chemicals. Among those, particulate matters (PM) have been pointed out by epidemiological studies due to their potential endocrine disrupting and carcinogen properties We aimed to estimate the association between PM2.5 and PM10 exposure and the risk of breast cancer among women in a case-control study nested in the French E3N cohort.

METHODS: Our study focused on 5222 invasive breast cancer cases diagnosed between 1990 and 2010 and 5222 randomly selected controls matched to cases. Assessment of PM2.5 and PM10 exposures were estimated by land use regression (LUR) models and assigned to the geocoded residential postal codes of participants for each year from recruitment 1990 through 2011. We estimated odds ratios (OR) and 95% confidence intervals (CI) for breast cancer using conditional adjusted logistic regression models.

RESULTS: We found a positive association between breast cancer risk and PM2.5 (OR=1.15, 95%CI: 1.00-1.31, per 10µg/m3) and PM10 (OR=1.07, 95% CI: 0.99-1.15). These results were confirmed estimating PM2.5 and PM10 exposure with a chemistry transport model (CHIMERE).

CONCLUSIONS: We found suggestive evidence of an association between air pollution exposure and incidence of breast cancer risk in French woman

P-1081 Is Cadmium Exposure associated with Thyroid Cancer? A National Health and Nutrition Examination Survey Analysis

Eric Alerte[1], Mathilda Alsen[1], Eric Genden[1], Maaike Van Gerwen[1]
[1]*Icahn School of Medicine at Mount Sinai, New York, USA*

INTRODUCTION
The increasing thyroid cancer incidence in the past few decades might be partially explained by the changing prevalence of environmental exposures, including to the heavy metal cadmium. Although cadmium is known to accumulate in the thyroid gland and has been labeled a carcinogen, an association between cadmium exposure and thyroid cancer has not been demonstrated to date. To assess this potential effect of cadmium exposure, this study investigated the association between blood cadmium levels and thyroglobulin antibodies (TgAb) as previous studies showed that positive TgAb predicts the presence of thyroid cancer in patients with thyroid nodules.

METHODS: Using the 2007-2012 National Health and Nutrition Examination Survey (NHANES), participants of 20 years and older without thyroid disease/ cancer with reported blood cadmium and thyroid function levels were included (n=7,383). TgAb and cadmium were log-adjusted. Models with cadmium as a log-adjusted continuous variable and divided into quartiles of exposure, adjusted for age groups, sex, race, BMI groups, alcohol, smoking, and iodine status were assessed using complex survey design.

RESULTS: The geometric mean of cadmium across all participants was 0.348 ng/mL (standard error (SE): 0.005). After adjustment, there was no significant association between continuous cadmium levels and TgAb (β=0.057, 95% confidence interval (CI): -0.004; 0.119. Models with cadmium divided into quartiles showed that though quartile 2 and 3 were associated with increased TgAb, this association was only significant for quartile 4 (β=0.193, 95% CI: 0.069; 0.317), versus quartile 1.

DISCUSSION
High levels of cadmium were positively associated with TgAb levels indicating that cadmium exposure needs to be further explored as a potential risk factor for thyroid cancer, especially given the widespread use and exposure of the general population to cadmium. This includes in-depth studies into the potential carcinogenic mechanism of cadmium on the thyroid gland.

P-1085 Household Cooking Fuel and Gallbladder Cancer Risk: A Multi-Centre Case Control Study in India

Krithiga Shridhar[1], Manigreeva Krishnatreya[2], Ranjit Kumar[3], Dimple Kondal[1], Mouchumee Bhattacharyya[2], Banti Kalita[1], Prakriti Snehil[1], Sumita Sarma Barthakur[4], Gayatri Bharali[4], Amulya Kumar Singh[5], Amal Chandra Kataki[2], Ashok Ghosh[3], Dorairaj Prabhakaran[1], Poornima Prabhakaran[1], Preet Kaur Dhillon[1,6]

[1]Public Health Foundation of India, Gurugram, India, [2]Dr.Dr.Bhubaneshwar Borooah Cancer Institute, Guwahati, India, [3]Mahavir Cancer Sansthan and Research Centre, Patna, India, [4]Sri Sankaradeva Netralaya, Guwahati, India, [5]Akshat Seva Sadan, Patna, India, [6]Genentech Roche, USA

BACKGROUND-AIM: Evidence from India, a country with certain unique cancer patterns (e.g., high incidence of gallbladder cancers (GBC)) and distinct risk exposures such as 'biomass burning' for cooking, may offer insights into the role of indoor air pollution in cancer etiology. We evaluated the association between household cooking fuel and GBC risk in a case-control study conducted among long-term residents (i.e., at least 10-years) of North-East and East Indian regions of Assam and Bihar, with high-risk for GBC and intense 'biomass burning'. We explored if these associations were accounted-for by healthy diet, fire-vents and 'daily exposure duration'.

METHODS: We recruited men and women aged 30-69 years from hospitals between 2019 and 2021, with newly diagnosed, biopsy-confirmed GBC (N=214) and unrelated controls frequency-matched by age, sex and region (N=166). Information about cooking fuel, lifestyle, personal and family history, socio-demographics and physical measurements was collected. We tested associations using multivariable logistic regression analyses adjusted-for confounders.

RESULTS: All participants (73.4% women) were categorised based on lifetime use and duration of predominant cooking fuel. Group-1: LPG for ≥20 years (13.5%); Group-2: LPG for 1-19 years with no concurrent biomass (15.6%); Group-3: LPG 1-19 years with concurrent biomass (12.9%); and Group-4: Biomass for ≥20 years (57.9%). Compared to group-1, GBC risk was higher in group-3 [OR=2.69, 95%CI (1.07-6.72)] and group-4 [OR=2.44, 95%CI (1.07-5.56)] but not in group-2 (p-trend=0.020). The associations strengthened in women-only analysis; and attenuated with high daily consumption of fruits-vegetables, but did not alter with fire-vents or 'daily exposure duration'.

CONCLUSIONS: With cautious interpretation for residual confounding, sample-size limitations and possible errors in exposure, the findings identify 'biomass burning' as a modifiable risk factor for GBC in high-risk regions. It further highlights 'clean fuel replacement' can mitigate the risk; and a healthy diet can partially reduce the risk.

P-1086 Lifetime Chronic Arsenic Exposure and Gallbladder Cancer Risk: Evidence from Endemic Regions of India

Krithiga Shridhar[1], Debapriya Mondal[2], Manigreeva Krishnatreya[3], Ranjit Kumar[4], Dimple Kondal[1], Steena Kuriakose[5], Vinutha Ragavaiah Sarma[1], Soumyajit Sarkar[6], Sumita Sarma Barthakur[7], Gayatri Bharali[7], Amulya Kumar Singh[8], Amal Chandra Kataki[3], Ashok Ghosh[4], Abhijit Mukherjee[6], Dorairaj Prabhakaran[1], Poornima Prabhakaran[1], Preet Kaur Dhillon[1,9]

[1]Public Health Foundation of India, Gurugram, India, [2]St. Georges University of London, London, UK, [3]Dr.Bhubaneshwar Borooah Cancer Institute, Guwahati, India, [4]Mahavir Cancer Sansthan and Research Centre, Patna, India, [5]Centre for Chronic Disease Control, New Delhi, India, [6]Indian Institute of Technology, Kharagpur, India, [7]Sri Sankaradeva Netralaya, Guwahati, India, [8]Akshat Seva Sadan, Patna, India, [9]Genentech Roche, USA

BACKGROUND-AIM: Evidence for the associations of varying levels of arsenic in drinking water and digestive tract cancers is limited. Data from endemic regions of India, with high incidence of a rare digestive tract cancer-gallbladder cancer (GBC)- may explain the role of chronic arsenic exposure in cancer etiology. We evaluated the associations between arsenic levels in groundwater and GBC risk in a case-control study conducted among residents of Assam and Bihar (2019-2021), the two most arsenic-impacted states of India next to West Bengal.

METHODS: We recruited men and women aged 30-69 years from hospitals (73.4% women), with newly diagnosed, biopsy-confirmed GBC (N=214) and unrelated controls frequency-matched by age, sex and region (N=166). Information about lifetime residential history, lifestyle, personal and family history, socio-demographics and physical measurements was collected. Average-weighted lifetime arsenic concentration (AwLAC) was estimated extrapolating district-level groundwater monitoring data (2017-2018) and lifetime residential history. Accounting for confounders, tertiles of AwLAC (ug/L) was modelled in multivariable logistic regression analysis (Range: Zero-448.39; median (IQR): T1-0.45(0.0-1.19); T2-3.75(2.83-7.38); T3-17.6(12.34-20.54)).

RESULTS: A higher proportion of participants in the highest tertile of AwLAC compared to the lowest tertile consumed tube-well water for drinking (67.7 vs. 27.9%) with purification (45.2 vs. 25.5%) and reported unsatisfactory water-quality (49.2 vs. 25.0%). These participants in the highest and in middle tertiles of AwLAC were associated with an increased risk of GBC versus the lowest tertile with OR (95%CI) of 2.43(1.30-4.54) and 2.00(1.05-3.79) respectively (p-trend=0.007). The associations remained consistent with 'average-maximum arsenic concentration (any-time)' as exposure variable and in a sub-set with block-level AwLAC estimations.

CONCLUSIONS: Despite limitations of one-time arsenic levels, sample-size and potential residual confounding, the findings indicate chronic arsenic exposure, including low-levels, is a risk factor for GBC. Tackling 'arsenic pollution' may help reduce the burden of GBC and other health outcomes.

P-1092 The relation between air pollution and multiple sclerosis hospital admission in Kerman, Iran using generalized additive models

Mohammad Amin Farahmandfard[1], Hossein Ali Ebrahimi[1], Narges Khanjani[1], Moghaddameh Mirzaee[1], Hoda Kamali[1]

[1]*Kerman University of Medical Sciences, Kerman, Islamic Republic of Iran*

BACKGROUND AND AIM: Air pollution may affect the nervous system and act as an environmental risk factor in increasing multiple sclerosis (MS) incidence and attacks. The aim of this study was to investigate the possible relation between air pollution and MS in Kerman, Iran.

METHODS: This was an ecological study. Data on ambient air pollutants and meteorological variables were inquired from the Kerman Environmental Protection Agency and the Kerman Meteorology Organization, respectively. MS attack incidence data were obtained from Kerman's Shafa hospital MS Registry. Generalized Additive Models with lags were used for estimating Relative Risks.

RESULTS: During 2008 - 2020, 4913 attacks occurred among MS patients in Kerman which 3739 were female. The strongest relation between CO with MS attacks was seen in the under 30 year's group in lag 0 (RR = 1.6544), for O3 in the over 50 year's group in lag 5 (RR =1.0181), for SO2 in lag 5 (RR =1.0237), for NO2 in females in lag 0 (RR =1.0126), for PM10 in the over 50 year's group lag 3 (RR =0.9828) and for PM2.5 in lag 5 (RR = 0.9832).

CONCLUSIONS: Ambient CO,O3, NO2 and SO2 might be important risk factors for MS attacks in Kerman.

KEYWORDS: Air pollution, Multiple sclerosis, Environmental factors, Epidemiology, Kerman

P-1093 Association of copper exposure with prevalence of chronic kidney disease among a Chinese elderly population

Fanjia Guo[1], Yaoyao Lin[2], Lin Meng[2], Lihe Peng[3], Yongming Zhang[4], Huafang Zhang[4], Xue Zhang[3], Mingjuan Jin[1], Jianbing Wang[5], Mengling Tang[2], Kun Chen[1]

[1]Department of Public Health, Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [2]Department of Public Health, Fourth Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [3]Physical and Chemical Laboratory, Jiashan Center for Disease Control and Prevention, Jiashan, China, [4]The Fourth Affiliated Hospital, Zhejiang University School of Medicine, Yiwu, China, [5]Department of Public Health, National Clinical Research Center for Child Health of Children's Hospital, Zhejiang University School of Medicine, Hangzhou, China

BACKGROUND AND AIM: Metal exposures are suspected to associate with the risk of chronic kidney disease (CKD). Copper (Cu) is an essential yet toxic trace element in humans. Epidemiological evidence on the association of Cu exposure with CKD remains inconsistent. We aim to investigate the association of blood Cu and its co-exposure to other metals with CKD.

METHODS: A cross-sectional study was conducted among 3,286 Chinese elderly adults in Zhejiang, China. The whole blood levels of Cu as well as other 10 metals were measured by inductively coupled plasma mass spectrometry (ICP-MS). CKD events were defined as the presence of albuminuria or <60 mL/min/1.73m2 estimated glomerular filtration rate (eGFR). Multivariable logistic regression and linear regression models were applied to assess the single-metal association of Cu with kidney function. The Bayesian kernel machine regression (BKMR) was used to estimate associations of the metal mixture with CKD.

RESULTS: In the logistic models, we observed a positive dose-dependent association of blood Cu with CKD prevalence after adjusting for multiple covariates. Positive linear dose-response associations with blood Cu were also found for CKD and negative for eGFR. The positive association between blood Cu and CKD risk also observed in BKMR model and stronger at lower level of manganese (Mn).

CONCLUSIONS: The whole blood level of Cu was remarkably associated with the prevalence of CKD and showed positive dose-response relationships in the elderly Chinese population. The toxicity of Cu on kidney function could be antagonized by the exposure of Mn. These findings have provided new clues of the potential roles of Cu in kidney health, and the needs to develop not only recommended intake but also safe limits for Cu.

KEYWORDS: copper, chronic kidney disease, whole blood, BKMR analysis, manganese.

P-1102 The synergistic effects of Particle Radioactivity (Gross Beta Activity) and PM2.5 on Cardiovascular Diseases Mortality

Shuxin Dong[1], Petros Koutrakis[1], Longxiang Li[1], Brent Coull[2], Joel Schwartz[1,3], Anna Kosheleva[1], Antonella Zanobetti[1]

[1]Department of Environmental Health, Harvard T. H. Chan School of Public Health, Boston, USA, [2]Department of Biostatistics, Harvard T. H. Chan School of Public Health, Boston, USA, [3]Department of Epidemiology, Harvard T. H. Chan School of Public Health, Boston, USA

BACKGROUND: Although the effects of fine particulate matter (particulate matter ≤2.5 μm aerodynamic diameter; $PM_{2.5}$) on cardiovascular diseases (CVD) morbidity and mortality are well established, little is known about CVD health effects of particle radioactivity (PR). In addition, there are still questions about which of the $PM_{2.5}$ physical, chemical, or biological properties are mostly responsible for its toxicity.

METHODS: We investigated the association between PR, measured as gross β-activity from highly resolved spatiotemporal predictions, and mortality for CVD, myocardial infarction, stroke, and all-cause non-accidental mortality in Massachusetts (2001-2015). Within both difference-in-difference (DID) approach and generalized linear mixed-effect model frameworks, we fit gross β-activity-alone, PM2.5 alone, gross β-activity&$PM_{2.5}$ models and examined the interaction between $PM_{2.5}$ and gross β-activity.

RESULTS: We found significant associations between gross β-activity/$PM_{2.5}$ and each mortality cause. Using the DID approach and adjusting for $PM_{2.5}$, we found the highest associations with MI (RR=1.16, 95% CI: 1.08, 1.24) and stroke (RR=1.11, 95% CI: 1.04, 1.18) for an IQR increase (0.055 mBq/m3) in gross β-activity. We found a significant positive interaction between $PM_{2.5}$ and gross β-activity, with higher associations between $PM_{2.5}$ and mortality at a higher level of gross β-activity. We also observed that the associations varied across age groups. The results were comparable between the two statistical methods with and without adjusting for $PM_{2.5}$.

CONCLUSIONS: This is the first study that, using highly spatiotemporal predictions of gross β-activity, provides evidence that PR increases CVD mortality and enhances $PM_{2.5}$ CVD mortality. Therefore, PR can be an important property of $PM_{2.5}$ that must be further investigated. Addressing this important question can lead to cost-effective air quality regulations.

KEYWORDS: cardiovascular disease; death; particle radioactivity; death

P-1105 Serum levels of per- and polyfluoroalkyl substances (PFAS) and aggressive prostate cancer risk in the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial

Jongeun Rhee[1], Kathryn Barry[2], Wen-Yi Huang[1], Joshua Sampson[3], Jonathan Hofmann[1], Debra Silverman[1], Mark Purdue[1], Sonja Berndt[1]

[1]National Cancer Institute, Rockville, USA, [2]University of Maryland, Baltimore, USA, [3]U.S. Food and Drug Administration, Silver Spring, USA

BACKGROUND AND AIM: Per- and polyfluoroalkyl substances (PFAS) are group of chemicals commonly used in producing non-stick cookware, textiles, and firefighting foams. Exposure to PFAS is widespread in the U.S., with detectable serum levels in 98% of U.S. adults. Epidemiologic studies have suggested positive associations between PFAS and prostate cancer incidence and mortality, but the evidence is limited. We aimed to evaluate the association between pre-diagnostic serum concentrations of PFAS and aggressive prostate cancer risk in a large prospective study.

METHODS: We conducted a nested case-control study within the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial, which enrolled participants from 1993-2001 from 10 U.S. centers. Cases (N=750) included men diagnosed with aggressive prostate cancer (Stage III/IV or Gleason score≥8) at least 1 year after the blood collection. Male controls (N=750) were individually matched to cases based on age, race/ethnicity, study center, year of blood collection, and vial type. Pre-diagnostic serum concentrations of eight PFAS, including perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), and perfluorohexane sulfonic acid (PFHxS), were measured. Conditional logistic regression was used to estimate odds ratios (ORs) and 95% confidence intervals (95% CIs) for the association between PFAS and prostate cancer risk.

RESULTS: Preliminary analyses showed null associations between serum PFAS concentrations and the risk of aggressive prostate cancer (e.g., PFOS: ORcontinuous = 0.93, 95% CI: 0.83-1.05). However, differences were observed by calendar year of blood draw, with later years (1998-2004) suggesting a positive association for some PFAS, such as PFHxS (ORcontinuous = 1.12, 95% CI: 1.01-1.46) and PFOS (ORcontinuous = 1.20, 95%CI: 0.97-1.49).

CONCLUSIONS: This large prospective study did not provide evidence for an association between serum concentrations of individual PFAS and aggressive prostate cancer risk; however, an association among men with blood draws during later years, where measured serum PFAS concentrations were higher, cannot be ruled out.

P-1110 Occupational Hazards among Health Workers in Hospitals of Mukalla City, Yemen

Abdulla Bin-Ghouth[1]
[1]*Hadhramout University, Mukalla,* اليمن

BACKGROUND: Occupational health is a neglected public health issue among healthcare workers in developing countries like Yemen and they may expose them to various forms of hazards, which have had negative consequences on their wellbeing and performance at work.
Objective: The study aims at exploring the forms of occupational health hazards prevalence and methods to mitigate these hazards among Health Care Workers (HCW) in governmental hospitals in Mukalla city.

METHODS: It is a cross-sectional study conducted among health workers in the main hospitals in Mukalla city in Hadhramout province in eastern Yemen. The sample size is calculated statistically as 366 workers from different categories including doctors, nurses and lab technicians. A sample of 391 workers were selected randomly who were distributed to be representative and proportional to the size of each professional category.

RESULTS: The prevalence of biological hazards among the healthcare workers accounted for 298 (76%) whereas the non-biological hazards accounted for 306 (78%). The most prevalent biological hazards are needle prick injury (80%) followed by exposure to contact with contaminated material (75%), while the most frequent non-biological hazards are back pain (79%) followed by extra-time work (72%). In logistic regression age, gender and duration of work and professional category have significant association with exposure of health workers to biological hazards while only gender is the only variable associated with non-biological hazards.

CONCLUSIONS: There is a high prevalence of occupational hazards (biological and non-biological) among health workers in hospitals of Mukalla city. A prevention and infection control and patient safety programs are highly recommended in Mukalla hospitals to save health workers and patients.

P-1122 The impact of farm animal exposures on Campylobacter jejuni antibody levels in rural agricultural communities of Iowa, USA

Ian Buller[1,2], Joseph Shearer[1,2,3], Jared Fisher[1], Laura Beane Freeman[1], Gabriella Andreotti[1], Dale Sandler[4], Christine Parks[4], Karen Krogfelt[5,6], Charlotte Jørgensen[5], Rena Jones[1], Jon Hofmann[1]

[1]Occupational and Environmental Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Rockville, USA, [2]Cancer Prevention Fellowship Program, Division of Cancer Prevention, National Cancer Institute, Rockville, USA, [3]Heart Disease Phenomics Laboratory, Epidemiology and Community Health Branch, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, USA, [4]Chronic Disease Epidemiology Group, Epidemiology Branch, National Institute of Environmental Health Sciences, Research Triangle Park, USA, [5]Department of Virus & Microbiological Special Diagnostics, Statens Serum Institut, Copenhagen, Denmark, [6]Department of Science and Environment, Roskilde University, Roskilde, Denmark

BACKGROUND AND AIM: Campylobacter infections transmitted primarily through improperly cooked meat are the leading bacterial cause of diarrhea worldwide. How exposures to farm animals and animal waste (e.g., through occupational contact or residential proximity to animal feeding operations [AFOs]) contribute to infections has been relatively understudied.

METHODS: We measured antibodies against Campylobacter jejuni using an enzyme-linked immunosorbent assay in participants from Iowa in the Biomarkers of Exposure and Effect in Agriculture study (n=304 farmers; n=146 non-farming controls from similar communities). Participants self-reported occupational animal contact within the past year. We used a statewide database of permitted AFOs that included animal counts standardized by animal size and manure production to characterize the intensity of AFO exposure within 5km of participants' residences. We performed linear regressions of log-transformed optical density units (ODs) for immunoglobulin (Ig) A, G, and M antibody levels in relation to occupational animal and low/high AFO exposures, using non-farming controls with low AFO exposure (n=96) as the referent group. We adjusted for age, season, and other potential confounders. We further examined antibody levels by occupational contact with specific animal types.

RESULTS: Occupational animal contact was associated with elevated IgA and IgG OD levels in those with low AFO exposure (geometric mean ratio [95% confidence interval]; IgA:1.34[1.07-1.67]; IgG:1.34[1.13-1.57]) as well as those with high AFO exposure (IgA:1.48[1.12-1.95]; IgG:1.34[1.09-1.65]). Antibody levels were higher in farmers raising poultry (IgA:2.20[1.03-4.71]; IgG:2.11[1.35-3.32]), swine (IgA:1.52[1.04-2.22]; IgG:1.50[1.17-1.94]), and dairy cattle (IgG:1.65[1.18-2.31]), particularly for IgG levels in those who reported spending time in poultry (2.29[1.25-4.19]) or swine (1.63[1.25-2.12]) confinements within the past month. We found no significant relationships between occupational animal contact and IgM or AFO exposure alone and any antibody levels.

CONCLUSIONS: Occupational animal contact may be a stronger determinant of C. jejuni exposure than residential proximity to AFOs in agricultural communities.

KEYWORDS: Campylobacter, animal exposures

P-1125 Health Risk Assessment for Pest Control Workers Using Biocidal Products after COVID-19 Outbreak: A Comparison of EU and US

Sangji Lee[1], Lita Kim[1,2], Yun-Hee Choi[1,2], Kyoung Whan Moon[1,2,3]

[1]Department of Health and Safety Convergence Science, Korea University, Seoul, Republic of Korea, [2]Bk21 FOUR R&E Center for Learning Health System, Korea University, Seoul, Republic of Korea, [3]Institute of Health Sciences, Korea University, Seoul, Republic of Korea

After the COVID-19 outbreak, the workloads of disinfection have remarkably increased. As disinfectants are harmful to human, health risk assessment of disinfection workers is needed to ensure their safety. However, the acceptable operator exposure level (AOEL) for most disinfectants are not established. Moreover, the method of calculating the AOEL varies across the countries. This study aims to identify the health risks of disinfection workers based on two different risk assessment methods of EU and US after the COVID-19 outbreak.

We surveyed 533 disinfection workers to identify exposure patterns of disinfectants. The inhalation and dermal exposure were calculated based on different work types. The AOEL was calculated and compared using the EU and US methods. The health risks of workers are determined by hazard index based on whether the exposure exceeds AOEL.

Workers used 53 chemicals from 175 biocidal products, and only 34 chemicals (65%) had AOEL. 17 Chemicals with absorption factors for each route or AOEL were selected for risk assessment. When compared the estimated AOEL was calusing EU and US methods, only 2 (4%) were the same. The result of health risk assessment showed 10 (19%) were exceed 1 (acceptable level) using EU method, while 9 (17%) were exceed 1 using US method.

This study performed the health risk assessment of disinfection workers based on EU and US methods after the COVID-19 outbreak. Only 65% had an AOEL, and health risks of workers were differd according to risk calculation methods of EU and US. Given the increasing use of biocides after the COVID-19 outbreak, AOEL need to be established for health risk assessment of workers.

Biocides, Risk assessment, Reference dose, AOEL, COVID-19, pest control worker

P-1126 The Effectiveness of Occupational Health and Safety Management System (OHSMS) Application in the R.O.K. Navy and Improvement Plan

Sangji Lee[1], Yun-Hee Choi[1,2], Da-An Huh[3], Kyoung Whan Moon[1,2,4]

[1]Department of Health and Safety Convergence Science, Korea University, Seoul, Republic of Korea, [2]BK21 FOUR R&E Center for Learning Health System, Korea University, Seoul, Republic of Korea, [3]Institute of Health Sciences, Korea University, Seoul, Republic of Korea, [4]Department of Health and Environmental Science, Korea University, Seoul, Republic of Korea

The Republic of Korea Navy is applying OHSMS (Occupational Health and Safety Management System) to 3 type of units(repair, engineer, ammunition) for workplace safety. Several studies have argued that implementing OHSMS in the workplace is problematic and that measures are needed to improve its effectiveness. Moreover, since OHSMS focuses on corporate safety, it should be adequately reviewed when applied to the military, but studies have not been conducted yet. This study aims to confirm the effectiveness of the Navy's OHSMS and to identify improvement measures.

We surveyed 599 members of the units to determine the impact of OHSMS on unit safety conditions (systems, management, activities). for engineer and ammunition units, the safety conditions were compared according to whether they were OHSMS certified. In the repair units without the OHSMS non-certified comparator, the safety conditions according to the OHSMS application period were compared. To confirm the improvement plan of OHSMS, we surveyed 29 Naval OHSMS experts and analyzed IPA (Importance-performance Analysis) and AHP (Analytic Hierarchy Process).

There was no statistical difference in the level of safety conditions according to whether OHSMS was applied and the operating period, so the effectiveness of OHSMS could not be confirmed. The Navy's OHSMS needed gradual improvement due to its low overall performance. In particular, there was an urgent need for improvement in 1.organizational roles, responsibilities, 2.consultation and participation of members, 3.support, and 4.capabilities. Among them, consultation and participation of members was rated the most as a result of importance weight analysis through AHP.

In this study, the effectiveness of the Navy's OHSMS has not been confirmed, and consultation and participation of members was a vital improvement factor. This can be used as basic data for the practical application of OHSMS in the Navy in the future.

P-1133 Occupational injuries and extreme heat: An analysis from the hot desert climate of Kuwait

Barrak Alahmad[1,2], Ali Al-Hemoud[3], Petros Koutrakis[1]
[1]Harvard T H Chan School of Public Health, Boston, USA, [2]Faculty of Public Health, Kuwait University, Kuwait City, Kuwait, [3]Kuwait Institute for Scientific Research, Kuwait City, Kuwait

BACKGROUND–Temperatures in the harsh summer times of Kuwait commonly exceed 40°C during the day. Since 2015, a ministerial law banned employees from working under the sun (11am to 4pm) from June 1st to August 31st of every year. The vast majority of the affected employees are migrant workers in outdoor jobs such as construction and hospitality.
AIM–We assessed the risk of occupational injuries associated with outdoor extreme hot temperatures during the summertime ban period in Kuwait.
METHODS–We collected daily occupational injuries that are reported to the Ministry of Health's Occupational Health Department for five years from 2015 to 2019. We examined counts of occupational injuries during the same summertime ban period from June 1st to August 31st in each of the five years. We fitted generalized additive models with a quasipoisson distribution in a time series design. A 7-day moving average of daily mean temperature was modelled with penalized splines adjusted for relative humidity, time trend and day of the week.
RESULTS–During the June-August summertime ban, the daily average temperature was 39.4°C(±1.8°C). There were 7.2, 7.6 and 9.4 reported injuries per day in the summer months of June, July and August, respectively. The exposure-response relationship was S-shaped with a decrease in risk at very extreme hot temperatures. Compared to the 10th percentile of summer temperatures in Kuwait (37.4°C), the average day with a temperature of 39.4°C increases the risk of injury by 1.38-fold (95% confidence intervals: 1.30-1.46). Similarly, temperatures of 40°C and 41°C were associated with relative risks of 1.41 (1.33-1.49) and 1.34 (1.21-1.49), respectively. The risks leveled off at 42°C (relative risk 1.21; 0.93-1.57).
CONCLUSIONS–We found substantial increases in occupational injury risk from extremely hot temperatures despite the summertime ban in Kuwait. Calendar-based rather than heat- or risk-based regulation may be inadequate to provide occupational protections for migrant workers.

P-1134 Evaluation of lung inflammation from daily exposures to fine and ultrafine particulate matter in a trade school

Kynda Tinawi[1], Alan da Silveira Fleck[1,2], Maximilien Debia[1,2], Céline Plante[3], Audrey Smargiassi[1,2,4]
[1]Centre De Recherche En Santé Publique (CRESP), Montreal, Quebec, Canada, [2]Department of Environmental and Occupational Health, School of Public Health, University of Montreal, Montreal, Quebec, Canada, [3]Direction de Santé Publique du Centre Intégré Universitaire de Santé et de Services Sociaux du Centre-Sud-de-l Île-de-Montréal, Montreal, Quebec, Canada, [4]Institut National de Sante Publique du Québec (INSPQ), Montreal, Quebec, Canada

BACKGROUND - Daily short-term exposure to ambient fine particles ($PM_{2.5}$; < 2.5 µm) in the general environment has been related to acute respiratory effects such as respiratory symptoms and inflammation, emergency room visits for respiratory conditions and mortality. Although exposure is higher in trade/occupational settings, acute respiratory effects of daily exposures remain unexplored.
OBJECTIVE - To evaluate the association between daily exposures to fine particles ($PM_{2.5}$) and Ultrafine Particles (UFP; < 0.1 µm), and fractional exhaled nitric oxide (FeNO), a relevant indicator of lung inflammation, in two trade settings from a construction school.
METHOD - A repeated-measure panel study was carried out on students performing welding and bricklaying activities (n=30). $PM_{2.5}$ and UFP concentrations were measured daily (area measurements with direct-reading instruments) and fractional exhaled FeNO were measured two times per day, pre-work and post-work, for 5 consecutive days. Mixed GLM models were used to assess associations.

RESULTS: - Daily geometric mean exposure to $PM_{2.5}$ from welding and bricklaying activities were respectively 183 µg/m³ (σg=3.5) and 90.8 µg/m³ (σg=1.6). Daily geometric mean UFP concentrations for these activities were 106,000 (σg=1.6) particles/cm³ and 4,400 (σg=1.7) particles/cm³. Combining bricklaying and welding activities, for a 10,000 particles/cm³ increase in UFP, there was a 0.2 ppb (95%CI: 0.05-0.3) increase in FeNO inter-day. There was also a tendency for a small increase in FeNO (0.2 ppb; 95%CI: -0.06 - 0.5) per 100 µg/m³ of $PM_{2.5}$. Further analyses will be performed with additional participants and stratified by occupational trade.
CONCLUSION - Bricklaying and welding activities expose workers daily to $PM_{2.5}$ and UFP that may contribute to recurrent pulmonary inflammation and impair respiratory health.

KEYWORDS: particulate matter, occupational exposures, short-term exposure, pulmonary inflammation.

P-1136 Association between night shift work and different categories of non-occupational physical activity in the Shahedieh cohort study

AmirHoushang Mehrparvar[1], Mahsa Nazari[2], Seyed Saeed KhayatZadeh[3], Mohammad Javad Zare Sakhvidi[2]
[1]Occupational Health Department, School of Public Health, Shahid Sadoughi University of Medical Sciences, Yazd, Islamic Republic of Iran, [2]. Industrial diseases research center, Shahid Sadoughi University of Medical Sciences, Yazd, Iran, [3]. Department of Nutrition, School of Public Health, Shahid Sadoughi University of Medical Sciences, Yazd, Iran

INTRODUCTION
Shift-work has been associated with physical and mental health problems. This study aimed to explore the association between shift-work and different non-occupational physical activities in Iranian adults enrolled in the Shahedieh cohort study (SCS).

METHODS: The participants were men enrolled in the SCS (2014-2017). Different categories of non-occupational physical activity were quantified by the International Physical Activity Questionnaires and presented (as continuous by the metabolic equivalent of task [MET]), and dichotomous for defining sedentary/non-sedentary behavior based on MET). Shift-work status was asked through a face-to-face interview. The odds of having a sedentary behavior associated with shift-work, and the association between shift-working and daily MET of each category of activity were modeled using adjusted logistic regression and multiple linear regression (presented as odds ratio [OR] and beta respectively, with 95% confidence intervals [CI]). Results are based on the models adjusted for hypothesized confounders.

RESULTS: of 5132 men, 13.3% were shift-worker (more educated, and younger than non-shift-workers). Shift-workers had 20% lower odds of sedentary behavior compared to non-shift-workers (OR = 0.80; 95% CI: 0.60-0.98). Shift-working was associated with higher daily MET related to time spent on driving (ß=0.88; 95%CI: 0.75: 1.02), walking (ß=0.45; 95%CI: 0.33: 0.56), and light manual handling (ß=0.06; 95%CI: 0.01: 0.10), but the negative association with heavy sports activities (ß=-0.01; 95%CI: -0.03:-0.00), time spent on house cleaning (ß=-0.03; 95%CI: -0.06:-0.01), watching television (ß=-0.11; 95%CI: -0.20:-0.02), and working with a computer (ß=-0.13; 95%CI: -0.21:-0.06).
CONCLUSION: Shift-workers spent more energy on non-occupational activities than non-shift-workers, especially on outdoor activities. It implies the importance of considering shift-working as a possible effect modifier in the studies with hypotheses related to exposures linked to residing in outdoor environments such as the use of greenspace and ambient air pollution.

KEYWORDS: Shift-Work, Physical Activity, Occupational Health

P-1138 Occupational heat exposure and prostate cancer risk: a pooled analysis of case-control studies

Alice Hinchliffe[1], Juan Alguacil Ojeda[2], Wendy Bijoux[3], Manolis Kogevinas[1], Florence Menegaux[3], Marie-Elise Parent[4], Beatriz Pérez Gomez[5], Sanni Uuksulainen[6], Michelle Turner[1]

[1]Isglobal, Barcelona, Spain, [2]Centro de Investigación en Salud y Medio Ambiente (CYSMA), Universidad de Huelva, Huelva, Spain, [3]Center for Research in Epidemiology and Population Health CESP - INSERM, Villejuif, France, [4]Institut national de la recherche scientifique, Quebec City, Canada, [5]Instituto de Salud Carlos III | ISCIII · Department of Epidemiology of Chronic diseases, Madrid, Spain, [6]Finnish Institute of Occupational Health, Helsinki, Finland

BACKGROUND AND AIM: Heat exposures occur frequently in many indoor and outdoor occupations. In our previous work, we observed some evidence for a positive association of occupational heat exposure and breast cancer risk. Here we seek to examine potential associations with prostate cancer risk in a large multi-country study.

METHODS: We performed a pooled analysis of data from 3,175 histologically confirmed prostate cancer cases and 3,529 frequency-matched controls from studies in three different countries, Spain, France, and Canada. The Finnish job exposure matrix, FINJEM, was used to apply estimates of occupational heat exposure to the lifetime occupational history of participants. Three main exposure indices were used: ever vs. never exposed, lifetime cumulative exposure (heat stress years) and duration of exposure (years) with a lag period of 5 years. We estimated odds ratios (ORs) and 95% confidence intervals (CIs), using conditional logistic regression models stratified by 5-year age groups and study and adjusted for potential confounders.

RESULTS: A total of 32% of cases and 33% of controls were classified as being ever occupationally exposed to heat. Highest heat exposed occupations included ore and metal furnace operators, firefighters, and bakers. We found no evidence for an association of ever occupational heat exposure and prostate cancer risk (OR 0.92; 95% CI 0.83, 1.03). There were also no associations observed in the highest categories of lifetime cumulative exposure or duration, and there was no evidence for a trend. Results did not change when stratifying by Gleason scores. When analysing the Spanish case-control study separately using a Spanish job exposure matrix developed for local working conditions, some odds ratios were elevated, though results were imprecise.

CONCLUSIONS: Findings from this pooled study have provided no strong evidence for an association between occupational heat exposure and prostate cancer risk.

KEYWORDS: prostate cancer, occupational exposures, heat, pooled analysis

P-1141 Oxidative stress in workers in indoor and outdoor environments

Marco Panizzolo[1], Federica Ghelli[1], Giulia Squillacioti[1], Enrico Bergamaschi[1], Roberto Bono[1], Valeria Bellisario[1]
[1]*Department of Public Health and Pediatrics, University of Turin, Turin, Italy*

BACKGROUND AND AIM: Occupational exposure to particles can raises important health issues for exposed workers. High concentrations of these particles can be found in a variety of occupational and environmental contexts, depending on the type of scenario, whether indoors or outdoors working environments. The aim of this study was to investigate the role that indoor and outdoor environments play in altering oxidative stress levels in workers in relation to the exposure to particles.

METHODS: 162 subjects were recruited; 62 were subjects working in indoor environments (13 employed in the handling of waste, 49 not exposed to this task), 100 subjects working in outdoor environments (65 employed in sweeping of the streets, 35 not exposed to this task). Oxidative stress was assessed by analysing 15-F2t-isoprostane concentrations in urine samples of all the recruited subjects. In addition, a questionnaire was administered to each to obtain information among which gender, age, BMI, smoking habits. Statistical analyses were done using SPSS and 15-F2t-Isoprostane concentrations were compared each other using the Kruskal-Wallis test.

RESULTS: The analyses showed a higher level of 15-F2t-Isoprostane in workers working in indoor environment when compared to workers working in outdoor environments ($P<0.01$). Furthermore, the employed in the handling of waste in indoors show the highest level of 15-F2t-isoprostane ($P<0.05$) while, subjects not exposed to this task in indoors, place themselves at intermediate 15-F2t-isoprostane levels.

CONCLUSIONS: This study shows that higher levels of oxidative stress were found in both exposed and unexposed workers in indoor environments. Analysing the responses to the questionnaire, we also controlled tobacco smoke exposure because it may have a role in the redox imbalance recorded in workers.
These results hypothesise that particle dilution in outdoor environments may be directly associated with lower levels of oxidative stress in the workers.

KEYWORDS: occupational exposure, environmental exposure, particle emissions.

P-1152 Contribution of Occupational Risk Factors to Lifespan Inequalities across Socio-Occupational Groups in France

Narges Ghoroubi[1,2], Mary Beth Terry[3], Emilie Counil[1,4]

[1]French Institute for Demographic Studies (ined), Aubervilliers, France, [2]Paris Saclay University, Doctoral School of Public Health (EDSP), Villejuif, France, [3]Columbia University Mailman School of Public Health, Department of Epidemiology, New York, USA, [4]Institut de Recherche Interdisciplinaire sur les Enjeux Sociaux - Sciences sociales, politique, santé, IRIS (UMR 8156 CNRS - EHESS - U997 INSERM), Aubervilliers, France

BACKGROUND AND AIM: Occupational risk factors can mediate the effect of socioeconomic status on mortality; however, the reduction in social disparities in mortality that could be achieved by modifying employment and working conditions has been under-studied. Our aim was to quantify the role of occupational risk factors (lack of job control, job insecurity, and unemployment; and in men only: occupational physical activity (OPA)) in producing socio-occupational inequalities in lifespan among the French population.

METHODS: We reviewed the literature on 75 occupational risk factors and selected four of them with a robust all-cause mortality effect size. We used the Health and Career Path survey (SIP-2006) to estimate differential exposures in each French socio-occupational group (SOG) by sex. Then, using the life tables published by The French Institute of Statistics and Economic Studies and developing a method based on population attributable fractions, we estimated loss in life expectancy attributed to workplace exposures by SOG and sex.

RESULTS: Based on life expectancy estimated at age 35 and depending on SOG, from one to three years of life lost for men, and from 0.6 to two years for women are attributed to a combination of high OPA, low job control, job insecurity, and unemployment compared to those who had low OPA, high job control, no concerns about job loss and were employed. The difference in life expectancy at age 35 between senior executives and manual workers would have been reduced from 6.3 to 4.4 years for men and from 3.2 to 2.2 years for women if socio-occupational exposures had been set at the theoretical minimum level for the four risk factors.

CONCLUSIONS: Our results, although based on a limited number of workplace factors due to large data gaps, show that improving employment and working conditions would substantially lessen social inequalities in life expectancies.

P-1153 Agricultural pesticide exposure assessment in Latin America and the Caribbean. A review study

Melisa Romero Asís[1], Mariana Eandi[1], Maria Osley Garzón Duque[2], Nicole Builes[3], Camila Arias Gonzalez[3], Mariana Butinof[1]

[1]Escuela de Nutrición- Facultad de Ciencias Médicas-Universidad Nacional De Córdoba, Córdoba, Argentina, [2]Facultad de Medicina- Escuela de Graduados -Universidad CES., Medellín, Colombia, [3]Facultad de Medicina-Universidad CES, Medellín, Colombia

The region of the Americas shows heterogeneous agricultural labor scenarios. The measurement of pesticide exposure is a challenge and a necessary requirement for prevention. A systematic review of the scientific literature was carried out to identify the methodologies to assess exposure to agricultural pesticides in Latin America and the Caribbean (LAC).

PubMed, Scielo and Lilacs were searched (January 2010 and April 2021). Keywords selected: "pesticides", "occupational exposure", "farmers", "pesticide exposure" and "Latin America". Eighty-two publications from 11 countries were retained for analysis. The exposure assessment methods (EAMs) were analyzed, categorized into direct and indirect, analyzing the productive context of the study, according to whether it belonged to the formal or informal economy.

Most of the articles analyzed came from Brazil (41%) and Colombia (23%); cross-sectional designs predominated (64%). The term "exposure" appears as a scattered concept in the literature; 67% of the studies evaluated exposure to pesticides in informal agricultural contexts where family work was identified, in contrast to formal productive environments where it was not reported. The types of EAMs used were: a) indirect methods (58%): surveys, index construction, and measurement of environmental parameters (water and soil); b) direct methods (15%): biomarkers in blood, urine and other human matrices; c) combination of both methods (27%). Significant differences were identified between the EAMs used (direct/indirect) according to the context (formal/informal) of study (p= 0.016). The use of indirect EAM was more frequent in productive contexts of the informal economy.

Pesticide exposure assessment in LAC is heterogeneous and implemented through methods that are difficult to identify and classify. In the informal economy, family work prevails and there is less knowledge about pesticide exposure. Knowledge about these processes is necessary to reduce risks and vulnerabilities.

Pesticides - exposure - assessment methods - agriculture

P-1161 Physically strenuous work in a hot climate and reduced kidney function in the sugarcane industry

Katie Applebaum[1], Magda Castrillo[2], Morgan Byrne[3], Daniel Brooks[4]
[1]George Washington University, Milken Institute School of Public Health, Department of Environmental and Occupational Health, Washington, USA, [2]Pantaleon Group, Chinandega, Nicaragua, [3]George Washington University, Milken Institute School of Public Health, Department of Epidemiology, Washington, USA, [4]Boston University School of Public Health, Department of Epidemiology, Boston, USA

BACKGROUND AND AIM: Sugarcane workers are reportedly at increased risk of chronic kidney disease of non-traditional causes (CKDnt). Most prior studies have focused on a limited number of jobs, yet suspected risk factors of hot climatic conditions and strenuous work are common across jobs in the industry. We examined whether reduced kidney function was associated with working in hot climatic conditions and strenuous work in an industry-wide program.

METHODS: Data from a surveillance program at a Nicaraguan sugarcane planation 2015-2020 involved random collection of blood, allowing estimation of glomerular filtration rate (eGFR), for all employees. Any eGFR <=60 mL/min/1.73m2 was classified as low. Jobs were classified by whether outside and whether physical labor. Analyses restricted to males <50 years old who were non-supervisors. Multivariable models were used to estimate adjusted odds ratios (aORs) and 95% confidence intervals (CIs) comparing odds of low eGFR for working outside with inside, either adjusted for or stratified by age. Among outside workers, odds of low eGFR for each laborer job was compared with non-laborers. Models also adjusted for repeated measures and harvest period.

RESULTS: Analyses included 2,884 employees with 6,144 eGFR measures. There was no difference in odds of low eGFR between working outside or inside. Among those outdoors, laborers had increased odds of low eGFR compared with non-laborers (OR=3.58, (95% CI 1.85-6.94)). The association was most pronounced among those <=30 years old (OR=11.89 (95% CI 1.68-84.03)). Jobs of seed loader, seeder/reseeder, and weeder had >=6-fold increased odds of low eGFR relative to outdoor non-laborers (p<0.001).

CONCLUSIONS: Physically strenuous jobs in combination with working outside in a hot climate was consistently associated with reduced kidney function, with strongest influence in younger workers. Our results suggest more research should evaluate younger workers in physically demanding jobs to help identify prevention strategies.

KEYWORDS: CKDnt, heat, work

P-1174 Assessment of Portuguese firefighters' lifestyle: results from an online survey

Sónia Namorado[1,2,3], Laura Carmona[4], Raquel Pinheiro[5], Joana Faria-Anjos[6], Maria José Chambel[4]
[1]Department of Epidemiology, National Institute of Health Doutor Ricardo Jorge, Lisbon, Portugal, [2]NOVA National School of Public Health, Public Health Research Centre, Universidade NOVA de Lisboa, Lisbon, Portugal, [3]Comprehensive Health Research Center, Universidade NOVA de Lisboa, Lisbon, Portugal, [4]CicPsi, Faculdade de Psicologia da Universidade de Lisboa, Lisbon, Portugal, [5]National Fire Service School, Sintra, Portugal, [6]Instituto de Emergência Médica, Lisbon, Portugal

Firefighters are an occupational group exposed to multiple agents, such as heat, fatigue, noise and chemical substances. Exposure to these agents can have a severe impact on their health. In addition, lifestyle behaviors may also affect their health and well-being. As such, the aim of this study was to assess health-related lifestyle behaviors in Portuguese firefighters.

Data was obtained via an online survey using an adapted version of the FANTASTIC Lifestyle Assessment Inventory that included questions on relationships with family and friends, physical activity, nutrition, tobacco and alcohol consumption, sleep and stress, career and shifts. The access link to the survey was disseminated through collaboration with the National School of Firefighters. Data was collected between April 24th and May 27th 2021.

From the 861 participating firefighters, the majority were men and had less than 40 years old. Around half were married and were firefighters for more than ten years. The majority referred to have people to talk about important things and to give and receive affection. Regarding physical activity the majority did not practice physical activity in the professional context. Only a quarter reported to have healthy eating habits and the majority reported the consumption of high-calorie foods and to be exceeding their ideal weight. More than a third reported smoking and around 16% reported driving motor vehicles after consuming alcohol. Around 40% reported to consume more than 3 caffeine drinks per day. Around a tenth reported to almost never have good quality sleep and only around 78% reported to have difficulties sleeping. About 43% didn't have capacity to manage stress in their day to day life and about 57% were not able to relax in their free time. Around 40% reported not being happy with their work and a third reported to do periodic medical exams.

P-1177 Impact of the COVID-19 pandemic on a pilot sample of women enrolled in the SEMILLA birth cohort study

Alexis Handal[1], Fadya Orozco[2], Stephanie Montenegro[3], Alexa Kort[1]
[1]University of Michigan, Ann Arbor, USA, [2]Universidad de San Francisco de Quito, Cumbaya, Ecuador, [3]CTT-USFQ/Proyecto Semilla, Cumbaya, Ecuador

BACKGROUND AND AIM
Project SEMILLA, a community-engaged epidemiological cohort study, assesses environmental, occupational, and social factors among pregnant women in a major flower-growing region of Ecuador and the impact of these factors on child growth and development. The COVID-19 pandemic has presented an unprecedented challenge to the implementation of the SEMILLA study. This paper presents the results of a pilot qualitative study with SEMILLA participants examining the impact of the pandemic on their lives.

METHODS: SEMILLA follows pregnant women and their infants up to 18 months of age. Methods include obtaining prenatal urine samples, maternal and neonatal blood samples to assess thyroid hormone levels, and data on working conditions, environmental exposures (home/work), stress, social support, maternal health, socioeconomic factors, and infant neurodevelopment, growth and nutritional status. During the initial months of the pandemic, SEMILLA researchers observed important impacts of the pandemic in the study region and with enrolled participants. In April 2020, we conducted phone interviews with currently enrolled participants (n=11), to assess the experiences of the participants during this time. Semi-structured questions addressed concerns and worries as well as changes in activities (work/home) due to the pandemic.

RESULTS: Emergent themes from qualitative analysis include economic insecurity and job loss, food insecurity and food access issues, strained relationships at home including interpersonal violence, responsibilities at home including additional burdens for participants regarding schooling of other children. Fear and worry about being infected, about having a healthy pregnancy and a healthy delivery and baby, and fear of family members being infected prevailed.
CONCLUSION: Findings from this pilot study helped shape protocol changes and revisions to capture the new reality for women participating in SEMILLA during the pandemic; changes which are critical for understanding the impact of the COVID-19 pandemic on the lives of pregnant women and their families in the region.

P-1178 The environmental risk factors of birth defects in Iraq

Jeffrie Quarsie[1], Kali Rubaii
[1]*Netherlands School of Public and Occupational Health, Netherlands*

BACKGROUND AND AIM: Ever since the war started in 2003, Iraqi doctors have reported an increase in the birth of children with congenital anomalies. According to them, the rise in incidence has been attributed to war-related heavy metal pollution e.g. from depleted uranium and white phosphorus. As the war impeded quality research, the current post-conflict situation has allowed renewed space for quality research. The aim of the study is to assess to what extent exposure to environmental pollution might be associated with the incidence of congenital anomalies in Iraq.

METHODS: We conducted a case-control study in Fallujah, a heavily bombarded city, comparing 50 parents of children with birth defects and 50 parents of children without birth defects. We used a questionnaire to comprehensively document environmental exposure and history of residence of each couple. Further, we complemented the interviews with biomonitoring through hair analysis of parents on heavy metals using ICP-MS. In addition, we took soil samples of the city of Fallujah using grid sampling and compared this to a control city in northern Iraq which has been less bombarded. We used Stata to statistically assess the differences in case and control groups regarding exposure and heavy metal concentrations, correcting for confounders like age and socio-economic status.

RESULTS: Comprehensive data analysis will take place in the summer 2022. Our preliminary results already point to a striking discrepancy between the occupation of the fathers of children children with congenital anomalies and the fathers of the control group. The fathers of the birth defects are more often construction workers, working on houses often damaged or levelled by war.

CONCLUSIONS: Having a child with a congenital anomaly in Iraq might be associated with paternal environmental exposure, possibly through epigenetic pathways.

KEYWORDS: Congenital anomalies, Military pollution, Teratogenicity, Epigenetics, Exposome

P-1179 Associations between traffic-related air pollutants and preterm birth in a North Carolina birth cohort, 2003-2015

Alison K. Krajewski[1], Thomas J. Luben[1], Joshua L. Warren[2], Monica P. Jimenez[3], Kristen M. Rappazzo[1]
[1]USA Environmental Protection Agency, Office of Research and Development, Center for Public Health & Environmental Assessment, Research Triangle Park, USA, [2]Yale School of Public Health, Department of Biostatistics, New Haven, USA, [3]Oak Ridge Institute for Science and Education (ORISE) Postdoctoral Fellow at US EPA, Research Triangle Park, USA

BACKGROUND AND AIM: Preterm birth (PTB; <37 weeks completed gestation) is associated with exposure to fine particles and ozone, but less is known about associations with nitrogen dioxide (NO_2) and other traffic-related air pollutants, such as benzene, toluene, ethylbenzene, and xylene (BTEX). We estimated the associations between PTB and NO_2, with and without adjustment for BTEX.

METHODS: We examined the associations between PTB and gestational exposure to NO_2 in a North Carolina singleton birth cohort (N=1,367,507) from 2003-2015. Daily 8-hour max NO_2 concentrations from a hybrid-model with a spatial resolution of 1km² were aggregated to census tracts and linked to residential address at delivery, then averaged across each week of pregnancy. We obtained annual average ambient concentrations for BTEX for census tracts from the 2011 National Air Toxics Assessment. Modified Poisson regression models with robust errors were used to estimate risk differences (RD(95% CIs)) per 10-ppb increase in NO_2, adjusted for gestational parent marital status, race/ethnicity, age at delivery, Medicaid status, month of conception, and BTEX.

RESULTS: The median (IQR) NO_2 across each day of pregnancy was 15.0(10.2) ppb and 1.6(1.1) ppb for BTEX. The associations between NO_2 and PTB were of similar magnitude across each week of gestation. RDs with and without adjustment for BTEX varied. RDs per 10-ppb increase NO_2 exposure during each week of gestation ranged from -7(95% CI: -14,1) in weeks 17 and 23 to 0(-6,5) in week 36 per 10,000 births, respectively. Adjusting for BTEX, RDs ranged from 19(13,25) in week 36 to 36(27,44) in week 24 per 10,000 births, respectively.

CONCLUSIONS: While the association between NO_2 exposure and PTB were generally null across each week of gestation, when adjusting for BTEX, we observed a consistent pattern of increased risk of PTB with NO_2 exposure.

KEYWORDS: air pollution, preterm birth, nitrogen dioxide, reproductive outcomes

P-1181 Associations between Repeated Measures of Urinary Phthalate Metabolites with Hormones and Timing of Natural Menopause: The Study of Women's Health Across the Nation

Ning Ding[1], Emily Zheutlin[2], Siobán Harlow[1], John Randolph[3], Bhramar Mukherjee[4], Sung Kyun Park[1,2]
[1]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, USA, [2]Department of Environmental Health Sciences, School of Public Health, University of Michigan, Ann Arbor, USA, [3]Department of Obstetrics and Gynecology, School of Medicine, University of Michigan, Ann Arbor, USA, [4]Department of Biostatistics, School of Public Health, University of Michigan, Ann Arbor, USA

BACKGROUND AND AIM: Studies on phthalate metabolites and sex hormones during the menopausal transition are limited and have yielded conflicting results. We aimed to examine the associations of phthalate metabolites with hormones including estradiol, testosterone, follicle-stimulating hormone (FSH), sex hormone-binding globulin (SHBG), anti-Müllerian hormone (AMH), and the timing of natural menopause.

METHODS: We examined 1,189 midlife women from the Study of Women's Health Across the Nation aged 45-56 years in 1999-2000 who had complete information on phthalate metabolites and hormones while not receiving hormone therapy. Urinary concentrations of 12 phthalate metabolites were repeatedly measured in 1999-2000 and 2002-2003. Hormones were measured at the same time points. Linear mixed-effect models were used to calculate percent differences (%D) and 95% confidence intervals (CIs) in serum concentrations of estradiol, testosterone, FSH, SHBG, and AMH per doubling in urinary phthalate metabolites. Cox proportional hazards models were used to calculate hazard ratios (HRs) and 95% CIs of natural menopause per doubling increase in urinary phthalate metabolites.

RESULTS: We observed significant associations of phthalate metabolites with lower testosterone concentrations: mono (7-carboxy-2-methyloctyl) phthalate (MCOP) (%D: -2.08%, 95% CI: -3.66, -0.47), and mono-n-butyl phthalate (MnBP) (%D: -1.99%, 95% CI: -3.82, -0.13), after adjusting for multiple comparisons with false discovery rates < 5%. Lower AMH concentrations were also found with higher MECPP (%D: -14.26%, 95% CI: -24.10, -3.14), MEHHP (%D: -15.58%, 95% CI: -24.59, -5.50), and MEOHP (%D: -13.50%, 95% CI: -22.93, -2.90). No associations were observed for other hormones or timing of natural menopause.

CONCLUSIONS: These results suggest that exposure to phthalates may affect circulating levels of testosterone in midlife women. Exposure to phthalates may also dimmish the ovarian reserve. Given the endocrine-disrupting role of phthalates, future studies are warranted to evaluate their impact on health outcomes among midlife women.

KEYWORDS: Phthalates; endocrine-disrupting chemicals; hormones; midlife women; menopause

P-1185 Urinary concentrations of non-persistent endocrine disrupting chemicals and fecundability in a preconception cohort study

Amelia Wesselink[1], Elizabeth Hatch[1], Ellen Mikkelsen[2], Michael McClean[1], Kathryn Tomsho[3], Birgit Claus Henn[1], Ganesa Wegienka[4], Kenneth Rothman[1], Lauren Wise[1]

[1]Boston University School of Public Health, Boston, USA, [2]Aarhus University Hospital, Aarhus, Denmark, [3]Harvard T. H. Chan School of Public Health, Boston, USA, [4]Henry Ford Health System, Detroit, USA

BACKGROUND AND AIM: Non-persistent endocrine-disrupting chemicals (EDCs) are found in consumer products including personal care products, plastics, and cleaning supplies. EDCs can affect hormonal pathways involved in reproduction. We examined prospectively the association between urinary concentrations of select non-persistent EDCs and fecundability, the per cycle probability of conception.

METHODS: We used data from PRESTO and Snart Foraeldre.dk, web-based preconception cohort studies that recruited female participants who were aged 21-45 years, residents of North America or Denmark, and trying to conceive without fertility treatment (2013-2019). Participants completed a baseline questionnaire and follow-up questionnaires every 8 weeks for up to 12 months. A subset of 207 participants residing in Boston, Massachusetts (n=119), Detroit, Michigan (n=18), or Aalborg, Denmark (n=70) provided urine samples during in-person clinic visits. We measured concentrations of 7 phenols, 4 parabens, triclocarban, 15 phthalate metabolites and 2 phthalate alternative metabolites using on-line solid-phase extraction-high-performance liquid chromatography-isotope dilution-tandem mass spectrometry. We used proportional probabilities models to estimate fecundability ratios (FR) and 95% confidence intervals (CI), adjusting for potential confounders.

RESULTS: Concentrations of some non-persistent EDCs were associated with reduced fecundability. The adjusted FR for the highest vs. lowest quartile of benzophenone-3 was 0.53 (95% CI: 0.28-0.99), with evidence of a monotonic association. Bisphenol S and 2,5'-dichlorophenol, and ethyl paraben concentrations were also associated with reduced fecundability. Among phthalate metabolites, mono-ethyl phthalate (highest vs. lowest quartile: FR=0.71, 95% CI: 0.45-1.12), monocarboxyoctyl phthalate (highest vs. lowest quartile: FR=0.71, 95% CI: 0.44-1.14), and the non-phthalate plasticizer cyclohexane-1,2-dicarboxylic acid monohydroxy isononyl ester (≥0.6 µg/g creatinine vs. <limit of detection: FR=0.59, 95% CI: 0.37-0.95) were associated with reduced fecundability.

CONCLUSIONS: Biomarkers of some non-persistent EDCs were associated with reduced fecundability. Future analysis of additional urine specimens in these cohorts will enable examination of chemical mixtures on fecundability.

P-1188 Association between maternal $PM_{2.5}$ exposure and gestational diabetes mellitus in Tokyo, Japan

Takehiro Michikawa[1], Seiichi Morokuma[2], Shin Yamazaki[3], Ayako Yoshino[3], Seiji Sugata[4], Akinori Takami[3], Kazushige Nakahara[2], Shinji Saito[4], Junya Hoshi[4], Kiyoko Kato[2], Hiroshi Nitta[3], Yuji Nishiwaki[1]
[1]Toho University, Tokyo, Japan, [2]Kyushu University, Fukuoka, Japan, [3]National Institute for Environmental Studies, Tsukuba, Japan, [4]Tokyo Metropolitan Research Institute for Environmental Protection, Tokyo, Japan

INTRODUCTION
Recent epidemiological findings suggested that $PM_{2.5}$ exposure is a risk factor for diabetes, and the association between $PM_{2.5}$ and glycaemia and insulin resistance provided the biological mechanistic support. Based on these, a hypothesis has been proposed that maternal exposure to $PM_{2.5}$ contributes to the development of gestational diabetes mellitus (GDM). However, the association between $PM_{2.5}$ and GDM was controversial, and there was limited evidence regarding exposure to specific components of $PM_{2.5}$. In this study, we examined the association between the $PM_{2.5}$-GDM association in the Asian population.

METHODS: From 2013 to 2015, we had permission to the Japan Society of Obstetrics and Gynaecology, and obtained the data on all mothers who delivered births after 22 gestational weeks at 39 cooperating hospitals in 23 Tokyo wards from the Japan Perinatal Registry Network database. We collected fine particle on a filter each day at one fixed monitoring site, and analysed carbon and ion components of $PM_{2.5}$. The average concentrations of $PM_{2.5}$ and its components over the 3-month before pregnancy, the first trimester (0-13 gestational weeks) and the second trimester (14-27 weeks) were calculated, and assigned to each mother. We applied a multi-level logistic regression analysis.

RESULTS: of the 83,319 mothers (mean age at delivery = 33.7 years), the proportion of GDM was 4.8%. The median concentration of total $PM_{2.5}$ over the first trimester was 16.1 (interquartile range (IQR) = 3.6) $\mu g/m^3$. When we simultaneously included three exposure windows of total $PM_{2.5}$, only exposure over the first trimester was associated with GDM (odds ratio per IQR = 1.09, 95%CI = 1.02-1.16). for specific components, we observed the association between exposure to carbon constituents over the first trimester and GDM.
CONCLUSION: Our findings provided the additional evidence for the association between maternal exposure to $PM_{2.5}$ and GDM.

P-1196 Exposure to ambient sulfur dioxide during gestation and risk of preterm birth among people in North Carolina, 2003-2014

Adrien Wilkie[1,2], Thomas Luben[3], Kristen Rappazzo[3], Kristen Foley[4], Courtney Woods[5], Marc Serre[5], David Richardson[2], Julie Daniels[2]

[1]Oak Ridge Institute for Science and Education (ORISE) Postdoctoral Fellow at US EPA, Research Triangle Park, USA, [2]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA, [3]USA Environmental Protection Agency, Office of Research and Development, Center for Public Health & Environmental Assessment, Research Triangle Park, USA, [4]USA Environmental Protection Agency, Office of Research and Development, Center for Environmental Measurement and Modeling, Research Triangle Park, USA, [5]Department of Environmental Science and Engineering, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA

BACKGROUND AND AIM: Coal-fired power plants are major contributors of ambient sulfur dioxide (SO2) air pollution. Epidemiological literature suggests an adverse association between SO2 exposure during gestation and preterm birth (PTB; <37 weeks completed gestation). PTB is strongly associated with infant mortality and increased risk for later life morbidities. We investigated associations between SO2 and PTB in North Carolina and evaluated whether the associations were modified by race/ethnicity.

METHODS: We assembled a retrospective, administrative cohort of singleton births in North Carolina from 2003-2014. We used USEPA CMAQ data to assign SO2 gestational exposures to eligible births for the entire pregnancy and trimesters. We used multivariable generalized linear regression to estimate risk differences (RD (95%CI)) per 1-ppb increase in SO2, adjusted for gestational parent education, marital status, and season of conception. Multi-pollutant models were additionally adjusted for criteria air co-pollutants (CO, O3, PM2.5, NO2).

RESULTS: The median SO2 across exposure windows was ~3.5 (IQR: 4) ppb. The overall baseline risk for PTB was 8800 per 100,000 live births. When stratified by race/ethnicity, the baseline risk for PTB was 12200, 7900, and 7100 per 100,000 live births among non-Hispanic Black, non-Hispanic white, and Hispanic births, respectively. Regardless of exposure window, SO2 was adversely associated with PTB with the strongest associations observed for the entire pregnancy period. RDs per 1-ppb increase in SO2 averaged across the entire pregnancy were 133.5 (95%CI: 117.0, 149.9) and 195.7 (171.6, 219.7) per 100,000 live births for single- and multi-pollutant models, respectively. for multi-pollutant models, we observed similar RDs for non-Hispanic Blacks (239.4 (200.7, 278.2)) and non-Hispanic whites (211.5 (182.4, 240.7)) with smaller RDs for Hispanics (119.8 (80.7, 158.9)).

CONCLUSIONS: Across exposure windows, the results for our adjusted single- and multi-pollutant models showed adverse associations between SO2 and PTB, with some evidence of effect measure modification by race/ethnicity.

KEYWORD: PTB

P-1197 Ambient temperature and preterm birth risk in New York City: A time-series analysis

Ariel Yuan[1], Kathryn Lane[1], Carolyn Olson[1], Kazuhiko Ito[1]
[1]*New York City Department of Health and Mental Hygiene, New York, USA*

BACKGROUND AND AIM: Recent studies suggest an association between daily variation in ambient temperature during pregnancy and preterm birth (PTB). Our objective is to examine the short-term effects of heat and cold on PTB risk from 2008 to 2016 in New York City (NYC).

METHODS: We applied quasi-Poisson regression with distributed lag nonlinear models to estimate the cumulative relative risk (CRR) of daily counts of spontaneous PTB (<37 weeks gestation) and outdoor temperature, and to estimate the fraction of PTBs attributable to temperature, by season, using NYC Vital Statistics birth records and National Weather Service daily temperature data at LaGuardia airport. Models were adjusted for within-season trends and daily number of pregnant people at risk for preterm delivery. Heat and cold were defined as the 95th versus 50th percentile of maximum temperature during the warm season and 5th versus 50th percentile of minimum temperature during the cold season, respectively. Maternal race/ethnicity was assessed for effect modification.

RESULTS: Our analysis consisted of 38,593 spontaneous PTBs. Heat was not associated with PTB during the warm season [CRR: 0.98 (95% CI: 0.92, 1.05)]. There was a nonlinear association between cold and PTB. During the cold season, the CRR was 1.08 (0.99, 1.17) for cold up to three days before delivery (lag 0-3). The estimated fraction of PTBs attributable to cold was 9.3% (-0.6%, 17.4%), which corresponded to 81 (-2, 154) cold-attributable PTBs over the 9-year study period. Among non-Hispanic Blacks, the CRR was 1.20 (1.04, 1.39) for cold over lag 0-3 days, and an estimated 23.2% (10.3%, 34.3%) of non-Hispanic Black PTBs, equivalent to 69 (29, 105) PTBs, were attributable to cold.

CONCLUSIONS: Heat had no measurable impact. Cold potentially increased risk of PTB. Our finding for the impact of cold on non-Hispanic Black PTBs warrants additional research.

P-1199 The association of congenital heart defects with prenatal exposure to air pollutants: An umbrella review

Sophie Michel[1], Aishwarya Atmakuri[2], Ondine Solveig Von Ehrenstein[1,3]
[1]Department of Epidemiology, UCLA School of Public Health, University of California, Los Angeles, USA, [2]Department of Molecular, Cell, and Developmental Biology, UCLA College of Life Sciences, University of California, Los Angeles, USA, [3]Department of Community Health Sciences, UCLA School of Public Health, University of California, Los Angeles, USA

BACKGROUND AND AIM: for idiopathic congenital heart defects (CHD), air pollution during fetal development is a potential risk factor. However, findings of previous epidemiological studies and consequently of systematic reviews, have been mixed. We aimed to synthesize and evaluate the extant evidence on associations between gestational exposure to air pollutants and CHD subtypes, using a systematic review of reviews approach ("umbrella review").

METHODS: We systematically searched PubMed, Embase, and Epistemonikos for published and unpublished systematic reviews. The search was supplemented by the use of internet search engines and hand-searching of reference lists. The Risk of Bias in Systematic Reviews ("ROBIS") tool was used to evaluate included systematic reviews.

RESULTS: We identified ten systematic reviews, including eight meta-analyses. Moderately strong evidence for an increased risk of coarctation of the aorta following prenatal exposure to NO2 was provided by five reviews, which reported statistically homogeneous pooled odds ratios of 1.10 to 1.20 (95% confidence interval range: 0.99 to 1.41). Also, there was limited evidence for positive associations between SO2 and coarctation of the aorta, PM10 and atrial septal defects, NO2 and pulmonary artery and valve anomalies, and for both, PM2.5 and NO2 and Tetralogy of Fallot. Findings for other pollutant-CHD associations were inconsistent. Based on the ROBIS tool, a high or unclear risk of bias rating was assigned to eight out of ten reviews.

CONCLUSIONS: Beyond the increased risk of coarctation of the aorta following exposure to NO2, a clear pollutant-outcome pattern was not identified. These incoherent findings may partly be explained by differences in methods used across the reviews (e.g., inclusion criteria) as well as between individual studies (e.g., exposure and outcome assessment methods). Further establishment of and adherence to systematic review methods for environmental exposures and children's health may improve the validity and consistency of future systematic review findings.

P-1201 Metabolome-wide association study of prenatal exposure to air pollution and adverse birth outcomes in the Atlanta African American Maternal-Child cohort

Zhenjiang Li[1], Anne L Dunlop[2], Jeremy A Sarnat[1], Haoran Cheng[1], Youran Tan[1], Dana Boyd Barr[1], Anke Huels[3], Alicia Smith[2], Carmen Marsit[1], Dean P Jones[4], Donghai Liang[1]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Department of Gynecology and Obstetrics, School of Medicine, Emory University, Atlanta, USA, [3]Department of Epidemiology, Rollins School of Public Health, Emory University, Atlanta, USA, [4]Department of Medicine, School of Medicine, Emory University, Atlanta, USA

BACKGROUND: African Americans (AA) are disproportionately exposed to high air pollution and elevated risks of adverse birth outcomes, while the underlying mechanisms are still largely unknown. We aimed to address the knowledge gaps by investigating the associations between air pollution exposures, perturbations in maternal metabolome, and preterm (PTB) and early term birth (ETB).

METHODS: In 288 participants from the Atlanta AA Maternal-Child cohort we performed metabolomic profiling using high-resolution mass spectrometry with liquid chromatography in early gestation serum samples. Using spatiotemporally-resolved machine learning models, we estimated individual residential exposures to nitrogen dioxide, fine particulate matters, and ozone during the first trimester and one-year before conception. Using the meet-in-the-middle approach, we investigated whether the maternal metabolic perturbations associated with air pollution are also associated with PTB and/or ETB.

RESULTS: After quality control, 13,980 and 11,106 metabolic features were extracted from HILIC and C18 chromatography columns, respectively. In the HILIC column, 95 and 190 metabolic features were associated with at least one air pollutant (false positive discovery corrected $q<0.2$) during the first trimester and one-year before conception, respectively, while 3 and 4 features were associated with PTB and ETB. From C18, 243 and 48 features were associated with first trimester and one-year before conception exposures, while 5 and 1 were associated with PTB and ETB, respectively. Perturbations in purine metabolism were associated with both air pollution and PTB in pathway enrichment analysis. Using chemical annotation, we confirmed inosine and inosinic acid, which were enriched in purine metabolism and involved in DNA damage and repair.

CONCLUSIONS: The findings suggested a potentially critical role of purine metabolism in connecting air pollution exposures and PTB, which may support future development of sensitive biomarker and targeted interventions to reduce adverse birth outcomes induced by air pollution exposures.

P-1203 Cadmium may affect testosterone levels as a hormone-like disruptor in adult males

Yidan Qiu[1,2], Yuebin Lv[1], Miao Zhang[1], Saisai Ji[1], Bing Wu[1,3], Feng Zhao[1], Yingli Qu[1], Qi Sun[1], Yanbo Guo[1,4], Yuanduo Zhu[1], Xiao Lin[1], Xulin Zheng[1,3], Zheng Li[1], Hui Fu[1], Yawei Li[1], Haocan Song[1], Yuan Wei[1,4], Liang Ding[1], Guangdi Chen[5], Ying Zhu[1], Zhaojin Cao[1], Xiaoming Shi[1]

[1]China CDC Key Laboratory of Environment and Population Health, National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, China, [2]Department of Big Data in Health Science, School of Public Health, Zhejiang University, Hangzhou, China, [3]Center for Global Health, School of Public Health, Nanjing Medical University, Nanjing, China, [4]Department of Epidemiology and Biostatistics, School of Public Health, Jilin University, Changchun, China, [5]Institute of Environmental Health, School of Public Health, and Bioelectromagnetics Laboratory, School of Medicine, Zhejiang University, Hangzhou, China

BACKGROUND AND AIM: Sex hormones play an important role in human health, and sex hormone disorders can cause a series of relevant consequences. Cadmium is ubiquitous in the environment, while little is known on the relationship between cadmium exposure and sex hormones in adult males. The purpose of this study is to explore the potential association between cadmium exposure and serum testosterone as well as serum testosterone to serum estradiol ratio (T/E_2) among Chinese adult males.

METHODS: Adult male aged ≥18 years old who participated in China National Human Biomonitoring program from 2017 to 2018 were surveyed. Blood cadmium, urine cadmium and urine cadmium adjusted with creatinine were measured, serum testosterone and serum estradiol were measured, and T/E_2 was calculated. Multiple linear regression models were used to analyze association of cadmium exposure with serum testosterone and T/E_2 in adult males.

RESULTS: Among Chinese adult males ≥ 18 years old, the weighted geometric means (95% CI) of blood cadmium, urine cadmium and urine cadmium adjusted with creatinine levels were 1.23 (1.12, 1.35) μg/L, 0.63 (0.56, 0.71) μg/L and 0.53 (0.47, 0.59) μg/g, respectively. The geometric means (95% CI) of serum testosterone and T/E_2 were 18.56 (17.92, 19.22) nmol/L and 143.86 (137.24, 150.80). After adjusting for all covariates, tertiles of cadmium exposure were positively associated with log-transformed serum testosterone (lgT) (all Ptrend < 0.05). Moreover, tertiles of cadmium exposure were positively associated with log-transformed serum testosterone to serum estradiol ratio [$lg(T/E_2)$] (all Ptrend < 0.05).

CONCLUSIONS: In Chinese adult males, cadmium exposure may affect serum testosterone and T/E_2 as a hormone-like disruptor.

KEYWORDS: testosterone, testosterone to estradiol ratio, China National Human Biomonitoring, cadmium.

P-1211 Urinary biomarkers of inorganic arsenic exposure, inorganic arsenic metabolism, and birth weight in Tacna, Peru, 2019

Diego Fano-Sizgorich[1,2], Matthew O. Gribble[4], Dana B. Barr[3], Cinthya Vasquez-Velasquez[1], Julio Aguilar[6], Claudio Ramirez[6], Jeffrey K. Wickliffe[4], Maureen Lichtveld[5], Gustavo F. Gonzales[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Centro Latinoamericano de Excelencia en Cambio Climático y Salud, Universidad Peruana Cayetano Heredia, Peru, [3]Emory University, Atlanta, USA, [4]University of Alabama at Birmingham, Birmingham, USA, [5]University of Pittsburgh, Pittsburgh, USA, [6]Universidad Nacional Jorge Basadre Grohmann, Peru

BACKGROUND AND AIM: Arsenic exposure during pregnancy has been related to adverse birth outcomes such as low birthweight. The province of Tacna is located in southern Peru. It is characterized by elevated arsenic levels in drinking water, nonetheless, its mean birth weight is greater than the country's average. Thus the aim of this study was to evaluate the effect of urinary arsenic species on birth weight in Tacna pregnant women in 2019.

METHODS: 160 pregnant women ≤24 weeks were recruited from different health centers of Tacna, and followed up to delivery. First morning voids of urine were sampled in the second and third trimester; they were encouraged to avoid consuming seafood at least three days before sampling. Arsenic species (AsIII, AsV, MMA, DMA and arsenobetaine) were analyzed by ICP-MS. Birth outcomes data was obtained from the clinical records of Hospital Hipólito Unanue. Inorganic arsenic exposure was measured as the sum of inorganic and methylated species in urine, adjusted for arsenobetaine. Inter-individual differences in arsenic toxicokinetics were measured using the principal components of the relative concentrations of inorganic, methylated, and dimethylated arsenic in urine. We considered inorganic arsenic exposure, and arsenic toxicokinetics, individually and with an interaction term as predictors of birth weight.

RESULTS: Mean birth weight was 3618.71g, while mean tAs, iAs, MMA and DMA were 41.62, 3.52, 2.49, and 35.61µg/L, respectively. The estimate of the beta coefficient for the association of arsenic with birth weight was 0.21 (95%CI -2.31;2.74) for inorganic arsenic, while for arsenic toxicokinetics it was11.88 (95%CI -22.35;46.12), and for the interaction between them was 0.33 (95%CI -0.83;1.49).

CONCLUSIONS: In this population, we did not find evidence that arsenic exposure affected birth weight. This null association could be due to study limitations as sample size or factors not measured.

KEYWORDS: Arsenic, Birth weight, Peru, Latin America

P-1215 Residential greenspace and birth outcomes in the Chemicals in Our Bodies cohort, San Francisco, California

Lara Cushing[1], Hasibe Caballero-Gomez[1], Ana Pelegrini Guimaraes[2], Nicholas Depsky[3], Stephanie Eick[4], Tracey Woodruff[5], Rachel Morello-Frosch[3]

[1]University of California Los Angeles, Los Angeles, USA, [2]San Francisco State University, San Francisco, USA, [3]University of California Berkeley, Berkeley, USA, [4]Emory University, Atlanta, USA, [5]University of California San Francisco, San Francisco, USA

BACKGROUND AND AIM: Evidence from prior studies is inconclusive regarding the association between residential proximity to greenspace and birth outcomes. Psychosocial stress increases the risk of adverse birth outcomes and may modify associations with greenspace. We evaluated the effects of residential greenspace on gestational age and fetal growth and whether they differed with experiences of psychosocial stressors.

METHODS: Chemicals in Our Bodies is a demographically diverse prospective cohort of pregnant people in San Francisco, California (N = 815). Three measures of greenspace were constructed using the birth parent's residential address and secondary data: normalized difference vegetation index (NDVI) and percent green or blue space within 500m, and Euclidean distance to the nearest park. We used linear regression to estimate the association between quartiles of greenspace measures, completed gestational week and birthweight for gestational age z-scores (BWz), adjusting for parental age, education, smoking, parity, food insecurity, race/ethnicity, nativity, traffic within 500m, and noise. We stratified by perceived stress and depression.

RESULTS: Comparing quartile 1 vs. 4, NDVI and percent green and blue space were not strongly associated with differences in mean completed weeks of gestation (β=-0.05 [95% confidence interval -0.57, 0.48] and 0.09 [-0.39, 0.57]) or mean BWz (β=-0.07 [-0.35, 0.21] and -0.11 [-0.36, 0.14]). Low NDVI (quartile 1 vs. 4), low percent green and blue space (quartile 1 vs. 4), and high distance to nearest park (quartile 4 vs. 1) were weakly associated with reductions in gestational age among parents reporting high levels of stress or depression (β=-0.73 [-2.83, 1.36], -1.31 [-3.47, 0.85], and -0.47 [-1.92, 0.99] weeks). Associations were slightly stronger when we considered 1km buffer distances, but still not statistically significant.

CONCLUSIONS: We did not find strong evidence that residential greenspace is associated with reductions in gestational age or birthweight in this study population.

KEYWORDS: nature, urban, perinatal

P-1217 Maternal Vitamin D levels modify the association between pre-pregnancy Triclosan exposure and neonatal anogenital distance

Yan Zhang[1], Yunjie Ren[1], Yu Gao[1], Ying Tian[1]
[1]*School of Public Health, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

BACKGROUND AND AIM: Triclosan (TCS) is widely used as an antibacterial agent in consumer products and is suspected of having endocrine-disrupting properties, limited epidemiological studies examined the developmental effects of TCS exposure before pregnancy. Meanwhile, Vitamin D deficiency is a global health issue and the consequences of vitamin D deficiency during pregnancy cannot be underestimated. We investigated association between maternal TCS exposure and anogenital distance (AGD) and other genital measurements in infants at birth after considering maternal vitamin D status.

METHODS: Participating 258 women were recruited from Shanghai Birth Cohort between 2012 and 2013. TCS concentration was quantified from maternal urine samples collected before pregnancy. Vitamin D was measured by maternal plasma during early pregnancy. A standardized measure of AGD was obtained in infants at birth. Anogenital index (AGI) was defined as AGD divided by weight (kg) at examination. Effect modification by Vitamin D was estimated.

RESULTS: We found no significant associations between maternal TCS and AGD in male or female infants. However, after stratified by maternal plasma vitamin D status (deficiency (<20ng/ml) versus insufficiency or sufficient (≥20 ng/mL)), per unit increase in maternal lg concentration of TCS, AGI increased on average by 0.23 in male infants (95% confidence interval (CI): 0.02, 0.45) when maternal VD concentration was lower than 20 ng/mL. No significant association was observed between maternal TCS and AGD in male infants when VD concentration is higher than 20 ng/mL. Furthermore, no significant association of maternal TCS with AGD or AGI was found in female infants.

CONCLUSIONS: These data support the hypothesis that maternal TCS exposure at environmental levels can adversely affect male reproductive development especially when maternal Vitamin D status is deficiency. Further prospective cohort studies with longitudinal measures are warranted to confirm these findings.

KEYWORDS: triclosan, Vitamin D, anogenital distance, anogenital index, birth cohort

P-1219 Proximity to restorative environment: Perception vs. Reality

Seung-Ah Choe[1], Chae-Bong Kim, Seyoung Kim, Tammy Kim
[1]*Korea University, Seongbuk-gu, Republic of Korea*

Proximity to restorative environment is known to be associated with health outcomes. for couples who are trying to conceive, neighborhood environment may affect reproductive function. This study assessed the association of duration of infertility with self-perceived and actual restorative environment, respectively. We analyzed the data of 500 participants of PRegnancy and UrbaN Environment (PRUNE) study, which is an ongoing mobile-based prospective cohort study of infertile couples. We assessed the perceived proximity to park and blue space (river, lake, stream, etc.) and actual environment of home address (NDVI within 500m and distance to blue space). Most of participants were women (64.9%) and 37 years and beyond (50.8%). Duration of infertility was ≥ 2 years in 167 (40.3%). Mean distance to blue space was shorter when the participants reported proximity of blue space, while mean NDVI was not different according to the perceived proximity. When adjusting for age and body mass index, perceived proximity to blue space was associated with lower risk of infertility for ≥ 2 years (relative risk = 0.78, 95% confidence interval: 0.62, 0.97). Associations of infertility for ≥ 2 years with perceived proximity to park, NDVI, and actual distance to blue space were close to null. In a sample of infertility couples living in urban area, we observed a positive association between perceived proximity to blue space and duration of infertility which was not replicated for actual distance. To optimize reproductive health, interventions to improve perceived environment would be necessary.

P-1227 Health risk assessment of phthalates exposure through lipid peroxidation in children with asthma

I-Jen Wang[1], Jung-Wei Chang[2], Wan-Ting Chang[3], Po-Chin Huang[3]
[1]Department of Pediatrics, Taipei Hospital, Ministry of Health and Welfare; School of Medicine, National Yang-Ming University; China Medical University, Taiwan, [2]Institute of Environmental and Occupational Health Sciences, School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan, [3]National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli, Taiwan,

BACKGROUND: Global prevalence of asthma in children has dramatically increased in the past decades. Recent studies revealed that Taiwanese children are still exposed to considerable amounts of phthalates after the 2011 incident of phthalates-tainted food products. Up-to-date findings indicated that phthalates may increase malondialdehyde (MDA), a lipid peroxidation marker, in asthma patients. The role of phthalates in the increased occurrence of childhood asthma through lipid peroxidation remains unclear. We want to assess the association between phthalates exposure and MDA in children with asthma.

METHODS: We recruited 125 children with clinically-diagnosed asthma and around 98 controls from Taipei Hospital since January 2019. Participants provided urine specimen and questionnaire. Eleven phthalate metabolites and MDA were analyzed by liquid chromatography tandem-mass spectrometry (LC-MS/MS) and ELISA, respectively. Pearson correlation and related statistical method were used to analyze the relationship of urinary phthalate metabolites or MDA in asthma children.

RESULTS: BMI in asthma children was significantly higher than that in control (p=0.005) whereas no similar phenomena was observed for other demographic factors. Mother ever had cigarette smoking in pregnancy and current burn incense at home in the case group were marginally significantly higher than those in control. Meanwhile, the median levels of urinary MEHP (72.18 v.s 68.81 ng/mL), MiNP (28.75 v.s 23.51 ng/mL), and MDA (6.87 v.s. 5.86) in asthma children were higher than those in control, though failed to reach statistical significance. Age was positively correlated with urinary MDA (r=0.159, p=0.018) and MEP (r=0.13, p=0.058). Urinary MEP was highly correlated with the other phthalate metabolites which indicated a common exposure source.
CONCLUSION: Certain phthalates may increase lipid peroxidation markers in asthma children.

KEYWORDS: Phthalate metabolites; lipid peroxidation; asthma.

P-1232 Psychosocial stress exposure and lung function in childhood: effect modification by child sex

Nadya Rivera[1], Hector Lamadrid-Figueroa[2], Adriana Mercado Garcia[3], Cecilia Sara Alcala[1], Lourdes Schnaas[4], Carmen Hernandez[4], Martha Maria Téllez-Rojo[3], Robert O. Wright[1,5,6], Maria Jose Rosa[1], Marcela Tamayo-Ortiz[7]
[1]Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, USA, [2]Center for Population Health Research of National Institute of Public Health (INSP), Cuernavaca, Mexico, [3]Center for Nutrition and Health Research of National Institute of Public Health (INSP), Morelos, Mexico, [4]National Institute of Perinatology, Mexico City, Mexico, [5]Department of Pediatrics, Icahn School of Medicine at Mount Sinai, New York, USA, [6]Institute for Exposomic Research, Icahn School of Medicine at Mount Sinai, New York, USA, [7]Mexican Institute of Social Security (IMSS), Mexico City, Mexico

BACKGROUND: Psychosocial stress is linked with adverse childhood respiratory outcomes, but the influence of exposure timing and sex differences has not been completely elucidated.
Aim: Examine the association between prenatal and concurrent maternal stress and lung function in children and explore sex differences.

METHODS: Analyses included 283 mother-child pairs from the Programming Research in Obesity, Growth, Environment and Social Stressors cohort in Mexico City. Lung function was tested at ages 8-11 years and age, height and sex adjusted z-scores were estimated for FEV1, FVC, FEF25-75% and FEV1/FVC. Psychosocial stress during pregnancy and concurrent to the lung function was assessed using the Crisis in Family Systems Revised questionnaire. Exposure to stress during both periods was categorized as low prenatal-low current, low prenatal-high current, high prenatal-low current and high prenatal-high current. Effect modification by sex was examined with interaction terms and in stratified analyses. Models were adjusted for maternal age and education at enrollment and concurrent report of a smoker in the home.

RESULTS: We found no associations between stress and lung function in our main models. There was a significant interaction between stress and sex in relation to FEV1 and FVC z-scores. In stratified models, low prenatal-high current stress was associated with lower percent predicted FEV1 in males (β: -0.509, 95%CI [-0.94, -0.08]) but not in females (β: 0.11, 95%CI [-0.35, 0.56]) when compared to low prenatal-low current stress. Low prenatal-high current stress was associated was associated with lower percent predicted FVC in males (β: -0.56, 95%CI [-0.96, -0.16]) but not in females (β: 0.31, 95%CI [-0.16, 0.78]) when compared to low prenatal-low current stress.

CONCLUSIONS: Time varying associations between stress children's lung function are sex-dependent and greater in males. Results highlight the importance of considering the emotional environment and the susceptibility by sex.

P-1234 Incident COPD and Its Disparities Associated with Low-concentration Air Pollution in American Older Adults: A National Cohort Analysis

Tszshan Ma[1], Haisu Zhang[1], Joel Schwartz[2], Qian Di[3], Weeberb J. Réquia[4], Howard H Chang[5], Stefanie Ebelt[1], Kyle Steenland[1], Christine Ekenga[1], Noah Scovronick[1], Jeremy A. Sarnat[1], Liuhua Shi[1]

[1]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, USA, [2]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, USA, [3]Vanke School of Public Health, Tsinghua University, Beijing, China, [4]School of Public Policy and Government, Fundação Getúlio Vargas, Brasília, Brazil, [5]Department of Biostatistics and Bioinformatics, Rollins School of Public Health, Emory University, Atalnta, USA

BACKGROUND: Risk of air pollution-related Chronic Obstructive Pulmonary Disease (COPD) and corresponding disparities associated with air pollutant exposures are less clear at concentrations below current National Ambient Air Quality Standards (NAAQS).

METHODS: We constructed a national U.S. population-based cohort of those aged ≥65 from the Medicare Chronic Conditions Warehouse (2000-2016), combined with high-resolution population-weighted air pollution datasets, to investigate the association of long-term exposure to low-level air pollution and incident COPD. We defined four distinct low-exposure sub-cohorts comprised of individuals who were always exposed to low-levels of: (1) PM2.5 (annual mean ≤12-μg/m³), (2) NO2 (annual mean ≤53-ppb), (3) O3 (warm-season mean ≤50-ppb), and (4) low levels of all three air pollutants. We further tested effect modification by individual- and community-level characteristics.

RESULTS: of the 18.8 million individuals, 64.2% (12.1-million), 99.3% (18.7-million), 75.4% (14.2-million), and 54.1% (10.2-million) were always exposed to low-level annual PM2.5, NO2, O3, and all three air pollutants, respectively. Among the single-pollutant low-exposure cohorts, a 5-μg/m³ increase in PM2.5, 5-ppb increase in NO2, and 5-ppb increase in warm-season O3 were associated with an increase in COPD rate ranging between 9-12%, 1-2%, and 11-12%. Associations with each individual pollutant were also significant in the cohort exposed to low-levels of all three pollutants. There was evidence of linearity in concentration-response relationships for NO2 and O3 at levels below the current NAAQS. for PM2.5, there was a sharp increase in risks at levels above 10-μg/m³. Further, individuals in communities with lower household incomes, lower educational attainment, and lower numbers of active doctors experienced higher risk.

CONCLUSIONS: Our study suggests exposures to low-level PM2.5, NO2, and warm-season O3 were associated with incident COPD. Subgroup differences suggest individual and contextual factors contributed to COPD disparities under effects of air pollutant exposures.

P-1241 Associations between exposure to ambient fine particulate matter (PM2.5) and prevalence of chronic respiratory disease in Senegalese adults: Results from the demographic health survey (DHS) 2011

Bailey Glenn[1], Youssef Oulhote[1], Lisa Chasan-Taber[1], Leon M. Espira[2], Christopher S. Crowe[3], Peter S. Larson[1,3,4]
[1]Department of Biostatistics and Epidemiology, School of Public Health and Health Sciences, University of Massachusetts, Amherst, USA, [2]Center for Global Health Equity, University of Michigan, Ann Arbor, USA, [3]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, USA, [4]Social Environment and Health Program, Survey Research Center, Institute for Social Research, University of Michigan, Ann Arbor, USA

BACKGROUND AND AIM: The prevalence of chronic respiratory conditions such as asthma and chronic bronchitis has been increasing in Africa over the past decade. Recent studies show that exposure to air pollution is associated with increased risk of chronic respiratory diseases. However, very few studies have been conducted in sub-Saharan Africa using estimated measurements of particulate matter (<2.5 um; PM2.5). The aim of our study is to investigate the association between PM2.5 exposure and prevalence of asthma/chronic bronchitis in Senegal.

METHODS: This study used data from the Demographic and Health Survey (DHS 2011 collected from October 2010 to April 2011 throughout Senegal. Using their geographic location of survey clusters, we linked data for 19,843 Senegalese adults to remotely sensed and gridded annual concentrations of PM2.5. We estimated covariate-adjusted associations of PM2.5 with prevalence of self-reported asthma/chronic bronchitis using logistic regressions while accounting for survey weights and clustering. We also evaluated potential effect modification by gender.

RESULTS: The prevalence of asthma/chronic bronchitis was 2.99%.The adjusted association between PM2.5 and asthma/chronic bronchitis prevalence was 1.03 (95%CI: 0.99 – 1.06). The association between PM2.5 and asthma/chronic bronchitis significantly differed by gender (p=0.008) with stronger associations in males (prevalence odds ratio [pOR] = 1.09; 95%CI: 1.03-1.15), compared to females (pOR = 1.01; 95%CI: 0.97 – 1.05).

CONCLUSIONS: Our results suggest that increasing levels of ambient exposure to PM2.5 puts individuals at a higher risk for chronic respiratory diseases, especially men even when taking possible indoor exposures to air pollutants into account. These findings have significant policy implications and should be built upon in future research using more refined measures of PM and prospective designs.

P-1243 Effects of smoking cessation on respiratory health and related chronic diseases

Xu Xiaocheng[1], Zhanlu Lv[2], Tiansen Zou[1], Han Zhang[1], Lingchuan Guo[2], Bin Luo[3], Jinliang Zhang[1]

[1]State Key Laboratory of Environmental Criteria and Risk Assessment, Chinese Research Academy of Environmental Sciences, Beijing, China, [2]Center for the Risk Assessment and Research, Chinese Research Academy of Environmental Sciences, Beijing, China, [3]Institute of Occupational Health and Environmental Health, School of Public Health, Lanzhou University, Lanzhou, China

OBJECTIVE: This study aims to understand the effects of smoking cessation on respiratory symptoms and chronic diseases.

METHODS: From 2015 to 2018, 1583 male residents aged 18-70 from 7 counties of Huaihe River Basin were selected as participants. Logistic regression model was used to analyze the effects of smoking or smoking cessation on respiratory symptoms and chronic diseases.

RESULTS: The smoking rate was 49.3%, and the smoking cessation rate was 26.3%. The prevalence rates of respiratory symptoms and chronic diseases was various 3.3% to 20.0%. Compared with current smokers, never smokers had a lower risk of cough, chronic cough, expectoration, chronic expectoration, wheezing, shortness of breath, and bronchial asthma/chronic bronchitis (OR=0.25~0.62), and smokers who quit smoking had a lower risk of cough (OR=0.63), but a higher risk of shortness of breath, hypertension, coronary heart disease/stroke, and diabetes than current smokers (OR= 1.44~2.40). Smokers who quit smoking due to illness had a higher risk of wheezing, shortness of breath, bronchial asthma/chronic bronchitis, coronary heart disease/stroke, and chronic gastritis/gastrointestinal ulcer (OR=1.85~2.62), while smokers who quit smoking for other reasons had lower risks of cough (OR=0.52), chronic cough (OR=0.20) and expectoration (OR=0.53), but higher risks of hypertension (OR=1.54) and coronary heart disease/stroke (OR=2.20) than current smokers. All the above were statistically significant (P<0.05).

CONCLUSIONS: Smoking cessation without illness could reduce the risk of respiratory symptoms and chronic diseases in rural male of Huaihe River Basin. Therefore, effective strategies are needed to encourage current smokers to quit.

P-1244 Environmental impact of microbes on Awba dam: it's effect on ecotourism

Taiwo Alawode, Funmilola Ajani, Victoria Adetunji
[1]*University of Ibadan, Ibadan, Nigeria*

BACKGROUND AND AIM: Recreational use of water is often given inadequate consideration and care. This is of particular concern as the recreational use of water is becoming popular in Nigeria. Many of these are increasingly contaminated by domestic sewage and industrial effluents. This study is therefore relevant in assessing the environmental impact of microbes on ecotourism in Awba dam.

METHODS: A total of nine water (n=9) and soil (n= 9) samples were collected at entry, middle and the end of the Awba dam for heavy metal analysis and microbial assay. Total aerobic plate count, Isolation and characterization of strains was
done using standard methods. The presumptive E. coli isolates were subjected to agglutination tests with specific E. coli O157:H7 . for the antibiotic sensitivity test, the Bauer-Kirby disc diffusion
method was used to test the sensitivity of the isolates. Statistical analysis of ANOVA was used and Duncan multiple range test was used to separate the means.

RESULTS: All the values obtained for the total aerobic count and total coliform count for soil and water were higher than EPA recommended value for recreational waters. for the antibiotic Sensitivity Profile, isolates from Awba dam showed the highest sensitivity (16.17mm) to ciprofloxacin while lowest was with Augmentine (8.25mm). Generally, E.coliO157:H7
isolates were highly sensitive to Oflatoxin and Ciproflaxin(93.3%) while the isolate was completely resistant to Ampicilin and Cefuroxime.

CONCLUSIONS: The presence of E.coliO157:H7 in the dam
can make the dam unfit for recreational activities and also for the community household chores, if not well treated. The University management should device means of controlling
waste water that enters into the dam by providing alternate channels of discharge to reduce the growth and spread of the microbes in the dam.

P-1251 Nitrate Ingestion from Drinking Water and Ovarian Cancer Risk in the Agricultural Health Study

Samantha Ammons[1], Jessica Madrigal[1], Cherrel K. Manley[2], Johnathan N. Hofmann[1], Dale Sandler[3], Laura E. Beane Freeman[1], Rena R. Jones[1], Mary H. Ward[1]

[1]National Cancer Institute, National Institutes of Health, Bethesda, USA, [2]Department of Epidemiology, University of North Carolina Chapel Hill Gillings School of Public Health, Chapel Hill, USA, [3]Epidemiology Branch, Chronic Disease Epidemiology Group, National Institute of Environmental Health Sciences, National Institutes of Health, Durham, USA

BACKGROUND AND AIM: N-nitroso compounds (NOCs) formed endogenously after nitrate/nitrite ingestion cause ovarian cancer in animals. Few epidemiologic studies have evaluated the association of drinking water nitrate with ovarian cancer risk, and the only previous investigation observed increased risks with higher intake.

METHODS: We evaluated nitrate exposure from drinking water and ovarian cancer risk in the Agricultural Health Study, a cohort of pesticide applicators and their spouses in Iowa and North Carolina. for the enrollment water source (1993-1997; N=29,408), we computed average nitrate concentrations for women on public water supplies (20% of participants) from historical monitoring data and estimated nitrate concentrations in private wells (76%) using random forest models; 4% used other water sources and were excluded. We used Cox regression models adjusted for age, body mass index, smoking status, and menopausal status to estimate hazard ratios (HR) and 95% confidence intervals (CI) for nitrate quartiles and the 90th percentile. Among those with dietary data (collected at first follow-up; N=13,465), we calculated HRs for < and ≥ median nitrate concentration (1.47 mg/L), stratified by median dietary intakes of vitamin C (145.1 mg/day), as higher intake decreases endogenous NOC formation.

RESULTS: We identified 122 ovarian cancer cases through 2018 (Iowa) and 2014 (North Carolina). Risk was elevated (HR=1.67, CI:0.82–3.37, P-trend=0.19) for women in the 90th percentile (≥6.81 mg/L NO3-N) versus the lowest quartile (≤0.75 mg/L). The association with higher average nitrate exposure (> median) was stronger among women with low vitamin C intake (HR<median=2.20, CI:0.77-6.27) versus those with high vitamin C intake (HR>median=1.14, CI:0.58-2.25), although the interaction was not significant (P-interaction=0.28).

CONCLUSIONS: Although we cannot rule out the possibility our findings are due to chance, they suggest that higher average nitrate levels in drinking water may increase ovarian cancer risk and that vitamin C intake may modify this relationship.

KEYWORDS: nitrate, ovarian cancer

P-1258 Environmental influences and prediction of *Escherichia coli* concentration in freshwater recreational beaches in Southern Ontario

Johanna Sanchez[1], Jordan Tustin[1], Cole Heasley[1], Mahesh Patel[2], Jeremy Kelly[3], Anthony Habjan[3], Ryan Waterhouse[3], Ian Young[1]

[1]Ryerson University, Toronto, Canada, [2]Toronto Public Health, Toronto, Canada, [3]Niagara Region Public Health, Niagara Region, Canada

BACKGROUND AND AIM: The concentration of *Escherichia coli* is used in Canada as an indicator of fecal pollution in freshwater recreational beaches, and is associated with recreational water illness among beachgoers. This study examines the environmental predictors of *E. coli* in Toronto and Niagara Region beaches to inform beach monitoring programs and reduce beachgoer illness risks.

METHODS: Our first objective used advanced analytical methods to examine region-specific environmental predictors of *E. coli* at 18 beaches in Toronto and Niagara Region. Mixed-effects models investigated regional differences, while the application of path analysis identified intervariable relationships and pathways associated with *E. coli* in Niagara Region. Our second objective involves the development of region-specific predictive models using a novel Bayesian Network approach to provide real-time assessments of beach water E. coli concentrations in our study regions.

RESULTS: *E. coli* observations were collected from 2007-2019 for Toronto and 2011-2019 for Niagara Region. In the mixed-effects analysis, substantial clustering of *E. coli* values at the beach level was observed in Toronto, while minimal clustering was seen in Niagara, suggesting an important beach-specific effect in Toronto beaches. Air temperature and turbidity were positively associated with *E. coli* in all models in both regions. In the path analysis, we found that water turbidity was an important mediator for the indirect effect of environmental variables overall and in beach-specific models. Results from these analyses informed the development of region-specific Bayesian Network predictive models, which are currently being tested and finalized.

CONCLUSIONS: Poor beach water quality could result in an increased risk of recreational water illness among the beachgoers. The development of accurate predictive models will guide beach managers in decision-making and risk communication to reduce recreational water illness risks among beachgoers.

KEYWORDS: *E. coli*, water quality, recreational water illness
